A.1 Additional systematic review results

A.1.1 Corticosteroids compared with no corticosteroids RCTs

A.1.1.1 Illness recovery outcomes

The Metcovid trial recorded respiratory function at 120-day follow-up[1]. They found that patients in the corticosteroid treatment arm had significantly higher measurements of forced expiratory volume in 1 second and forced vital capacity than patients in the placebo group. However, there was no difference found on tests of physical function (such as a 6-minute walk test[2]), raising doubts over whether the lung function test result difference was clinically meaningful. There was a high risk of bias due to missing outcome data for respiratory function - only around half of surviving patients were able to return to the hospital and complete the assessments, with others excluded from the analysis.

The COVID-STEROID trial assessed health-related quality of life at 1 year[3]. The investigators reported no significant difference between treatment groups but meaningful interpretation was not possible as the analysis only included 3% (16 participants) of the trial's planned sample size after premature termination of trial recruitment on publication of the RECOVERY dexamethasone results.

REMAP-CAP evaluated health-related quality of life and disability at 180 day follow-up. They found no significant difference in mean European Quality of Life – 5 Domains (EQ-5D) score, mean EQ-5D visual analogue scale score or WHO Disability Score between randomised groups. The trial was underpowered to detect a meaningful difference in these outcomes due to premature termination of recruitment after publication of RECOVERY's dexamethasone results[4].

A.1.1.2 Biological measurements

i) Physiological outcomes

Three trials have performed a randomised comparison of oxygenation measurements but all used different analysis methods - change in an oxygenation ratio over time between treatment groups assessed using a linear mixed effects model[5], mean change from baseline of an oxygenation ratio[6] and a comparison of proportions in each treatment group with an oxygenation ratio below a specified threshold at follow-up[7]. None found a statistically significant difference between treatment groups, although findings are limited by risk of bias, imprecision, and potential publication bias.

ii) Virological outcomes

Viral clearance has been assessed in three trials using variable outcome definitions and analysis methods. Two RCTs found no difference between treatment groups in the proportion who remained SARS-CoV-2 PCR positive at 5 or 7 days[7,8]. One small trial found a median of 3 days longer duration of SARS-CoV-2 PCR positivity in the corticosteroid treatment group compared to usual care[9]. Conclusions are limited by risk of bias due to unclear randomised allocation concealment, inconsistency, imprecision, and potential publication bias.

iii) Biochemical outcomes

Amongst three RCTs assessing treatment effects on blood inflammatory markers, all found significantly lower levels of mean or median C-reactive protein (CRP) in those randomised to receive corticosteroids compared to those who were not, at one or more follow-up time points[6,8,10]. Generalisability of findings across all corticosteroids are reduced as these trials all used methylprednisolone as the intervention treatment.

In the two RCTs assessing other blood markers, no significant differences between treatment groups were observed in lymphocyte count, platelets, ferritin, D-dimer or LDH measurements[6,8]. Certainty of findings relating to biochemical outcomes are limited by risk of bias, imprecision, and potential publication bias.

iv) Transcriptomic outcomes

No RCTs have assessed transcriptomic responses to corticosteroid treatment.

A.1.2 IL-6 RA RCTs

A.1.2.1 Illness recovery outcomes

Only the REMAP-CAP trial has evaluated patient-centred outcomes at longer-term follow-up among IL-6 RA RCTs. They found a statistically significant improvement in health-related quality of life (measured by EQ-5D index score) in those randomised to IL-6 RA treatment compared with controls in a Bayesian analysis[11]. However, 180-day follow-up was only performed in a subset of sites. Related outcomes of mean EQ-5D mean score and WHO Disability Score did not show a statistically significant impact of IL-6 RA treatment.

A.1.2.2 Biological measurements

i) Physiological outcomes

No IL-6 RA RCTs reported on outcomes of direct physiological measurements.

ii) Virological outcomes

No IL-6-RA RCTs reported on outcomes of viral clearance.

iii) Biochemical outcomes

Twelve RCTs compared a measure of CRP levels between participants randomised to IL-6 RA treatment and those randomised to usual care/placebo. Analysis methods included using a linear mixed effects model[12], comparing treatment groups for difference in mean change of CRP from baseline[13,14] and comparing differences in mean CRP at follow-up time points[15-22]. Of these trials, 8/12 found significantly lower levels of CRP in those treated with IL-6 RAs.

The findings of three RCTs that assessed treatment effects on neutrophil:lymphocyte ratio were consistent in finding a lower ratio in those treated with IL-6-RAs[17,20,23]. Where other measures were assessed, no significant treatment effect on measures of ferritin, D-dimer, lymphocyte count or LDH were found [12,17,20-23]. Certainty of findings are limited by risk of bias, imprecision, and potential publication bias.

iv) Transcriptomic outcomes

No RCTs reported on transcriptomic response to IL-6 RA treatment.

A.1.3 JAKI RCTs

A.1.3.1 Illness recovery outcomes

One JAKI RCT assessed breathlessness and functional recovery at 28-day and 90-day follow-up with no difference between treatment arms seen[24].

A.1.3.2 Biological measurements

i) Physiological outcomes

One JAKI RCT – TOFACOV - assessed change in PaO2/FiO2 ratio at 7 days and found no statistically significant difference between treatment groups[25]. TACTIC-R assessed several oxygenation measurements at 14 days, with no difference seen between treatment groups[24].

ii) Virological outcomes

One JAKI RCT demonstrated no difference between treatment groups for first negative SARS-CoV-2 PCR result[24].

iii) Biochemical outcomes

Four JAKI RCTs have assessed treatment effects on CRP. CRP fell more quickly in one trial in the tofacitinib group compared to usual care[26]. In two larger trials, there was no significant difference in treatment groups in follow-up CRP levels[24,27]. A small trial assessing the mean difference in CRP at study day 5 also found no significant difference between treatment groups[28]. No significant difference in ferritin or D-dimer levels were observed between treatment groups[26,27].

iv) Transcriptomic outcomes

No RCTs have reported transcriptomic effects of JAKI treatment.

A.1.4 Higher dose compared with standard dose corticosteroids RCTs

A.1.4.1 Illness recovery outcomes

COVID-STEROID-2 is the only trial that has reported long-term patient-centred outcomes in the form of health-related quality of life (measured on EQ-5D[29] domains and visual analogue scale) at 1 year. They found no statistically significant difference between treatment groups although signals were broadly positive towards higher dose corticosteroids[30]. Certainty of findings could have been limited by the self-reported outcome measurement. However, research staff administered a standardised questionnaire to collect the assessment data and both the research staff and participant were blinded to treatment allocation.

A.1.4.2 Biological measurements

i) Physiological outcomes

Two higher dose corticosteroid RCTs reporting oxygenation measurement outcomes found a significantly improved oxygenation index or oxygenation saturations at one or more follow-up time points for those treated with higher dose corticosteroids[31,32]. One trial did not find a significant difference in mean oxygen saturations between groups at day 7 follow-up[33]. Certainty of findings were limited by risk of bias due to unclear or inadequate randomised allocation concealment and lack of information about pre-specified analyses, inconsistency, imprecision, and potential for publication bias.

ii) Virological outcomes

A single RCT compared mean rate of change in SARS-CoV-2 PCR cycle threshold value between those treated with higher dose corticosteroids and those treated with lower dose corticosteroids, finding no significant difference between treatment groups[34]. Conclusions are limited by imprecision and the potential for publication bias.

iii) Biochemical outcomes

Amongst two of four higher dose corticosteroid RCTs analysing differences in CRP, a significantly lower CRP level was found in those treated with higher dose corticosteroids compared with lower dose corticosteroids. This was assessed by comparing CRP levels at a single follow-up time point[31,32]. The remaining small trials did not report a significant difference when comparing the time between treatment groups to 50% reduction in CRP level from baseline but was limited by imprecision[35], and another no difference in mean CRP at day 7[33]. Confidence in findings is increased by the potential for a dose-response gradient in treatment effect with several RCTs comparing corticosteroids with no corticosteroids also finding significantly lower levels of CRP. Certainty is lowered by risk of bias relating to the randomisation process and lack of information about pre-specified analyses, potential for publication bias and the fact that all trials assessing this outcome used methylprednisolone as the intervention corticosteroid.

Neutrophil:lymphocyte ratio was lower in participants randomised to higher dose corticosteroids in a single small RCT assessing this outcome[31].

iv) Transcriptomic outcomes

No RCTs have reported higher dose corticosteroid treatment effect on transcriptomic measures.

B.1 Data Analysis Plan

B.1.1 Long-term follow-up analysis assessments

Extended analysis of the RECOVERY trial immunomodulatory therapy comparisons
Data Analysis Plan

1 Background

1.1 Introduction

The RECOVERY trial has demonstrated a mortality benefit for hospitalised COVID-19 patients receiving the immunomodulatory therapies dexamethasone, tocilizumab and baricitinib[1-3]. Nevertheless, important questions remain regarding the effects of treatments longer-term and across the full spectrum of hospitalised patients; the balance of immunomodulatory treatments and non-coronavirus infection risks; and the precise biological pathways via which beneficial effects of treatment are mediated.

This extended analysis will utilise the unique resource of the RECOVERY randomised comparison populations as a basis for targeted further analysis after linkage of new individual participant-level data. The outputs of this project are likely to have direct clinical relevance and the potential to inform future therapeutic options in the context of the ongoing global COVID-19 pandemic.

The purpose of this Data Analysis Plan is to define the planned assessments for the extended analysis prior to unblinding to individual participant treatment allocation. All pre-specified analyses will be performed and presented. Given the exploratory nature of the questions this project seeks to address, it is not possible to pre-specify all analyses and further exploratory analyses may be conducted depending on initial findings.

1.2 The RECOVERY trial

The RECOVERY trial is a randomised, controlled, open-label, platform clinical trial evaluating potential therapies for patients hospitalised for COVID-19[4]. Eligible patients are randomly allocated between one or more treatment arms, each given in addition to the usual standard of care.

RECOVERY has recruited over 45,000 participants to date[5], finding a 28-day all-cause mortality benefit of treatment with three immunomodulatory therapies:

- Dexamethasone for hospitalised patients on oxygen or invasive mechanical ventilation support at randomisation, in a population of 6425 participants randomised in a 2:1 allocation of usual standard care:dexamethasone, recruited between 19th March 2020 and 8th June 2020.[1]
- Tocilizumab for hospitalised patients with hypoxia and C-reactive protein ≥75 mg/L at randomisation (which could be done immediately after the main randomisation or up to 21 days later), in a population of 4116 patients randomised in a 1:1 allocation of usual standard care: tocilizumab, recruited between 23rd April 2020 and 24th January 2021.[2]

- Baricitinib for all hospitalised patients, in a population of 8156 participants randomised in a 1:1 allocation of usual standard care: baricitinib, recruited between 2nd February 2021 and 29th December 2021.[3]

1.3 Rationale for extended analysis

RECOVERY is a streamlined, pragmatic trial designed to generate high-quality evidence about potential life-saving therapies in the context of an unprecedented global pandemic.

Despite the clear benefits demonstrated for dexamethasone, tocilizumab and baricitinib, important questions do remain that have direct relevance for clinical care and for informing prospective therapeutic options for COVID-19.[6]

The large RECOVERY randomised comparison populations are a unique resource to use as a basis for targeted further analysis with the addition of new linked individual participant level data allowing additional clinical and research questions to be answered. The randomised treatment allocation can minimise bias from unmeasured confounding[7].

1.3.1 Clinical outcomes beyond 28 days

The follow-up period for the initial treatment assessments was at 28 days after randomisation. It is also essential to evaluate the impact of treatment on clinical outcomes beyond this time-point to understand the full effects of trial treatments on longer-term clinical outcomes, including mortality, time in hospital, use of organ support and post-Covid recovery.

1.3.2 Extended safety evaluation

Immunomodulatory therapies have potential harmful effects which it is important to understand in the context of new widespread therapeutic use for COVID-19. For example, all of these treatments may confer increased risk of non-coronavirus infections through immunomodulatory actions. Understanding the burden of these effects will be useful to inform optimal clinical care of patients receiving these therapies.

Corticosteroids, such as dexamethasone, are associated with a wide range of undesirable effects, including immunosuppressive effects, hyperglycaemia, thromboembolism, vertebral and long bone fractures, psychiatric reactions and peptic ulceration with perforation and haemorrhage[8].

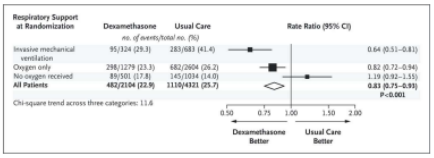

Interleukin-6 receptor antagonists, such as tocilizumab, are associated with immunosuppressive effects, gastrointestinal perforation and acute liver injury[9].

Janus kinase inhibitors, such as baricitinib, are associated with immunosuppressive effects, diverticulitis and gastrointestinal perforation, acute liver injury and venous thromboembolism[10].

1.3.3 Treatment effects across the full spectrum of hospitalised patients

In the RECOVERY dexamethasone comparison, respiratory support at randomisation was an important determinant of treatment efficacy. In those who were not receiving any oxygen or respiratory support at randomisation there was still high mortality (14-18%) but there did not appear to be a treatment benefit and a clinically significant harm from treatment was not excluded (Figure 1). The precise reasons for these results, and the clinical implications, remain uncertain.

Figure 1: Effect of dexamethasone on 28-day mortality, according to respiratory support at randomisation[1]

Given our knowledge of the potential harmful effects of the immunomodulatory therapies, including immunosuppressive effects, assessing for treatment-related risks in patients at high risk of secondary infection at randomisation (e.g. those who are immunosuppressed) will also inform our clinical understanding of the risk-benefit balance of immunomodulatory therapies in these patient groups.

1.3.4 Biological mechanisms of treatment effect

Understanding the biological effects of treatment and the precise biological pathways that beneficial effects of treatment are mediated via will inform potential treatment strategies for COVID-19 and any similar diseases in the future.

The impact of immunomodulatory treatments on oxygenation, routinely-measured blood markers (e.g. CRP, neutrophil-leucocyte ratio) and SARS-CoV-2 viral clearance will delineate mechanisms of treatment effect and potentially flag markers associated with poor treatment response for further evaluation.

Multi-omics profiles can pinpoint biological pathways that treatments are acting upon in COVID-19, for example through differential gene expression analysis in serial host transcriptomic samples[11].

1.4 Aims of extended analysis

- Assess the in-depth clinical and biological effects of immunomodulatory therapies for COVID-19
- Understand the full spectrum of host and pathogen risk factors which predict outcomes and modify the effects of immunomodulatory therapy in COVID-19
- Identify potential causal pathways through which the beneficial effects of immunomodulatory treatment for COVID-19 are mediated

2 Extended clinical analysis of the RECOVERY trial immunomodulatory therapy comparisons

This section details the proposed extended analysis of clinical outcomes. The effect of the immunomodulatory treatment on long-term mortality, discharge from hospital admission, non-coronavirus infections, long Covid, patient-reported outcomes and other safety events of particular interest for each immunomodulatory treatment will be evaluated at short-term

(28 days following randomisation) and long-term (6 months following randomisation unless otherwise stated) follow-up points. The outcome assessments will involve intention-to-treat comparisons among all randomised participants in the relevant treatment comparison.

Some of the assessments will be included in the RECOVERY trial 6-month assessments – these will be found in the RECOVERY Statistical Analysis Plan[12] and RECOVERY Definitions and Derivation of Baseline Characteristics and Outcomes document[13], while others are novel assessments for the extended clinical analysis. The detailed derivation of these outcomes is described in the extended analysis data definitions and derivation document.

2.1 Capture of extended clinical analysis assessments

The data for these outcomes will be captured from multiple sources through healthcare record linkage, including; trial follow-up electronic case report forms, hospital admissions data; mortality data; primary care records and community prescribing data, and through linkage with other research databases, such as the International Severe Acute Respiratory Coronavirus Clinical Characterisation Consortium (ISARIC4C) (https://isaric4c.net/).

Diagnoses will be tabulated by the categories defined for analysis of cause-specific mortality. Additional subcategories will be considered (

- All-cause mortality
- Time to first occurrence of major non-COVID infection
- Any non-coronavirus infection

The following subgroups will be examined based on information at randomisation:

- Age (<70; 70-79; 80+ years)
- Time since illness onset (≤7 days; >7 days)
- Requirement for respiratory support at baseline (None; Oxygen only; Non-invasive ventilation; Invasive mechanical ventilation (including ECMO)
- Predicted non-coronavirus infection Risk Group: three risk groups with approximately equal number of non-coronavirus infections based on factors recorded at randomisation (see Section 5.5.2)
- Use of corticosteroids (for the tocilizumab comparison) and/or tocilizumab (for the baricitinib comparison)

2.2.5 Sensitivity analyses

2.2.5.1 *Varying diagnostic code position for outcome derivation*

Sensitivity analyses will be conducted for the primary and secondary assessments by restricting the diagnostic code position that the outcome is derived from within the hospital admission datasets to the first diagnostic position only.

2.2.5.2 *Inclusion of peri-randomisation episode events*

Sensitivity analyses will be conducted for the primary and secondary assessments by including events that occurred within the hospital admission episode that the patient was randomised within (i.e. peri-randomisation episode events)

2.2.5.3 *Removal of respiratory tract infection events*

Clinically-diagnosed respiratory tract infections and healthcare record coding entries may be indistinguishable from deterioration of underlying COVID-19 disease. Therefore, sensitivity analyses will be conducted for the primary assessment and the "Any non-coronavirus infection" secondary assessment by excluding respiratory tract infection events.

The detailed derivation of outcomes included in the statistical analysis is described separately in the

3 Extended biological analysis of the RECOVERY trial immunomodulatory therapy comparisons

This section details the proposed extended analysis of biological assessments. This aspect of the analysis is exploratory and aims to understand the impact of the immunomodulatory treatments on patient physiological, biochemical, virological and multiomics parameters. This knowledge aims to increase understanding of the biological impacts and mechanisms of the immunomodulatory treatments.

3.1 Capture of extended biological analysis data

The data for these assessments will be captured through the ISARIC4C study and will be available for RECOVERY participants who were also recruited to ISARIC4C. The detailed derivations of assessments included in the analysis is described separately in the extended analysis definitions and derivation document.

For all biological analysis assessments, the analysis will take place in the subset of participants with linked ISARIC4C data (the RECOVERY-ISARIC4C population), unless otherwise stated. Additional exploratory assessments may be conducted at a later date if deemed appropriate.

3.2 Definitions of extended biological analysis assessments

3.2.1 Exploratory assessments

3.2.1.1 *Daily rate of change in C-reactive protein (CRP)*

- The daily rate of change in CRP (measured in mg/L) will be calculated for the period from baseline to study day 28.
- For all treatment comparisons, the difference in the mean daily rate of change in CRP will be compared between all RECOVERY-ISARIC4C participants allocated the intervention and all RECOVERY-ISARIC4C participants allocated usual care.

3.2.1.2 *Daily rate of change in neutrophil:lymphocyte ratio (NLR)*

- The NLR is calculated as $\frac{Neutrophil\ count\ (x10^9/L)}{Lymphocyte\ count\ (x\ 10^9/L)}$
- The daily rate of change in NLR will be calculated for the period from baseline to study day 28.
- For all treatment comparisons, the difference in the mean daily rate of change in NLR will be compared between all RECOVERY-ISARIC4C participants allocated the intervention and all RECOVERY-ISARIC4C participants allocated usual care.

3.2.1.3 *Daily rate of change in creatinine*

- The daily rate of change in creatinine (measured in µmol/L) will be calculated for the period from baseline to study day 28.
- For all treatment comparisons, the difference in the mean daily rate of change in creatinine will be compared between all RECOVERY-ISARIC4C participants allocated the intervention and all RECOVERY-ISARIC4C participants allocated usual care.

3.2.1.4 *Daily rate of change in ordinal scale score*

- The ordinal scale score is defined as follows:

Ordinal Scale Score	Description
1	Discharged alive from hospital
2	In hospital, no supplemental oxygen
3	Low oxygen requirement (FiO_2 > 0.21 & ≤ 0.32)
4	Moderate oxygen requirement (FiO_2 > 0.32 & <0.50)
5	High oxygen requirement (FiO_2 ≥0.50)
6	On non-invasive ventilation or high flow nasal oxygen
7	On invasive mechanical ventilation (including ECMO)
8	Death

- The daily rate of change in ordinal scale score will be calculated for the period from baseline to study day 28.
- For all treatment comparisons, the difference in the daily rate of change in ordinal scale score will be compared between all RECOVERY-ISARIC4C participants allocated the intervention and all RECOVERY-ISARIC4C participants allocated usual care.
- The daily rate of change in ordinal scale score will be treated as a continuous outcome with repeated measures in the analysis

3.2.1.5 *Time to first occurrence of SARS-CoV-2 viral clearance*

- Defined as a negative SARS-CoV-2 test result (of any type).
- Assessed in the subset of RECOVERY-ISARIC4C participants who had a repeat SARS-CoV-2 test within 28 days from the date of randomisation.

  - Non-invasive ventilation or high flow nasal oxygen;
  - Invasive mechanical ventilation (including ECMO).

3.2.1.7 *Transcriptomic assessments*

- Normalised log-fold gene expression changes will be calculated based on baseline and post-randomisation measurements.
- Differentially expressed genes will be compared between randomised groups.
- Definitions will be finalised after access to biological sample data.

3.2.2 Sensitivity analyses

3.2.2.1 *Complete case analysis*

Sensitivity analyses will be conducted for daily rate of change of CRP, NLR and creatinine using complete case analysis – restricting to individuals with no missing data for the assessment

3.2.2.2 *Excluding participants with outlying mean deviations from their own fitted slopes*

Sensitivity analyses will be conducted for daily rate of change of CRP, NLR and creatinine by excluding the 5%, 10% or 15% of participants with the most extreme mean deviations from their own fitted slopes, based on the distribution of mean deviations across all participants.

3.2.2.3 *Follow-up time period to study day 14*

Sensitivity analyses will be conducted for daily rate of change of CRP, NLR, creatinine and ordinal scale score using follow-up data to study day 14 (rather than study day 28).

4 Details of analyses

4.1 Analysis Populations

The intention to treat (ITT) population will be all participants randomised in the treatment comparison, irrespective of treatment received. For all extended clinical analysis assessments, the ITT population will be used wherever possible. For outcomes among subsets of the randomised comparison all participants for whom data is available will be included.

For all extended biological analysis assessments, the sub-population of all RECOVERY participants with linked ISARIC4C data available – the RECOVERY-ISARIC4C population - will be used, unless otherwise stated.

In the dexamethasone and baricitinib comparison populations, it is known from the original trial results that there is a small age imbalance between the randomised groups: through the play of chance during simple randomisation. Participants allocated dexamethasone were a mean of 1.1 years older than participants allocated usual standard care[3] and participants allocated baricitinib were a mean of 0.8 years older than participants allocated usual standard care[3]. Age and respiratory support at randomisation are the strongest determinants of clinical outcome risk. Therefore, analysis methods adjusting for age and respiratory support at randomisation are planned for all treatment comparisons.

4.2 Sample size, power and minimum detectable effect size

The relevant treatment comparisons analysed have already completed recruitment and therefore sample size is fixed. The focus for the extended clinical analysis outcomes is on minimum detectable effect size for each outcome, based on sample size and power, and its clinical relevance.

Table 2 below shows calculations of minimum detectable effect sizes with number of events from preliminary blinded data:

*Table 2: Minded event numbers and minimum detectable effect sizes for extended clinical analysis outcomes**

Outcome	Comparison (Dexamethasone n=6625) (Tocilizumab n= 4116)	Number of events	Minimum detectable effect size (Risk increase with treatment)		Minimum detectable effect size (Risk decrease with treatment)	
			80% power at 2P <0.05	90% power at 2P <0.05	80% power at 2P <0.05	90% power at 2P <0.05
Time to first occurrence of major non-COVID infection at 28 days	Dexamethasone	805	HR 1.23	HR 1.27	HR 0.81	HR 0.78

4.3 Methods of analysis

4.3.1 Baseline comparability of randomised groups

The following characteristics will be described separately for patients randomised to each treatment comparison:

- Age
- Sex
- Ethnicity
- Time since COVID-19 symptoms onset
- Time since hospitalisation
- Current respiratory support
- Comorbidities (diabetes, heart disease, chronic lung disease, tuberculosis, HIV, severe liver disease, severe kidney impairment, immunosuppression, severe mental illness)
- Hospital Frailty Risk Score[14]
- Use of systemic corticosteroid (including those allocated to corticosteroid)
- Use of other relevant treatments (e.g. remdesivir, interleukin-6 receptor antagonist)
- Baseline measurement of assessment parameter (if applicable)

For analyses that require deviation from the ITT population (i.e. outcomes for which data is only available from a subset of the randomised comparison), the same characteristics will be described separately for patients randomised to each treatment comparison within the subset population.

In sub-population analyses, if there are any important imbalances between the randomised groups in key baseline subgroups, analyses will be adjusted for the relevant baseline characteristic(s) in addition to age and respiratory status.

4.3.2 Analyses of time to first event

For all treatment comparisons, time-to-event analyses will be conducted using a Cox regression model adjusted for:

- Baseline age in three categories (<70 years, 70 to 79 years and ≥80 years)
- Baseline respiratory support status in four categories when available (None; Oxygen only; Non-invasive ventilation, Invasive mechanical ventilation)
    - For the dexamethasone comparison, data regarding non-invasive ventilation is not available so the Oxygen only and Non-invasive ventilation categories will be combined to give a single "Oxygen, non-invasive ventilation unknown" category.
    - For the tocilizumab comparison, only 9 participants did not require oxygen or ventilation due to the hypoxia inclusion criteria, so the None and Oxygen only groups will be combined to give a single "No ventilator support" category,

The Cox regression model will estimate adjusted hazard ratios, with 95% confidence intervals and p-values(based on the Wald chi-square statistic[15]) reported.

4.3.2.1 Censoring Rules

- Day of randomisation is study day 1
- For the outcome of time to all-cause mortality at 6 months, participants will be censored at the earliest of withdrawal of consent or study day 184.
- For the outcome of time to discharge from hospital at 6 months, participants will be censored at the earliest of withdrawal of consent or study day 184. Patients who die in hospital will be censored after 6 months after randomisation in order to achieve an unbiased estimate of the recovery rate[16].
- For all other time to event outcomes, participants will be censored at the earliest of death, withdrawal of consent, exit from the NHS date (if available) or on study day 28 (for 28 day analyses) or study day 184 (for 6 month analyses).

4.3.3 Analyses of categorical outcomes

For all treatment comparisons, an age- and respiratory support status-adjusted log-binomial regression model will be constructed for the estimation of adjusted risk ratios, with 95% confidence intervals and p-values (based on the Wald chi-square statistic) reported.

4.3.4 Analyses of continuous outcomes with repeated measures

For each participant, linear regression will be used to estimate the daily rate of change of a parameter from all their available measurements between baseline and study day 28. The validity of making such a linearity assumption will be assessed graphically. Participants with the mean deviation from their own fitted slope in the top 1% of the distribution of mean deviations across all participants will be excluded from the analysis.

For all treatment comparisons, the mean rate of change of the parameter will be compared between randomised groups using a linear regression model with subject-specific daily rate of change as the outcome variable, and adjusted for age group and baseline respiratory support status.

Normality of the residuals of the linear model will be assessed before including randomised treatment allocation in the final model and transformations considered if appropriate.

4.3.5 Analyses of ordinal outcomes with repeated measures

The ordinal scale score will be treated as a continuous outcome using the analysis methods above.

4.3.6 Analyses of differential gene expression

Raw RNASeq count data will be normalised for library size and composition. Log-fold change in gene expression will be compared between randomised groups based on hypothesis testing with correction for multiple testing to identify differentially expressed genes[17,18]. These will be presented and mapped to biological processes through publically-available ontological databases for aiding interpretation[19].

Final methods to be confirmed, e.g. depending whether sufficient repeated measures available

4.4 Allowance for multiplicity of comparisons

Formal adjustment will not be made for the multiplicity of testing in analyses. However, due allowance for multiple testing will be made in the interpretation of the results: taking into account the nature of events (including timing, duration and severity), the comparison in question (i.e. interpreted in the light of observed effects on relevant other comparisons) and by requiring more extreme p-values to infer evidence of effect in such analyses.

4.5 Subgroup analyses

4.5.1 Tests for heterogeneity or trend

Tests for heterogeneity of the proportional effect observed in specific subgroups will be conducted to assess whether there is any good evidence that the effect in particular subgroups differ materially from the overall effect seen in all patients combined. In interpretation, allowance will be given for multiple comparisons and for other differences between the subgroups.

For all treatment comparisons, tests for heterogeneity or linear trend (for 3 or more ordered groups) will be performed through the inclusion of an interaction term between the treatment assignment and the subgroup of interest in the relevant regression model.

4.5.2 Prediction of baseline non-coronavirus infection risk

Baseline-predicted risk of non-coronavirus infection will be estimated by using data from all available participants and constructing a multivariable logistic regression model with hospital care or death with non-coronavirus infection at 6 months as the outcome variable and including the baseline characteristics listed in section 5.3.1 as covariates. The regression model will additionally adjust for treatment allocation (with usual care designated the reference category) and for all possible two-way interactions between the above baseline characteristics and treatment allocation. These additional terms will be ignored when calculating baseline-predicted risk, however, in order to ensure that the estimates corresponded to risk if assigned usual care. Patients will then be subdivided into three approximately equally-sized groups (Low/Medium/High) on the basis of their predicted risk.

4.6 Missing data

As the extended clinical analysis outcomes are derived from routine healthcare datasets the completeness of outcome ascertainment cannot be definitive. For the purposes of analyses, the absence of a relevant routine healthcare data entry record is regarded as the outcome having not occurred for that participant. The coverage of the routine healthcare datasets (participant represented in the dataset at any time) will be presented as counts and percentages of all participants in the treatment comparison.

In the extended biological analysis, missing CRP, NLR and creatinine baseline and follow-up data will be imputed using multiple imputation to impute the baseline value and subject-specific daily rate of change and will be performed separately for each treatment arm.

The following variables will be included in the imputation model;

- Baseline measurement of the relevant assessment parameter
- Baseline rate of change of the relevant assessment parameter (estimated using linear regression in an analogous way to that of follow-up rate of change by using each participant's available measurements of the parameter between hospital admission and randomisation)
- Age
- Baseline respiratory support group
- Sex
- Ethnicity
- Duration of hospitalisation group
- Diabetes mellitus
- Heart disease,
- Liver disease
- Kidney disease
- Chronic lung disease
- Severe mental illness
- Immunosuppression
- Hospital frailty risk score group
- Time to discharge alive from hospital group (in the following categories: discharged alive study day 1 to study day 5; discharged alive study day 6 to study day 10; discharged alive study day 11 to study day 28; not discharged alive by study day 28).

Variables were included in the imputation model if there was clinical suspicion that they would be an important predictor of baseline or follow-up measurements of the parameters or they were a characteristic that informed missingness of rate of change of a parameter from exploration of data.

The number of imputations used will be ≥ to the % of incomplete cases in the data, with a minimum of 10. Results across imputations will be combined using the methods of Rubin[20].

For subgroup analyses, if a large proportion of data is missing for a variable, a separate unknown category will be reported for the subgroup. If a small proportion of data is missing, it will not contribute to the subgroup analysis but will to the overall result.

B.1.2 Exploratory analysis assessments

Extended biological analysis of the RECOVERY trial immunomodulatory therapy comparisons

This section details the proposed extended analysis of biological assessments. This aspect of the analysis is exploratory and aims to understand the impact of the immunomodulatory treatments on patient physiological, biochemical, virological and multiomics parameters. This knowledge aims to increase understanding of the biological impacts and mechanisms of the immunomodulatory treatments.

1. Capture of extended biological analysis data

The data for these assessments will be captured through the ISARIC4C study and will be available for RECOVERY participants who were also recruited to ISARIC4C. The detailed derivations of assessments included in the analysis is described separately in the extended analysis definitions and derivation document.

For all biological analysis assessments, the analysis will take place in the subset of participants with linked ISARIC4C data (the RECOVERY-ISARIC4C population), unless otherwise stated. Additional exploratory assessments may be conducted at a later date if deemed appropriate.

2. Definitions of extended biological analysis assessments

Ordinal Scale Score	Description
1	Discharged alive from hospital

8	Death

- The daily rate of change in ordinal scale score will be calculated for the period from baseline to study day 7.
- For all treatment comparisons, the difference in the daily rate of change in ordinal scale score will be compared between all RECOVERY-ISARIC4C participants allocated the intervention and all RECOVERY-ISARIC4C participants allocated usual care.
- The daily rate of change in ordinal scale score will be treated as a continuous outcome with repeated measures in the analysis.

vi) Time to first occurrence of SARS-CoV-2 viral clearance

- Defined as a negative SARS-CoV-2 test result (of any type).
- Assessed in the subset of RECOVERY-ISARIC4C participants who had a repeat SARS-CoV-2 test within 28 days from the date of randomisation.

vii) Time to first occurrence of neutropenia

- Defined as a neutrophil count of <1 x 10^9/ L.

viii) Time to first occurrence of hyperglycaemia

- Defined as a blood glucose of ≥11.1 mmol/L.

ix) Time to first occurrence of liver injury

- Defined as a liver transaminase of ≥225 U/L.

x) Self-care at hospital discharge

- Defined as an ability to self-care at hospital discharge that is the same or better compared with before the illness.
- Assessed in the subset of RECOVERY-ISARIC4C participants who were discharged alive from hospital.

xi) Subgroup analysis of extended respiratory support group at randomisation

- Extended respiratory support group at randomisation defined as:
  - No oxygen requirement;
  - Low to moderate oxygen (FiO_2 >0.21 & <0.5);
  - High oxygen (FiO_2 ≥ 0.5);
  - Non-invasive ventilation or high flow nasal oxygen;
  - Invasive mechanical ventilation (including ECMO).

xii) Transcriptomic assessments

- RNA Sequencing (RNA-Seq) gene expression count data is collected at ISARIC study enrolment, study day 3, day 9 and day 14 for ISARIC4C participants in Tier 1 and Tier 2.
- Normalised log-fold gene expression changes will be calculated based on baseline and post-randomisation measurements.
- Differentially expressed genes will be compared between randomised groups.
- Definitions will be finalised after access to biological sample data.

Sensitivity analyses

i) Complete case analysis

Sensitivity analyses will be conducted for daily rate of change of CRP, NLR and creatinine using complete case analysis – restricting to individuals with no missing data for the assessment.

ii) Altering follow-up time period

Sensitivity analyses will be conducted for daily rate of change of CRP, NLR, creatinine and ordinal scale score using data for the period from baseline to study day 14 and separately using data for the period from baseline to study day 28 (compared with study day 7 used in the main analyses).

Details of analyses

1. Analysis Populations

For all biological analysis assessments, the sub-population of all RECOVERY participants with linked ISARIC4C data available – the RECOVERY-ISARIC4C population - will be used, unless otherwise stated.

2. Methods of analysis

Baseline comparability of randomised groups

The following characteristics will be described separately for patients randomised to each treatment comparison:

- Age
- Sex
- Ethnicity
- Time since COVID-19 symptoms onset
- Time since hospitalisation
- Current respiratory support
- Comorbidities (diabetes, heart disease, chronic lung disease, severe liver disease, severe kidney impairment, immunosuppression, severe mental illness)
- Hospital Frailty Risk Score
- Use of systemic corticosteroid (including those allocated to corticosteroid)
- Use of other relevant treatments (e.g. remdesivir, interleukin-6 receptor antagonist)
- Baseline measurement of assessment parameter (if applicable)

For analyses that require deviation from the RECOVERY-ISARIC population (i.e. outcomes for which data is only available from a subset of this population), the same characteristics will be described separately for patients randomised to each treatment comparison within the subset population.

In sub-population analyses, if there are any important imbalances between the randomised groups in key baseline subgroups, analyses will be adjusted for the relevant baseline characteristic(s) in addition to age and respiratory status.

Analyses of continuous outcomes with repeated measures

For each participant, linear regression will be used to estimate the daily rate of change of a parameter using all that participant's available measurements between baseline and study day 7. The validity of making such a linearity assumption will be assessed graphically.

For all treatment comparisons, the mean rate of change of the parameter will be compared between randomised groups using a linear regression model with subject-specific daily rate of change as the outcome variable, and adjusted for age group and baseline respiratory support status.

Normality of the residuals of the linear model will be assessed before including randomised treatment allocation in the final model and transformations considered if appropriate.

Analyses of ordinal outcomes with repeated measures

The ordinal scale score will be treated as a continuous outcome using the analysis methods above.

Analyses of differential gene expression

Raw RNASeq count data will be normalised for library size and composition. Log-fold change in gene expression will be compared between randomised groups based on hypothesis testing with correction for multiple testing to identify differentially expressed genes[1,2]. These will be presented and mapped to biological processes through publically-available ontological databases for aiding interpretation[3].

Final methods to be confirmed, e.g. depending whether sufficient repeated measures available

3. Missing data

Missing CRP, NLR, creatinine and ordinal scale score baseline and follow-up data will be imputed using multiple imputation. Multiple imputation by chained equations (MICE) will be used to impute the baseline value of the parameter and the outcome variable of subject-

specific daily rate of change[4]. The imputation will be performed separately for each treatment arm. The number of imputations used will be ≥ to the % of incomplete cases in the data, with a minimum of 10. Results across imputations will be combined using the methods of Rubin[5].

The following variables will be included in the imputation model;

- Baseline measurement of the relevant assessment parameter
- Age
- Baseline respiratory support group
- Sex
- Ethnicity
- Diabetes mellitus
- Heart disease,
- Liver disease
- Kidney disease
- Chronic lung disease
- Severe mental illness
- Immunosuppression
- Hospital frailty risk score group
- Time to discharge alive from hospital group (an auxiliary variable in the following categories: discharged alive study day 1 to study day 4; discharged alive study day 5 to study day 7; discharged alive study day 8 to study day 14; discharged alive study day 15 to study day 28; not discharged alive by study day 28).

Variables were included in the imputation model if they were a characteristic that informed missingness of rate of change of a parameter from exploration of data or if there was strong clinical suspicion that they would be an important predictor of baseline or follow-up measurements of the parameters.

The following codes below were not included in non-coronavirus infection outcomes from death datasets unless a SARS-CoV-2 ICD-10 code (U071 or U072) was completely absent from the death certificate.

The rationale for this is when a cause of death on the death certificate was recorded as "COVID Pneumonia" it frequently resulted in the recording of an ICD-10 code for both COVID-19 (e.g. U071) and an ICD-10 code for pneumonia (e.g. J189).

Do I need NHS REC review?

To print your result with title and IRAS Project ID please enter your details below:

Title of your research:

Multi-dimensional analysis of the RECOVERY trial immunomodulatory therapy comparisons

IRAS Project ID (if available):

Your answers to the following questions indicate that **you do not need NHS REC review for sites in England.**

This tool only considers whether NHS REC review is required, it does not consider whether other approvals are needed. You should check what other approvals are required for your research.

You have answered **'YES'** to: Is your study research?

You answered **'NO'** to all of these questions:

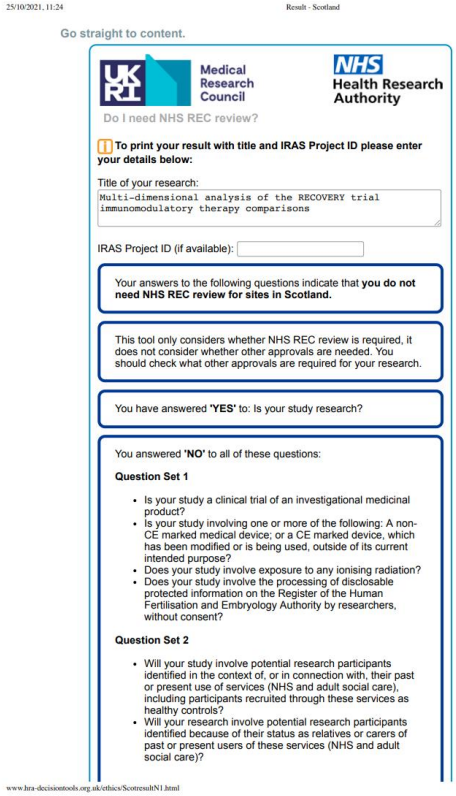

Question Set 1

- Is your study a clinical trial of an investigational medicinal product?
- Is your study one or more of the following: A non-CE marked medical device, or a device which has been modified or is being used outside of its CE mark intended purpose, and the study is conducted by or with the support of the manufacturer or another commercial company (including university spin-out company) to provide data for CE marking purposes?
- Does your study involve exposure to any ionising radiation?
- Does your study involve the processing of disclosable protected information on the Register of the Human Fertilisation and Embryology Authority by researchers, without consent?

Question Set 2

- Will your study involve potential research participants identified in the context of, or in connection with, their past or present use of services (NHS and adult social care), including participants recruited through these services as healthy controls?
- Will your research involve prospective collection of tissue (i.e. any material consisting of or including human cells)

D. Publication Plan

i) Main RECOVERY long-term follow-up publication

The manuscript for this publication has been drafted, which will report mortality and major non-COVID infection as primary outcomes at long-term follow-up in all RECOVERY treatment comparisons. The major non-COVID infection outcome uses the derivation created for this thesis extended analysis. This publication will also include the systematic review and meta-analysis of longer-term mortality from Chapter 2.

ii) Method development publication

The method development testing from Chapter 4 of the major non-COVID infection outcome with a focus on diagnostic accuracy against the RECOVERY and ISARIC4C CRF data and the baricitinib randomised comparison will be submitted for publication to disseminate objective data regarding the validity of the major non-COVID infection assessment derived from RCD. The clinical codelists used for the assessment will also be made publically available. Other assessments will be considered for future separate publication depending on interest.

iii) Data linkage process

The description of the processes involved in linking RECOVERY with ISARIC4C, as well as the associated value, difficulties and solutions encountered will be submitted for publication to disseminate the methods used for this and increase awareness of the linked dataset for future research.

iv) Exploration of detailed dexamethasone treatment effects

The exploration of the role of frailty in determining the heterogeneity of dexamethasone treatment effect, the systematic evaluation of other potential treatment-related harms (outside of infection) and the randomised comparisons of commonly-measured biomarkers will be submitted for publication to disseminate findings with regard to the potential

determinants of the risk-benefit balance of corticosteroid treatment in hospitalised patients with COVID-19, and for utilisation in future research.

v) Dexamethasone effect on gene expression data

The randomised comparison of gene expression data in the dexamethasone comparison will be published to disseminate findings for utilisation in future research.
