SHEPPI Monthly Report: Epidemiology, Data Integrity and Patient Care Indicators

Data compiled to 26 Feb 2022

Epidemiology

In the last 30 days (between 28 January and 26 February), **2028** patients with malaria have been entered into the surveillance system across the SHEPPI clinics. Of these patients, 904 (44.6%) had falciparum malaria, 889 (43.8%) had vivax malaria, 121 (6.0%) had malariae malaria, 7 (0.3%) had ovale malaria and 106 (5.2%) had mixed species malaria. Since the inception of the SHEPPI surveillance system, 107307 cases of malaria have been recorded.

Table 1. Malaria case numbers by *Plasmodium* species and clinic during the last 30 days

Clinic	<i>P. falciparum</i>		<i>P. vivax</i>		<i>P. malariae</i>		<i>P. ovale</i>		Mixed		Total	
	N	%	N	%	N	%	N	%	N	%	N	%

1. Introduction and Rationale

Mimika Regency, located in the southern part of Papua, has the highest burden of malaria in Indonesia, with Annual Parasite Incidence more than 400 times higher than the national average. Cases are concentrated mainly in Timika, the capital city. A good understanding of the epidemiology of malaria and current treatment practices is required to optimize effective control and elimination strategies. District-specific malaria surveillance and targeted response is pivotal for effective malaria control in Mimika.

The national electronic malaria surveillance system (eSISMAL) is used by public government hospitals and clinics. Its completeness and timeliness are often an issue for health facilities in the rural part of high-endemic areas with limited computer and internet access, such as in Mimika. Health clinics in Mimika typically have a poor medical record system. In addition, patients often forget to bring their medical cards, and healthcare providers often fail to address this by retrieving medical records. Robust measures of the true burden of disease require quality surveillance.

It is also hard to estimate the risk of recurrence without a unique patient identification system to identify representations reliably. Incomplete surveillance data undermines the interpretation of case trends and the associated impact of malaria control practices and interventions. Robust malariometric surveillance is critical for optimizing healthcare, which can be improved with simple and standardized data collection and timely feedback to healthcare staff.

2. Outline of Statistical Analysis

2.1 Specific objectives of the study

- Describe the epidemiology and current management of malaria in Timika, Papua.
- Assess the impact of enhanced malariometric surveillance and data feedback on the quality of malaria care in primary healthcare centers in Timika, Papua.

2.2 Endpoints

All endpoints will be calculated using data entered into the database for the study period of January 2019 to December 2023 and will be presented monthly unless stated otherwise. The database used was EpiData (until November 2022), and it continued with REDCap.

2.2.1. Primary Endpoint:

- Number of patients diagnosed with malaria stratified by species

2.2.2. Secondary Malariometric Endpoints:

- Slide positivity rates for each Plasmodium species
- Proportion of patient presentations identified as recurrent visits within 6 months

2.2.3. Secondary Endpoints – Data Quality:

- Proportion of patients with missing register numbers
- Proportion of patients with missing age data
- Proportion of patients with missing weight data

- Proportion of patients with missing gender data
- Proportion of female patients with missing pregnancy status
- Proportion of patients with missing parasite data
- Proportion of patients assigned a malaria card number
- Proportion of patients with missing data to calculate DHP prescription accuracy
- Proportion of patients with missing data to calculate PQ prescription accuracy

2.2.4. Secondary Endpoints – Quality Management:

- Proportion of patients with malaria due to any Plasmodium species correctly prescribed the recommended age/weight-based dose of DHP according to the national guidelines
- Proportion of patients with *P. vivax* or *P. ovale* malaria correctly prescribed the recommended age/weight-based dose of PQ according to the national guidelines
- Proportion of infants < 6 months of age or <6 kg inappropriately prescribed PQ
- Proportion of pregnant women inappropriately prescribed PQ

2.3 Exposures of Interest

2.3.1. Factors affecting malaria epidemiology:

Site : clinic, drug stock-out period
Patient : age, sex, pregnancy

2.3.2. Factors affecting data quality

Site : clinic, staffing
Interventions : CQI workshops

2.4 Definitions

2.4.1. Age Groups

Children will be considered as any patient aged ≤ 15 years.
Childhood will be stratified into patients <1 years, 1-5 years, and those >5-15 years.

2.4.2. Prescribing Accuracy

Prescribing accuracy will be measured based on the number of tablets directed by the national guideline on malaria treatment (Buku Saku Penatalaksanaan Kasus Malaria, 2020).

ACT Underdosing : Patients receiving fewer DHP tablets than directed in guideline

ACT Overdosing : Patients receiving more DHP tablets than directed in guideline

PQ Underdosing : Patients receiving fewer PQ tablets than directed in guideline

PQ Overdosing : Patients receiving more PQ tablets than directed in guideline

3. Summary of statistical analyses

3.1 Description and baseline characteristics

Descriptive summary statistics of baseline diagnostic methods, treatment algorithms (including dosing and exclusions), second-line regimens used during stock outages, and data collection processes will be presented.

Slide Positivity Rate (SPR) between 2019 and 2023 will be derived from laboratory records at each clinic and calculated as the number of positive malaria slides divided by the total number of blood films examined. SPR will be stratified by species, and presented by month for the observational period. RDT results will not be considered.

The absolute number of malaria cases stratified by species will be presented over time (monthly). Malaria cases will be temporally related to key events such as stock outs and the COVID-19 pandemic. The proportion of malaria patient attending any of the study clinics will be presented per year, stratified by species, clinic, and age.

A summary of relevant baseline patient characteristics will be presented for all malaria patients. Variables presented will include parasite species, age group, weight by age groups, sex, pregnancy, and lactating status. Depending on data distribution, continuous data will be presented as mean and 95% confidence interval (95%CI) or median and inter-quartile range (IQR).

Table: Microscopy Slide Positive Rate for each Plasmodium species, 2019-2023

Figure: Microscopy Slide Positive Rate (SPR) for each Plasmodium species and clinic by month, 2019-2023

Table: Baseline Characteristic by clinic, 2019-2023

Figure: Malaria cases per month by Plasmodium species, 2019-2023

Figure: The proportion of malaria patients attending clinics each year, stratified by Plasmodium species, 2019-2023

Figure: The proportion of malaria patients, stratified by Plasmodium species and age group, 2019-2023

3.2 Data Quality:

The proportions of missing Data Quality Endpoints (Section 2.2) will be presented for each metric. Variables likely to determine data quality will be explored including clinic and the number of staff in malaria corner.

The proportion of patients with available data to determine DHP and PQ dose will be presently. The impact of CQI will be assessed by comparing the proportion of missing data in the 5 months before and 5 months after the first and second CQI.

In the first 5 months, data integrity to calculate DHP and PQ prescription accuracy will be tabulated for different patients characteristics (clinic, age group, and gender) to identify populations at greatest risk of missing data.

Figure: Proportion of missing data needed to calculate DHP and PQ Prescription Accuracy, by month

Figure: Data Integrity, 2019-2023

3.3 Quality of Clinical Management

3.3.1 Primaquine Administration

The proportion and absolute numbers of patients diagnosed with *P. vivax* or *P. ovale* malaria who were and were not prescribed PQ will be presented. The prescribing accuracy will be presented in terms of overdosing (too many tablets) and underdosing (too few tablets) according to the recommended age/weight-based PQ in the national antimalarial guidelines. These data will be graphed over time (monthly) and temporally related to key events such as CQI and drug stock outs.

For all patients with available data, the mg/kg total dose of PQ administered will be calculated and presented as a histogram. Reference lines will mark 3.5 mg/kg to indicate the low dose used in Indonesia and at 7 mg/kg to indicate the high dose that should be more optimum for high relapse periodicity area.

Pooled quarterly prescribing accuracy will also be presented. Accuracy will be compared from first 5 months of 2019 (pre CQI), second 5 months of 2019 (post CQI) and last 5 months of 2023. For the first 5 months of 2019, the risk of over and under dosing will be presented in table for different patients characteristics (clinic, age group, and gender) to determine populations at greatest risk of incorrect dosing.

Frequency of inappropriate treatment will be graphed over time (monthly) for both pregnant women and infants.

3.3.2 DHP Administration

The proportion and absolute numbers of patient diagnosed with any malaria who were and were prescribed DHP will be presented. The prescribing accuracy will be presented in terms of overdosing (too many tablets) and underdosing (too few tablets) according to the recommended age/weight-based DHP in the national antimalarial guidelines. These data will be graphed over time (monthly) and temporally related to key events such as CQI and drug stock outs.

For all patients with available data, the mg/kg daily dose of DHA administered will be calculated and presented as a histogram, with reference line at 2 and 4 mg/kg to indicate the range of optimal dose. The same approach will be used for piperazine, with reference line at 16 and 32 mg/kg.

Pooled quarterly prescribing accuracy will also be presented. Accuracy will be compared for the first 5 months of 2019 (pre CQI), the second 5 months of 2019 (post CQI) and last 5 months of 2023. For the first 5 months of 2019, the risk of over and under dosing will be presented in table for different patients characteristics (clinic, age group, and gender) to determine populations at greatest risk of incorrect dosing.
