Genes to treat hereditary cardiac disease can be transferred to the heart by intravenous (IV) administration of a cardiac tropic vector such as AAVrh.10. However, some recessive genetic diseases of the heart such as dilated cardiomyopathy type 2A resulting from TNNI3 mutations, may require very high levels of transgene expression since the endogenous gene is in the top 1 percentile of cardiac gene expression. A significant proportion of intravenous vector traffics to the liver, with concomitant high levels of unwanted liver expression so optimal cardiac expression is required. With the goal of maximizing cardiac transgene expression while minimizing liver transgene expression, we used AAVrh.10 vector administered intravenously to C57Bl/6 mice (dose at 4 x 10^{12}gc/kg) to screen expression cassettes with 5 liver-specific miRNA targets (mir122, 148, 192, 194, 208) and 5 cardiac-specific promoters (TNNI3, PLN, TNNT2, MYOZ2, ANKRD1) for the optimal high cardiac / low liver expression. Using the CAG strong ubiquitous promoter as the 100% comparator, screening of the 5 miRNAs yielded the maximum suppression of liver expression with mir122 (liver 0.5% that mediated by CAG), but at the price of suppression of cardiac expression (10.4±16.3% of CAG). In contrast, mir194 mediated the highest cardiac expression (116±26% of the level mediated by CAG) with liver expression reduced to 6.2±0.9% of CAG. Screening of the 5 cardiac-specific promoters demonstrated that all were associated with low liver expression (all <1% that of CAG), but at the price of low cardiac expression (all <8% that of CAG). With the goal of increasing the cardiac expression while minimizing liver expression, we used the TNNI3 cardiac-specific promoter as the example (TNNI3 mediated cardiac expression that was 2.6±0.61% of CAG), and added enhancers MYH6/7, CS-CRM4 or CMV to assess improvement. The highest cardiac expression was with the TNNI3-CMV combination (87.9±57.1% that of CAG), but with higher liver expression (10.2±5.2% of CAG). Two cardiac enhancers (MYH6/7 and CS-CRM4) were added to the TNNI3 promoter and while they respectively provided 2.4 and 7.5-fold enhanced expression in heart compared to TNNI3 promoter alone, the total cardiac expression level was <20% of that provided by the non-specific CAG. We further tested if a combination of cardiac specific promoter and enhancer with a target for a liver-specific miRNA could provide better performance. The CS-CRM4 enhancer combined with the TNNI3 promoter gave 12.0% of the cardiac expression level provided by the CAG promoter and addition of a mir192 target increased this only to 16.0%. However, the addition of a mir192 target suppressed hepatic expression by 5.8-fold. Overall, this study suggests that while cardiac specific promoters can provide cardiac selectivity and high cardiac expression with the addition of enhancer elements, similar levels of cardiac selectivity and higher cardiac expression can also be achieved by liver specific miRNAs.

605. Systemic Administration of a Novel Cardiotropic AAV Vector Encoding BAG3 Rescues Left Ventricle Functional Deficits in a Mouse Model of Myocardial Infarction

Lisa M. Stanek, Bryan Mastis, Charles Gualtieri, Tyler Ironside, Cynthia Pryce, Elizabeth Scott, Emily Grandell, David Ma, Giridhar Murlidharan, Thomas Matthew Edwards, John Reece-hoyes, Roberto Calcedo, Sherry Cao, Charles F. Albright, Laura K. Richman

Affinia Therapeutics, Waltham, MA

Gene therapy with adeno-associated virus (AAV) vectors is emerging as a promising therapeutic platform for the treatment of cardiovascular disease. Unfortunately, effective gene delivery to the heart and safety concerns have been major limitations to clinical translation. We have identified a novel AAV capsid (ATC-0108) by a machine learning guided rational design approach that demonstrates significantly improved cardiac transduction and robust liver detargeting compared with wild-type AAV9. To test the performance of our capsid in a disease-relevant context, we employed a mouse model of myocardial infarction (MI) with diminished left ventricular (LV) function and B-cell lymphoma 2 (Bcl-2) associated anthanogene-3 (BAG3) as a therapeutic transgene. BAG3 has emerged as a promising drug target for patients with heart failure and genetic cardiomyopathies. BAG3 is a 575 amino acid member of the BAG family of proteins that plays a critical role in cardiac contractility and Ca2+ homeostasis (Felman A., 2016). Decreased levels of BAG3 were found in the ventricular myocardium of patients with end-stage heart failure (HF) due to either coronary artery disease or idiopathic dilated cardiomyopathy. Animal models of heart failure including trans-aortic banding and myocardial infarction models in mice and pigs show similar reductions in BAG3

following these procedures. It has previously been shown that AAV9-mediated expression of BAG3 improves LV function in a murine model of myocardial infarction (MI) when delivered systemically at 1e14 vg/kg (Knezevic T., 2016). Here we sought to determine if we could improve LV function in a murine MI model using our novel cardiac capsid ATC-0108 expressing BAG3. Myocardial infarction was surgically induced by a distal ligation of the left anterior descending (LAD) coronary artery creating sustained ischemia and infarction in the LV anterior wall. Cardiac infarction was confirmed by weekly ultrasound echocardiography. Six weeks following surgery, when MI mice showed significantly diminished LV function compared to control mice (that did not undergo surgery), MI mice received IV injection of ATC-0108 expressing human BAG3 under the control of a cardiac promoter (ATV-0134). Based on biodistribution studies performed in unoperated wild type mice we selected an IV dose of 2e12 vg/kg that led to >70% transduction of the mouse myocardium. Following systemic injection of ATV-0134 MI mice demonstrated a 40% improvement in LV function by echocardiography. Histological analysis of heart tissues confirmed the presence of a surgically-induced infarct in all MI mice with no evidence of test article related safety findings in any tissue analyzed (heart, skeletal muscle and liver). Immunohistochemistry demonstrated transduction of 70% of the myocardium and BAG3 expression throughout the heart with little to no expression in liver or skeletal muscle. The results of this study confirm that our novel cardiotropic AAV capsid demonstrates safety and robust therapeutic efficacy in an animal model of cardiac dysfunction. ATC-0108 encoding BAG3 provided significantly improved cardiovascular function in the MI mouse model. A highly cardiotropic liver detargeted may provide a novel therapeutic option for the treatment of cardiovascular disease.

606. Systemic Administration of CBN-1100, a New Recombinant Parvovirus Vector with a Non-AAV Capsid, Shows Favorable Biodistribution and Reduced Liver Tropism in Nonhuman Primates

Salvatore Iovino[1], Samantha Smith[1], Leila Malkoc[1], Melvys Valledor[2], Michael Rak[2], Jeffrey Moffit[3], Sebastian Aguirre[2], Marc Abrams[4]

[1]Translational Biology Team, Carbon Biosciences, Waltham, MA,[2]Platform Development Team, Carbon Biosciences, Waltham, MA,[3]Nonclinical Development Team, Carbon Biosciences, Waltham, MA,[4]Carbon Biosciences, Waltham, MA

Most systemically-administered viral gene therapies which have achieved marketing approval or are in late-stage development are recombinant AAV vectors, representing only one genus (dependoviridae) within the parvovirus family. Despite their strong pharmaceutical attributes universal applicability is limited by high seroprevalence in the human population, limited cargo capacity, and safety and efficacy concerns related to high levels of liver transduction. To overcome many of these limitations, Carbon Biosciences is developing hybrid parvovirus vectors containing capsids from non-primate-derived autonomous parvoviruses and genomes packaged with AAV2 inverted terminal repeats (ITRs). The new recombinant vector CBN-1100 offers the ability to package genomes of at least 5.5 kb, low potential for neutralization by human antibodies, and has been shown to transduce cell types of therapeutic interest. Importantly, CBN-1100 maintains the strong manufacturability and scalability properties of AAV vectors. In this report, we present the tissue distribution, preliminary tolerability, and gene expression profile of CBN-1100 in mice and cynomolgus macaques at several dose levels. We observed strong viral genome copy numbers and transgene expression in tissues of therapeutic interest including kidney and heart. Remarkably, liver distribution and liver gene expression were extremely low in comparison to AAV historical data. CBN-1100 also exhibited a favorable tolerability profile, with clinically insignificant elevation of liver transaminases or complement factors. These compelling pharmacological properties, powered by a wild-type parvovirus capsid that is >80% divergent from AAV vectors at the amino acid level, support further development of CBN-1100 and related vectors for therapeutic applications which are out-of-reach for current gene therapy technologies.

607. Evaluating the Transduction Efficiency of Different AAV Serotypes on hiPSC Derived Cardiomyocytes

Georgios Kosmidis

Ncardia, Leiden, Netherlands

Gene therapy holds great promise for the treatment of a wide range of genetic disorders. Adeno-associated viruses (AAVs) have emerged as versatile and efficient vectors for gene delivery due to their ability to transduce a variety of cell types with minimal immunogenicity. In recent years, the integration of AAV-based gene therapy with human induced pluripotent stem cell (hiPSC) technology has unlocked new possibilities for personalized medicine and disease modeling. The identification of AAV vectors with the highest transduction efficiency, lowest toxicity and best efficacy in ameliorating disease-specific phenotypes, is crucial for efficiently selecting which vectors pass on subsequent preclinical and clinical studies. hiPSC derived cell models allow us to assess all three of these key aspects. In fact using high content screening as a readout, the first two of these parameters, transduction efficiency and cytotoxicity, can be evaluated quickly and cost-effectively prior to the more laborious task of efficacy analysis with the use of other elaborate functional assays. In order to evaluate AAV transduction efficiency in hiPSC derived cardiomyocyte cells (hiPSC-CMs) a panel of AAVs of different serotypes, all expressing GFP, was tested at several MOI values in our bioreactor generated (healthy control) hiPSC-CMs called Ncytes. Fluorescence intensity levels for GFP were recorded daily for a period of 10 days post transduction using a microplate reader. At the final experimental timepoint the nuclei of the transduced hiPSC-CMs were stained with Hoechst dye and the cells were imaged using a high content image confocal microscope. The parameters of cell %viability (number of nuclei/average number of nuclei of vehicle control), %transduction efficiency (number of GFP+ nuclei/number of total nuclei) and average fluorescence intensity were analyzed for all conditions. Most AAV serotypes at their respective MOIs, had an acceptable GFP signal (2-7x fluorescence intensity above local background). The only vector that failed to transduce hiPSC-CMs was AAV4. For all other vectors transduction efficiency increased with increasing MOIs as expected. The most efficient transductions were achieved using AAV1 and AAV5 vectors. Cytotoxicity was observed at higher MOIs (>10.000) for several vectors. Using our high content

imager we now have a suitable platform to evaluate the transduction efficiency and cytotoxicity of test AAVs. This not only helps us to identify which AAV serotypes are most suitable for transducing our Ncyte cells but also allows us to assess the transduction potential of AAVs supplied by our clients cost effectively, prior testing their efficacy in downstream functional assays.

608. Novel Human Heart-Derived Adeno-Associated Viruses Are Cardiac-Specific Gene Carriers for Effective *In Vivo* Gene Delivery to Mammalian Hearts and Human iPS-Derived Cardiomyocytes

Daniel Zeissler[1], Sebastian Grieskamp[1], Dorothea Kehr[1], Stephanie Simon[2], Philipp Schlegel[2], Eric Meinhardt[2], Hugo A. Katus[2], Malte Loos[3], Arne Hansen[3], Martin Busch[4], Andreas Jungmann[1], Julia Ritterhoff[1], Patrick Most[1]

[1]Molecular and Translational Cardiology, Heidelberg University Hospital, Heidelberg, Germany,[2]Cardiology, Heidelberg University Hospital, Heidelberg, Germany,[3]Experimental Pharmacology and Toxicology, Hamburg University Hospital, Hamburg, Germany,[4]AaviGen, Heidelberg, Germany

Introduction: Recombinant adeno-associated viral (rAAV) vectors currently used in clinical trials for cardiac gene therapy (GT) lack myocardial specificity. rAAV9, being clinically probed in human cardiomyopathy GT trials, exerts high hepatic toxicity resulting in fatal liver failure and death in several patients. As such, rAAVs with high cardiac specificity and ability to transduce the human heart would be close to an ideal vector for human cardiac GT. **Hypothesis:** We therefore hypothesized that the human heart may be a source for identifying novel AAVs, therefore capable to transduce human myocardium, with appropriate cardiac specificity to enable safe and effective gene transfer to mammalian hearts in vivo. **Approach and Results:** We identified AAV9 and AAV6 in myocardial biopsies from heart failure patients as serotypes known to effectively transduce myocardium in vivo and in vitro, respectively. Additionally, a group of novel AAVs (AAVcor1-3) with sequences close to rAAV13 were discovered. HEK-293 high-titer producible vectors with cloned rAAVcor1, 2 and 3 and rAAV9 capsid sequences were used for in vivo biodistribution analysis with a CMV-YFP reporter cassette in mice (each n=6 mice). 2 weeks after i.v. injection (per rAAV 1E12 vgc/kg), the rAAVcor group equaled rAAV9s excellent cardiac transduction and YFP mRNA expression abilities by vgc and mRNA levels in left ventricles (LV). In contrast to rAAV9s significantly higher hepatic than cardiac enrichment, all three rAAVcor vectors were almost undetectable in liver and other organs (e.g. brain) with a 1000-fold higher heart/liver vgc ratio than rAAV9. From this group, rAAVcor1s biodistribution was further compared with rAAV9 in mice using a cardiac troponin (cTnT)-YFP reporter system with clinically relevant dosages (5E12, 5E13, 5E14 vgc/kg; n=6 animals). 2 weeks after i.v. injection, rAAV9 showed high dose-dependent hepatic YFP protein IHC and IB expression. In contrast, rAAVcor1 unveiled the desired dose-dependent homogeneous cardiac YFP protein expression in cardiomyocytes (CM) but no detectable hepatic YFP protein expression. Given its high cardiac specificity, rAAVcor1 with the cTNT-relaxin family peptide receptor 1 (rfxp) inotropic response gene, which can be acutely activated using the peptide ligand relaxin (rel), was injected into mice (5E13 vgc/kg; n=6 animals). After 2 weeks, the murine hearts showed high cardiac-restricted rfxp mRNA levels and significant increase in cardiac contractile performance by LV catheterization in response to 50 µg single i.v. rel. injection. Subsequent i.v. injection of rAAVcor1 and rAAV9 in adult farm pigs (1E12 vgc/kg, n=3 animals per vector), each with a CMV-YFP reporter system, confirmed the high cardiac specificity of rAAVcor1 over AAV9 (>1000-fold) and homogeneous LV and RV transduction of the human-sized hearts. In hiPS-CM-EHTs, the ability of rAAVcor1 (1E9 vgcs per EHT) to homogenously transduce a human myocardial tissue equivalent was validated using YFP protein expression analysis via microscopy and FACS from dissociated EHTs. **Conclusion:** rAAVcor1, discovered in human failing myocardium, combines the clinically desirable properties of high and homogeneous *in vivo* transduction of murine and human-sized pig hearts with excellent liver detargeting after systemic injection and producibility. Such characteristics may destine rAAVcor1 as a suitable vector for safe and effective human cardiac GT.

609. Development of Cardiomyopathy Variant Knock-in Mouse Strains for Gene Therapy Proof-of-Concept

Hideki Uosaki[1], Tatsuya Anzai[2], Ryo Kawakami[3], Takeshi Tokuyama[1], Razan E. Ahmed[1], Fuad Gandhi Torizal[1], Yasumitsu Nagao[4], Hirofumi Nishizono[5], Norimichi Koitabashi[6]

[1]Division of Regenerative Medicine, Center for Molecular Medicine, Jichi Medical University, Shimotsuke, Japan,[2]Department of Pediatrics, Jichi Medical University, Shimotsuke, Japan,[3]Department of Cardiovascular Medicine, Gunma University Graduate School of Medicine, Maebashi, Japan,[4]Center for Experimental Medicine, Jichi Medical University, Shimotsuke, Japan,[5]Medical Research Institute, Kanazawa Medical University, Uchinada, Japan,[6]Department of Cardiovascular Medicine, Gunma University Graduate School of Medicin, Maebashi, Japan

Gene therapy is a rapidly expanding field, but the development of gene therapy for cardiomyopathy is still limited. One reason for this is the lack of suitable mouse models to demonstrate proof-of-concept in vivo. However, with recent advancements in genome editing using CRISPR/Cas9, it is now easier and faster to generate mouse models with knock-in variants for cardiomyopathy. Therefore, we aimed to develop these mouse strains and test the effectiveness of gene therapy. We created mutant mouse strains intending to model four types of cardiomyopathy by introducing variant knock-ins in Mybpc3, Lmna, Tnni3, and Bola3 genes. All the strains exhibited reduced heart function and/or shorter lifespan. For example, Tnni3 and Bola3 homozygous mutant mice survived for only two to three weeks after birth. In contrast, Mybpc3 and Lmna mutant mice lived longer despite their impaired heart function.To gain proof of concept, we utilized Mybpc3 mutant strains—nonsense (Q84X) and missense mutations (R824Q). MYBPC3 mutations are frequently associated with hypertrophic cardiomyopathy (HCM), and one clinical trial has recently been initiated for MYBPC3-associated HCM using adeno-associated virus (AAV). HCM often progresses to develop ventricular systolic dysfunction, termed HCM with left ventricular systolic dysfunction

(HCM-LVSD). Thus, it is intriguing to ask if gene therapy could treat HCM or even HCM-LVSD following pathological cardiac remodeling. We first examined the characteristics of Q84X and R820Q. Q84X is the orthologous mutation of Q76X that was a causative gene for fatal congestive heart failure in an infant. Q84X homozygous mice displayed reduced systolic function even at two weeks but survived for almost a year. Meanwhile, R820Q is associated with familial HCM and HCM-LVSD in patients. In mice with R824Q, the equivalent of R820Q, cardiac hypertrophy, and mild systolic dysfunction developed spontaneously at 8 weeks old, recapitulating the HCM-LVSDphenotype.Next, we examined if gene therapy is effective in these HCM models. To this end, we constructed a vector expressing Mybpc3 under the control of a cardiomyocyte-specific, cardiac troponin T promoter and packaged it into AAV serotype 9 capsid. First, we tested the AAV in adult Q84X mice by administering 1 x E+14 vg per head. Although Mybpc3 expression was observed, heart function remained low, indicating that gene therapy may not be effective once pathological cardiac remodeling is completed. Next, we administered the AAV to R820Q mice that began to develop hypertrophy at 8 weeks of age at a dose of 1.76 x E+13 vg per head. Echocardiography and cardiac catheter revealed that AAV gene therapy significantly suppressed the deterioration of cardiac function over time. The overexpression of fetal genes of cardiomyocytes was also significantly suppressed, and mitochondrial gene abnormalities and myocardial fibrosis were attenuated.Our genetically modified mouse strains with cardiomyopathy variants accurately replicated the human cardiomyopathy symptoms. They can be used as models to examine the effectiveness of AAV-based gene therapy. The administration of gene therapy with AAV, even at a stage when cardiac remodeling has already begun, but not yet completed, successfully suppressed cardiac dysfunction and prevented the transition to HCM-LVSD.

610. Developing an AAV-Based Gene Therapy for MYBPC3 Mutation-Associated Hypertrophic Cardiomyopathy

Therese Salameh[1], Hongbin Xu[1], Hong Duan[1], Yogeshwar Sharma[1], Deepthi Yedlapudi[1], Chao Ren[2], Jingsong Cao[1], Zhong-Dong Shi[1]

[1]Frontera Therapeutics, Bedford, MA,[2]Frontera Therapeutics, Shanghai, China

Hypertrophic cardiomyopathy (HCM) is a highly prevalent cardiovascular genetic disorder affecting approximately 0.2% (1:500) individuals worldwide. This disease which potentially results in heart failure or sudden cardiac death, is characterized primarily by left ventricular hypertrophy, diastolic dysfunction, myocyte disarray, and interstitial fibrosis. Loss-of-function mutations in *MYBPC3,* the gene encoding cardiac myosin-binding protein C (cMyBP-C), is one of the primary causes of genetic HCM. Most pathogenic mutations of *MYBPC3* arise via frameshift, nonsense, or conserved RNA splice site mutations on a single allele that results in protein truncation, which is more likely to degrade resulting in lower total cMyBP-C protein levels (haploinsufficiency). Haploinsufficiency of *MYBPC3* contributes to sarcomeric dysfunction and deregulation of contraction and relaxation in cardiac myocytes. Restoration of cMyBP-C haploinsufficiency offers a viable therapeutic approach for the treatment of HCM. We are developing an AAV-based therapy to treat MYBPC3-associated HCM. We have engineered AAV vectors encoding human cMyBP-C protein. We showed that systemic delivery of AAV vectors effectively restores cMyBP-C to cardiomyocytes in a *Mybpc3* knockout (KO) mouse model. AAV vector treatment of neonatal *Mybpc3* KO mice (on P1) caused a significant reduction in heart weight to body weight ratio in comparison to the vehicle-treated group, indicating there was an improvement in cardiac hypertrophy. Our data also showed a correlation between the level of cMyBP-C protein restored in cardiomyocytes and the reduction in heart weight to body weight ratio. In addition, treatment of the *Mybpc3* KO mice with AAV vectors showed a significant reduction in HCM-associated biomarkers in the heart, including the genes encoding atrial and B-type natriuretic peptide and tissue inhibitor of matrix metalloproteinase-1, a marker of fibrosis which is a hallmark of this disease. Biodistribution studies demonstrated that our vector specifically targeted the heart as evidenced by the lack of protein and mRNA expression in liver and skeletal muscle. Furthermore, no clinical abnormalities or safety concerns were observed in our studies. These data demonstrate that our AAV vectors are capable of restoring cMyBP-C deficiency and improving cardiac hypertrophy and associated biomarkers in a murine model that resembles the human condition of HCM and support the continued development of this AAV-based gene therapy.

611. Epicardial Hydrogel for Cardiac Gene Delivery

Gabriella Kabboul[1,2], Luiza DaMotta[3], Christopher B. Doering[4], Andrés J. García[3], Rebecca D. Levit[2]

[1]Wallace H. Coulter Department of Biomedical Engineering, Georgia Institute of Technology & Emory University, Atlanta, GA,[2]Division of Cardiology, Department of Medicine, Emory University, Atlanta, GA,[3]Woodruff School of Mechanical Engineering & Petit Institute for Bioengineering and Bioscience, Georgia Institute of Technology, Atlanta, GA,[4]Department of Pediatrics, Emory University & Children's Healthcare of Atlanta, Atlanta, GA

Introduction: The use of adeno-associated virus (AAV) has emerged as a novel approach to deliver genes to the heart. However, clinical translation of AAV-based cardiac therapies has been largely unsuccessful owing to pre-existing neutralizing anti-AAV antibodies and poor cardiomyocyte transgene expression. An effective delivery method is a significant barrier in cardiac gene therapy. Epicardial hydrogel delivery of AAV may overcome obstacles to cardiac gene transfer. Here we investigate the delivery of an epicardial hydrogel encapsulating AAV. We hypothesize that hydrogels delivered to the epicardial surface through the pericardial space may result in longer tissue residence time, reduced off-target effects, and minimal vascular washout; consequently, shielding the virus from immune-mediated neutralization and increasing cardiac gene uptake. **Methods:** Degradable hydrogels were synthesized with 4-arm poly(ethylene glycol) maleimide-terminated (PEG-4MAL) macromer mixed with a crosslinker. AAV9 encoding mCherry and luciferase driven by the CMV promoter was encapsulated in the gels. A viral dose of 1E12 vector genomes was delivered to male Sprague-Dawley rats by epicardial hydrogels (n=7) or intravenous (IV) injection (n=5). Animals were randomized to receive AAV by only one delivery method. After 28 days, bioluminescence imaging was performed to quantify vector biodistribution and serum was collected to measure anti-AAV9 antibody titers. Bioluminescent expression was quantified from *in*

vivo images with regions of interest drawn around the heart and liver. Histology was performed to assess transgene expression in the heart. **Results:** Animals receiving epicardial hydrogels showed a 9-fold higher average radiance in the heart compared to animals receiving AAV intravenously ($p<0.01$). In the liver, animals that received epicardial hydrogels showed significantly lower average radiance in comparison to animals that received AAV via IV injection ($p<0.05$). In addition, anti-AAV9 IgG titers were 2-folds lower in serum from animals receiving epicardial hydrogels in contrast to IV delivery. Immunofluorescent analysis of cardiac tissue indicated epicardial hydrogels enable epicardial and myocardial transduction, while systemic delivery showed sparse mCherry expression in the myocardium. **Conclusion:** These results support the potential benefits of epicardial hydrogel-AAV delivery to effectively transfer therapeutic transgenes to the heart with minimal off-target transduction and lower humoral immunity generated compared to systemic AAV administration. Future studies will focus on optimizing epicardial hydrogels for AAV release and demonstrating cardiac therapeutic efficacies.

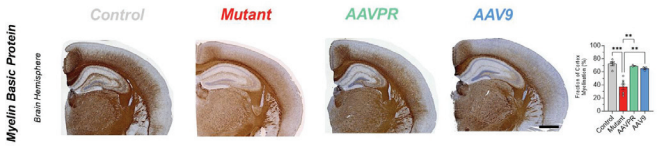
612. Clinical Grade Human Adenovirus 5 Vector Overexpressing TIMP-3 is Safe and Efficacious in a Pig Model of Vein Graft Neointimal Hyperplasia

Stuart A. Nicklin[1], Samantha Carmichael[2], Sarah J. George[3], Collin Berry[4], Alex McConnachie[4], Nawwar Al-Attar[1], Stefano Colloca[5], Rachel Dakin[4], Menzo Havenga[6], Angelique Lemckert[6], Rebecca Bayliss[7], Rebecca Wallace[7], Alan L. Parker[7], Raimondo Ascione[3], Andrew H. Baker[4,8]

[1]University of Glasgow, Glasgow, United Kingdom,[2]Greater Glasgow and Clyde NHS, Glasgow, United Kingdom,[3]University of Bristol, Bristol, United Kingdom,[4]University Of Glasgow, Glasgow, United Kingdom,[5]ReiThera Srl, Rome, Italy,[6]Batavia Biosciences, Leiden, Netherlands,[7]Cardiff University, Cardiff, United Kingdom,[8]Centre for Cardiovascular Science, University of Edinburgh, Edinburgh, United Kingdom

Late failure of saphenous vein bypass grafts remains a major clinical problem. Mechanisms that drive neointima formation after implantation of grafts are thought to be pivotal in creating an environment through which accelerated atherosclerosis can ensue, and cause graft failure. We previously showed that research grade human adenoviral serotype 5 vectors overexpressing the human tissue inhibitor of metalloproteinase-3 (TIMP-3) gene delivered ex-vivo to saphenous vein in a pig model reduced neointimal formation at both 1 month and 3 months post grafting. Here, in advance of a first-in-human clinical study, we generated a clinical lot of Ad-TIMP-3 and assessed safety and efficacy in the pig saphenous vein-to-carotid interposition graft model. We produced Ad5.CMVTO.TIMP-3, a first generation E1/E3 deleted adenovirus serotype 5 vector expressing TIMP-3 under control of the CMVIEP and Tet repressor (TO) transcriptional elements under GMP conditions to perform a preclinical in-vivo trial at the Bristol Translational Biomedical Research Centre (TBRC) facility. A randomised blinded single-dose placebo-controlled trial was undertaken using the established porcine model of right carotid artery interposition of autologous saphenous vein (aSV) (n=11 per group of crossed Large White x Landrace female, 60-65kg pigs, approx 6 months old). Outbred Large White/Landrace pigs were randomised to receive aSV pre-treated with either Ad5.CMVTO.TIMP-3 or placebo (vehicle). Ad5.CMVTO.TIMP-3 or placebo was instilled into the vein lumen. The vein was incubated at room temperature for 30 minutes prior to flushing the lumen and then grafting end-to-end into the carotid artery. The 4-week single-dose toxicology study demonstrated no treatment-associated adverse findings or mortalities. All cardiovascular parameters remained within normal range during graft implantation and resection surgery and no differences in blood clinical chemistry were detected between animals grafted receiving Ad5.CMVTO.TIMP-3-treated or control-treated veins. At 1 month post vein grafting, a significant 26% reduction in intimal area was observed in Ad-TIMP-3 treated grafts using the clinical grade viral vector, compared to the placebo. Based on this, and the prior efficacy studies, we are progressing to a first-in-human study to begin in 2024 to assess the safety of gene therapy for vein graft failure.

Wednesday Posters: Neurologic Diseases



613. Systemic AAV-Delivered Targeted Gene Editing Restores Cerebrovascular Disease and Prevents Associated Neurodegeneration in ACTA2 R179H-Related Multisystemic Smooth Muscle Dysfunction Syndrome (MSMDS)

Vijai Krishnan, Sabyasachi Das, Christiano Alves, Christian Lino Cardenas, Takahiko Imai, James Hai, Aarushi Gandhi, Pazhanichamy Kalailingam, David Chung, Mark E. Lindsay, Benjamin P. Kleinstiver, Patricia L. Musolino

Massachusetts General Hospital, Boston, MA

Objective: MSMDS is an ultrarare genetic smooth muscle (SMC) myopathy with dysfunction in the vascular, respiratory, enteric, and genitourinary systems. The most severe forms are caused by missense variation at arginine 179 of the ACTA2 gene. Neurological manifestations include cerebral small vessel disease (cSVD) and ischemic strokes (IS). IS commonly occur during episodes of hypotension or anesthesia suggesting severe impairment of cerebral autoregulation and neurovascular coupling, mechanisms required for responsive cerebral blood flow (CBF) during during arterial flow. We developed a conditional knock in ACTA2 R178H mouse model where only smooth muscle cells are mutant and found an accelerated form of neurodegeneration with classic histopathological and behavioral features commonly seen in neuronal proteinopathies associated with Alzheimer-related degenerative disorders. Using a custom CRISPR-Cas9 (VRQR+) adenine base editor (ABEs) delivered by two AAV-intein constructs we achieved high levels of correction of the disease-causing G-to-A mutation. Here we characterized the neurodegeneration caused by a SMC-specific ACTA2R179H mutant in a mouse model and determined whether targeted gene correction of SMCs can improve cerebral vascular function (SMC contractility, BBB permeability, CA and NC) and ameliorate neurodegeneration. Methods: Our murine MSMDS model encompasses a whole-body smooth muscle activation

of the mutation using Myh11-cre (Myh11-Cre:Acta2$^{R179fl/+}$). For *in vivo* delivery of the ABE, we cloned an intein-split construct compatible with dual adeno-associated virus (AAV) delivery. The constructs were packaged in two AAV serotypes, including AAV9 and our novel AAVPR capsid, injected systemically by retroorbital single dose injection at P3. Neurodegeneration was evaluated in treated and untreated mice and animals underwent various assessments, including physiology, behavior, and immunohistochemistry 8 weeks after treatment. Results: Examination of myelin basic protein (MBP) expression by immunohistochemistry in 8 week old *Myh11-Cre:Acta2*$^{R179Hfl/+}$ mice show significant loss of MBP in mutant *Myh11-Cre:Acta2*$^{R179Hfl/+}$ mice. Demyelination coincided with neuronal loss revealed by NeuN nuclei staining in various cortical and hippocampal regions. Furthermore, neurofibrillary tangles and Congo red-positive aggregates in the cortex and hippocampus, highlight that a defective neurovascular smooth muscle cell function can trigger characteristic protein aggregates associated with neurodegeneration. Impaired motor and cognitive performance in behavioral tests including Y maze, the rotarod and open field were observed starting at 4 weeks of life. Gene targeted correction significantly rescue myelination (Fig. 1), decreased pathological microglial and astrocytic activation of the *Myh11-Cre:Acta2*$^{R179Hfl/+}$ mice. Additionally, Myh11-cre:Acta2R179Hfl/+ mice treated with gene therapy exhibit improved sensorimotor behavior. Conclusion: Our findings analyzed the start of vascular dysfunction culminating in neurodegeneration in MSMDS. We also present evidence that targeted gene therapy as a promising approach to mitigate neurodegeneration in MSMDS mouse models, offering hope for potential future treatments.

614. Patient-Derived iPSC-Neurons and Microglia for Modeling Friedreich's Ataxia

Anusha Sivakumar[1], Priyanka Mishra[2], Carla Pernaci[1], Avalon Johnson[3], Angelyn B. Solis[3], Rafael A. Badell-Grau[4], Veenita Khare[5], Sydeny Gillette[3], Emily A. Hansen[3], Nicole Coufal[3], Stephanie Cherqui[6]

[1]1Department of Pediatrics, University of California, University of California, San Diego, La Jolla, CA,[2]University of California San Diego, San Diego, CA,[3]Department of Pediatrics, University of California, University of California, San Diego, La Jolla, CA,[4]Department of Pediatrics, Division of Genetics, UCSD, La Jolla, CA,[5]Department of Pediatrics, Division of Genetics, UCSD, San Diego, CA,[6]Department of Pediatrics, Division of Genetics, University of California, San Diego, La Jolla, CA

Friedreich ataxia (FA) is a neurogenerative disorder caused by homozygous GAA expansion mutation in the first intron of frataxin (*FXN*) gene. FXN is a mitochondrial protein, and its deficiency leads to mitochondrial iron overload, defective energy production, and oxidative stress. We previously showed complete rescue of neurologic complications of FRDA in YG8R mice with a single, systemic infusion of wild-type hematopoietic stem and progenitor cells (HSPC), and rescue was mediated by FXN transfer from engrafted HSPC-derived microglia to diseased neurons. We next developed an autologous stem cell transplantation approach using CRISPR/Cas9-mediated excision of GAA repeats in FRDA patients' CD34$^+$ HSPCs that increased frataxin expression and improved mitochondrial functions. The aim of the current study is to understand the mechanism of rescue of the neurodegeneration by HSPC in FRDA and to this end to investigate the complex interaction between microglia and neurons in the disease pathogenesis. Thus, we generated a cohort of four different FRDA patient-derived induced pluripotent stem cells (iPSCs) along with the CRISPR/Cas9-gene edited FRDA iPSCs, two familial carriers and two unrelated control lines. These iPSCs were then used for generating neurons and microglia (iMG). iPSC derived FRDA neurons displayed characteristic apoptotic and mitochondrial phenotype of the disease, such as non-homogenous microtubule staining in neurites, increased caspase-3 expression, mitochondrial superoxide levels, mitochondrial fragmentation, and partial degradation of the cristae compared to healthy controls. These defects were fully prevented in the gene edited neurons. RNASeq analysis of FRDA and gene edited neurons demonstrated striking improvement in gene clusters associated with endoplasmic reticulum (ER) stress in the isogenic lines. Gene edited neurons demonstrated improved ER-calcium release, normalization of ER stress response gene, *XBP-1,* and significantly increased ER-mitochondrial contacts that are critical for functional homeostasis of both organelles, as compared to FRDA neurons. Ultrastructural analysis for these contact sites displayed severe ER structural damage in FRDA neurons, that was undetected in gene edited neurons. Similarly, FRDA-iMGs displayed activated, amoeboid morphology with compromised phagocytosis, mitochondrial dysfunction and attenuated Ca^{2+} release while the edited-iMGs exhibit a phenotype comparable to controls. These studies support that both neurons and microglia are impacted in FRDA, that can be rescued by our gene-editing approach.

615. ZIP Delivery, A Novel Peptide Delivery System for the Brain

Barbara Bailus[1,2], Stephen Scheeler[1], Kizito-Tshitoko Tshilenge[1], Ningzhe Zhang[1], Swati Naphade[1], Sally Mak[1], Kenneth Wilson[1], Robert O'Brien[1], Mahru An[1], Brian Rossmiller[1], Stanislav Moraz[1], Jennifer Suoja[1], Maria Sanchez[1], Tyne McHugh[1], Akos Gerencser[1], Lisa Ellerby[1]

Delivery of therapies to the central nervous system remains a major challenge in treating neurodegenerative disorders. In an effort to overcome this challenge we developed a novel cell penetrating peptide based on the Zika virus called ZIP-delivery. To test our ZIP-delivery system we focused on Huntington's Disease (HD) a rare neurodegenerative disorder caused by a CAG expansion in Exon 1 of the Huntingtin gene which results in a toxic protein and protein fragments being formed. In the last twenty five years much progress has been made in both understanding the basic genetics of HD and developing tools for treating HD. However, one area that still needs further optimization is the method of delivery to the brain for these novel therapies. We were able to attach ZIP-delivery to Cas9n, creating ZIP-Cas9n. ZIP-Cas9n is able to cross the blood brain barrier and achieve widespread distribution in a murine model of

HD by an intravenous injection. ZIP-Cas9n was also able to achieve high recombination efficiency in Huntington patient derived human neuronal stem cells, and striatal organoids, which makes it a promising technology for both therapeutic and disease modeling applications. Additionally, we attached ZIP-delivery to EGFP. ZIP-EGFP achieved widespread distribution in the murine brain from an intravenous injection. Furthermore, ZIP-EGFP showed widespread distribution and penetration in human cortical organoids. Our presentation will highlight the different applications and promise of ZIP-delivery as a therapeutic delivery model.

616. Phenotypic Rescue of STXBP1 *In Vitro* and *In Vivo* Models Using AAV-STXBP1 Gene Replacement Approach

Sijia Wu, Brian Harvey, Elena Morozova, Ayan Ghoshal, Adam Sheehy, Kevin Ghaemi, Moore Arnold, Manzhao Long, Chris Hinckley, Sharanya Unnikrishnan, Nicholas B. Gallo, Anh Nhu, Ramiro Massol, Chris Ehrenfels, Pete Clarner, Jinkuk Choi, Davide Gianni, Wan-Hung Lee, Kelly Bales

Biogen, Cambridge, MA

STXBP1-related developmental and epileptic encephalopathy (STXBP1-DEE) is a rare genetic epilepsy and neurodevelopmental disorder caused by heterozygous loss-of-function mutations in the STXBP1 gene. STXBP1-DEE is characterized by refractory seizures, developmental delay, intellectual disability, and motor dysfunction. Here, we evaluated effects of AAV-STXBP1 gene replacement in *in vitro* and *in vivo* models of the disorder. We demonstrate a dose-dependent increase in STXBP1 protein in STXBP1$^{-/-}$ iPSC-derived NGN2 neurons treated with AAV-STXBP1, resulting in the rescue of neurotransmission phenotypes. To evaluate effects in vivo, neonatal Stxbp1$^{+/-}$ mice were treated with AAV-STXBP1 and a dose-dependent increase of STXBP1 expression was observed. Importantly, AAV-STXBP1 improved measures of cortical function detectable by electroencephalogram (EEG) as well as motor and cognitive behavioral phenotypes. These results demonstrate that AAV-mediated restoration of STXBP1 expression can robustly rescue a range of disease-associated phenotypes in models of STXBP1-DEE.

617. Delivery of *DARS2* via AAV9 as a Potential Therapeutic Approach for Leukoencephalopathy with Brainstem and Spinal Cord Involvement and Lactate Elevation

Bayley Lindsay[1], Brett Ratajczak[1], Yajie Liang[2], Miroslaw Janowski[2], Piotr Walczak[2], Ali Fatemi[1,3], Christina L. Nemeth[1,3]

[1]Moser Center for Leukodystrophies at Kennedy Krieger, Kennedy Krieger Institute, Baltimore, MD,[2]Department of Diagnostic Radiology and Nuclear Medicine, University of Maryland School of Medicine, Baltimore, MD,[3]Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD

Introduction: Leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL) is a rare neurological disorder caused by mutations in the *DARS2* gene, which encodes for the mitochondrial aspartyl-tRNA synthetase. Despite the wide phenotypic spectrum associated with LBSL - ranging from severe cerebellar hypoplasia and early demise in antenatal- or infantile-onset to mild spasticity and cerebellar ataxia in adult-onset - nearly all patients have compound heterozygous mutations on *DARS2*, the most common of which results in a frameshift mutation, premature termination, and decreased protein abundance. Methods: In this study, we aimed to restore the production of *DARS2* transcripts and functional protein in LBSL patient derived neurons through treatment with Adeno-Associated Viral (AAV) vectors, serotype 9, targeting the CNS. LBSL patient induced pluripotent stem cells (iPSCs) were differentiated into mature motor neurons according to an existing protocol and treated with the human *DARS2*- AAV9 vector under EF1a promoter on *in vitro* Day 11. Ten days after exposure, *DARS2* expression (qRT-PCR), neuronal arborization (high content imaging), mitochondrial energetics (Agilent Seahorse Mito Stress Test), and lactate levels (colorimetric assay) were measured. Results: Expression of *DARS2* transcripts including Exon 3 were increased in a dose-dependent fashion, suggesting the production of functional protein. *DARS2* gene expression was increased in parallel to increased neuronal arborization as measured by high content imaging. Increases in branching were evident before Day 21. On Day 21, mitochondrial analysis revealed increases to baseline oxygen consumption as well as increased max capacity without affecting cell viability. Lactate release from neurons as measured in spent media was decreased in a dose-dependent manner suggesting reduced mitochondrial stress. Together these data suggest that gene delivery is sufficient to induce functional changes to neuronal health which may have more widespread effects with systemic delivery. Conclusions: While further testing is needed to confirm these findings, it is promising that gene delivery increases normal DARS2 protein production, reducing the phenotypic burden *in vitro*. Additional studies are underway to investigate the effect of AAV9 treatment on electrophysical activity, long-term *in vitro* survival, and the effect of AAV9 *in vivo*. To date, studies suggest gene therapies may be a viable treatment for slowing or halting disease progression in those with mitochondrial tRNA synthetase disorders, such as LBSL.

618. The Peripheral Neuropathy of Adrenomyeloneuropathy (AMN)

Yasemin Özgür Günes[1], Andoni Echaniz-Laguna[2], Catherine Le Stunff[1], Romina Aron-Badin[3], Pierre-François Bougnères[4]

[1]INSERM, Le Kremlin-Bicêtre, France,[2]Department of Neurology, Bicêtre Hospital, Le Kremlin-Bicêtre, France,[3]CEA, CNRS, Université Paris-Saclay, MIRCen, Laboratoire des Maladies Neurodégénératives, Fontenay aux Roses, France,[4]Therapy Design Consulting, Vincennes, France

AMN prominently affects the spinal cord. However, peripheral neuropathy is a common feature in AMN although usually surpassed by spinal cord symptoms. Many patients have electrophysiological signs of axonal neuropathy or present with demyelinating neuropathy. We studied electrophysiological signs of axonal neuropathy in Abcd1 knock-out (Abcd1-KO) mouse model together with wild type mice as a control. Measurement of sensory nerve conduction velocity (NCV) was performed with a standard EMG Natus apparatus. Sensory nerve conduction velocity (NCV) measured at 24-month of age. We observed no significant difference between untreated 25.0 ± 5.3 mA (n=18), and

WT group 26.8 ± 5.3 mA (n=9). In contrast, obvious abnormalities of the axons were present in the sciatic nerve with electron microscopy (JM Vallat) in the absence of demyelination or inflammation. AMN seems associated with a structural peripheral neuropathy that does not alter electrophysiological parameters.

619. Novel AAV Gene Therapy Candidates Show Promise *In Vitro* and *In Vivo* for Treatment of PGAP3-CDG Syndrome

Julieth A. Sierra Delgado[1], Matthew Simon[2], Riya Talekar[1], Xiaojin Zhang[1], Abuzar Kaleem[1], Meysam Ganjibakhsh[1], Shrestha Sinha Ray[1], Shibi B. Likhite[1], Cathleen Lutz[2], Kathrin Meyer[1]

[1]Nationwide Childrens Hospital, Columbus, OH,[2]The Jackson Laboratory, Bar Harbor, ME

PGAP3-Congenital Disorder of Glycosylation (PGAP3-CDG) is a devastating, rare neurological condition that disrupts the synthesis of Glycosylphosphatidylinositol (GPI) anchors. PGAP3-CDG patients exhibit a diverse spectrum of symptoms that vary in age of onset and severity including developmental delay, intellectual disability, seizures, hypotonia, and characteristically high levels of serum alkaline phosphatase (hyperphosphatasia). Currently, there is no evidence of a close genotype-phenotype correlation. Current treatment strategies for PGAP3-CDG only focus on management of symptoms and do not impact disease progression. Furthermore, the intricate pathogenic mechanisms associated with PGAP3 mutations, particularly in neurons and astrocytes, remain poorly understood, impeding therapeutic advancements. This underscores the urgent need to unravel the pathophysiology and develop effective interventions for PGAP3-CDG. To achieve that, we have designed four different AAV9-mediated gene therapy constructs to restore PGAP3 function. To comprehensively evaluate these constructs across diverse mutations representative of the disease spectrum, we established an innovative PGAP3-CDG in vitro model. Primary fibroblasts from PGAP3-CDG patients were reprogrammed into induced neural progenitor cells and further differentiated into induced astrocytes (iAs) using a direct conversion protocol. PGAP3-CDG iAs displayed abnormal mitochondrial morphology in immunofluorescence studies, as well as significantly altered mitochondrial activity using the Seahorse XFe96 platform. In co-culture assays with healthy mouse GFP+ neurons, PGAP3-CDG iAs induced a high degree of neuronal death compared to healthy iAs. Moreover, we generated induced neurons (iNs) using the PGAP3-CDG patient fibroblasts via direct chemical conversion, finding reduced neurite length and neuron with neurite percentage compared to controls. We have optimized our in vitro AAV9 transduction protocol in both iAs and iNs, and we have successfully transduced our both of our in vitro models, showing a robust expression pattern. All constructs showed improvement on the cellular phenotype, with transduced iAs showing a remarkable improvement on neuronal support. The constructs are also being evaluated in vivo on a PGAP3 Knockout model, with some showing improvement of biochemical and clasping phenotypes, as well as in wild type mice for an initial safety assessment. Overall our candidates show efficacy on both in vitro and in vivo PGAP3-CDG Models. Collectively, the combined findings of this study will allow us to identify the optimal gene therapy vector for PGAP3-CDG treatment. These findings will support the development of upcoming IND-enabling studies.

620. Exploring Galectin-3 as a Biomarker for Disease Progression and Gene Therapy of Canavan and Other Neurodegenerative Diseases

Morgan Mooney[1], Peiyi Guo[1], Jie Wang[1], Anoushka Lotun[1], NhatAhn Nguyen[1], Guangping Gao[1,2,3], Dominic J. Gessler[1,3]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Li Weibo Institute of Rare Diseases Research, UMass Chan Medical School, Worcester, MA,[3]Co-corresponding Authors, Worcester, MA

Canavan Disease (CD), a fatal neurodegenerative disorder, stems from mutations in the Aspartoacylase (ASPA) gene, culminating in the brain's buildup of N-acetylaspartate (NAA). This disease tragically leads to patient's demise in early childhood. It is marked by severe symptoms including inability to walk, lack of head control, macrocephaly, and failure to meet developmental milestones. At the cellular level, spongiform degeneration and astrogliosis are prominent, yet the exact pathomechanism is unclear, but critical to develop gene therapy and monitor therapeutic response. A pivotal aspect of neurodegeneration is neuroinflammation driven by microglial activation. Probing into CD's cellular dynamics, single-cell RNA sequencing was performed comparing wild type (WT), knockout (KO), and AAV gene therapy-treated KO mouse brains. A striking finding was the substantial elevation of galectin-3 (Gal-3) in KO brains, an intracellular and secreted key protein in immune response. This led to the hypothesis that Gal-3 plays a critical role in CD pathogenesis via microglial activation, potentially allowing to monitor disease trajectory and therapeutic response. Using the Nur7 mouse model, which mirrors CD's severe neurological symptoms yet with a comparatively longer lifespan, we traced the onset and escalation of CNS histopathology. Vacuolization and neurodegeneration were initially observed on post-natal day 14, intensifying rapidly thereafter. Intriguingly, this degeneration localized to specific brain regions, paralleling a surge in activated microglia. Notably, early stages showed Gal-3 positive microglia levels akin to WT, but these levels increased significantly as the disease progressed. These findings prompted us to investigate Gal-3's potential as a biomarker for tracking CD progression and gene therapy response. Early intervention in asymptomatic Nur7 mice with rAAV-mediated ASPA expression achieved WT-level Gal-3 expression and absence of neurodegeneration, suggesting early treatment's potential to prevent disease onset and microglial activation. Furthermore, symptomatic juvenile Nur7 mice displayed a gradual increase in ameboid Gal-3 positive microglia in brain areas with disease progression. Treatment at this symptomatic stage resulted in the absence of neurodegeneration and normalization of Gal-3 positive microglia levels, akin to WT controls, indicating a reversal of microglial activation. To understand Gal-3's role in CD's pathomechanism, we engineered Gal-3/Aspa double-knockout mice, with studies currently ongoing. Our preliminary data suggest that Gal-3 could function as a promising biomarker for monitoring CD progression and gene therapy responsiveness, potentially extending

to other neurodegenerative diseases. Moreover, targeting Gal-3 could enhance rAAV-based gene therapies, offering new hope in modifying disease trajectories.

621. AAV-Mediated Gene Supplementation Provides Thorough Correction in Two Models of Vanishing White Matter Disease

Jessica A. Herstine[1,2,3], Tamara J. Stevenson[4], Sergiy Chornyy[1], Pi-Kai Chang[4], Jessica Rediger[1], Julia Wentz[4], Nettie Pyne[1], Alex Sunshine[1], Erika Scholl[4], Tatyana A. Vetter[1,2], Kevin M. Flanigan[1,2,3], Joshua Bonkowsky[4], Allison M. Bradbury[1,2,3]

[1]Center for Gene Therapy, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics, The Ohio State University, Columbus, OH,[3]Center for Clinical and Translational Science, The Ohio State University, Columbus, OH,[4]Department of Pediatrics, University of Utah School of Medicine, Salt Lake City, UT

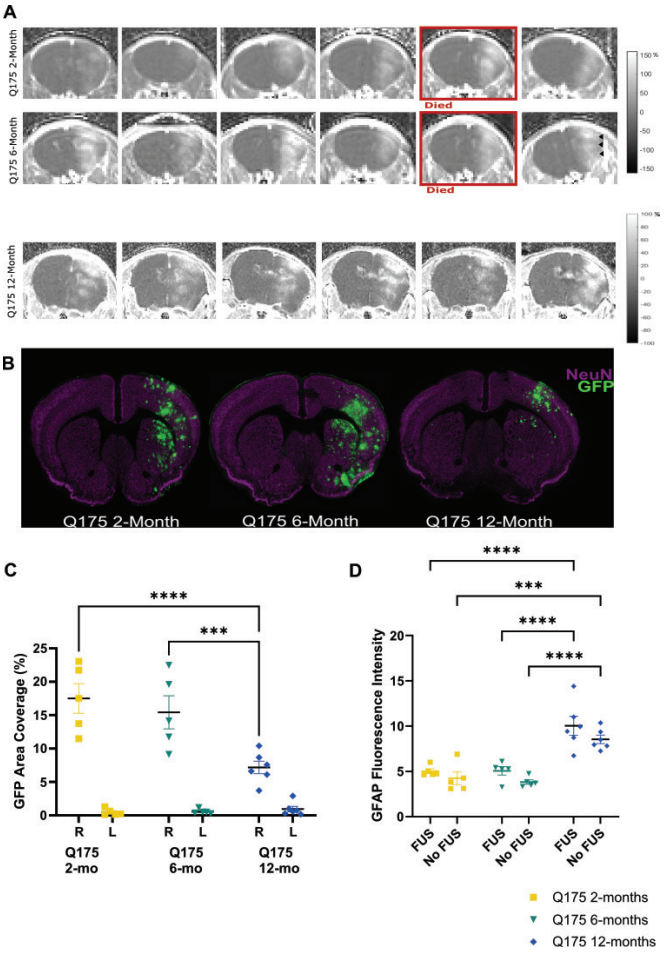
Vanishing White Matter Disease (VWM) is a progressive childhood leukodystrophy that presents with ataxia, spasticity, neurological decline, and seizures which lead to premature death. There are no treatments. Caused by autosomal recessive, loss of function mutations in the subunits of eukaryotic initiation factor 2B (eIF2B), VWM most commonly originates from pathologic variants in subunit 5 (*EIF2B5*). Due to VWM's monogenic nature and the size of the *EIF2B5* transgene, it is a promising candidate for adeno-associated virus (AAV)-mediated gene supplementation therapy. Prior studies in in vitro and in vivo models of VWM revealed that astrocytes are a critical target for therapy, as their differentiation, morphology, and function are impaired, thus mediating disease progression. To better understand disease mechanisms and to serve as a baseline for correction, we first aimed to characterize the newly identified and severe VWM *Eif2b5*^{I98M} murine model with clinically relevant readouts such as motor function, gait mapping, and myelin loss through magnetic resonance imaging. We found that these mice display significant loss of mobility, ataxic gait, and demyelination all within a strikingly short life span (5.5 months). Molecular characterization indicates that the integrated stress response (ISR)—a molecular pathway regulated by eIF2B that rescues homeostasis during cellular stress—is dysregulated, supporting our findings that these mice are displaying classic and severe VWM phenotypes. To provide targeted correction of disease, we designed gene replacement constructs to drive therapeutic *EIF2B5* transgene expression in astrocytes. We tested multiple iterations of the glial fibrillary acidic protein (GFAP) promoter, including one ***novel*** intermediate form—gfaABCD1405—and found robust astrocyte targeting throughout the neuroaxis. Therefore, we are currently evaluating three astrocyte-specific, and one ubiquitous therapeutic AAV vectors in two murine VWM models, *Eif2b5*^{R191H} and *Eif2b5*^{I98M}, and are monitoring disease progression using molecular, biochemical, behavioral, and imaging readouts. Our data suggests that the astrocyte-targeted gene therapy delays disease progression, partially rescues body weight and motor function, and attenuates myelin loss in both models. The life spans of the *Eif2b5*^{I98M} animals treated with AAV9-gfaABC(1)D-*EIF2B5* ($p<0.0001$), AAV9-CAG-*EIF2B5* ($p<0.001$), and AAV9-gfaABCD1405-*EIF2B5* ($p<0.01$) are also significantly increased, with our current longest extension in life expectancy exceeding 1 year of age in our gfaABC(1)D-treated cohort. Expression analysis through RT-qPCR indicates we achieved increased expression of the *EIF2B5* transgene in the CNS of treated mice. Overall, we anticipate the development of a lead astrocyte-targeted gene therapy candidate in which the data will be strengthened through the evaluation of clinically relevant measures in two murine models of VWM, allowing for expeditious translation to the clinic. Our findings support the importance of targeting the underlying disease mechanisms through the modification and tailoring of the AAV vector design.

622. The miREX Platform Technology Allows for Highly Efficacious X-Reactivation for Treatment of X-linked Disorders

Cassandra Dennys[1], Samantha L. Powers[2], Mohammadreza Khani[1], Song Lou[3], Shibi B. Likhite[2], Lucas Sass[1], Andrea Sierra Delgado[2], Stuart Sater[1], Ostin Arters[4], Sanchita Bhatnagar[5], Bryn Martin[1], Deep Singh[6], Kathrin Meyer[7]

[1]Alcyone Therapeutics, Lowell, MA,[2]Nationwide Children's Hospital, Columbus, OH,[3]UC Davis, Davis, MA,[4]Moscow, ID,[5]UC Davis, Davis, CA,[6]Alcyone Therapeutics, Waltham, MA,[7]Nationwide Childrens Hospital, Columbus, OH

X chromosome inactivation is a developmentally regulated process in females, wherein one X chromosome per cell is inactivated through a complex stepwise process involving the Xist RNA. This process allows for dosage regulation in females for X-linked gene expression. As a consequence, female tissue affected by X-linked genetic disorders, such as Rett Syndrome, will be a mixture of cells expressing the mutated version of the gene or the healthy copy depending on which X chromosome is active in any given cell. This mosaicism complicates gene replacement strategies significantly as the healthy cells are at risk of being overdosed. Notably, all cells that express the loss of function mutation contain a healthy copy on the silenced chromosome which, upon re-expression, could ameliorate the disease phenotype. Thus, mechanisms that regulate X-inactivation may be an effective therapeutic strategy for Rett Syndrome and other X-linked disorders. miR106a is a natural regulator of X-inactivation that binds to Xist. Here, we show that sequestration of miR106a via miREX technology (miRNA sponge for Endogenous Gene Expression by X-Reactivation) allows X chromosome reactivation and expression of target genes such as MeCP2. Furthermore, viral vector-based delivery of miREX showed efficacy in both Rett patient derived astrocytes and neurons, with a broad spectrum of MeCP2 mutations, as well as in a severe female Rett mouse model. Moreover, the technology was also efficacious in several other X-linked disorders when tested in various patient cell lines. This demonstrates that miREX may serve as a platform therapy for multiple diseases. To ensure optimal therapeutic benefit, effective targeting of the central nervous system is critical for success in the treatment of neurological disorders including Rett Syndrome. For this purpose, Alcyone Therapeutics has developed a novel intra-CSF drug delivery platform (FalconTM) allowing to optimize drug delivery to the brain. The Falcon technology allows studying and optimizing drug biodistribution taking into consideration disease related changes in CNS anatomy and CSF flow dynamics. Thus, the Falcon technology



will ensure optimal delivery of miREX in Rett Syndrome patients further improving the therapeutic potential of our novel treatment for X-linked disorders.

623. Focused Ultrasound-Mediated Delivery of AAV9-Based Gene Therapy in Aged Huntington's Disease Mice

Bernie S. Owusu-Yaw[1], Yongzhi Zhang[1], Lily Garrett[2], Alvin Yao[3], Kai Shing[4], Rita Batista[5], Miguel Sena-Esteves[5], Jaymin Upadhyay[6], Kimberly Kegel-Gleason[4], Nick Todd[1]

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[2]Northeastern University, Boston, MA,[3]Harvard University, Cambridge, MA,[4]Massachusetts General Hospital, Harvard Medical School, Charlestown, MA,[5]UMass Chan Medical School, Worcester, MA,[6]Boston Children's Hospital, Harvard Medical School, Boston, MA

Background: There are currently no cures for Huntington's disease (HD), and lowering HTT mRNA via RNA interference (RNAi) gene therapy appears to be a promising strategy. However, gene delivery to the central nervous system (CNS) is challenging due to the presence of the blood brain barrier (BBB). Focused Ultrasound (FUS) with microbubbles (MB) can be used to temporarily disrupt the BBB in a non-invasive manner to deliver therapeutic genes to the CNS. Safe and reversible BBB opening has been reported from phase one clinical trials in patients with Alzheimer's disease, Parkinson's disease and Amyotrophic Lateral Sclerosis. To date, no studies have been conducted to investigate the safety of FUS-mediated BBB opening in HD patients and there have been no preclinical studies testing the FUS-mediated delivery of adeno-associated viral vectors (AAVs) in mouse models of HD. The breakdown of the BBB has been described in Huntington's disease and other neurodegenerative diseases. Therefore, it is important to determine the impact of HD neuropathology on FUS-mediated BBB opening and subsequent gene delivery. Here, we tested the delivery of a ssAAV9 containing a miRNA (miR1050) targeting HTT mRNA using FUS in combination with MB to the right striatum of 2-month, 6-month, and 12-month-old zQ175 HD mice. **Methods:** This study compares FUS-mediated AAV9 delivery in zQ175 2-month, 6-month, and 12-month-old zQ175 HD mice(N=6 per group). FUS-BBB opening was performed by targeting the right striatum. Mice received four sonications (burst length=10 ms, frequency= 1Hz, total duration= 120s), in the right striatum following the tail vein injection of microbubbles. AAV9-U6-miR10150-CBA-GFP at 5.5 x 10^{11} vg/mouse (2.2 x 10^{10} vg/g) was administered immediately after FUS treatment via tail vein injection. Then gadolinium-enhanced T1-weighted images were acquired to quantify the extent of BBB opening. Mouse brains were harvested after 3 weeks for immunohistochemistry. Brain sections were co-stained with GFP and antibodies recognizing GFAP/Iba1/NeuN/S100β. **Results:** BBB opening was confirmed in all three groups through T1-weighted contrast MRI indicating gadolinium leakage in the brain parenchyma (Figure 1A).Greater GFP expression was observed in the sonicated hemisphere of the three HD cohorts compared to the untreated side (Figure 1B). However, the GFP area coverage was significantly lower in zQ175 12-month mice compared to the younger mice (Figure 1C).It has been reported that FUS-BBB opening can lead to astrocyte and microglial activation. We did not observe any significant differences in astrocytic activation between the FUS-treated and untreated side across the age groups (Figure 1D). There were significantly higher levels of GFAP activation in the zQ175 12-month group in both hemispheres compared to the younger cohorts, which is in line with previous studies demonstrating increased astrocyte activation during HD progression in this mouse model. Staining for Iba1 has been carried out and the slides are being processed. Cell counts are also ongoing to determine the cellular transduction efficiencies across the different age groups.

624. Sandhoff Disease is Corrected in a Murine Model by scAAV9-*HEXM* Gene Transfer

Brianna M. Quinville[1], Alex E. Ryckman[1], Natalie M. Deschenes[1], Melissa Mitchell[2], Kshitiz Singh[2], John G. Keimel[3], William F. Kaemmerer[3], Jagdeep S. Walia[1,2]

[1]Centre for Neuroscience Studies, Queen's University, Kingston, ON, Canada,[2]Department of Pediatrics, Queen's University, Kingston, ON, Canada,[3]New Hope Research Foundation, North Oaks, MN

Sandhoff disease (SD) is an autosomal recessive lysosomal storage disorder characterized by progressive neurodegeneration due to an excessive accumulation of GM2 gangliosides (GM2) in neurons. The resulting widespread neuronal dysfunction eventually leads to death, typically by age 4 in the most common, infantile form. The hydrolysis of GM2 in humans is solely conducted by a single lysosomal enzyme, β-hexosaminidase A (HexA), a heterodimer comprised of an α- and

a β-subunit, encoded by genes *HEXA* and *HEXB*, respectively. SD arises from a deficiency or absence of β-subunits, and consequently, accumulated GM2. Engineered from the human α-subunit, a novel μ-subunit encoded by *HEXM*, homodimerizes to form a stable HexA isoenzyme named HexM. Previously, a proof of concept study demonstrated improved survival in a *Hexb*$^{(-/-)}$ murine model of SD following transfer of the *HEXM* gene packaged in a self-complementary adeno-associated viral vector, serotype 9 (scAAV9). This study assessed the dose response of a scAAV9-*HEXM* treatment in the *Hexb*$^{(-/-)}$ murine model when utilizing a novel method of dual delivery, via intravenous (IV) and intra-cisterna magna (ICM) routes, utilizing osmotic induced flow and ancillary administration of immunosuppressants. A total of 10 cohorts (n = 10/cohort), received simultaneous infusions of vector or vehicle through IV and ICM routes. The study design enables a comparison of treatment efficacy between delivering a total dose through a single route or splitting it between two routes. The researcher who conducted the procedure, behavioural testing, and all analyses was blinded to which infusate each animal received. Behavioural and blood collections were done at specific time points until the mice reached their humane endpoint. Upon termination, tissue and blood samples were collected for analysis of Hex enzyme activity, GM2 accumulation, histology, vector biodistribution, and immune response. Survival results showed a clear dose response and added benefit when a total dose is split between the IV and ICM routes compared to IV alone. While untreated SD mice live only ~16 weeks, the median life span was 88 weeks (>5.5-fold increase) in the IV-only cohort receiving the high dose, and 105 weeks (>6.5-fold increase) in the dual-delivery cohort receiving the same high dose. The heterozygous control group had a median survival of 95.5 weeks. Both high-dose cohorts showed consistent behavioural performance over a two-year lifespan with no observable differences compared to the heterozygous control group. Results of the GM2 accumulation assays and the HexM enzyme activity assays correlated with survival and the added survival benefit of dual delivery. The dual high-dose cohort showed a 92% reduction in GM2 ($p < 0.0001$) compared to untreated SD mice and a >51-fold increase in Hex enzyme activity in sera ($p < 0.005$) compared to heterozygous controls. Hex enzyme activity in both brain and spinal cord regions was significantly higher in cohorts that received an ICM vector infusion compared to the IV-only groups ($p < 0.05$ - $p < 0.0001$). Vector biodistribution shows a dose response in brain regions. This study demonstrates a strong dose-response and greater than two-year gene expression durability in this novel gene therapy for SD with implications for improved survival and quality of life in a clinical setting.

625. Dual Site Administration of AAV Gene Therapy for Treatment of Feline GM1 Gangliosidosis

Amanda L. Gross[1], Courtney Garrett[1], Juan Rodriguez[1], Douglas R. Martin[1,2]

[1]Scott Ritchey Research Center, Auburn University College of Veterinary Medicine, Auburn, AL,[2]Department of Anatomy, Physiology and Pharmacology, Auburn University College of Veterinary Medicine, Auburn, AL

GM1 gangliosidosis is a fatal neurodegenerative disease caused by a deficiency of lysosomal β-galactosidase (βgal). There are currently two ongoing clinical trials for the treatment of GM1 gangliosidosis using adeno-associated viral (AAV) gene therapy administered either intravenously (IV) or in the cerebrospinal fluid (CSF) via the cisterna magna (CM). Preclinical trials of either administration route show that single site treatment significantly increases lifespans in a feline model of GM1 gangliosidosis. We hypothesize that deficiency in efficacy caused by either single site injection will be addressed by the additive effect of combinatorial administration. GM1 cats received $6.0x10^{13}$ vector genomes/kg of AAV9 split equally between IV and CM administration at approximately 2 months of age. Four animals will be followed to humane endpoint and four animals will be evaluated 16 weeks following treatment. Untreated GM1 animals survive approximately 8.0 ± 0.6 months while treated animals have a significant increase in average lifespan to 13.2 ± 2.8 months, with 3 animals in the long term cohort still alive at 16.4, 14.2 and 8.8 months of age (Figure 1A). Clinical assessments include neurological exams, CSF biomarkers, and 7T magnetic resonance imaging (MRI) and spectroscopy (MRS). Postmortem analysis included βgal and AAV distribution. Neurological abnormalities, which in untreated GM1 animals lead to an inability to stand and humane endpoint by 8 months of age, were attenuated in all treated animals (Figure 1B). Aspartate aminotransferase (AST) and lactate dehydrogenase (LDH), biomarkers of central nervous system damage when measured in the CSF, were both reduced in in treated animals in comparison to untreated animals. 7T magnetic resonance imaging (MRI) revealed a delay in progression of neurodegeneration and preservation of brain architecture. While animals are ongoing we are unable to determine if CM+IV administration of AAV is better than either single administration route however, the combined treatment did significantly improve length and quality of life in GM1 cats.

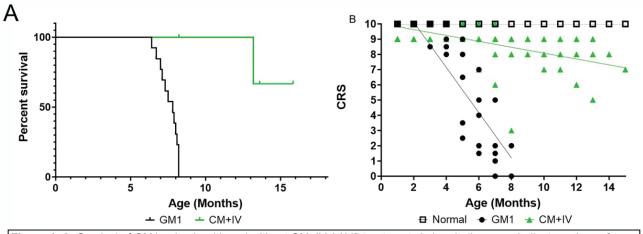


Figure 1. A. Survival of GM1 animals with and without CM+IV AAV9 treatment. A drop in the curve indicates a loss of an animal in the cohort. P=0.0018. **B.** Clinical rating score (CRS) of treated animals. A decrease in value designates progression of neurological deficits. A line of best fit is graphed for each cohort.

626. Developing an AAV-Based Gene Therapy for CSA Related Cockayne Syndrome

Aine Scholand[1], William Callahan[1], Cassandra Izzo[1], Robert King[2], Miguel Sena-Esteves[1], Ana Rita Batista[1]

[1]Neurology / Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Radiology, UMass Chan Medical School, Worcester, MA

Cockayne syndrome (CS) is an autosomal recessive, progressive developmental and neurodegenerative disease, primarily caused by mutations in the CSA/ERCC8 or CSB/ERCC6 gene. Mutations in CSA account for approximately 30% of cases, and it results in defects in transcription-coupled nucleotide excision repair and dysregulation of RNA Pol II mediated transcription. Patients with CS present cutaneous photosensitivity, severe growth failure, dwarfism, short life span and a progressive degeneration of the central nervous system, as well as eye abnormalities (congenital cataracts and retinal degeneration) and hearing loss. CSA is also involved in repair of

oxidative DNA damage, and mitochondrial metabolism, and contribute to the severe manifestations of growth failure and neurodegeneration seen in children.Currently there are no therapies for these patients, with the disease being managed symptomatically. We designed a new self-complementary AAV vector encoding human CSA under a CBA promoter. Initial in vitro experiments in CSA knock-out (KO) HEK293T cells, as well as in CS patient fibroblasts, show that restoration of CSA expression also restores cell survival in a killing assay using the chemotherapeutic drug Illudin S. We tested the therapeutic efficacy of the vector by neonatal ICV injection in CSA/XPA KO mice. This mouse model is a double CSA and XPA KO model, with a very aggressive phenotype, displaying very low body weight (< 5 g at weaning) and median survival of 22 days. We documented an increase in lifespan >8-fold, with the median survival for treated mice recorded at 189 days. Western blot and immunohistochemistry analysis show broad distribution of human CSA in the brain, as well in peripheral tissues. However, we also observed an increase in kidney and liver metabolites in treated animals, when compared to age-matched C57BL6/J controls, as well as presence of microbleeds in the brain, and an increase in autophagy markers in brain and liver. These observations are likely significant contributors to the limited lifespan of the model compared to WT mice. More experiments to investigate impact in metabolism of treatment of CSA/XPA KO mice are currently ongoing. The success of these AAV proof-of-concept experiments support transition to a clinical trial in CS patients.

627. Clinical Safety and Efficacy of EXG001-307 in SMA Type 1 Patients: A Next-Generation AAV-Based Gene Therapy

Zhenhua Wu[1], Chunjuan Song[1], Wenhui Li[2], Xiaojing Li[1], Xiaomei Zhu[2], Hui Li[2], Meijia Yang[1], Wenshu Yang[1], Rui Ji[1], Kuan Lu[1], Yanna Zhang[1], Haifeng Li[3], Lijun Wang[1], Guo-jie Ye[1], Qiang Shu[3], Yi Wang[2]

[1]Exegenesis Bio Inc., Spring House, PA,[2]Children's Hospital of Fudan University, Shanghai, China,[3]The Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China

Spinal muscular atrophy (SMA) is an autosomal recessive neurodegenerative disorder that leads to progressive muscular weakness and hypotonia. Gene therapy for SMA has been successfully developed, and the commercialized medicine Onasemnogene abeparvovec (Zolgensma), which was approved by FDA in 2019 as a one-time administration to SMA patients below the age of 2 years, demonstrated significant clinical benefits including prolonged survival and motor milestone achievement . However, current gene therapy faces various challenges including insufficient expression of the *SMN1* gene in the target organs/tissues and off-target organ toxicity such as liver failure. Thus, there is a need for improved gene therapies for SMA with tissue specific *SMN1* expression and reduced off-target toxicity. We developed an AAV-based gene therapy, EXG001-307, favoring neuronal transgene expression. Nonclinical studies have demonstrated that EXG001-307 improved the survival rate, further enhanced the motor function, and significantly reduced toxicity in the SMA mouse model. Moreover, our clinical trial demonstrated an excellent safety and efficacy profile for EXG001-307. The IND for EXG001-307 was approved by the National Medical Products Administration (NMPA) in China and an open-label, multicenter, single-arm, non-randomized, single-dose escalation clinical trial to evaluate the safety and efficacy of a single IV injection of EXG001-307 in patients with type 1 SMA is ongoing and patients enrollment for the Phase 1have been completed. Main inclusion criteria are: 1) SMA is diagnosed with bilateral allelic SMN1 mutations (deletions or point mutations) and 2 copies of the *SMN2* gene; 2) On the day of administration, the age of the subject shall not exceed the 180th day after birth; 3) The clinical history and physical signs are consistent with the symptoms of type 1 SMA. Six patients have been enrolled, and two doses have been studied, $1.1x10^{14}$ vg/kg and $1.5x10^{14}$ vg/kg. EXG001-307 were well tolerated in both groups, with the most common test article related adverse events (AEs) as fever, transient sinus tachycardia; mild elevation of aspartate aminotransferase (AST), troponin I, creatine kinase-MB (CK-MB), activated partial thromboplastin time (APTT) and prothrombin activity; and a reduction trend in platelet, lymphocyte and white blood cell counts. No occurrence of dose-limiting toxicity (DLT), or test article related >Grade 2 serious AEs (SAEs), or ≥ Grade 2 elevation of transaminases or cardiac enzymes in the trial has been reported. All patients achieved significant increase in CHOP-INTEND scores. All three patients in $1.1x10^{14}$ vg/kg group achieved head control in 3-6 months post dose, while all three patients in $1.5x10^{14}$ vg/kg group achieved head control in 1-2 months post dose. The first patient in $1.1x10^{14}$ vg/kg dose group has achieved sitting without assistance around 10 months post dose. In summary, while first-generation gene therapies like Zolgensma have shown substantial benefits for SMA patients, challenges persist in achieving sufficient *SMN1* gene expression in the target organs and avoiding off-target toxicity. Our AAV-based gene therapy, EXG001-307, tackles these issues by favoring neuronal transgene expression. Positive outcomes in our clinical trial, including patients reaching significant milestones with well-tolerated responses, highlight the potential of EXG001-307 as a promising next generation treatment for SMA. Ongoing research in this direction aims to advance EXG001-307, providing targeted SMN expression and minimizing off-target effects for improved outcomes in SMA patients.

628. SKG1201: Liver De-Targeting Vector for Spinal Muscular Atrophy Gene Therapy via Intrathecal Injection

Hui Liu, Carol Huang, Yanqun Shu, Qiu Yao, Xia Liu, Shihua Cao, Ruojie Wang, Yu Wu, Peilu Li, Yanjun Shen, Xiaorui Bian, Li Wang, Xinyi Wu, Qi Deng, Xing Ding, Yuwen Du, Hao Luo, Jay Hou

Skyline Therapeutics, Cambridge, MA

Spinal muscular atrophy (SMA), a devastating neuromuscular disease involving multiple organ dysfunction, is caused by homozygous deletion or mutation of the survival motor neuron (*SMN*)1 gene, resulting in reduced expression of SMN protein, which leads to degeneration of α motor neurons in the spinal cord and muscle atrophy. Gene replacement therapy, Onasemnogene abeparvovec (Zolgensma) demonstrated significant clinical benefits for type I SMA patients. However, due to its high systemic adeno-associated virus (AAV) dose, the adverse events were accompanied, such as significant liver and blood-related toxicity. Moreover, the adverse events observed after intrathecal injection (IT) of Zolgensma in Type II SMA patients in the recent STRONG trial were consistent with what noticed after its intravenous (IV) delivery. Hence, a new AAV gene therapy for

SMA with better safety and efficacy profiles is still in desperate need. Previously we developed SKG0201 for type I SMA patients. A single IV administration of SKG0201 successfully demonstrated an outstanding potency with no liver toxicity compared to the reference vector (scAAV9-CMVen/CB-hSMN1). Currently SKG0201 is in investigator-initiated trials (IIT) to validate its clinical benefits. Recently, we have innovatively developed another novel AAV-mediated gene replacement product (SKG1201) which meticulously comprises liver de-targeting capsid and packaged with a fully optimized SMN expression cassette. Single intracerebroventricular (ICV) delivery in SMNΔ7 mice at postnatal day 1 resulted in a significant improvement in the body weight and extension in the lifespan at less than 1/10 IV doses of SKG0201. Hence, relative to IV delivered SKG0201, IT delivered SKG1201 at a tenfold lower dose could potentially produce an equivalent effect in the brain and spinal cord of the animals. Additionally, head-to-head comparing to the reference vector, SKG1201 showed much better efficacy with the median survival time of ~3 months at a low dosage of 7.5E9 vg/mouse (5E12 vg/kg). Furthermore, SKG1201 consistently demonstrated higher SMN expression level in the spinal cord and much less distribution in the liver compared to the reference vector by IT delivery in adult FVB mice. Currently both nonclinical toxicology and biodistribution studies are being planned to evaluate its safety and biodistribution in cynomolgus monkeys. In summary, SKG1201, a new generation vector which exemplifies a synergistic effect of liver de-targeting and restoration of high expression in the spinal cord, is a prospective gene therapy product for IT delivery to type II/III SMA patients.

629. AAV-RNAi Mediated Lowering of *HTT* for the Treatment of Huntington's Disease

Johanna Adams[1], Brenda Richards[1], Catherine O'Riordan[1], Martin Goulet[1], Robert G. Jackson[2], John Bladon[2], Ye He[2], Zhengyu Luo[2], Christian Mueller[1], Shyam Ramachandran[1], Bradford Elmer[1]

[1]Genomic Medicine Unit, Sanofi, Waltham, MA,[2]IVWG, Sanofi, Cambridge, MA

Huntington's disease (HD) is a fatal, monogenic neurodegenerative disease that affects between 5-17 of every 100,000 persons. Expanded trinucleotide repeats in the huntingtin gene (*HTT*) confer a toxic gain-of-function that causes progressive motor, cognitive and neuropsychiatric impairment for which there is currently no disease modifying treatment. Partial suppression of HTT mRNA and protein in the brain has been demonstrated to be both safe and efficacious in animal models of HD, providing proof-of-concept for a HTT lowering therapeutic strategy that is agnostic to allele type. Artificial microRNAs (amiRNAs) act at the transcriptional level to reduce levels of target RNA, and when expressed from adeno-associated viral (AAV) vectors enable long-term target knockdown. Here, we designed novel amiRNAs targeting *HTT* mRNA and evaluated them *in vitro* and *in vivo* for target engagement and strand loading analysis. We also validated phenotypes in the BACHD rat model of HD for future efficacy studies. Using an updated miRNA screening process to ensure amiRNAs have a low propensity for off-targeting, we designed and screened amiRNA sequences for *in vitro* knockdown of endogenous, human *HTT* mRNA. These amiRNA candidates were ranked *in vitro* based on capacity to reduce *HTT* mRNA and small RNAseq strand processing data to inform selection of five HTT amiRNA sequences for *in vivo* studies. Intrastriatal injection of AAV-HTTamiRNA candidates was performed in HD model YAC128 mice which express full length human mutant HTT. Striatal tissue taken at six weeks post-dosing shows significant *HTT* mRNA knockdown leading to robust 53-63% knockdown of mutant HTT protein. Notably, most sequences have improved strand loading bias *in vivo* relative to *in vitro* assessments. We also validated robust behavioral phenotypes in the BACHD rat model of HD, finding a significant decrease in several open field metrics (male and female) and a robust decrease in rotarod fall latency (females) relative to wildtype. Importantly, intrastriatal administration of our AAV-HTTamiRNA candidates generates significant lowering of striatal HTT protein by 26-47%, proving viability for efficacy studies. Ultimately, four HTTamiRNA candidates show strong therapeutic potential for the treatment of Huntington's disease.

630. From Review to Readiness: CMT4J and the Road to Clinical Trials

Sydney Cooper[1], Keith Gottlieb[2], Souad Messahel[2], Rachel Thomas[2], Jocelyn Duff[3], Terry Pirovolakis[2], Michael Shy[4], Carsten G. Bonnemann[5], John Day[6], Susan Iannaccone[1]

[1]University of Texas Southwestern Medical Center, Dallas, TX,[2]Elpida Therapeutics, Encino, CA,[3]CureCMT4J/Talia Duff Foundation, Ipswich, MA,[4]University of Iowa, Iowa City, IA,[5]NINDS/NIH, Bethesda, MD,[6]Stanford Medicine, Palo Alto, CA

First described in 2007, Charcot-Marie-Tooth Disease Type 4J (CMT4J) is an autosomal recessive neurological disease caused by loss-of-function mutations in the FIG4 gene. It is characterized by progressive loss of motor and sensory neuronal function, with a wide spectrum of symptoms and varying severity. CMT4J is an ultra-rare, severe version of CMT found in less than 0.24% of patients. A review of over 50 published cases of CMT4J characterized the heterogeneity of symptom onset in this patient population. The majority of affected individuals exhibited symptoms before adulthood while a subset experienced adult-onset disease, and a smaller group had unspecified symptom onset. Earlier onset is associated with more severe disease progression, while later onset shows a slower progression, sometimes with symptoms that resemble Parkinsonism. Most common initial symptoms include muscle weakness, neuropathy, and gait difficulties. Progression of the disease can lead to respiratory impairment and dependence on a wheelchair. Treatment is currently limited to management of these symptoms. To address the unmet needs of CMT4J patients and facilitate future therapeutic interventions, the Bespoke Gene Therapy Consortium (BGTC) has selected CMT4J as a leading neurological program for its platform. Furthering this partnership, Elpida Therapeutics will conduct a prospective, observational natural history study aimed at characterizing CMT4J's clinical and genetic spectrum. In this study, 20 individuals will be recruited across four specialized medical centers. Over five years, annual evaluations will be conducted, encompassing a comprehensive array of assessments. These include clinical and neurological exams, laboratory tests to investigate potential biomarkers, CMT-specific outcome measures, neuropsychological tests, nerve conduction studies, muscle fat fraction as measured by MRI, pulmonary function tests, and scoliosis series

x-rays. These assessments will provide invaluable insights into the disease course, inform future therapeutic strategies, and enhance readiness for clinical trials in this rare neurodegenerative disorder.

631. Trial Readiness for First Gene Therapy Interventions in Cockayne Syndrome

Robert Thompson[1,2], Amanda Nagy[1], Nina Gold[2], Eric Macklin[1], Terry Flotte[3], Florian Eichler[1]

[1]Neurology, Massachusetts General Hospital, Boston, MA,[2]Genetics, Massachusetts General Hospital, Boston, MA,[3]University of Massachusetts Medical School, Worcester, MA

CockayneSyndrome (CS) is an autosomal recessive disorder caused by pathogenic variantsin ERCC8 and ERCC6, leading to defective nucleotide excision repair. Patientswith CS develop a progressive, variably severe presentation characterized bygrowth failure, microcephaly, global developmental delay, premature aging,photosensitivity, and multi-organ system pathology. No disease-modifyingtreatment is available. Pre-clinical studies on intracerebroventricularadministration of scAAV9-mediated hERCC8 gene replacement have prompted trialdesign for CS. The report of a 15-point CS severity score in the literature aswell as a medical record review provides a framework for quantifying diseaseseverity and estimation of the window for intervention. We performed a literature review in PubMed assessing papersrelated to CS published between 1992 and 2023. We identified 11 relevant articlesand applied the 15-point CS severity score to define the disease course andsteepest rate of decline after symptom onset. This previously published severity scaleassigns a score of 0 to 3 (0 indicating worst disease and 3 indicating nodisease) for head circumference, weight/height, neurosensorial symptoms,autonomy/motor development, and communication. Giventhe risk of insertional oncogenesis with gene therapy, we reviewed theliterature on whether defective nucleotide excision repair increases cancerrisk in CS. Next, we performed a retrospective chart review on 4 patientsfollowed at our center with ERCC8-related CS (3 living, 1 deceased). We thencalculated a severity score for each patient at 3 different time points. Weused these data to inform our proposed clinical trial design. The literature indicates that classic CS patients decline mostrapidly in the first 2 years of life and their symptoms typically plateauthereafter. Patients with growth failure at birth may have symptoms tooadvanced to warrant trial enrollment. Review of the literature suggests that,despite their defective nucleotide excision repair, patients with CS do nothave an increased risk of cancer (possibly related to arrested transcription). Asexpected severity scores for patients in our cohort declined with time, indicatingworsening disease burden. At last examination the living patients (ages 3-4)had severity scores of 5, 6, and 8, suggesting moderate to severe disease. Thedeceased patient (age 17) was neurologically assessed 3 months prior to deathand had a score of 1 indicating very severe disease. Basedon the existing literature, the optimal time of enrollment in a gene therapytrial would be under 2 years of age which is when patients typically experiencemilder symptoms. The natural history of our deceased 17-year-old patient parallelsreported natural history data in the literature. To exclude patients withgrowth failure at birth or severe motor and communication impairments, wepropose that a severity score of <5 be used as an exclusion criterion.Primary objectives would be safety and tolerability of scAAV9-ERCC8gene therapy, increased MFD free survival, and improved growth parameters.Primary endpoints would be the absence of dose limiting toxicities, time tooccurrence of major functional disabilities, duration of survival,stabilization of CS severity scores and growth parameters, and neurologicalassessments (e.g. brain MRs, developmental scales). Our secondary objectivewould be to assess non-neurological disease burden. Secondary endpoints wouldinclude standard assessments of disease in the pertinent organ systems. Recoveryof RNAsynthesis (decreased in CS) pre and post gene therapy would be an exploratoryendpoint. We will monitor oncogenic risk post gene therapy.

632. An iPSC Based Platform to Develop AAV Gene Therapies for ALS Using Specific and Robust Phenotypic Assays Covering Multiple Disease-Relevant Readouts

Isabel Onofre, Kimberly Riegman, Benoit Samson Couitre, Asha Das, Shushant Jain, Georgios Kosmidis

Ncardia, Leiden, Netherlands

The formation and accumulation of protein aggregates is a hallmark of many neurodegenerative diseases such as Parkinson's disease, Alzheimer's disease, frontotemporal dementia or amyotrophic lateral sclerosis (ALS). Misfolding and self-aggregation of proteins consequently lead to alterations in important neuronal functions and progressive neurodegeneration. Currently, available treatments partially ameliorate the symptomatology but do not modify the course of the disease. It is of major interest to develop therapies that can prevent aggregates formation and accumulation, thus, changing patient's prognosis. To enable fast and confident selection of effective therapies we developed specific and robust phenotypic assays to study protein mis-localization and aggregation with iPSC-derived *in vitro* models. In this study, we developed assays with human iPSC-derived motor neurons to study mis-localization and aggregation of TAR DNA-binding protein 43 (TDP-43), a recognized hallmark for ALS as well as multiple neurodegenerative diseases. In addition, mis-splicing of STMN2 and electrophysiological dysfunction were robustly quantified. Utilizing a AAV based gene therapy, we successfully achieve high transduction efficiencies in complex co-cultures of motor neurons and astrocytes, reduce TDP-43 aggregation. alleviate the electrophysiological deficits associated with the motor neurons derived from mutated iPSC lines. Use of a human, physiologically relevant in vitro system, allowed for not only validation of the therapeutic but also enable advancements of a subset of therapeutics with a higher degree of confidence.

633. Relevance of Sex as a Biological Variable in Assessing the Efficacy of a Gene Replacement Therapy for a Mouse Model of XLID98

Eve Racette[1], Melissa Mitchell[2], Peter Gagolewicz[1,3], R. David Andrew[1,3], Jagdeep S. Walia[1,2,3]

[1]Centre for Neuroscience Studies, Queen's University, Kingston, ON, Canada,[2]Department of Pediatrics, Queen's University, Kingston, ON, Canada,[3]Department of Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada

Five to ten percent of intellectual disability (ID) cases in males are linked to mutations of various genes located on the X chromosome, one of which is the Neurite Extension and Migration Factor gene (*NEXMIF*). The loss of NEXMIF causes X-Linked Intellectual Developmental Disorder 98 (XLID98), a syndrome characterised by intellectual disability, autism spectrum disorders and drug-resistant epilepsy. While the role of NEXMIF is poorly understood, studies have suggested its involvement in neurite outgrowth and orientation, in neuronal migration and in gene expression. Previous studies of the role of Nexmif in rodents have only been carried out in males, limiting the relevance of these models for the assessment of future gene therapy. Our hypothesis is that the loss of Nexmif causes a variety of neuronal phenotypes due to the alteration of neurodevelopmental processes, such as motility, neurite growth, synaptic formation, gene expression, etc. To verify this hypothesis, we assessed **a)** cognitive impairments using behavioural assays, **b)** hippocampal network excitability and short term facilitation using *ex vivo* local field potential recordings and **c)** gene expression alterations in the brain using MicroArrays. Similar to what is observed in XLID98 patients, loss of Nexmif is associated with sex-specific phenotypes in mice. Affected females are hyperactive in the Open Field test and their hippocampal network activity is decreased as compared to age-matched controls. Affected males are hypoactive in the Marble Burying test, indicative of a lack of interest for the external environment, have hyperactive hippocampal networks and display abnormal gene expression patterns. Interestingly, males also present with adult-onset obesity and frequent seizures. Our data suggests that, like in humans, XLID98 is associated with a variety of sex-specific phenotypes, further reinforcing the relevance of assessing both sexes in the development of gene replacement therapy for this disorder.

634. Development of Helper Dependent Adenovirus Vector (HdAd) Delivery Methods for Wide-Spread Transduction of the Cerebellum

Neda Mokhberian[1], Emre Kul[1], Uchechi Grace Okoroafor[1], Aberman Leah[1], Samuel M. Young[1,2]

[1]Department of Anatomy and Cell Biology, University of Iowa, Iowa City, IA,[2]Department of Otolaryngology, University of Iowa, Iowa City, IA

Helper-dependent Adenoviral vectors (HdAd) are non-toxic, high-capacity viral vectors for gene therapy approaches. They have tremendous potential to treat neurodevelopmental and neurodegenerative disorders that require expression of large transgenes or multiple transgene cassettes from a single vector. In particular, hereditary cerebellar ataxias are monogenic disorders which result in debilitating impairments in movement, cognition, behavior, and ultimately premature death are attractive candidates for HdAd gene therapy approaches. However, cerebellar intracranial injections of HdAd vectors result in limited restricted distribution of the viral vector to the site of injection. Therefore, optimizing delivery techniques to maximize vector distribution and achieve wide-spread transgene expression is an important step in developing viable HdAd gene therapy approaches for cerebellar disorders. Convection-enhanced delivery (CED) is a direct intracranial injection technique that facilitates broad distribution of macromolecules and viral vectors to broad areas within the brain. More importantly, this technique has had tremendous success in clinical trials with AAV vectors to treat human neurological disorders. Therefore, we set out to evaluate CED approaches with HdAd in a mouse cerebellum. We compared this CED to a traditional single bolus injection with a small glass needle. In addition, we optimized our injection protocols to maximize the number of transduced Purkinje cells. Our results demonstrate that these two different delivery techniques results in different transduction pattern and spread within the cerebellar tissue. Further results and implications of our findings will be discussed.

635. Engineering ARMMs with Engagers to Direct Biodistribution to Specific Neurons as a Therapeutic Strategy for Friedreich Ataxia

Wendy Zhao[1], Zahra Baghbantaraghdari[1], Brandon Gerhart[2], Mike Thomas[1], Shu-Lin Liu[1], Jennifer A. Badji[1], Kevin Le[1], Silvia Piccinotti[1], Qin Yu[1], Jill S. Napierala[3], Joseph F. Nabhan[1]

[1]Vesigen Therapeutics, Cambridge, MA,[2]Neurology, University of Texas Southwestern Medical Center, Dallas, TX,[3]Neurology, University of Texas Southwestern Medical Center, Cambridge, MA

The pathological insufficiency of Frataxin (FXN) in Friedreich's ataxia (FA) is caused by bi-allelic expansion of an intronic trinucleotide sequence, GAA, in the *FXN* gene. The expanded repeat region drives formation of heterochromatin and limits potentiation of transcription and access to the transcription start sequence. Consequently, FXN expression in patient cells is reduced by >70% compared to healthy non-carrier levels. FA is a multi-system disease that primarily manifests in sensory proprioceptive neurons and cardiomyocytes. Various strategies such as gene replacement with AAV or FXN protein or mRNA supplementation to treat the loss of proprioceptive functions in FA have encountered significant challenges. Vesigen has been developing a novel approach to potentially treat the major component of FA pathology. We explored the use of ARMMs (ARRDC1-Mediated Microvesicles) as a non-viral and proprioceptor-targeted delivery vehicle for Cas9/gRNA protein complexes to excise the pathogenic repeat expansion in *FXN*. We screened and identified a pair of gRNAs that can efficiently excise the GAA repeat containing region and demonstrated that ARMMs-mediated delivery of Cas9 and 2 gRNAs successfully excise the GAA repeat containing region in a) a cell line containing the non-pathogenic expansion and b) FA iPSC-derived neurons containing bi-allelic pathogenic expansions. Additionally, we developed a strategy to target ARMMs to the proprioceptive neurons. To assist the evaluation of targeted delivery of Cas9/gRNA by surface engineered ARMMs, we established an in vitro testing system and demonstrated targeted delivery using a proprioceptor-specific engager. In summary, our approach provides the foundational evidence for a disease-modifying strategy for FA that could potentially significantly improve the quality of life across the FA patient population.

636. Restoration of Normal Gene and Protein Expression in Mouse and Human Disease Models ofSCN2A Haploinsufficiency Using Zinc Finger Activators

Andrew Olin[1], Jennifer Hodges[1], Yolanda Santiago[1], Jason Eshleman[1], Luke Bogart[2], Jack Hsiao[2], Mary Gulino[2], Madison Riley[2], Stephanie Hromadka[2], Stephanie Petit[2], Patrick Dunn[1], Jisoo Lee[1], Daniel Chung[1], Giulia Cisbani[3], Chiara Melis[3], Finn Peters[3], Toufan Parman[1], Eloise Hudry[2], Katie Worringer[2], Gregory Davis[1], Amy Pooler[1], Bryan Zeitler[1]

[1]CNS, Sangamo Therapeutics, Inc., Richmond, CA,[2]Novartis, Cambridge, MA,[3]Evotec, Hamburg, Germany

Approximately three hundred babies are born each year in the USA with mutations causing SCN2A haploinsufficiency, a rare neurodevelopmental disorder for which no effective treatment exists. These patients suffer global developmental delays commonly associated with autism spectrum disorder (ASD) and intellectual disability (ID), and comorbidities with sleepimpairment and gastrointestinal disturbances. SCN2A haploinsufficiency is caused by de novo loss-of-function mutations in the SCN2A gene resulting in insufficient gene expression and abnormally low levels of its encoded protein, neuronal voltage-gated sodium channel Nav1.2. A potential therapeutic approach to treating genetic haploinsufficiency disorders involvestranscriptional upregulation of the healthy allele to restore normal protein levels. We utilized our zinc finger transcriptional activator (ZFA) platform to upregulate SCN2A expression in healthy and disease model neurons in vitro and in vivo in wildtype (WT) and heterozygous Scn2a+/- mice. In a proof-of-concept study, several hundred ZFAs targeting multiple transcription start sites were designed and screened to identify hot spots for gene activation.We identified several ZFAs targeting either the human SCN2A or mouse Scn2a promoter that upregulated the target gene up to two-fold with high specificity. Selective upregulation of target gene expression by ZFAs subsequently increased and restored Nav1.2 protein to normallevels in vitro in both Scn2a+/- mouse cortical neurons and engineered human embryonic stem cell (hESC)-derived neurons containing common patient mutations modeling SCN2A haploinsufficiency. In adult mice treated intravenously with an AAV. PHP.B ZFA, a 1.5-2-fold increase in Scn2a and Nav1.2 expression was confirmed in multiple brain regions using bulk RT-qPCR and immunohistochemistry (IHC). Upregulation of Scn2a levels by more than 2-fold was verified at the single-cell level via multiplexed in situ hybridization (ISH) and IHC. Corroborating the results in WT mice, Scn2a upregulation was also observed in the brains of Scn2a+/- mice treated with AAV9-ZFA four weeks following intracerebroventricular (ICV) administration.Taken together, our results demonstrate a proof-of-concept that targeted SCN2A upregulation by ZFAs increases gene expression in human and mouse models of SCN2A haploinsufficiency and restores Nav1.2 levels to normal in Scn2a+/- mouse cortical neurons, thereby providing support for the advancement of a ZF Activator approach to treat SCN2A haploinsufficiency.

637. Zinc Finger Mediated Repression and Replacement of MFN2 Leads to the Rescue of Cellular Disease Phenotype in CMT2A Patient-Derived Cells

Mohammad Samie, Luke Workley, Matthew Mendel, Mihika Jalan, Lee Jisoo, Patrick Dunn, Jason Eshleman, Hung Tran, Sarah Hinkley, Bryan Zeitler, Amy Pooler

Sangamo Therapeutics, Inc., Richmond, CA

Charcot-Marie-Tooth Type 2A (CMT2A) is a dominant negative disease caused by damage to motor and sensory neurons. Patients develop progressive muscle weakness and atrophy at an early age in the feet, ankles, and legs that ultimately leads to paralysis. CMT2A symptoms are a result of loss of function mutations in the Mitofusin 2 (MFN2) gene. MFN2 is a GTPase protein expressed on the outer mitochondria membrane and responsible for mitochondrial fusion, metabolism, and transport. Considering the critical role MFN2 protein plays in mitochondria homeostasis and function, biallelic repression of the mutated gene is predicted to reduce disease toxicity but would potentially result in a loss-of-function phenotype due to lack of a healthy protein. Indeed, complete loss of MFN2 in animal models is known to be lethal. Thus, in a proof-of-concept study, we developed a novel approach to repress both the mutant and healthy endogenous alleles, and to replace them with a functional/healthy cDNA of MFN2. The goal of this repress and replace strategy is to simultaneously rescue the disease phenotype and restore MFN2 protein function in cells. A library containing more than 400 engineered zinc finger repressors (ZFRs) was initially screened in human and rodent neuronal cell lines and the lead ZFRs were packaged into AAV and screened in human iPSC-derived GABAergic and rat primary cortical neurons *in vitro*. We identified ZFRs that repressed MFN2 mRNA and protein by more than 90% over a wide dose range with minimal detectable off-target activity as measured by global transcriptomics analysis, in both human and rat primary neurons. Lead ZFRs were cloned into a vector expressing a codon optimized MFN2 transgene. Vectors containing both the MFN2 transgene and the ZFR under a single neuronal promoter were tested for expression and activity of both MFN2 and ZFR in primary rat neurons and human iPSC-derived GABAergic neurons. We were able to observe a significant reduction of the endogenous MFN2 gene in both rat and human neurons, simultaneously we observed significant expression of MFN2 transgene from the MFN2 cDNA, replacing the endogenous MFN2 in the cells. To evaluate the feasibility of the repress and replace strategy, we evaluated the efficacy of the vector in patient derived cells. The vector restored wildtype MFN2 while concurrently knocking down endogenous mutant MFN2 in the cells which led to a rescue of the mitochondria depolarization phenotype observed in disease cells. Together, these data confirm that the repress and replace strategy could potentially provide a novel therapeutic approach for the treatment of CMT2A.

638. AAV Conjugated to Antibodies Against P75^{NTR}: A New Platform to Develop Pain Therapeutics Targeted to Nociceptive Sensory Neurons

Adina Buxbaum[1], Mathieu Desclaux[2], Jennie Lipinski[1], Sando Dickinson[1], Chun Wai Yip[2], Osama Chaudry[1], Robert Breese[1], Poulami Samai[2], Karole D'Orazio[2], Lynn Macdonald[1], Christos Kyratsous[2], Sven Moller-Tank[2], Nicole Alessandri-Haber[1]

[1]Neuroscience, Regeneron Pharmaceuticals, Tarrytown, NY,[2]Regeneron Genetic Medicines, Regeneron Pharmaceuticals, Tarrytown, NY

Chronic pain is a prevalent condition, affecting about 20% of the population, with a high unmet need for pain relieving drugs with high efficacy and low off-target side effects. Despite decades of preclinical research, standard of care remains opioids and non-steroidal anti-inflammatory drugs. Antibody-based delivery of therapeutic cargo to the cells underlying pain pathology may provide improved drug efficacy and reduced off-target effects. Cross functional, in-house efforts identified the neurotrophin receptor p75^{NTR} as a potential candidate for targeting the peripheral nervous system. We find that antibodies against p75^{NTR} internalize in sensory neurons in Dorsal Root Ganglia (DRG) and Trigeminal ganglia (TG), as well as the parasympathetic nervous system in the colon and sympathetic neurons. When anti-p75^{NTR} antibodies were conjugated to AAV particles and injected systemically, GFP expression driven by the viral episome was detected in 85-95% of the DRG neurons and GFP expression was enhanced 7-fold relative to undecorated AAV. Local, subcutaneous injections of anti-p75^{NTR} conjugated to AAV demonstrated the ability to travel retrogradely from the injection site to innervating sensory neurons; Injection of anti-p75^{NTR} -conjugated AAVs in the whisker pad transduced ipsilateral, but not contralateral TG neurons. Similarly, when anti-p75^{NTR} -conjugated AAVs were injected into the synovial fluid in the knee, ipsilateral lumbar DRG neurons exhibited GFP expression at similar levels to DRG neurons from animals that were injected systemically with up to 8x the viral load.The ability to non-invasively and specifically deliver AAVs or other therapeutic cargo to nociceptive sensory neurons has been a great unmet need in the pain field. The voltage-gated sodium channel Nav1.7 is one of the best validated pain targets; genetic and physiological evidence support its key role in pain processing. Therefore, we generated an shRNA targeting mouse Nav1.7 and packaged it in AAV9 with modified tropism. We demonstrate here that intrathecal delivery of AAV expressing an shRNA targeting mouse Nav1.7 effectively reduced thermal hyperalgesia in a preclinical animal model of inflammatory pain. Systemic or local subcutaneous injections of AAV conjugated to antibodies against p75^{NTR} could be transformative in the development of therapeutics for chronic pain, especially in the context of challenging targets such as Nav1.7.

639. Translating Lumbar Intrathecal RNAi-Based Gene Therapy for CMT1A Using CMT1A Mice, Human Cells, and Non-Human Primates

Lindsay M. Wallace[1], Merlin Thangaraj[1], Marina Stavrou[2], Brian Price[3], Gloria Zender[1], Bilal Bayazit[1], Noah Taylor[4], Kleopas A. Kleopa[5], Scott Q. Harper[6]

[1]Nationwide Children's Research Institute, Columbus, OH,[2]The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus,[3]Armatus Bio, Columbus, OH,[4]Nationwide Children's Hospital, Columbus, OH,[5]The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus,[6]Ohio State University & Nationwide Children's Hospital, Columbus, OH

Background: CMT1A is the most common inherited demyelinating peripheral neuropathy, affecting ~1.5 million people. It is caused by *PMP22* gene duplication, leading to over-expression of the PMP22 protein, myelin sheath destabilization in Schwann cells (SC), secondary axonal loss, and disability. We propose that normalizing PMP22 levels is the most direct route to CMT1A treatment. To do this, we developed an AAV9 vector expressing an engineered miRNA (scAAV9-U6-miR871) that reduces *PMP22* expression and improves neuropathy in a CMT1A mouse model following lumbar intrathecal (IT) delivery. This program received orphan drug and rare pediatric disease designations from FDA for the treatment of CMT1A, and we are now working to demonstrate safety and translatability by assessing potential off-target effects in human cells, as well as demonstrating biodistribution, target engagement and tolerability in *Macaca fascicularis*. Although lumbar IT delivery of AAV9 in NHPs was previously tested, to our knowledge no one has examined SC transduction using this route of administration in a large animal model. Methods: For off-target studies, we designed lentiviruses expressing U6-miR871 and a puromycin resistance gene, or puromycin alone. We transduced human neuron, hepatocyte, or SC cultures, collected RNA after puromycin selection, and performed RNA-seq to assess gene expression changes, followed by binding assays to empirically determine if miR871 and potential target sites on downregulated transcripts are real. In NHPs, we IT-delivered 2 doses of AAV9-U6-miR871 (6e13 or 1.2e14 vg/animal), or saline, and analyzed animals 6- or 12-weeks later. We performed clinical and neurological observations and collected longitudinal samples to assess hematology, serum, coagulation, chemistry, and urine parameters. Prior to study termination, animals underwent ophthalmic testing, electrocardiogram, nerve conduction studies, and testing for AAV9 neutralizing Abs, followed by histopathological and molecular analysis of necropsied tissues. Results: We found minimal transcript reductions in miR871-treated cells versus controls. Importantly, *PMP22* was significantly reduced by miR871 in each cell line, supporting target engagement in humans. Bioinformatics analyses do not support binding of downregulated transcripts by miR871, but we are empirically assessing target site interactions. These results support that our RNAi approach is on-target and safe. NHP studies support translatability of scAAV9-U6-miR871, with both doses well-tolerated, resulting in efficient transduction of PNS tissues even in distal nerves. Subclinical DRG inflammation was noted in some treated animals, but in-life observations showed no behavioral abnormalities, no clinical chemistry alternations, and no impairment of nerve conduction. Importantly, we also demonstrate PMP22 protein knockdown *in vivo*, supporting target engagement. Discussion: We provide the first detailed biodistribution analysis of an intrathecally-delivered AAV9 vector targeting Schwann

cells in the PNS of *Macaca fascicularis*, along with promising safety data *in vivo* and in human cell lines representing organs highly transduced by AAV9. Collectively, our data support biodistribution to peripheral nerves, target engagement, safety, tolerability, and the therapeutic potential of scAAV9-U6-miR871. We believe this study not only supports translation of CMT1A gene therapy, but also establishes a strategy to treat other demyelinating neuropathies.

640. Development of hfCas12Max-Based Gene Editing Therapy for Huntington's Disease

Dong Yang[1], Guoling Li[1], Xiaoqing Wu[1], Jin Zheng[1], Lecong Wang[1], Tong Li[1], Shaoran Wang[1], Xuan Yao[1], Alvin Luk[1], Hui Yang[1,2], Linyu Shi[1]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Institute of Neuroscience, Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Huntington's disease (HD), a lethal and inherited disease, is the most frequent autosomal dominant neurodegenerative condition caused by the CAG trinucleotide repeat expansion in the exon 1 of the huntingtin (*HTT*) gene, resulting in the production of mutant huntingtin (mHTT) protein with an elongated polyglutamine tract which leads to progressive disruption of neuronal physiology. This disorder is characterized by the progressive degeneration of neurons in the striatum and cerebral cortex, manifesting as chronic movement, psychiatric problems, and cognitive impairments that appear during mid-life and slowly progressive decline over two decades until death with no approved treatment. It was reported knockdown of *HTT* effectively inhibits the formation of mHTT protein. Here, we introduce a novel CRISPR-DNA gene-editing approach using high-fidelity Cas12Max (hfCas12Max), an engineered Cas12i variant demonstrating high editing efficiency and specificity, with guide RNA targeting *HTT* (g*HTT*) as a potential treatment for HD. **Methods:** We constructed a single recombinant adeno-associated viral (AAV) vector packaging for both hfCas12Max and g*HTT*. Subsequently, we performed bilateral intrastriatal injections of either AAV-hfCas12Max-g*HTT* or PBS to the striatum of 3-month-old zQ175 mice, a knock-in (KI) mouse model of HD. Four weeks after the injection, we evaluated the indel efficiency and mHTT protein levels in the striatum. We then checked for mHTT protein aggregation in the striatum four months after the injection and monitored any changes in motor function of the zQ175 KI mice monthly beginning one month after the injection. **Results:** In the zQ175 KI mice treated with AAV-hfCas12Max-g*HTT*, the indel ratio of *HTT* reached 67.5% ($p<0.001$) and the knockdown efficacy of mHTT protein was up to 72% ($p=0.0018$) in the striatum four weeks after the injection when compared to the zQ175 KI mice injected with PBS (Fig.1a). The mHTT protein aggregates in the striatum of zQ175 KI mice 4 months after injection the AAV-hfCas12Max-g*HTT* was decreased 80% when compared to those zQ175 KI mice treated with PBS. Notably, the levels were almost rescued to those observed in wild-type mice ($p<0.01$, Fig. 1b). Furthermore, zQ175 KI mice treated with AAV-hfCas12Max-g*HTT* showed shorter traverse times on the balance beam at 1-, 2-, 3-, and 4-month post-injection, indicating motor improvements (at 4-month; $p=0.0003$) when compared to the zQ175 KI mice treated with PBS at 4-month post-injection. Their agility approached that of wild-type mice, suggesting near-normalization of motor function in the beam test (Fig. 1c). **Conclusions:** Our findings provide a solid foundation of using AAV-hfCas12Max-g*HTT* gene-editing therapy approach to treat HD, which has demonstrated to reduce the mHTT protein level and improve the motor function in mouse model of HD.

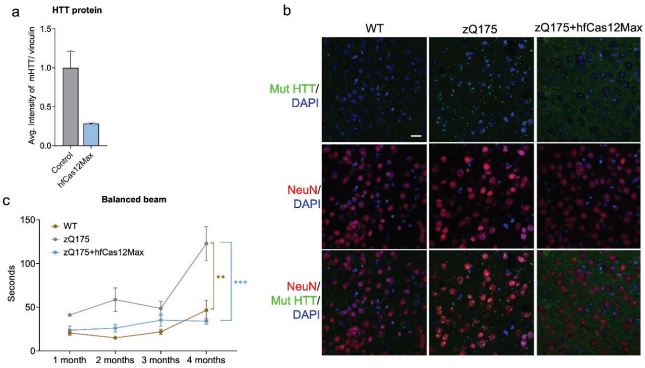

Figure 1. The treatment effect of AAV-hfCas12Max-g*HTT* in HD mice. (p<0.01, ***p<0.001)**

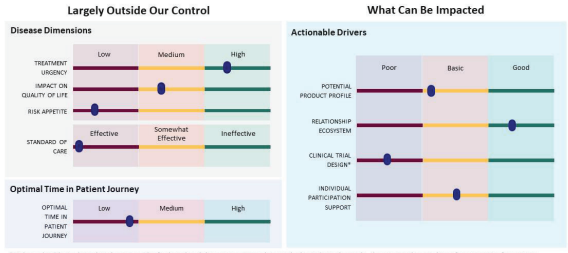
641. Understanding Drivers of Patient Acceptance Towards Invasive Gene Therapy Clinical Trials



Carl Vandeloo[1], Olivier Baron[1], Alok Gangaramany[2], Christina Hanschke[2], Kerrie-Anne Ho[3], Hritika Parekh[4], Jesper Jørgensen[3]

[1]UCB Pharma, Anderlecht, Belgium,[2]Final Mile Consulting, New York, NY,[3]UCB Pharma, Slough, United Kingdom,[4]Final Mile Consulting, Mumbai, India

INTRODUCTION: The unique properties of gene therapies (GTs) present certain challenges in identifying patients willing to participate in GT clinical trials. Patients may lack trust and can be apprehensive about participating, particularly where the GT administration route is highly invasive. Concerns are heightened as GTs are new, highly technical, and levels of patient understanding can vary (efficacy, safety, durability of response). Patients express concerns that participation in GT trials may exclude them from taking part in future trials. This study aims to understand what drives patient GT acceptance, how it changes over time, and how key stakeholders, such as researchers and trial investigators, can support patient choice. **METHODS:** A literature review performed on 13 rare diseases and neurologic conditions, and insights from patient, caregiver, healthcare provider (HCP), and clinical research organization (CROs) interviews helped identify key drivers of patient GT acceptance. An acceptance framework was developed, and actionable drivers, and barriers to participation were identified. The acceptance framework comprised three elements: disease dimensions, optimal time in a patient journey, and actionable drivers (rated qualitatively low, medium, high). **RESULTS:** In total, 102 articles/conference proceedings were identified exploring behavioral aspects of each disease, caregiver preferences, clinical decision-making, patient-provider communication, trial acceptance, altruism, and GT acceptance; insights were gathered from 10 patients/caregivers, 20 HCPs, and one CRO. Research and stakeholder interviews identified trial design and individual participation support as key drivers of patient GT acceptance. The acceptance framework (**Figure 1**) showed that convergence of several elements makes patients more receptive to

GT trials. Key insights include: (1) Acceptance is a dynamic process that evolves over time. Patients and caregivers may be more receptive to GTs at certain points in the treatment journey, but not in others due to disease severity/prognosis, quality of life (QoL) impact, and standard of care (SoC) efficacy. Openness to GT trials is higher at certain points along the journey; (2) Acceptance is not binary. Agreeing to try GT does not negate hesitation; patients may still have questions and concerns. Even when people agree to take part, support is needed to ensure they feel confident to participate; (3) Acceptance is different from participation. Despite GT openness, several logistic and personal factors need to be addressed to support participation (patient demographics, trial knowledge, risk and benefit perceptions, personal motivations). It is important to have mechanisms in place to help participants overcome the practical barriers when GT trials are designed. Disease archetype (slowly/rapidly degenerative, early development disruption, adaptable) is a critical factor affecting GT acceptance, treatment urgency, QoL impact, and risk appetite. SoC perception can vary by disease; actionable drivers can be strengthened through engagement strategies. **CONCLUSIONS:** When developing GTs, it is critical to take account of three elements: disease dimensions, optimal time in a patient journey, and actionable drivers to increase the likelihood of patient participation in GT clinical trials.

Figure 1. Summary of GT Acceptance Framework

*Only applicable in clinical trial context. The further the sliders are positioned towards the right in the scale, the greater the window of opportunity for patient acceptance for a GT clinical trial.

642. A Zinc Finger Activator Platform to Restore Normal Gene & Protein Expression in Cellular Models of Dravet Syndrome

Jennifer L. Hodges[1], Andrew Olin[1], Yolanda Santiago[1], Dave Paschon[1], Irene Tan[1], Gillian Houlihan[1], Patrick Dunn[1], Jisoo Lee[1], Qi Yu[1], Annemarie Ledeboer[1], Giulia Cisbani[2], Chiara Melis[2], Finn Peters[2], Greg Davis[1], Amy Pooler[1], Bryan Zeitler[1]

[1]Sangamo Therapeutics, Inc., Richmond, CA,[2]Evotec, Hamburg, Germany

Dravet Syndrome (DS) is a severe neurodevelopmental disorder and epileptic encephalopathy characterized by intractable seizures, intellectual disability, motor deficits, and a 10% to 20% rate of premature death. Most DS cases are caused by *de novo* loss-of-function mutations in the *SCN1A* gene resulting in insufficient gene expression and abnormally low levels of its encoded protein, neuronal voltage-gated type I sodium channel, $Na_v1.1$. Genetic restoration of $Na_v1.1$ has been shown to reduce seizures and extend survival in various mouse models of DS. Our approach to restoring normal $Na_v1.1$ levels involves targeting a zinc finger protein fused to a novel transcriptional activator domain to the *SCN1A* promoter to drive transcriptional upregulation of the healthy allele. In contrast to other published transcriptional activator approaches that incorporate elements of bacterial or viral origin in the DNA-binding domain and/or effector domain, our zinc finger activator (ZFA) platform consists of human-derived components naturally expressed in the brain. In a proof-of-concept study, we identified several ZFAs targeting conserved regions of the *SCN1A* promoter that upregulated *SCN1A* gene expression by multiple-fold in human induced pluripotent stem cell (iPSC)-derived neurons and in mouse cortical and hippocampal neurons derived from wild-type (WT) and heterozygous $Scn1a^{+/-}$ mice modeling DS. Selective upregulation of target gene expression by ZFAs subsequently increased and restored $Na_v1.1$ to normal levels *in vitro* in disease-model $Scn1a^{+/-}$ mouse cortical neurons. Many ZFAs were shown by microarray analysis to be highly specific for activating the *SCN1A* gene with no detectable off target regulation in human iPSC-derived neurons. The functionality and safety of our ZFA approach was demonstrated *in vivo* in adult WT mice treated intravenously with an AAV.PHP.B-ZFA under control of the human Synapsin 1 promoter (hSyn1). No clinical or cellular signs of toxicity were observed, and significant upregulation of *Scn1a* mRNA levels was confirmed in single cells expressing the ZFA via multiplexed *in situ* hybridization and immunohistochemistry (ISH/IHC). Our results demonstrate proof-of-concept for our zinc finger transcriptional activator (ZFA) platform as a potential therapeutic approach to treating Dravet syndrome.

643. Low-Intensity Focused Ultrasound Targeting of AAV Serotypes to the Central Nervous System

Rachel M. Bailey[1], Ibrahim Youseff[2], Sydni Holmes[1], Irvin T. Garza[1], Rajiv Chopra[2], Bhavya R. Shah[2]

[1]Center for Alzheimer's and Neurodegenerative Diseases, UT Southwestern Medical Center, Dallas, TX,[2]Department of Radiology, UT Southwestern Medical Center, Dallas, TX

Recombinant adeno-associated virus (rAAV) vectors are routinely used for gene therapy due to their efficient gene transfer, safety profile, and long-term transgene expression in non-dividing cells, such as neurons. AAV9 is currently the most frequently used serotype for treating neurological disorders as it can be delivered in blood or cerebrospinal fluid (CSF) to broadly transduce the brain in a dose-dependent manner. Direct brain injections are effective for focal brain treatments but are an invasive procedure. With non-invasive systemic delivery, high vector doses are needed to achieve sufficient brain transduction in adults, which increases the risk of severe immune response. Use of transcranial low-intensity focused ultrasound (FUS) to temporarily open the blood brain barrier (BBB) can significantly reduce systemic vector doses and target rAAV vectors to select brain regions. To determine viral vectors amenable to FUS-mediated delivery, we assessed transduction of striatal neurons using a panel of naturally occurring and engineered AAV capsids in C57Bl/6 mice. Mice received an IV infusion of Definity microbubbles and underwent FUS-mediated opening of 3 targets in the striatum of the right hemisphere. BBB opening was confirmed using gadolinium-enhanced MRI and then mice were infused with $1x10^{12}$ vg/kg of an AAV vector. Three weeks after IV+FUS delivery, brain and liver transduction were assessed by measuring expression of the transcapsidated GFP reporter. Of the serotypes assessed, AAV9, AAV1, and AAV8 resulted in the highest brain transduction, while

AAV2, AAV4, and AAV5 resulted in little to no striatal transduction. These findings demonstrate that FUS-mediated delivery differentially enhances delivery of AAV serotypes to the brain. While IV+FUS delivery is promising for focal treatments, this limits the ability of AAV to efficiently transduce non-targeted brain regions. CSF delivery of AAV9 significantly reduces the amount of vector needed to achieve equivalent or greater brain transduction compared to systemic delivery and achieves high CNS transduction relative to the site of injection. Therefore, we hypothesized that transient disruption of the BBB can direct IT injected AAV to specific brain regions while also broadly transducing the hindbrain and spinal cord. To test our prediction that FUS-mediated opening of the BBB can enhance brain transduction of IT-injected AAV9, we performed a pilot study in C57BL/6 mice. Mice received an IT or IV injection of scAAV9/Cbh-GFP $4x10^{10}$ vg/mouse and FUS was used to unilaterally open the BBB in the hippocampus and the striatum in half of the IT treated mice and in all IV treated mice. Brains were assessed 3 weeks post-vector delivery for IHC staining with a GFP antibody. Tissues were also collected and processed for vector biodistribution. We found that compared to the FUS+IV route, FUS+IT resulted in 1) greater transduction of targeted brain region, 2) greater transduction of non-targeted hind brain regions, 3) greater transduction of spinal cord, and 4) decreased vector distribution to the liver. Compared to IT alone, FUS+IT delivery resulted in ~30% higher transgene expression in the hippocampus when FUS was applied. In an additional study, we found that IT+FUS delivery can also be used to target IT-injected AAV8 to the brain. Overall, these results support that IT+FUS delivery of AAV has the potential to provide greater treatment benefit with decreased risk of toxicity as compared to IT alone or IV+FUS delivery.

644. AAV Hamartin Gene Therapy in a Stochastic, Cranial Mouse Model of TSC1

Xandra O. Breakefield

Neurology, Massachusetts General Hospital / Harvard Medical School, Charlestown, MA

Tuberous sclerosis complex type 1 (Tsc1) is a dominantly inherited disease in which individuals are born with one defective allele for hamartin, with a somatic loss of the other allele, during development or later in life, leading to upregulation of cell growth in susceptible tissues. Ninety-five percent of affected individuals have brain involvement, including epilepsy, cognitive impairment, autism and/or sleep disorders. In the stochastic, cranial mouse model of Tsc1, loss of function of hamartin is induced at birth by injection of Cre recombinase encoded in an adeno-associated virus (AAV) vector into the cerebral ventricles at birth. This leads to: 1) proliferation of subventricular cells, 2) enlarged neurons, 3) elevated phosphorylation of ribosomal protein S6, 4) dysmyelination and 5) early death. Intravascular administration of an AAV9 vector encoding hamartin at postnatal day 21 led to significant ($p<0.05$) normalization of perturbations 1), 2) and 3), with a trend towards normalization of 4) by postnatal day 42, with extension of average lifespan from 50 days to over 150 days in 85% of animal receiving a dose of $5x10^{13}$1.5E13 vg/kg (n=11).

645. Clinical Dose Selection for ICV-Administered AAV9-NGLY1 Gene Replacement Therapy (GS-100)

Lei Zhu, William F. Mueller, Jennifer W. Cook, Alicia Newton, Selina S. Dwight, Brendan Beahm, Matt Wilsey, Becky Schweighardt

Grace Science LLC, Menlo Park, CA

GS-100 is an AAV9 gene replacement therapy for the treatment of N-glycanase 1 (NGLY1) Deficiency, an ultra-rare, debilitating recessive disorder due to loss-of-function mutations in the NGLY1 gene. Patients suffer from global developmental delay, intellectual disability, hyperkinetic movement disorder, elevated liver enzymes, (hypo)alacrima, and peripheral neuropathy. NGLY1 is a cytosolic enzyme that cleaves glycans from proteins as part of the degradation pathway. NGLY1 specifically cleaves between a GlcNAc residue and an asparagine residue on N-glycosylated proteins targeted for degradation. In NGLY1's absence, GNA (GlcNAc-Asn) accumulates as a biomarker of NGLY1 Deficiency. Increased levels of GNA can be detected in the CSF and plasma of NGLY1 Deficiency patients.We assessed the efficacy, safety, and biodistribution of intracerebroventricular (ICV) administration of GS-100 in a *Ngly1*$^{-/-}$ rat model that exhibits phenotypes similar to those found in patients. ICV administration of GS-100 to *Ngly1*$^{-/-}$ rats was associated with dose-dependent vector biodistribution and hNGLY1 mRNA expression, reduction in GNA biomarker levels, motor function improvement, and improvement in DRG disease-related pathology. Locomotor function in GS-100 treated rats, as assessed by rotarod, reached levels near wild-type following GS-100 treatment. In addition to the observed phenotypic improvements, GS-100 prevented disease progression over time in the *Ngly1*$^{-/-}$ rats. GNA reduction in CNS tissues and CSF significantly and inversely correlated with functional improvements in *Ngly1*$^{-/-}$ rats across all pharmacology studies. Additionally, the significant correlation between GNA levels in CNS tissues and CSF suggests that assessing CSF GNA levels in the clinic will provide a way to assess the activity of GS-100 in CNS target tissue. Safety and biodistribution of GS-100 were assessed in wild-type rats and NHPs. Based on these safety studies and the pharmacology studies in the *Ngly1*$^{-/-}$ rat model, the clinical starting dose of 4e14 vg/individual was selected as a dose anticipated to be both safe and offer the prospect of direct benefit to NGLY1 Deficiency patients. ICV administration at or near the clinical starting dose was not associated with any mortality, clinical observations, body weight changes, or changes in clinical pathology parameters that were considered adverse. Additionally, there were no negative treatment-related effects on functional observational battery testing or nerve conduction velocity (NCV). Widespread dose-dependent biodistribution of GS-100 vector DNA was detected in the brain, spinal cord, and multiple peripheral tissues in rats and NHPs.The GS-100 IND application has been approved by the FDA to support a first-in-human (FIH) open-label, dose-escalation Phase 1/2/3 study (National Clinical Trial identifier [NCT] 0619953) to assess the safety and efficacy of ICV-administered GS-100 in subjects with NGLY1 Deficiency. The co-primary outcomes in the pivotal part of the clinical trial will be a change from baseline in cerebrospinal fluid GNA biomarker and improvement or stabilization of motor function.

646. Astrocyte to Neuron Reprogramming for Neural Repair: The Impact of Promoters, Cellular and Regional Heterogeneity on Astrocyte Targeting

Jack W. Hickmott, Gajeni Prabaharan, Tom Enbar, Ricky Siu, Varanan Vejeyathaas, Cindi M. Morshead
Surgery, Donnelly Centre, University of Toronto, Toronto, ON, Canada

Neurogenesis in the adult brain is rare and restricted to specific neurogenic regions (*e.g.* the periventricular lining in the forebrain and the dentate gyrus in the hippocampus). Consequently, when neurons are lost due to brain injuries such as stroke, the result can be life long cognitive and physical impairment, depending on the location of the insult. Currently strategies to treat stroke seek to minimize neuron loss during the injury. There are no approved therapies for stroke recovery, with the exception of rehabilitation to promote neuroplasticity, which has limited success, highlighting the need for novel therapeutics. One promising avenue is direct cellular reprogramming to replace lost neurons. Astrocytes are abundant GFAP expressing cells that are activated following brain injury, making them a promising target for astrocyte to neuron (AtN) conversion. The approach involves the transduction of neural cells with adeno associated viruses (AAV) that will deliver proneural factors expressed from the astrocyte-specific, short human GFAP (shGFAP) promoter, resulting in astrocyte specific reprogramming. A number of considerations for optimizing AtN conversion include: (1) Astrocyte heterogeneity: astrocytes are a heterogenous cell population and the efficacy of AtN conversion within the distinct pools has not been explored, (2) Regional heterogeneity: the degree of AAV transduction varies across brain regions, and (3) Promoter promiscuity: the shGFAP promoter may not retain astrocyte specificity throughout the brain. Here we investigate the fidelity of the shGFAP promoter in driving astrocyte versus neuron specific gene transcription and compare it to the performance of an alternative astrocyte promoter from the human *S100B* gene. First, AAV5 expressing Cre from the shGFAP promoter (AAV5-shGFAP-Cre) was injected into two regions of the cortex (medial prefrontal cortex or motor cortex) of adult Ai14 (CAG-Lox-Stop-Lox-tdTomato) reporter mice. As predicted, astrocytes expressed tdTomato at 21 days post transduction. Surprisingly, we observed tdTomato+ neurons within the brain with significantly more tdTomato+NeuN+ cells in the medial prefrontal cortex compared to the motor cortex (52% and 11% of transduced cells, respectively; $p = 0.0105$). We next asked if *Gfap* is transcribed in NeuN+ cells using RNAScope for *Gfap* mRNA. Interestingly, *Gfap* mRNA was detected in NeuN+ cells in a regionally distinct manner (51% vs 42% of NeuN+ cells in the medial prefrontal and motor cortex, respectively, $p = 0.039$), revealing regional heterogeneity of *Gfap* RNA within neurons, which may account for off-target expression from the shGFAP promoter. A transcription factor binding site analysis of the shGFAP promoter revealed binding sites for 13 transcription factors modestly expressed in neurons, which is consistent with the shGFAP promoter driven expression in neurons. Given the shGFAP promoter driven transgene expression from AAV in neurons, we tested an alternative *S100B* derived astrocyte promoter. AAV5-S100B-EmGFP or AAV5-GFAP-EmGFP were injected into the motor cortex of C57Bl/6 mice. Interestingly, using this direct EmGFP reporter system (i.e. expression is not Cre dependent) we observed high specificity for the GFAP+ subpopulation of astrocytes with both promoters (55% vs 56% EmGFP+GFAP+ cells; shGFAP vs S100B promoters, respectively) and rare off-target expression in NeuN+ neurons (2% vs 3% EmGFP+NeuN+ cells; shGFAP and S100B promoters, respectively). These findings suggest that astrocyte specificity may be dependent on the Cre-Lox based reporter system. Together, these findings highlight neural cell heterogeneity as an important consideration when developing AtN reprogramming strategies for neural repair.

Wednesday Posters: Ophthalmic and Auditory Diseases

647. Preclinical Development of a Gene Augmentation Therapy for PRPF31-Associated Retinitis Pigmentosa

Lindsay Wong[1], Bin Wang[2], Ingrid Pardo[3], Steven Tabor[1], Ankur Thomas[2], Edward R. Guilmette[2], Zhongxiao Wang[1], Vic Kostrubsky[3], Ashley Mackey[1], Meihua Ju[1], Junghae Suh[2], Kip Connor[1], Devin S. McDougald[2]
[1]Ophthalmology Research Unit, Biogen, Cambridge, MA,[2]Gene Therapy Accelerator Unit, Biogen, Cambridge, MA,[3]Nonclinical Safety, Biogen, Cambridge, MA

Retinitis pigmentosa (RP) is a collection of inherited retinal dystrophies characterized by peripheral-to-central visual decline coinciding with the degeneration of outer retinal cell types. Autosomal dominant retinitis pigmentosa (adRP) affects approximately 20-30% of all RP patients, and mutations in the *Prpf31* gene account for the second leading cause of disease presentation. *Prpf31* encodes a ubiquitous factor in spliceosome assembly, and reduction in wild-type protein expression impacts alternative splicing and culminates in a retinal-specific phenotype. Gene replacement is an attractive approach to arrest retinal cell degeneration and visual loss for inherited blinding diseases. Here we describe the preclinical development of an AAV-mediated gene therapy for PRPF31-associated retinitis pigmentosa. AAV reporter vectors were screened in the context of mouse retina, human RPE cells, and nonhuman primate retina to provide a matrixed assessment of capsid and cargo performance across translational models. Following selection of optimal vector components, we assessed preclinical safety and proof of biology in the *Prpf31*$^{+/-}$ mouse model. Subretinal administration increased PRPF31 protein expression in target cell types including photoreceptors and retinal pigment epithelial cells (RPE). Moreover, gene transfer rescued RPE phagocytic deficits in this model to near wild-type function. Finally, we demonstrated the safety and expression profile of a lead vector candidate following subretinal administration in nonhuman primate.

648. Preclinical Development of a Combined Gene Silencing and Replacement Vector for Autosomal Dominant Retinitis Pigmentosa

Shabnam Majidi[1], Leslie Ramos[1], Lindsay Wong[2], Edward R. Guilmette[1], Steven Tabor[2], Bin Wang[1], Ishaq Viringipurampeer[2], Nicolas Lonfat[2], Venkata R. M. Chavali[2], Junghae Suh[1], Kip Connor[2], Devin S. McDougald[1]

[1]Gene Therapy Accelerator Unit, Biogen, Cambridge, MA,[2]Ophthalmology Research Unit, Biogen, Cambridge, MA

Retinitis pigmentosa (RP) is a collection of inherited retinal dystrophies characterized by a peripheral-to-central loss of vision mediated by photoreceptor degeneration. Mutations in rhodopsin (RHO) account for approximately twenty-five percent of autosomal dominant forms of RP where currently there is no effective treatment to halt visual decline. Rhodopsin is a G-protein coupled receptor specific to rod photoreceptors responsible for initiating the phototransduction cascade. Dominant RHO mutants exert toxic gain-of-function effects that disrupt important molecular processes culminating in activation of cell death signaling pathways. Here we describe a gene therapy strategy designed to halt rod loss and restore RHO function irrespective of the patient-specific mutation. We developed a vector that silences endogenous RHO transcripts via targeted expression of an artificial microRNA (amiR) thereby diminishing the presence of gain-of-function protein variants. Moreover, this approach simultaneously rescues wild-type rhodopsin function through rod-specific augmentation of an amiR-resistant RHO coding sequence. We evaluated several cargo configurations using an in vitro expression and target engagement assay. Lead cargo designs were packaged into various capsids and assessed in preclinical systems following subretinal administration. Nonhuman primate data reveals distinct effects upon retinal function and structure dependent on cargo, capsid, and dose selection. Collectively, these findings provide important considerations for lead vector selection, application in preclinical disease models of RHO-associated retinitis pigmentosa, and guidance towards optimal dose selection for clinical translation.

649. rAAV-Mediated *PEX1* Retinal Gene Augmentation Results in Long-Term Improvements in Retinal Function and Structure in a Mouse Model of Mild Zellweger Spectrum Disorder

Catherine Argyriou[1], Samy Omri[1], Erminia Di Pietro[1], Junwei Sun[2], Devin S. McDougald[2], Joseph G. Hacia[3], Jean Bennett[2], Nancy E. Braverman[1]

[1]Research Institute of the McGill University Health Centre, Montreal, QC, Canada,[2]University of Pennsylvania, Philadelphia, PA,[3]University of Southern California, Los Angeles, CA

Zellwegerspectrum disorders (ZSDs) are caused by autosomal recessive pathogenic variantsin any of 13 *PEX* genes required for peroxisome assembly andfunction. Most cases are due to *PEX1* deficiency, which causesprogressive retinopathy leading to blindness. We previously reported aproof-of-concept trial for AAV8.CMV.*HsPEX1*.HA retinal gene augmentationtherapy using our mouse model homozygous for PEX1-G844D, the murine equivalentof a common hypomorphic human ZSD allele [1]. Untreated mice display slowretinal degeneration that mimics the milder forms of ZSD. Subsequently, wereported the preliminary effects of *PEX1* gene delivery onretinal pigment epithelium (RPE) health in these mice, using a re-designedclinically-translatable vector (AAV8.CAG.*HsPEX1*) [2]. Wereport here for the first time the results of our long-term preclinicalefficacy trial using an optimized vector design and dose, and expanded andoptimized structural and functional outcome measures. 1.2x10^9 vg AAV8.CAG.*HsPEX1* was administered bysubretinal injection to 1-month-old homozygous PEX1-G844D and wt littermatemice. Control conditions included no injection, vehicle, and AAV8.CAG.eGFP. 2,4, and 6 mos post gene delivery, photopic and scotopic functional vision wasassessed by optomotor reflex, measuring spatial acuity and contrastsensitivity. Functional vision in *HsPEX1*-treated G844D mice wasnearly normalized across all measures starting at 2 mos, durable to theexperimental endpoint. Similarly, full-field flash electroretinogram (ffERG)(scotopic, photopic, c-wave) was significantly improved starting at 2 mos postgene delivery, and at 6 mos was over 5-fold that of untreated mice. Photopicand c-wave ffERG response improved over baseline, while the decline in scotopicresponse was attenuated. Retinal structure was also improved starting at 2 mosin *HsPEX1*-treated G844D mice, and at the 6-mo endpoint: (i) coneouter segment length and density were restored to near wt levels, (ii) outernuclear layer thickness was completely preserved at the ventral pole and over7-fold improved at the dorsal pole, (iii) RPE cell density was doubled andgeographic atrophy reduced by 90%, (iv) subretinal macrophage infiltration wasreduced by 30%, and (v) gliosis was strongly reduced. Finally, we measuredperoxisome metabolite levels in neural retina and RPE by LC-MS/MS. C26:0 lysophosphatidylcholinelevels (whose catabolism is impaired and thus accumulates in G844D mice) werereduced by 60-70% in tissues from treated relative to untreated mutants. Incontrast, ether phospholipid levels, whose biosynthesis is impaired and arethus reduced in G844D mice, were unchanged by treatment. These data demonstrate the potential of retinal gene augmentation therapy topreserve retinal health and visual functions in milder forms of ZSD. Theseindividuals are now detected at birth through newborn screening across theUnited States. Overall, our studies support continued development of *PEX1* retinalgene therapy and the transition to clinical trial enabling studies. 1. Argyriou C. *et al. 650. A Human iPSC-Derived RPE Culture System for the Functional Assessment of AAV Vectors Expressing Anti-TNF Alpha Antibodies

Chris Tully, Jessica Gumerson, Mi Shi, Ryan Kruse, Olivier F. Danos, Ye Liu, Brendan Lilley, Kwi Hye Kim

REGENXBIO Inc., Rockville, MD

Uveitis comprises a heterogenous group of inflammatory intraocular diseases that can result in vision loss. Non-infectious uveitis (NIU)

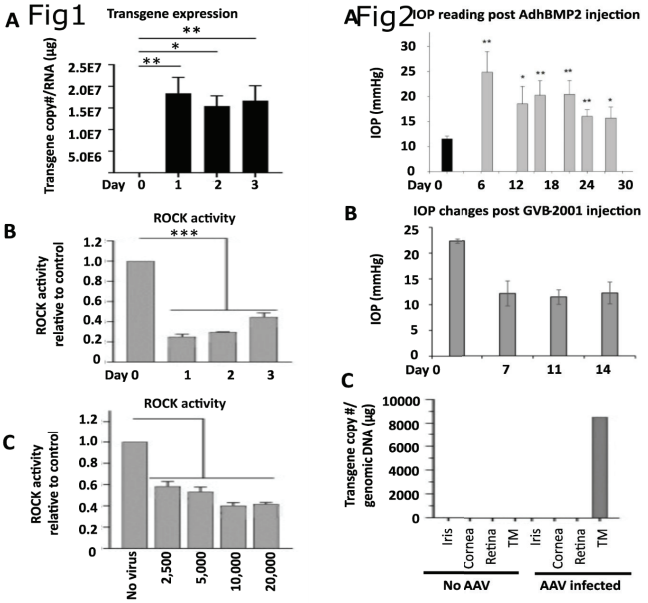
of the posterior segment of the eye can be difficult to treat, requiring long-term systemic immunosuppression associated with significant side effects. Tumor necrosis factor-alpha (TNFα) is a proinflammatory cytokine that has been implicated in NIU. To reduce local inflammation in eyes with NIU, we developed AAV vectors expressing anti-human TNFα antibodies in IgG, Fab and scFv formats. In vivo, the scFv showed significantly improved expression levels over IgG and Fab, generally by about three-fold. However, due to species incompatibility of human anti-TNFα antibodies against mouse TNFα, testing efficacy of the transgene product in mouse models of NIU posed a challenge. Thus, there was a need to develop a human in vitro model where the expression of antibodies and functional and biochemical outcome can be measured. Retinal pigmented epithelial cells (RPEs) function as a barrier and homeostasis regulator of the retina and may be disrupted in response to inflammation. Here, we cultured and maintained human induced pluripotent stem cell (iPSC) derived RPEs in porous membrane inserts for up to 60 days, allowing the cells to develop characteristic transepithelial electric resistance (TER) and observe changes induced by the addition hTNFα. Treatment of RPEs with low concentration of hTNFα reduced TER over time with dose dependency demonstrating that TER can be used as the primary outcome. Downstream effects of TNFα on released cytokines and proinflammatory markers were also characterized by analyzing collected media post exposure to TNFα using multiplexed Luminex panels. Once RPE culture conditions and readout measurements were established, RPEs were transduced with AAVs expressing anti-human TNFα antibodies. Efficacy of TNF-α inhibition of each transgene product was measured by monitoring TER and cytokine release. Up to 100% of TER was preserved at a multiplicity of infection (MOI) of 3e5 GC/cell IgG and scFv formats when treated with 0.8ng/ul hTNFα compared to 50% TER preservation in non-transduced cells. This study provides evidence that iPSC-derived RPE cultured in inserts has the potential to be utilized as a platform in human-specific ocular gene therapy development for TNFα-mediated inflammation.

651. Local Delivery of Vectorized Anti-TNF-Alpha Antibodies as a Treatment for Non-Infectious Uveitis

Mi Shi, Jessica Gumerson, Ryan Kruse, Chris Tully, Leo Kwok, Wei-Hua Lee, Justin Glenn, Kwi Hye Kim, Michele Fiscella, Olivier F. Danos, Ye Liu, Joseph T. Bruder, Brendan Lilley

REGENXBIO INC., Rockville, MD

Non-infectious uveitis (NIU) of the posterior segment of the eye requires a long-term systemic immunosuppression treatment, which is associated with significant side effects. We hypothesize that local inhibition of the proinflammatory molecule, TNF-α, is sufficient to suppress ocular inflammation, and thus, a single dose of adeno-associated virus (AAV) mediated delivery of TNF-α inhibitor has the potential to reduce disease severity and the treatment burden for NIU. Multiple formats of TNF-α inhibitors (IgG, Fab, and single chain antibody fragment variables (scFv)) were vectorized and transgene product (TP) expression was tested in 293T cells. Secreted inhibitors demonstrated robust anti-TNF-α activity in multiple cell-based assays (L929, HEK-blue and human iPSC-derived RPE cells). The affinity and binding kinetics of the recombinant inhibitors with TNF-α was measured using a Bio-layer Interferometry (BLI) assay. Furthermore, we demonstrated *in vivo* activity of AAV vectors expressing a subset of the TNF-α inhibitors in mouse ocular inflammation disease models (Experimental Autoimmune Uveitis (EAU) and an AAV-human-TNF-α overexpression target engagement model). A lead AAV vector expressing anti-hTNFa-scFv was evaluated in a study in non-human primates (NHP) and demonstrated dose-dependent transgenic protein expression in NHP ocular fluids and tissues and was well tolerated. These data together indicate that local AAV-mediated inhibition of TNF-α limits inflammation associated with uveitis and support further pre-clinical development of a vectorized therapeutic approach to the treatment of non-infectious uveitis.



652. A New Strategy of AAV-Based Gene Therapy to Treat Glaucoma and Ocular Hypertension

Carola J. Maturana, Ling Wu, Zulian Yao, Wei Wang, Bo Liang, Laura Hong

Iview Therapeutics Inc., Cranbury, NJ

Purpose: Glaucoma stands as a prominent contributor to irreversible blindness, presenting a formidable challenge for healthcare providers. Elevated intraocular pressure (IOP) is recognized as a significant risk factor in the development of glaucoma. While conventional treatments have demonstrated efficacy in reducing IOP, patient adherence to these interventions remains suboptimal. Gene therapy emerges as a promising avenue to tackle compliance issues, instilling renewed optimism for patients. The objective of this study was to create a new strategy of adeno-associated virus (AAV)-based gene therapy to mitigate IOP elevation by inhibiting the activity of Rho kinase (ROCK) in the human trabecular meshwork (HTM). The HTM plays a crucial role in keeping the resistance to the outflow of aqueous humor, a pivotal element in maintaining a physiologically balanced IOP. **Methods**: An AAV vector, named GVB-2001, was specifically engineered to express a transgene to inhibit the activity of Rho kinase (ROCK) in the trabecular meshwork. Research-grade GVB-2001 was manufactured for proof-of-concept studies. In the in vitro part, ROCK activity, measured by ELISA, served as a metric to assess the efficacy of viral transduction in primary culture of human trabecular meshwork (HTM) cells. Various time points post-infection and multiple Multiplicity of Infection (MOI) values were systematically tested. For the in vivo segment, an ocular hypertensive rat model was induced by infecting rat eyes with Ad. hBMP2. This model was employed to investigate whether intracameral injection of GVB-2001 could effectively reduce IOP. Rats were euthanized two weeks post-AAV injection, and quantitative polymerase chain reaction (qPCR) was conducted to examine the biodistribution of GVB-2001 within ocular tissues. **Results**: The transgene exhibited robust expression in HTM cells following viral infection, as illustrated in Figure 1A. Furthermore, AAV infection demonstrated a noteworthy and consistent reduction in ROCK activity within HTM cells across various time points and MOI levels, as depicted in Figures 1B and 1C. In the rat model, the IOP readings showed an increase following the injection of Ad. hBMP2, as illustrated in Figure 2A. Subsequently, a significant reduction in IOP was observed 7 days post-AAV injection, and this effect was sustained through day 14, as depicted in Figure 2B. Biodistribution analysis confirmed the exclusive detection of GVB-2001 in the trabecular meshwork (TM)

of rat eyes, with no presence in the iris, retina, or cornea, as shown in Figure 2C. Ongoing investigations include dose-escalating efficacy studies and toxicity assessments. **Conclusions**: GVB-2001 was a robust gene therapy for glaucoma treatment, demonstrating its capacity to lower intraocular pressure (IOP) by effectively inhibiting Rho kinase (ROCK) activity in the trabecular meshwork. The proof-of-concept animal study lends substantial support to the viability of a gene therapy strategy, showcasing the potential for achieving a stable and enduring reduction in IOP with a singular intracameral injection. Fig.1 *In vitro* characterization of GVB-2001. Fig.2 IOP was measured by TonoLab in rat model.

653. Innovative RNA-End Joining Technology Enables Full-Length ABCA4 Expression in Mouse Retinal Photoreceptors

Lukas C. Bachmann, Kathryn Hilde, Binh Chu, Theresa Slaiwa, Haunani E. Bautista, Ashley Renteria, Robert Cano, Allan Kaspar, Brian K. Kaspar

Insmed Gene Therapy, LLC, San Diego, CA

Stargardt Disease is the most prevalent form of inherited childhood blindness, affecting 1:9000 individuals in the United States. Stargardt disease is caused by mutations in the Abca4 gene encoding a large (256kDa) transmembrane protein that clears retinoids from photoreceptors. Loss of Abca4 leads to accumulation of toxic byproducts that cause degeneration of the photoreceptors and apposing retinal pigment epithelium. Despite a well characterized disease mechanism, treatment for Stargardt patients is restricted to symptom management, as there is currently no cure or method for stalling progressive vision loss. Monogenic inherited retinal diseases (IRDs) such as Stargardt disease are in principle particularly suitable for gene replacement therapy, both because there is loss of function of a single gene and because of the relative accessibility and "immune privilege" of the affected retinal tissue. In vivo mouse studies of Stargardt disease have established that Abca4 gene replacement can be an effective treatment, however a major challenge in gene therapy has been the ~5-kilobase cargo size limitation of AAV and thus an inability to replace large genes efficiently and safely such as Abca4. Insmed's RNA-end joining (REJ) technology hopes to address the challenges related to AAV-based gene therapy by delivering a gene of interest as fragments in two (or more) individual AAVs and subsequently reconstituting the full-length coding sequence on the mRNA level in the target cell. REJ is therefore uniquely positioned to potentially address the challenges of conventional gene therapy approaches, and in particular advance the use of AAV strategies in large gene related ocular diseases such as Stargardt disease. We have developed and characterized a therapeutic REJ-AAV-Abca4 gene replacement vector formulation that expresses Abca4 protein from two AAV8 vectors. Each construct drives expression of the N- or C-terminal half of the protein by the human GRK1 promoter. The two fragments join and elements designed to inhibit fragment expression function to block translation of truncated protein from either single AAV. Following subretinal injection in the Stargardt Disease mouse model of the two AAVs in a 1:1 ratio (~1E10 vg per fragment), Abca4 protein expression is restored to physiological or even supraphysiological levels. Abca4 is specifically expressed in photoreceptors and predominantly localizes to the photoreceptor outer segment, showing the intended biodistribution. Specific ddPCR to each construct shows a 1:1 ratio of genomic transduction in the photoreceptor cells and RT-ddPCR confirms expression and RNA-joining. REJ-junction specific in situ hybridization demonstrates widespread distribution within the target cells. Taken together, these results support further study of Abca4 gene therapy for Stargardt Disease.

654. A Novel Mutation-Independent CRISPR-Based Gene Therapy to Treat Autosomal Dominant Retinitis Pigmentosa

Antonio Casini[1], Ambra Sarracino[1], Laura Pezzè[1], Maddalena Bosetti[1], Matteo Bello[1,2], Sally Bertolini[1], Kalina Badowska[1], Matteo Ciciani[2], Federica Esposito[3], Alberto Auricchio[3], Anna Cereseto[2]

[1]Alia Therapeutics, Trento, Italy,[2]University of Trento, Trento, Italy,[3]TIGEM, Naples, Italy

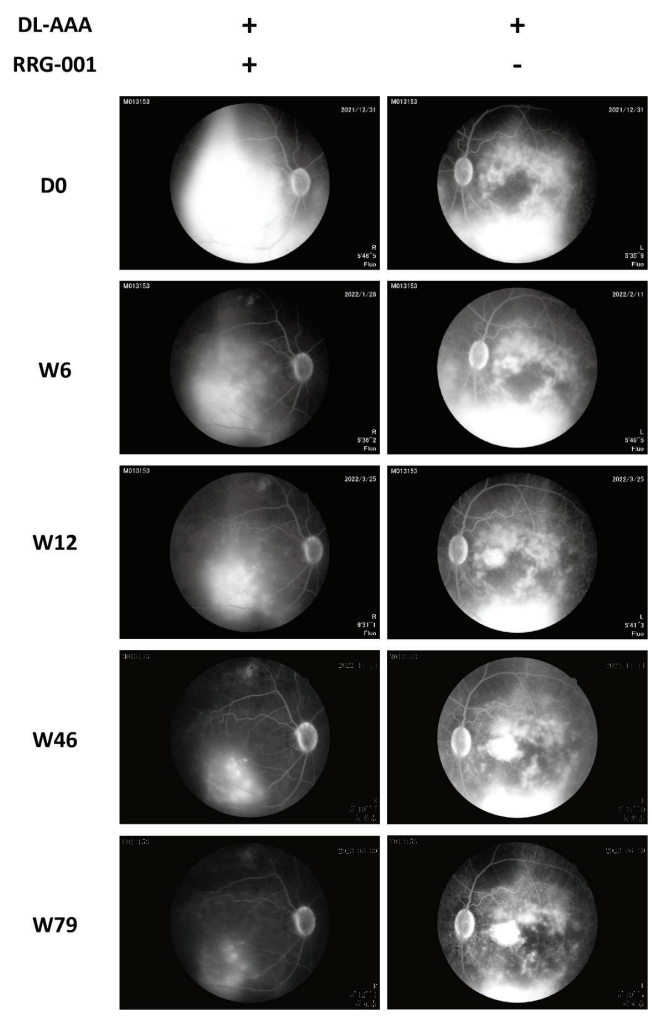
More than 200 RHO mutations causing autosomal dominant retinitis pigmentosa, a common form of severe retinal degeneration, have been identified to-date. In the absence of effective gene replacement approaches, this high genetic heterogeneity in patients makes the development of a personalized gene editing therapeutic approach challenging. In the attempt to generate an inclusive treatment option, we developed a mutation-independent CRISPR-based strategy to selectively abrogate the expression of the mutant form of RHO. Our strategy exploits a combination of two sgRNAs to introduce large edits in the mutated RHO allele by targeting respectively RHO intronic regions (bi-allelic cut) and a high-frequency non-pathogenic single nucleotide polymorphism (SNP) within the RHO gene (allele-specific editing). Exquisitely selective CRISPR editing tools are required to discriminate single nucleotide differences among genomic targets in order to selectively edit the desired SNP allele. We sourced novel CRISPR systems from natural human microbiome reservoirs exploiting a proprietary discovery platform for rapid hit to lead screening including highly efficient in silico PAM prediction, with immediate advantages for human therapeutics applications. Screening through

a range of different and novel PAM motives and smaller editors, we were able to identify candidates with superior target editing accuracy and optimal size range for all-in-one AAV in vivo delivery to overcome cargo limitation of current systems. By leveraging on our in silico discovery pipeline, we streamlined the identification of several candidates to edit the SNP locus, which were then tested side-by-side and ranked for their activity and allele specificity. After the identification of suitable intron-targeting guides, we identified nucleases which were able to consistently produce the desired large edits in the RHO locus, outperforming the SpCas9 benchmark. We validated the genome-wide specificity of the approach and demonstrated the ability to selectively downregulate mutated RHO at the mRNA and protein level in minigene-expressing cells. Thanks to the reduced protein size (<1100aa), the top candidate nuclease and both its sgRNAs were included into an optimized all-in-one AAV vector to evaluate the editing efficacy in a humanized mouse model bearing the human RHO P23H mutant allele. Optimizations of the candidate nuclease through directed evolution platforms were implemented to maximize allele discrimination, which is a critical attribute for clinical applications in autosomal dominant disorders. Our uniquely tailored approach based on the identification of compact, highly active and specific fully novel CRISPR nucleases from metagenomic samples offers a first-in-class mutation-independent and allele-specific targeting strategy for RHO-dependent adRP, which could be potentially extended to many other autosomal dominant conditions.

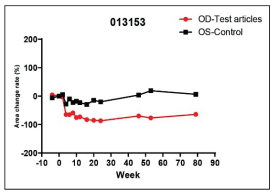
655. Preclinical Safety and Efficacy of Intein-Based Dual-AAV Gene Therapy for Stargardt Disease

Miquel Vila-Perelló, Marianna Di Scala, Izarbe Aisa, Victor Abad, Gerard Caelles, Julian Esteve Rudd, Silvia Frutos, David Favre

SpliceBio, Barcelona, Spain

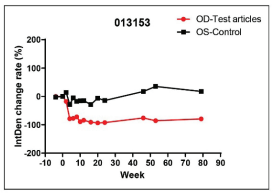


Purpose: There is currently no approved therapy for Stargardt disease (STGD1), an autosomal recessive inherited retinal dystrophy caused by mutations in *ABCA4*. AAV-mediated retinal gene therapy is safe and effective in humans, but a single AAV cannot deliver large genes such as *ABCA4*. Here we report the preclinical *in vitro* and *in vivo* characterization of a novel dual-AAV8 (SB007) encoding proprietary engineered split-inteins for the reconstitution of functional human ABCA4 protein (hABCA4) via protein trans-splicing (PTS). **Methods:** SB007 consists of two AAV8 expressing the N- and C-regions of the hABCA4 fused to Cfa-based split-inteins under the photoreceptor-specific promoter hGRK1. Expression (measured by WB), subcellular localization (IF), post-translational modifications (MS) and ATPase activity were tested *in vitro*. Subretinal injection of SB007 in Abca4$^{-/-}$ mouse and Abca4$^{ex42-/-}$ rat models, Göttingen mini-pigs (MP) and Cynomolgus macaques (NHP) were assessed longitudinally (FA, SD-OCT, ERG) and at necropsy by histology, hABCA4 expression in total retina (WB, CE), *in situ* mRNA or protein expression (RNAscope, IF) and accumulation of the bisretinoid A2E in total eyecup (LC/MS/MS), a pharmacodynamic marker (PD) of STGD1 in rodent models. **Results:** SB007 led to full-length high-level reconstitution of functional hABCA4 *in vitro.* Physiological levels of hABCA4 were achieved *in vivo* in Abca4$^{-/-}$ mice after sub-retinal injection of SB007 at 5E9-1E10 vg/eye. Overall, A2E accumulation was reduced by 30% (mouse) and 50% (rat) over control saline-injected groups, consistent with a 100% PD effect in the transduction area. A dose dependent A2E response was observed starting at 3E8 vg/eye and plateauing at 1 to 2E9 vg/eye in mice and rats, respectively. In MP and NHP, *in situ* analyses confirmed high-level hABCA4 expression in photoreceptors, including the cone rich NHP fovea. Histology safety findings were sporadically observed at SB007 doses ≥ 3E11vg/eye, mostly minimal/mild, without imaging or functional deficit (SD-OCT, ERG). **Conclusions:** The intein-based dual-AAV SB007 achieved high-level hABCA4 functional reconstitution *in vitro* and *in vivo* with dose-dependent reductions in A2E levels in two animal models of STGD1. These preliminary results support the safety profile and therapeutic potential of SB007 for Stargardt patients. Non-clinical IND-enabling studies are ongoing to support Ph1/2 clinical trial initiation.



656. RRG001: Innovative Anti-VEGF AAV Gene Therapy for Retinal Disease

Qingqiao Tan, Xinxing Liu, Xi Cao, Jie Huang, Qiuyu Chen, Kaiyu Gao, Rui Zhou



Refreshgene Therapeutics, Shanghai, China

Purpose: Sustained VEGF inhibition via Adeno-Associated Virus (AAV) delivery is promising for wet age-related macular degeneration treatment. We optimized a novel anti-VEGF drug to achieve efficacy at lower dose with better local accumulation in eyes. While laser-induced CNV model recovery spontaneously and shortly, DL-AAA induced persistent retinal neovascularization is an effective model for evaluating long-lasting therapeutic efficiency. This study is to evaluate anti-VEGF AAV gene therapy drug RRG-001 on DL-AAA induced persistent retinal neovascularization (PRNV) NHP model. Methods: Cynomolgus macaque monkey were applied for PRNV NHP modeling by DL-AAA intravitreal injection in both eyes. RRG-001 was subretinal injected into right eyes and vehicles were injected into left eyes 4 months after DL-AAA injection. IOP and OCT were performed before, after and 2 weeks after RRG-001 injection. FFA were performed before and 2,4,6,8,10,12,16,20,24,46,53 and 79 weeks after RRG-001 injection. The FFA data was analyzed by Image J to measure fluorescence area and intensity. All NHP experiments were finished under the support of Kunming Biomed International (KBI). And all animal procedures were approved in advance by the Institutional Animal Care and Use Committee of KBI. Results: In PRVN modeling, 2 monkeys were intravitreal injected with DL-AAA in both eyes. Four months later, RRG-001 or vehicle was subretinal injected into right or left eye respectively. In 013153# monkey which eye leakage maintained stable under vehicle treatment, RRG-001 treatment significantly reduced leakage and maintained inhibition to our last FFA examination at 79 weeks. In 050065# monkey which eye leakage became larger over time and grow to 4 folds larger at week 12 under vehicle treatment, RRG-001 treatment inhibited leakage growth to our last FFA examination at 79 weeks. Meanwhile, we did not find any RRG-001 drug-relative adverse reaction in DL-AAA treatment eye or contralateral eye. All monkeys' IOP before, after and 2 weeks after RRG-001 injection was at normal range. Conclusions: Our RRG-001 is a safe, well-tolerated and long-lasting drug for neovascularization inhibition in PRNV monkey model.

657. Efficacy and Safety of a Novel RPGR^{ORF15} Gene Therapy (FT-002) for the Treatment of RPGR-Associated XLRP

Zhong-Dong Shi[1], Hongbin Xu[1], Chao Ren[2]

[1]Frontera Therapeutics, Bedford, MA,[2]Frontera Therapeutics, Shanghai, China

Background: X-linked retinitis pigmentosa (XLRP) is a rare inherited retinal disease manifesting as impaired night vision and peripheral vision loss that progresses to legal blindness. One of the most common causes of XLRP is pathogenic variants in the retinitis pigmentosa guanosine triphosphatase regulator (RPGR) gene. Treatments for RPGR-XLRP are currently not available. FT-002 is a novel AAV5 gene therapy vector expressing codon-optimized hRPGR^{ORF15} under the control of a GRK1 promoter to rescue the functional/structural loss of the photoreceptor cells and improve visual function of XLRP patients via subretinal administration. **Results:** *In vitro*, FT-002 can efficiently transduce CHO-K1 cells and express polyglutamylated hRPGR^{ORF15} protein in a dose-dependent manner. *In vivo*, the efficacy of FT-002 was evaluated in 2-month-old male *Rpgr*-KO mice which is a slow progress model of XLRP. A one-dose, bilateral subretinal injection of FT-002 led to a significant rescue of the thickness of the retinal outer nuclear layer (ONL) on Day 270 post-dosing and a dose-dependent increase of ERG response at different flash intensities on Day 240 post-dosing. Persistent expression of hRPGR^{ORF15} protein (up to Day 270 post-injection), and time-dependent progressive rescue of rhodopsin mislocalization in the inner segment of the photoreceptor layer were observed, which correlated well with vector tissue distribution of FT-002 in the ONL of the retina. A GLP-compliant safety study with a 13-week recovery period in non-human primates confirmed that FT-002 was well tolerated with a favorable safety profile, supporting the translation of this AAV-based gene therapy into human patients. **Conclusion:** Together, the comprehensive preclinical assessment demonstrates that subretinal delivery of FT-002 led to durable hRPGR^{ORF15} expression in the retina and provided phenotypic and functional rescues of XLRP in the mouse model. The data supports the initiation of Ph I/II clinical study for the treatment of RPGR-associated XLRP patients with FT-002.

658. Mutation-Independent Genome Editing Approaches for Treatment of Stargardt Disease

Federica Fioretto[1,2], Eugenio Pugni[1], Erika Tenderini[1], Marida Sansonetti[1], Annarita Casciello[1], Maria Cascone[1], Francesca Razzano[1], Nadia Mazzaro[1], Mariangela Lupo[1], Elena Marrocco[1], Xabier Bujanda Cundin[1], Gennaro Gambardella[1], Ivana Trapani[1,2]

[1]TIGEM, Pozzuoli, Italy,[2]Advanced Biomedical Sciences, Università degli Studi di Napoli Federico II, Napoli, Italy

Genome editing via the CRISPR-Cas9 system is an exciting field of biomedical research which is gaining increasing interest for treatment of several diseases. However, classical genome editing approaches still have limitations, including: i. sequence-specificity, that limits its applicability to diseases with high allelic heterogeneity; ii. inability of the currently available techniques to achieve efficient precise integration of a corrective DNA template in post-mitotic cells. These limitations have thus far hindered development of effective gene editing

approaches for several inherited retinal diseases, including the most common form of inherited macular degeneration, Stargardt disease (STGD1), which is due to more than 1200 different mutations in the large retinal-specific *ABCA4* gene. Therefore, in this project, we aim to develop novel adeno-associated viral (AAV) vector-based genome editing strategies for integration of large templates in *ABCA4*, to allow correction of multiple mutations with a single therapeutic DNA template. To achieve integration of the template we planned to explore different repair pathways which are active in post-mitotic cells like photoreceptors, the target cells for STGD1 treatment. Accordingly, we have developed multiple candidate sets of AAV-Abca4 vectors for targeting either the murine or the human *ABCA4* gene. We side-by-side compared the different approaches *in vitro*, in cell lines, and found that they effectively mediate template integration at the endogenous locus, resulting in Abca4 expression. Subretinal delivery of the AAV-based approaches in the retina of *Abca4-/-* mice results in targeted DNA template integration, followed by productive reconstitution of *Abca4* expression in transduced photoreceptors. Further evaluation of the therapeutic efficacy of the approaches in *Abca4-/-* mice is ongoing.

659. A Novel AAV Capsid Mediated RS1 Gene Therapy Could Rescue the b-wave Amplitude of XLRS Animal Model to Wild Type Mice Level

Sisi Ma[1], Xing Wei[2], Haoliang Cui[1], Shan Zhang[1], Duanyang Wang[1], Cheng Wang[1], Ruifang Sui[2]

[1]Beijing InnoVec Biotherapeutics Inc., Beijing, China,[2]Peking Union Medical College Hospital, Beijing, China

X-linked retinoschisis (XLRS) is a neurodevelopmental retinal abnormality caused by mutations in the gene encoding the protein retinoschisin (RS1). It affects 1:5,000 to 1:25,000 males worldwide and is one of the most common causes of vision loss from macular degeneration in young men. An absent or mutated RS1 protein in the retina of patients with XLRS leads to abnormalities in the normal laminar structure of the retina, resulting in impaired visual acuity and increased propensity to retinal detachment. Currently, no approved treatments are available for XLRS and a replacement gene therapy could provide a promising strategy. We developed a novel AAV serotype AAV.IVT18, which could efficiently transfect photoreceptor and bipolar cells. At the same time, we also developed a new RS1 animal model, which carries R213W missense mutation the same as clinical patients. The $RS1^{R213W}$ mouse model had typical cysts in the retina, and the b-wave amplitude of scotopic ERG was greatly impaired, representing the similar phenotype of clinical patients. AAV.IVT18 mediated expression of RS1 could recover the degree of retinoschisis in the model animals significantly. Surprisingly, The ERG b-wave amplitudes of the treated groups were significantly increased than those of control group from 8 weeks post injection, and recovered to WT mouse level by 16 weeks of injection (Figure 1). The b/a ratio also recovered to the normal level close to that of WT mice, indicating that retinal signal transduction and visual function of mice were significantly restored. The preclinical data indicates that the gene therapy of AAV.IVT18 mediated RS1 expression might restore visual function of XLRS patients in future clinical study.

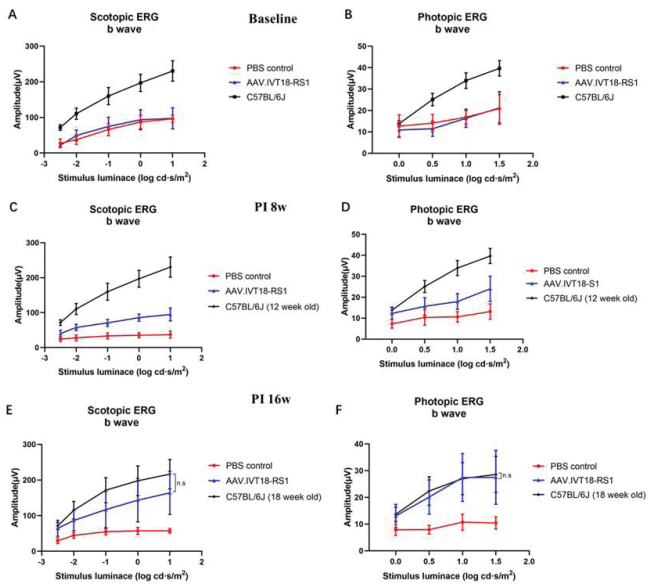

Figure 1. The ERG b-wave amplitudes of the mice.
Scotopic ERG b wave (A) and Photopic ERG b wave (B) of baseline.
Scotopic ERG b wave (C) and Photopic ERG b wave (D) of 8w post injection.
Scotopic ERG b wave (E) and Photopic ERG b wave (F) of 16w post injection.

660. ARMMs as Non-Viral Vehicles for the Delivery of Genome Editors to Treat Inherited Retinal Diseases

Jinling Yang, Wendy Zhao, Yashodhan Chinchore, Zahra Baghbantaraghdari, Jennifer A. Badji, Qiyu Wang, Chou-Wei Chang, Adam Miller, Qin Yu, Joseph F. Nabhan

Vesigen Therapeutics, Cambridge, MA

Inherited retinal diseases (IRD) are caused by monogenic mutations that lead to the decline in central vision and visual acuity. Most IRDs have no treatment options. Stargardt disease (STGD1) and Usher syndrome type II (USH2) are two of the most common autosomal recessive IRDs, which are caused by mutations in ABCA4 gene or USH2A gene. Due to the causal effects of genetic mutations in IRDs, genome editing has emerged as an attractive therapeutic strategy. However, sub-optimal packaging and delivery of gene editing components presents a major challenge to effectively correct the pathological mutations. Here, using our non-viral platform of engineered extracellular vesicles called ARRDC1mediated microvesicles (ARMMs), we demonstrated the potential utility of ARMMs in two genome editing strategies: base editing for STGD1 and CRISPR/Cas9 based exon-skipping for USH2. ARMMs were generated by packaging the adenine base editor with guide RNA (gRNA) either targeting the wild type sequence or a common ABCA4 mutation for STGD1. Western blotting and qPCR results showed that both genome editors and gRNAs were effectively packaged in ARMMs. Genome editing efficiency was assessed by Sanger and Next-generation sequencing in various ARMMs-treated cell lines, including an engineered cell line harboring the targeted pathological ABCA4 mutation. We were able to achieve robust A-to-G conversion at the ABCA4 mutation site directly or at a surrogate site in wild-type ABCA4. Furthermore, using ARMMs packaged with genome editors

and gRNA targeting the murine Abca4 sequence, we demonstrated in vivo editing of mAbca4 in ocular tissue following subretinal injection. For USH2A exon 13 skipping, we screened pairs of gRNAs for efficient excision of the genomic region harboring exon 13. ARMMs loaded with Cas9 and 2 gRNAs were generated and evaluated for functional delivery of RNP complexes. Efficient USH2A exon 13 excision was achieved with multiple combinations of gRNAs. Collectively, our data demonstrate functional delivery of therapeutic genome editors via ARMMs in various models and provide the foundation for further evaluation of ARMMs-mediated genome editing as an emerging strategy to treat IRDs.

661. Corneal Intrastromal AAV8 Delivery of Human SLC4A11 Gene Rescues Corneal Edema in *Slc4a11*$^{-/-}$ Mouse Model of Congenital Hereditary Endothelial Dystrophy

Wenlin Zhang[1], Doug Chung[2], Matthew L. Hirsch[3], Anthony J. Aldave[1]

[1]Stein Eye Institute, UCLA, Los Angeles, CA,[2]Stein Eye Institute, UCLA, Rancho Palos Verdes, CA,[3]University of North Carolina, Chapel Hill, NC

Purpose: Congenital Hereditary Endothelial Dystrophy (CHED) is caused by biallelic mutations in *SLC4A11*. The *Slc4a11*$^{-/-}$ mouse model recapitulates the clinical phenotype of CHED, characterized as progressive corneal edema and corneal endothelial dysfunction. We evaluated the efficacy of intrastromal delivery of a recombinant AAV8 vector encoding human SLC4A11 cDNA under transcriptional control of human elongation factor-1 alpha promoter - rAAV8-EF1α-hSLC4A11. **Methods:** A single corneal intrastromal injection of 3 µL rAAV8-EF1α-hSLC4A11 vector was performed in one eye of *Slc4a11*$^{-/-}$ mice at 4 weeks of age. Three dosages 10e9 (n = 13), 10e8 (n = 10), 10e7 vg/eye (n = 10) were tested. For each mouse, the eye receiving the AAV injection was randomized, and the contralateral eye served as the control. Anterior segment OCT was performed in both eyes before injection to measure baseline central corneal thickness (CCT, mean ± SEM) and bi-weekly after injection until post-injection week 14 (e.g. W14). Slit-lamp examination of the anterior ocular segment and retinal OCT were also performed bi-weekly post-injection to monitor for evidence of toxicity and host immune response. Mixed-effects analysis with post-hoc multiple comparisons was used to compare CCT values between AAV-injected eyes and control eyes at different post-injection time points. **Results:** AAV-injected eyes showed a sustained reduction of CCT from baseline in a dose-dependent manner, whereas untreated contralateral eyes showed a progressive increase in CCT. For the 10e9 vg/eye group, AAV-injected eyes showed a 66.2 µm reduction in CCT compared to control eyes at W14 (p = 0.002). The CCT (µm) at baseline, W6 and W14 were 161.1 ± 3.3, 143.4 ± 7.1 (p = 0.048), and 171.5 ± 10.9 (p = 0.41) in AAV-injected eyes and 160.2 ± 2.7, 176.2 ± 5.1 (p = 0.011), and 237.7 ± 11.1 (p < 0.0001) in control eyes. For the 10e8 vg/eye group, AAV-injected eyes showed a 37.8 µm reduction in CCT compared to control eyes at W10 (p = 0.0007). The CCT (µm) at baseline, W6, and W10 were 162.5 ± 3.2, 148.5 ± 5.6 (p = 0.021), and 170.9 ± 5.3 (p = 0.26) in AAV-injected eyes, and 166.7 ± 5.2, 169.2 ± 5.5 (p = 0.72) and 208.6 ± 6.3 (p = 0.0012) in control eyes. For the 10e7 vg/eye group, AAV-injected eyes showed a 43.0 µm reduction in CCT compared to control eyes at W8 (p = 0.02). The CCT (µm) at baseline, W6, and W8 were 152.8 ± 6.1, 152.3 ± 5.1 (p = 0.93) and 160.3 ± 5.7 µm (p = 0.31) in AAV-injected eyes, and 154.7 ± 3.4, 175.4 ± 7.4 (p = 0.012) and 203.3 ± 7.8 µm (p = 0.0001) in control eyes. Corneal subepithelial deposits were observed in a dosage-dependent manner in AAV-injected eyes. No evidence of anterior chamber inflammation was observed. Vitreous inflammation was observed in 2 out of 32 eyes injected with AAV vector. **Conclusions:** Intrastromal delivery of rAAV8-EF1a-hSLC4A11 effectively rescues corneal edema in *Slc4a11*$^{-/-}$ mice, indicating a functional recovery of corneal endothelial pump function. Corneal subepithelial deposits and vitreous inflammation may be associated with the immune responses to the rAAV8 vector.

662. The Effect of Antioxidant MitoQ on Cell Viability in Human Corneal Endothelial Cells Harboring *SLC4A11* Mutations Modelling Corneal Endothelial Dystrophies

Doug D. Chung[1], Saloni Gupta[1], Anthony J. Aldave[2]

[1]Ophthalmology, Stein Eye Institute, UCLA, Los Angeles, CA,[2]Stein Eye Institute/UCLA, Los Angeles, CA

Purpose: Solute carrier family 4 member 11 (*SLC4A11*) mutations are associated congenital hereditary endothelial dystrophy (CHED) and Fuchs endothelial corneal dystrophy type 4 (FECD4). These mutations are hypothesized to diminish oxidative stress protection in human corneal endothelial cells (hCEnC), ultimately leading to the loss of hCEnC viability and/or function. Therefore, we sought to determine the impact of MitoQ, a mitochondria-targeted antioxidant, on the viability of hCEnC-based models of CHED and FECD4 during oxidative stress to investigate the therapeutic potential of MitoQ. **Methods:** Cell-based models of CHED and FECD4 were generated in a hCEnC line, hCEnC-21T. Briefly, *SLC4A11* wildtype (*SLC4A11*^{WT}) and mutant (*SLC4A11*^{MU}) hCEnC lines were created to express either *SLC4A11* variant 2 (V2) or variant 3 (V3) by stable transduction of *SLC4A11*$^{-/-}$ hCEnC-21T with lentiviruses containing either *SLC4A11*^{WT}, an empty vector, or one of the following *SLC4A11* mutations: V2 mutants c.374G>A (CHED), c.1813C>T (CHED), c.2263C>T (CHED), or c.2224G>A (FECD4); V3 mutant homologs c.326G>A (CHED), c.1765C>T (CHED), c.2215C>T (CHED), or c.2176G>A (FECD4). Dose range assays were performed to determine the maximum non-toxic dose of MitoQ in hCEnC. Cell viability was measured by exposing MitoQ-treated and untreated cells to oxidative stress agent tBH followed by XTT assays and spectrophotometry to measure cell densities. **Results:** After 72 hours of media supplementation with MitoQ concentrations ranging from 0 to 0.25 µM, *SLC4A11* empty, V2^{WT} and V3^{WT} hCEnC exposed to ≤ 0.01 µM MitoQ retained over 90% of the cell density observed in untreated hCEnC. Media supplementation with 0.01 µM MitoQ led to increased viability in *SLC4A11* empty hCEnC, compared to MitoQ-free media, after exposure to 25-50 µM tBH. Each of the CHED-associated hCEnC lines demonstrated increased cell viability when treated with 0.01 µM MitoQ, compared to untreated, following exposure to 25 -50 µM tBH. The FECD4-associated V2^{MU} c.2224G>A and V3^{MU} c.2176G>A hCEnC lines exhibited no significant increase in viability when treated with 0.01 µM MitoQ, compared to untreated, following tBH exposure. **Conclusions:** Media supplementation with the antioxidant MitoQ has beneficial effects on cell viability in hCEnC harboring CHED-associated *SLC4A11* mutations following exposure to tBH-induced oxidative stress.

663. Biodistribution of ARMMs as Non-Viral Vehicles for Delivery of Therapeutic Payloads by Subretinal Administration in Minipigs and Non-Human Primates

Yashodhan Chinchore, Jinling Yang, Adam Miller, Pearl Moharil, Qin Yu, Joseph Nabhan
Vesigen Therapeutics, Cambridge, MA

Therapeutic delivery of genetic medicines to the back of the eye has been a challenge in treatment of inherited retinal diseases. Non-viral delivery offers many potential advantages over conventional viral delivery systems, especially for genome editing applications. We developed a novel non-viral platform that co-opts a class of extracellular vesicles called ARRDC1-mediated microvesicles (ARMMs) for delivery of therapeutic payloads. Using this platform, we previously demonstrated delivery of fluorescent proteins and nuclear genome modifiers in murine ocular tissue via subretinal injection, a clinically approved route-of-administration. However, the biodistribution characteristics of ARMMs in higher mammals is not known. We assessed biodistribution of ARMMs loaded with fluorescent proteins in Gottingen Minipigs and African Green Monkeys via subretinal injection. Eyes were harvested and assessed for colocalization of fluorescent proteins with cell type-specific markers for rod and cone photoreceptors and the Retinal Pigmented Epithelium (RPE) as a proxy for ARMMs uptake in these cell types of interest. Consistent with murine uptake data, we observed robust localization of ARMMs in the RPE in both minipigs and monkeys. In the neural retina, we observed a time-dependent increase in the localization of ARMMs with photoreceptors. Both rod and cone photoreceptors, including cones of the macular region in the monkey retina, showed ARMMs localization. Together, these data strongly suggest that ARMMs are non-viral vehicles that enable delivery of payloads to RPE and photoreceptors, two important cell types for many human retinal diseases.

Wednesday Posters: Musculo-Skeletal Diseases

664. Insights for Gene Therapy from Molecular Evolution - Why Has Dystrophin Remained the Same Size for 600 Million Years?

Hansell H. Stedman[1], Christopher D. Greer[2], Andrew Mead[2], Yafeng Song[2], Rachel Sweeney[2], Derek Stefanik[2], Leon Morales[2], Coral Kasden[2], Benjamin Kozyak[3]
[1]University of Pennsylvania Medical Center, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA,[3]University of Pennsylvania School of Medicine, Philadelphia, PA

Duchenne muscular dystrophy (DMD) has been regarded as a "Holy Grail" for gene therapy because of the high global incidence and extreme burden of the lethal monogenic disease. At almost 3 million basepairs, the enormous size of the causative X-linked DMD/dystrophin gene presents an exceptional target for novel mutations, with a majority represented by large, multi-exon frameshifting deletions and duplications. Designing effective gene therapies for DMD requires reconciling a mismatch between the largest gene (DMD) and smallest vector genome (AAV). In doing so, we mustconfront the limits of our current knowledge about the correlation of structure with function for the protein dystrophin. A central challenge reflects the nature of dystrophin's discovery: the protein accumulates to such low abundance that a positional cloning approach was required. Although this groundbreaking paradigm provided detailed information about the gene product's primary structure, it offered only the vaguest hint about its tertiary structure and function. Forty years later, less than 5% of dystrophin's largest domain, the rod, has been subjected to protein crystallography - the rest is "terra incognita". Here we use comparative phylogenomics to reconstruct a remote evolutionary history of dystrophin, its related and associated proteins, and other critical muscle proteins to develop a detailed model of the functional constraints on ancestral dystrophin genes. We find that unlike the promiscuous length of the 10-fold larger protein titin, dystrophin has been fixed in size at ~400 kD since its inception before the phylogenetic split between radially and bilaterally symmetrical organisms such as jelly fish (Cnidaria-Radiata) and most familiar land animal species (Bilateria). Even minor deviations from this optimal length, by deletion or duplication, produce Becker muscular dystrophy (BMD), associated with site-specific fragmentation of the internally truncated protein in muscle. This raises two related questions of relevance to gene therapy for DMD: (1) Why has dystrophin remained the same size for over 600 million years? (2) In which protein ancestral to dystrophin did the repetitive, spectrin-like triple helical region of the rod expand to its current size in Dp427, the 4 primary isoform of dystrophin in modern day human and cnidarian muscle? We propose testable answers to these questions on the basis of bioinformatic analysis, illustrated using novel software developed to aid visualization of the relationships between gene and protein structure across inferred branchpoints in remote phylogenesis. In related abstracts we present the implications of this derived evolutionary history, informing rational design of novel AAV transgenes with the potential to confer significantly improved functionality over conventionally miniaturized dystrophins.

665. A Central Challenge of Gene Therapy for Duchenne Muscular Dystrophy - Rational Design of Truncated, AAV-Compatible Rod Domains to Preserve Tensile Strength

Hansell H. Stedman[1], Coral Kasden[2], Leon Morales[2], Benjamin Kozyak[3]
[1]University of Pennsylvania Medical Center, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA,[3]University of Pennsylvania School of Medicine, Philadelphia, PA

Our reconstructed evolutionary history of dystrophin (presented elsewhere) suggests that the rod domain has been static in length since the protein's emergence about 600 million years ago. All prior expansion occurred in the context of an ancestral protein resembling modern-day microtubule-actin crosslinking factor (MACF) and, based on the gene structures, was driven by an intron-dependent process. Converging lines of evidence suggest that dystrophin coopted the rod domain from its ancestral MACF, and in doing so locked in a functional constraint tailored to the emerging protein's relocation from the cytoplasm to the cortical cytoskeleton and cell membrane. In this

scenario, the functional constraint is tensile strength, not length *per se*. The strength is conferred by the overlap between the interhelical loops of adjacent spectrin-like triple helical repeats, in which the interconnecting C-A helix has been shortened relative to that in the remote common ancestor. This is best visualized by comparing the X-ray crystal structures for triple helical repeats derived from a spectrin and a spectroplakin, e.g. 3EDV versus 5J1I, respectively. In spectrins and alpha-actinins, individual triple helical repeats have no mechanism for force transmission along the long axis except through the C-A helix, with cooperative unfolding of isolated triple helices at relatively low tensile loads. In contrast, the inter-loop hydrogen bonds between adjacent repeats of MACF and dystrophin has the potential to vastly increase tensile strength if the triple helix is simultaneously loaded across all three helices, as would be expected *in vivo*. The behavior of the helix bundle would be strongly impacted by the site and directionality of the applied load, like the tightening versus untying of a shoelace depending on whether one pulls on the loop or the free ends. If evolution has primarily selected for strength, not length, in force transmission between the sarcomere and the sarcolemma, this opens the possibility that novel transgenes could prioritize strength in small, AAV-compatible mimetics for dystrophin and utrophin. This suggested a series of testable hypotheses centered on the rational design of recombinant proteins in which the triple helices are cut and re-annealed across a transverse section at the three-dimensional midpoint. The transecting plane is placed where the highly conserved tryptophan residues in the A and C helices exhibit pi system polarization in the hydrophobic core. We used this approach to engineer a novel class of recombinant, miniaturized dystrophins and utrophins, denoted nanotrophin-#D and #U, where # denotes the number of remaining triple helical repeats downsized from > 20 in the native full-length proteins too big for AAV. Here we present the structural basis for the design of four preferred nanotrophins: nantrophin-4U, -4D, -5U and 5D. Of these four, the latter two are supported in part by X-ray crystal structures reported for the first spectrin-like repeats of utrophin and dystrophin. The positions selected for splicing the poorly conserved B helices were derived by the combined application of Hidden Markov Modelling and hypothetical protein rendering by AlphaFold. The transgenes resulting from this rational design approach have been synthesized and rigorously compared to conventional microutrophin and microdystrophin in the context of systemically delivered AAV vectors, with compelling results as reported in detail in a co-submitted abstract.

666. Exon Skipping for the Second Calponin Homology Domain of Dystrophin Using AAV. U7snRNA - *In Vitro* & Intramuscular Studies Using a Novel Murine Model of Duchenne Muscular Dystrophy

Alex Brinkman, Daniel Lesman, Ding Li, Dhanarajan Rajakumar, Atre Chaitrali, Yacidzohara Rodriguez, Camila Almeida, Nicolas Wein

Center for Gene Therapy, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH

Duchenne muscular dystrophy (DMD) is a progressive muscle-wasting disease, caused by mutations in DMD gene leading to absence of dystrophin. 5-6% of DMD patients have mutations in exons 6-8 encoding for the second calponin homology domain of dystrophin. To test the efficiency of a novel vectorized exon skipping (VES) for patients with these mutations, we developed a multiple VES constructs that was screened *in vitro* in HEK293 and patient fibroblasts differentiated into myotubes to select our best VES candidates that mediate exon 6-8 skipping. In addition, we tested our lead candidates in a new humanized hDMD mdx mouse called hDMDm7 that was generated using CRISPR/Cas9. This mouse model does not express murine dystrophin and additionally contains a nonsense mutation in exon 7 (hDMDm7) resulting in no human dystrophin expression. Intramuscular (I.M.) injections using selected VES constructs were performed for hDMDm7 mice at 6 and 7 weeks of age. Exon skipping was evaluated by RT-PCR, dystrophin expression by WB and IF, and muscle force using electrophysiology. This mouse model presents a reduction of muscle integrity with centronucleation (>90% at 3 and 6 months of age) using H&E staining. Little to no dystrophin expression was determined by western blot, and the average percent drop over 10 consecutive eccentric contractions was 59% in hDMDm7 vs 9% in hDMD. Four lead VES constructs were selected and evaluated in the hDMDm7. One VES construct was tested effective in muscle force measurement at 3 months of post I.M. injection, which brought the percent drop of eccentric contraction back to 40%. This exon skipping strategy was able to restore muscle functions following I.M. treatment for hDMDm7 mouse model. This VES for exons 6-8 could be beneficial for 5-6% of DMD patients.

667. Alternative Delivery of Adeno-Associated Virus 9 for the Treatment of Duchenne Muscular Dystrophy to Target CSF and Muscles- GFP Biodistribution Study in WT Mice

Cintia Gomez[1], Archana Iyer[1], Alex Brinkman[1], Florence Roussel[1], Ding Li[1], Daniel Lesman[1], Cassandra Dennys-River[1], Hannah Huang[1], Vicky McGovern[2], Arthur Burghes[2], Shibi B. Likhite[1], Dave Arnold[3], Kathrin Meyer[1], Nicolas Wein[1]

[1]Center for Gene Therapy, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH,[2]The Ohio State University, Columbus, OH,[3]University of Missouri, Columbia, MO

Duchenne muscular dystrophy (DMD) is a progressive muscle-wasting disease, caused by mutations in *DMD* gene leading to absence of dystrophin. Additionally, around one-third of patients present cognitive impairments. Several therapeutic approaches including exon-skipping have used efficient systemic delivery of adeno-associated virus (AAV). However, the high dose of vector needed to treat adult patients represents a risk, especially for the liver. We have investigated an alternative administration route using cerebrospinal fluid (CSF) delivery to avoid potential liver toxicity and improve brain transduction. Newborn C57BL/6 mice were intracerebroventricular (ICV) or face vein (FV) injected with 1E+11vg scAAV9.CBA.GFP to study virus biodistribution. After one and three months (mo) post-injection (pi), GFP expression on fresh organs was evaluated using fluorescent stereomicroscope. GFP mRNA and protein expression were assessed by RT-PCR and western blot (WB). Vector DNA

biodistribution was performed by ddPCR. At 1 mo and 3 mo pi, similar levels of GFP expression were observed in all muscles for CSF and systemic groups. However, a higher expression was detected in the brain after ICV injection and liver was less transduced by ICV injection compared to FV, which was confirmed by RT-PCR and WB. To conclude, CSF and systemic delivery allowed similar levels of muscle transduction by AAV9, although the brain transduction after ICV injection was superior and liver was less transduced, supporting the use of CSF delivery for the simultaneous distribution of AAV9 to muscles and CNS.

668. *In Vivo* Treatment of Duchenne Muscular Dystrophy Using Lentiviral Vectors Containing the Mini-Dystrophin Gene

Xiaoyu Wang[1], Yanghui Zhu[1], Taiqing Liu[1], Lingyan Zhou[1], Yunhai Fu[1], Jinhua Zhao[1], Yinqi Li[1], Yeteng Zheng[1], Xiaodong Yang[1], Xiangjie Di[1], Yang Yang[2], Zhi-Yao He[1]

[1]West China Hospital, Sichuan University, Chengdu, China,[2]Sichuan University, Chengdu, China

Duchenne muscular dystrophy is an incurable X-linked recessive genetic disorder caused by mutations in the dystrophin gene. Numerous researchers were working to restore truncated dystrophin using viral vectors, but their clinical application was hindered by the limited capacity for packaging and immunogenicity of these vectors. In this study, we developed four lentiviral vectors containing sequence-optimized and truncated dystrophin genes, which were regulated by muscle-specific promoters. They stably expressed mini-dystrophin *in vitro*. To evaluate the impact of the treatment *in vivo*, we administered the lentiviral vectors to neonatal mice. Treated mice showed an improvement in the expression of modified dystrophin, which was also restored in its distribution. Simultaneously, the treatment mice demonstrated a recovery of pulling strength and a reduction in the quantity of mononuclear cells. The therapeutic effect lasted for duration of 3-6 months *in vivo*. Additionally, we conducted an initial analysis on the insertion sites of the lentiviral vectors. To summarize, this study provided preliminary evidence for the feasibility and safety of using lentiviral vectors with mini-dystrophin for DMD gene therapy, and introduced a novel strategy for restoring truncated dystrophin.

669. Therapeutic Expression of Large Dystrophins and a CRISPR Base-Editor for Duchenne Muscular Dystrophy by Scarless RNA Trans-Splicing

Ryan H. Hsu[1], Claire E. Williams[1], Geraldine Maier[2], Miriam Gullo[2], Karen Lettieri[2], Cindy Alvarez[2], Kip J. Hermann[2], Lukas C. Bachmann[3], Samuel L. Pfaff[1]

[1]Salk Institute & UC San Diego, La Jolla, CA,[2]Salk Institute, La Jolla, CA,[3]Insmed Inc., San Diego, CA

Adeno associated viruses (AAVs) have proven to be safe and efficacious vectors for delivering genetic therapies. However, one major limitation that remains is its packaging capacity of ~4.7 kilobases (kb), restricting the scope of both gene-editing (e.g. CRISPR-Cas9 base editors) and gene-replacement therapies. To overcome this boundary, we engineered a novel high-efficiency RNA trans-splicing technology to express functional levels of any gene of interest by dual or triple AAV delivery, termed RNA end-joining (see abstract: *Optimization of RNA End Joining (REJ) to safely and efficiently express large proteins*, Bachmann et al.). In REJ, a coding sequence of interest is split into multiple viral genomes, each containing an exon. Each exon is flanked by synthetic engineered intron sequences and is packaged individually into AAV. These constructs are delivered to target cells *in vivo*, where the expressed RNAs undergo a trans-splicing reaction mediated by the endogenous spliceosome, resulting in high levels of scar-free mRNA that is translated into full-length protein. Duchenne muscular dystrophy (DMD) is a devastating monogenic disease characterized by progressive muscle degeneration, weakness, and eventual fatal cardiomyopathy. Despite clinical advancements in gene-replacement using micro-dystrophins designed to fit within AAV, their limited efficacy is becoming increasingly evident, underscoring the need for larger, more functional dystrophins. Toward this goal, research efforts have included engineering alternative CRISPR editors (<4.7 kb) or intein-based protein joining, which necessitates potentially antigenic foreign peptides and a scar which may disrupt protein function. In this work, we use REJ to develop dual- and triple-vector AAV therapeutic candidates for the delivery of a CRISPR Adenine Base Editor (dual, 6 kb), mini-dystrophin (dual, 7 kb), or full-length dystrophin (triple, 11 kb) and characterize their efficacy in DMD model mice. By intramuscular treatment, all delivery strategies result in functional levels of dystrophin expression with significant phenotypic improvements. We observe recovery in immunohistochemical markers of disease, such as centro-nucleation, morphology, and fibrosis. Transcriptomic signatures of disease are improved and *in situ* contractile force measurements demonstrate significant increases in muscle strength. In the gene-editing approach, up to 40% of muscle fibers exhibit restored dystrophin expression. Current work includes intravenous systemic treatment using myotropic AAV with comparable positive outcomes. These findings collectively validate REJ as a broadly applicable technology and identify several promising clinical candidates for further investigation in the pursuit of a treatment for Duchenne muscular dystrophy in patients.

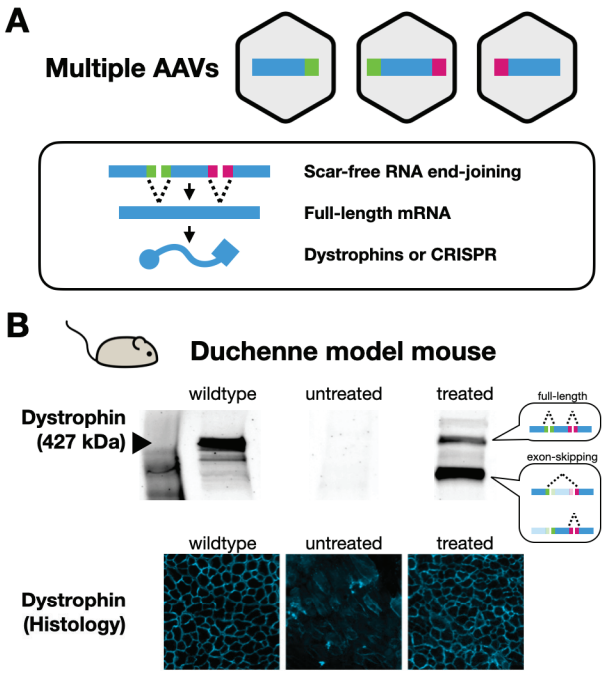

Figure Legend: (A) Large therapeutic genes (blue) are split, flanked by REJ modules (green, purple), and packaged into individual AAVs. Once delivered *in vivo*, the transcribed RNAs undergo trans-splicing and produce full-length mRNA, resulting in robust protein expression. (B) Triple AAVs encoding full-length dystrophin were delivered to DMD model mice by intramuscular injection. 4 weeks later, full-length dystrophin was detected along with exon-skipping products.

670. Disease Exacerbation in 3D MYOtissues Derived From Duchenne Muscular Dystrophy iPSC Reveals Muscle Strength Loss and Enables Gene Therapy Screening

Laura Palmieri[1,2], Louna Pili[1,2], Abbass Jaber[1,2], Melissa Moula[1], Ai Vu Hong[1,2], Riyad El-Khoury[1,2,3], Guy Brochier[3,4], Anne Bigot[5], David Israeli[1,2], Isabelle Richard[1,2], Sonia Albini[1,2]

[1]GENETHON, Evry, France,[2]Université Paris-Saclay, Univ Evry, Integrare Research Unit UMR_S951, Evry, France,[3]Institut de Myologie, Paris, France,[4]AP-HP, Centre de Référence de Pathologie Neuromusculaire Nord/Est/Ile de France, Paris, France,[5]Sorbonne Université, Inserm, Institut de Myologie, Centre de Recherche en Myologie, Paris, France

Duchenne muscular dystrophy (DMD) is a lethal muscle-wasting disease caused by the absence of Dystrophin, a protein essential to preserve muscle integrity continuously challenged by contractions. Gene therapy utilizing adeno-associated virus (AAV) to deliver truncated forms of dystrophin (µDys) is currently the most promising therapeutic approach. However, the therapeutic outcome in treated patients has not been as successful as anticipated by animal studies, underscoring the need for improved and high-throughput models for fast and accurate prediction of human response. Among the in vitro cellular models, organoid-like structures are becoming an appealing resource for disease modeling and replacement of animal models. Here, we describe the generation of MYOtissues, an in vitro 3D muscle platform based on direct myogenic conversion of human induced pluripotent stem cells (iPSC) and inclusion of fibroblasts to ensure proper muscle structure. MYOtissues derived from DMD-iPSC including DMD fibroblasts, show exacerbated pathogenic hallmarks such as fibrosis and muscle force loss, across the different DMD iPSC cell lines employed, independently from the genetic background of the DMD fibroblasts used. As proof of the suitability of our system for gene therapy screening, we showed that AAV9-mediated µDys gene transfer in DMD-MYOtissues improved muscle resistance and recovered, although only partially, membrane stability with consequent reduction of the inflammatory environment. Our data, obtained in three control and DMD cell lines including isogenic controls, were supported by transcriptomic analysis which demonstrated an amelioration of mechano-stability and inflammatory hallmarks but also reveals that only a partial correction of the deregulated pathways in DMD was achieved. This study highlights the suitability of our human in vitro system for gene therapy screening and supports the need for developing more efficient gene therapy strategies for DMD patients.

671. Systemic Delivery of Circular RNA Encoding Delta17-48 Dystrophin for Treatment of Duchenne Muscular Dystrophy

Luke Rhym, Tatiana Fontelonga, Deirdre Boyer, Doug Pecze, Corey Ciullo, Emily Fitzgerald, Sharmistha Kundu, Justin Lee, Allie Lundberg, Elena Minissale, Shobu Odate, Kristen Ott, Raya Shu, Trent Stevens, Rahul Vungutur, Robert A. Wesselhoeft, Yessica Wiryawan, Junghoon Yang, Nelson Chau, Tracy Dimezzo, Allen Horhota, Tom Barnes, Robert Mabry, Isin Dalkilic

Orna Therapeutics, Watertown, MA

Duchenne muscular dystrophy (DMD) is a severe degenerative muscle disorder caused by mutations in the *DMD* gene that results in the loss of dystrophin protein. Full-length dystrophin protein replacement therapy for patients has been infeasible using existing technologies due to the large open reading frame (11kb) of the dystrophin gene. Becker muscular dystrophy is a milder version of the disease where patients express truncated versions of the dystrophin protein, suggesting that significantly truncated, yet still functional, protein placement approaches could be utilized to slow DMD disease progression in patients. Current protein replacement gene therapies utilize adeno-associated virus (AAV) delivery systems; however, these are limited by their immunogenicity, which precludes their potential for repeat dosing, and their relatively small packaging capacity. As result, the focus of AAV-based systems has primarily been on extremely truncated versions of the dystrophin protein (micro-dystrophin, ~1/3 full length protein). At Orna Therapeutics, we are developing a novel, synthetic circular RNA technology (oRNA®), that can be delivered systemically to musculature via our lipid nanoparticle (LNP) platform, which shows durable expression, as well as multi-dosing capability. Moreover, our platform allows for significantly larger protein coding capacity, enabling therapeutic approaches that utilize much larger dystrophin variants than are not feasible with current AAV-based approaches. We have taken multiple dystrophin variants, including micro dystrophin,

Becker patient variants, and full-length dystrophin, cloned into our oRNA vectors and showed expression from oRNA *in vitro* in human skeletal muscle cells. For *in vivo* studies, we have focused on a Δ17-48 dystrophin variant which has been described in a mild Becker patient in the 1990s. The coding sequence for this variant (~5.9kb) is considerably larger than micro dystrophins utilized in AAV platforms. One of the important features of oRNA technology is that protein expression in cells is driven by a sequence-based internal ribosome entry site (IRES) element in a cap-independent manner. To identify IRES sequences that can drive high protein expression in muscle cells, we screened >3000 IRES sequences extracted from viral genomes using our proprietary FoRCE platform in primary human skeletal muscle myotubes. A subset of IRESs that showed high muscle activity *in vitro* were selected to generate dystrophin expressing oRNAs and tested *in vitro* and *in vivo* in the mdx model. Our lead muscle IRES sequence has shown ~10x improvement in protein expression in diaphragms from IV dosed mdx mice. Through further optimization of the coding sequence and LNP composition, we have demonstrated expression of Δ17-48 dystrophin protein at ~3% of WT levels in diaphragms of mdx animals dosed IV with a single dose of 5 mg/kg. This data represents the first evidence of expression of the Δ17-48 variant from a systemically delivered gene therapy platform *in vivo* and demonstrates the potential of oRNA® technology as a scalable, durable protein replacement platform with a large cargo capacity that can provide a differentiated therapy for DMD patients.

672. Exon Reframing by Prime Editors Restores Dystrophin Expression and Function in DMD Patient Cardiomyocytes

Michelle O'Connor[1], Sascha Hernandez[1], David Waterman[1], Serge Kyrychenko[1], Naqi Haider[2], Vivian Choi[1], John Stiller[1], Katya Kosheleva[3], Matthew Malloy[1], Andrew V. Anzalone[4], Jeremy Duffield[1]

[1]Prime Medicine, Cambridge, MA,[2]Prime Medicine, Arlington, MA,[3]Prime Medicine, Somerville, MA,[4]Broad Institute, Cambridge, MA

Duchenne muscular dystrophy (DMD) is a progressive degenerative muscle disease caused by mutations in the *DMD* gene which encodes dystrophin, a large intracellular protein that tethers the cytoskeleton to the extracellular matrix. Most disease-causing *DMD* mutations are large deletions that disrupt the reading frame, causing premature termination of translation and subsequent loss of dystrophin expression. Most current therapeutic options for patients, including exon-skipping antisense oligonucleotides (ASOs), require repeated administration. The long-term clinical benefit of other therapeutic approaches, such as the recently approved micro-dystrophin gene therapy Elevidys, is yet to be fully determined. Therefore, there is a significant unmet medical need for a one-time curative treatment for DMD. Restoration of functional dystrophin expression through Prime Editing of the endogenous *DMD* gene represents a potential curative therapeutic strategy. Our approach leverages Prime Editors to reframe an exon adjacent to the pathologic deletion through targeted nucleotide insertions or deletions, thereby restoring the correct reading frame, which results in expression of a nearly full-length dystrophin protein from the endogenous gene. Using this exon reframing strategy, we demonstrated restoration of dystrophin protein expression in patient iPSC-derived cardiomyocytes with three predominant DMD genotypes: exon 45 deletion, exon 46-50 deletion, and exon 51-55 deletion. Compared to the untreated patient cardiomyocytes, those corrected with the Prime Editor exhibited normalization of Ca2+ handling and contraction frequency, as well as elimination of arrhythmogenic activity. These data highlight the potential of exon reframing by Prime Editors as a therapeutic strategy for a large number of DMD patients with unmet medical need.

673. Cardioprotective Effects of AAV9-Micro-Utrophin Gene Therapy in Novel Hit-and-Run Acute Injury Model in the Muscular Dystrophy *Mdx* Mouse

Coral M. Kasden[1], Maria P. Corzo[1], Christopher D. Greer[1], Rufranshell Reyes[1], Tanvi Singh[1], Alaine Castillo[1], Benjamin Kozyak[2], Hansell H. Stedman[3]

[1]University of Pennsylvania, Philadelphia, PA,[2]University of Pennsylvania School of Medicine, Philadelphia, PA,[3]University of Pennsylvania Medical Center, Philadelphia, PA

Duchenne muscular dystrophy (DMD) is the most common childhood-onset muscle wasting disease worldwide, caused by genetic deficiency of dystrophin and resulting in premature death due to cardiorespiratory failure. Ongoing DMD gene therapy clinical trials delivering functional miniaturized dystrophin substitutes with Adeno-associated virus (AAV) are promising. However, issues continue to emerge with durability and lack of central tolerance to dystrophin epitopes in a majority of DMD patients. An alternative gene replacement approach is to deliver miniaturized utrophin (uUtro), the evolutionarily and functionally related protein to dystrophin that confers immunological safety and therapeutic protection against disease progression in skeletal muscle in DMD mouse and dog models. With skeletal muscle restoration, voluntary activity increases, placing greater strain on the heart. It remains untested whether AAV-uUtro is protective in the dystrophic heart during bouts of greater cardiac strain. **Methods**. Because cardiac dysfunction in mdx mice does not recapitulate end-stage cardiomyopathy in DMD patients, methods to pharmacologically accelerate cardiac injury with isoproterenol (ISO) have been utilized. However, mdx mice show variable susceptibility to cardiac injury by ISO. We've developed a novel cardiac injury method termed "double-hit" in which we challenge with ISO while simultaneously block the parasympathetic branch. We measured cardiac troponin I (cTnI) and Evans blue dye (EBD) uptake into damaged cardiac myofibers. We then developed the "hit and run," a novel method coupling the double-hit to a treadmill run to assess cardiovascular performance following a cardiac stressor. Serial cTnI levels were measured at baseline, after the double-hit, and after the run. Total run distance was recorded at baseline, following the double-hit, and 24 hours post-challenge. Following the hit and run challenge, a subset of mice were run daily for 2 weeks to assess the impact of daily activity on cardiac fibrosis and remodeling following a cardiac stressor. *Mdx* neonates were injected with AAV-uUtro and aged to 5 months or 10 months, with untreated littermate *mdx* and WT controls. **Results**. Following the double-hit, *mdx* mice had elevated cTnI levels (*mdx* 4.92 ng/mL v WT 0.28 ng/mL, p<.0001) and large percentage of EBD by area (mdx 4.68% v WT 0.35%, p=.0039). uUtro-treated *mdx* mice had significant reductions in both cTnI levels (1.21 ng/mL, p=0.0362) and %EBD (0.32%, p=.0002).

Surprisingly, in the hit-and-run assessment, the run exacerbated cTnI levels from post-double-hit levels in *mdx* mice in both age groups (10 mo mdx 4.15 to 9.18 ng/mL), while WT and uUtro-treated groups experienced a significant reduction in cTnI levels (10 mo final cTnI WT 0.50 ng/mL p=.0036, uUtro 1.5 ng/mL, p=.0083). *Mdx* mice ran fewer meters (10 mo 172.9 m) than both WT (10 mo 225.2 m, p=.0006) and uUtro-treated mice (10 mo 210.8 m, p=.013), and *mdx* mice dropped significant distance compared to baseline performance (% change *mdx* -16.6%) while both WT (-2.1%, p=.0208) and uUtro (+0.18%, p=.0334) maintained. uUtro-treated mice also had less cardiac fibrosis by area than *mdx* in an expression-dependent manner (uUtro 2.24% p=.0214, mdx 5.1%, WT 1.4% p<.0001). **Conclusions**. We developed a novel catecholamine-exercise stress test in the mdx mouse. AAV-uUtro protects *mdx*mice against acute cardiac injury and improves cardiovascular exercise performance following a cardiac stressor. AAV-uUtro's cardioprotective efficacy permits daily physical activity to match the improved skeletal muscle capacity in the treated *mdx* mouse out to the human equivalent of 40 years.

674. Combinatorial Antisense Oligonucleotide Gene Therapy Enhances Muscle Regeneration and Dystrophin Restoration for Duchenne Muscular Dystrophy

James S. Novak, Young Jae Moon, Ravi Hindupur, Iteoluwakishi H. Gamu, Jyoti K. Jaiswal

Center for Genetic Medicine Research, Children's National Hospital, Washington, DC

Low level dystrophin restoration is a major challenge towards realizing the full potential of the phosphorodiamidate morpholino oligomer (PMO)-based antisense oligonucleotide (AO) gene therapy for Duchenne Muscular Dystrophy (DMD). Our work has identified macrophages and myoblast fusion are required for PMO delivery to nascent muscle fibers. Poor myogenesis and excessive fibrosis induced by high TGFβ activity in DMD muscle contribute to poor efficacy of dystrophin PMO therapy. Using the severe DMD model (D2-*mdx*) that exhibits greater TGFβ activity, increased muscle degeneration, and poor myogenesis as compared to the milder B10-*mdx* model, we find significantly poor PMO-mediated dystrophin restoration in the severe D2-*mdx* muscle. To tackle poor dystrophin restoration by dystrophin PMO monotherapy, here we describe the use of a combinatorial PMO therapy that simultaneously inhibits macrophage TGFβ production and enhances myofiber dystrophin production. We developed a TGFβ inhibiting AO that significantly reduced TGFβ-mediated SMAD3 signaling in vivo. Use of this PMO allowed enhanced *in vivo* muscle regeneration following spontaneous or induced D2-*mdx* muscle injury. This was associated with reduced accumulation of fibroadipogenic progenitors and a notable increase in muscle regenerative capacity. Combinatorial use of this TGFβ-targeting PMO with dystrophin exon skipping PMO led to a significant increase in the extent of dystrophin expressing myofibers even after an acute single dose of PMOs. Chronic use of this combinatorial PMO therapy not only recapitulated these beneficial effects, but also reduced muscle degeneration and allowed greater improvement of muscle functional measures as compared to dystrophin exon skipping PMO monotherapy. Thus, our findings offer the first PMO combinatorial gene therapy for DMD that demonstrates the potential to tackle challenges associated with poor efficacy of PMO-mediated gene therapy for DMD, while simultaneously improving muscle restoration and reducing muscle loss.

675. Ridsipam's Safety and Efficacy in a Patient with Co-Existing Spinal Muscular Atrophy with Sickle Cell Disease

Momen Almomen, Shiakhah Aldossary, Walaa Albdulqader, Toqa Alhamrani, Nora Bastaki

King Fahd Specialist Hospital- Dammmam, Dammam, Saudi Arabia

Sickle cell disease (SCD) is a common genetically inherited autosomal recessive disease that is prevalent in certain ethnicities, including the Mediterranean region and African Americans. It is characterized by recurrent painful crises, reduced blood count, and recurrent infection. Spinal Muscular Atrophy (SMA) is a genetic autosomal recessive disease with a carrier frequency of one in 3000 in Saudi Arabia. Despite the relatively high carrier frequency of both diseases globally, patients with co-existing SMA and SCD have never been reported in the past. In this article, we present one patient with a dual diagnosis of SMA and SCD who received two different treatments, namely, Risdiplam and Hydroxurea. To our knowledge, this is the first ever to report this unique disease combination case in the literature and shed light on the safety and response to SMA-disease modifying therapy in SCD.

Wednesday Posters: Base Editing and Prime Editing

676. Designing a Base Editing Gene Therapy for Collagen VI-Related Dystrophy Informed by Mosaic Patient Phenotype

Gregory H. Boyek, Veronique Bolduc, Astrid Brull, Riley McCarty, A. Reghan Foley, Carsten G. Bonnemann

Neuromuscular and Neurogenetic Disorders of Childhood Section, NINDS/NIH, Bethesda, MD

Collagen VI-related dystrophies (COL6-RDs) are a group of genetic muscle disease existing on a spectrum of severity that ranges from the severe Ullrich congenital muscular dystrophy (UCMD) to the milder Bethlem muscular dystrophy. Patients with UCMD exhibit congenital onset weakness and hypotonia that prevents or causes the loss of ambulation and progressive respiratory insufficiency. Patients with Bethlem muscular dystrophy exhibit proximal weakness and contractures but remain ambulatory into adulthood, and intermediate phenotypes also exist. We have previously described a recurrent, de novo deep intronic variant in intron 11 of *COL6A1* (c.930+189C>T) that creates an in-frame pseudoexon insertion with a dominant negative mechanism of action. We then found this *COL6A1* pathogenic variant to be one of the most commonly identified causative variants in the *COL6* genes. This intron 11 variant in full heterozygosity results in a severe phenotype with minimal early symptoms that rapidly progress to a severe Ullrich congenital muscular dystrophy phenotype. Here, we describe our findings in a patient presenting with a milder

Bethlem muscular dystrophy phenotype in whom the intron 11 variant was present as somatic mosaic. The mosaic patient retained not only independent ambulation but running, ascending and descending stairs at age nine. Quantifying the degree of mosaicism showed that approximately 40% of patient cells are positive for c.930+189C>T. This provides us the rationale for a base-editing approach for correcting the intron 11 mutation, as correction of the mutation in just a proportion of cells comparable to a somatic mosaicism would be expected to be disease modifying. We have designed several base editor guide sequences based on predictive machine learning algorithms and are evaluating them in cultured patient fibroblasts. Our technique uses an easily translatable single-AAV vector with the potential to permanently ameliorate the severe Ullrich muscular dystrophy symptoms to a milder phenotype.

677. Engineered Viral-Like Particles-Delivered Base Editor Ribonucleoprotein Complex Confers Efficient Base Editing in hiPSC and hiPSC-Derived Cardiomyocytes

Yuan Zhou, Chen Zhang, Renzhi Han

Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN

CRISPR/Cas9 gene editing in human induced pluripotent stem cells (hiPSCs) has provided an exciting platform for disease modeling and translational research of various human diseases. However, the low editing efficiency poses a challenge for hiPSC engineering. In this study, we utilized engineered virus-like particles (eVLPs) to deliver base editor ribonucleoproteins (RNPs) for precise base editing in hiPSCs. Our findings demonstrate that eVLPs achieved a dosage-dependent increase in editing efficiency in hiPSCs, with peak efficiency ranging from 60% to 99% at various genomic loci. The eVLPs-delivered base editing had minimal impact on the pluripotency or differentiation capacity of hiPSCs. Furthermore, we demonstrated efficient base editing in a Duchenne muscular dystrophy (DMD) hiPSC cell line carrying a large deletion spanning exon 48 through 54. The eVLPs targeting the splice acceptor of exon 55 resulted in the efficient conversion of AG to GG (85.69% ± 0.58%) and enabled exon 55 skipping. The editing efficiency was maintained even after ten passages (87.20% ± 0.41%). In addition, eVLPs delivery rescued dystrophin expression in DMD hiPSC-derived cardiomyocytes, as examined by RT-PCR, Western blot, and immunofluorescence staining. These results highlight the great promise of eVLPs delivery of genome editor RNPs to facilitate hiPSC engineering.

678. First Correction by Prime Editing of Mutations in the *RYR1* Gene

Kelly Godbout[1,2], Joël Rousseau[2], Jacques P. Tremblay[1,2]

[1]Molecular Medecine, Laval University, Québec, QC, Canada,[2]Neurosciences, Centre de recherche du CHU de Québec, Quebec, QC, Canada

BACKGROUND AND AIMS: Our aim is to develop a gene therapy treatment for myopathies caused by mutations in the *RYR1* gene. This gene codes for a calcium channel named Ryanodine receptor 1 in muscle fibers. Its failure causes muscle weakness in patients, which degenerates into motor disabilities. Currently, there are no effective treatments for those diseases. We are therefore trying to develop a gene therapy by Prime editing to correct the mutations and restore the healthy sequence of the gene. Those disorders are mainly caused by the mutation of a single nucleotide. For our treatment, Prime editing, which allows the modification of a precise nucleotide in the DNA, will be used. We are actually achieving the correction of the T4709M in the *RYR1* gene. We are also working on correcting the G3191R mutations. Additionally, we are developing a treatment introducing a protective mutation in the *RYR1* gene. **METHODS:** Derived from the CRISPR/Cas9 technology, Prime editing is composed of a Cas9 fused to a reverse transcriptase and a prime editing guide (peg). We first built the required components for Prime editing by cloning. Several versions of the peg were constructed to optimize the efficiency of Prime editing. The treatment has been tested in several cell types (HEK293T, patient fibroblasts, myoblasts, and C2C12). Through manual cloning, we also generated, by Prime editing from normal myoblasts, a myoblast cell line carrying the T4709M mutation in the *RYR1* gene at the homozygous state. We have succeeded in producing the prime editor mRNA by *in vitro transcription* and in delivering it to myoblasts by electroporation, which allowed us to increase Prime editing's effectiveness. **RESULTS:** In HEK293T cells, we achieved 35% editing for the T4709M mutation and 55% for the G3191R mutation by plasmid DNA delivery. In the T4709M mutant myoblast cell line, we corrected the mutation at 59% after three doses of the treatment when the Prime editing components were delivered as RNAs. It is to be noted that people who are heterozygous for the T4709M mutation are healthy. We have, therefore, reached our *in vitro* goal, which was to exceed 50% of correction. We also successfully introduced the protective mutation in the *RYR1* gene at 33% in myoblasts by delivering the Prime editing components as RNAs. **CONCLUSIONS:** These results are the first demonstration in the scientific community that it is possible to correct mutations in the *RYR1* gene. This project paves the way for treating RYR1-related myopathies by gene therapy. These breakthroughs will significantly impact the treatment of other hereditary diseases. Indeed, this method can be applied to other genetic mutations, and in each case, only the pegRNA would need to be modified!

679. Systematic Off-Target Analyses of Base-Editing Therapeutic Leads Show Reduced Off-Target Editing, Reduced Bystander Editing, and Increased On-Target Editing by Hybrid Guide RNAs

Dominique L. Brooks[1], Madelynn Whittaker[1], Aidan Quigley[1], Ishaan Jindal[1], Rebecca Ahrens-Nicklas[2], Kiran Musunuru[1], William Peranteau[2], Xiao Wang[1]

[1]Cardiovascular Institute, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[2]Children's Hospital of Philadelphia, Philadelphia, PA

Phenylketonuria (PKU) and hereditary tyrosinemia type 1 (HT1) are autosomal recessive disorders linked to the phenylalanine hydroxylase (*PAH*) gene and fumarylacetoacetate hydrolase (*FAH*) gene, respectively. Potential therapeutic strategies to ameliorate disease include corrective editing of pathogenic variants in the *PAH* gene and, as a variant-agnostic approach, inactivation of the 4-hydroxyphenylpyruvate dioxygenase (*HPD*) gene, a modifier of

HT1, via adenine base editing. Here we evaluated the off-target editing profiles of therapeutic lead guide RNAs (gRNAs) that when combined with adenine base editors correct recurrent *PAH* variants or disrupt the *HPD* gene in human hepatocytes. To mitigate off-target mutagenesis, we systematically screened hybrid gRNAs with DNA nucleotide substitutions. Comprehensive and variant-aware specificity profiling of these hybrid gRNAs with OligoNucleotide Enrichment and sequencing (ONE-seq) identified certain hybrid gRNAs that dramatically reduced off-target editing and reduced bystander editing, while actually increasing on-target editing either *in vitro* or *in vivo*, e.g., in a humanized PKU mouse model treated with lipid nanoparticles (LNPs) with adenine base editor mRNA and a standard versus hybrid gRNA. These studies highlight the remarkable utility of hybrid gRNAs to improve the safety and efficacy of base-editing therapies. Moreover, they recommend a novel strategy for de-risking of LNP editing therapies: rather than the usual approach of assessing a standard gRNA by techniques such as ONE-seq, compiling a large list of nominated candidate genomic sites, and extensively analyzing the candidate sites for off-target editing in treated cells—instead using variant-aware ONE-seq to screen hybrid gRNAs and identify a hybrid gRNA that has preserved or improved on-target editing while reducing the number of nominated candidate off-target sites requiring further evaluation to a few or even zero.

680. Base Editor-Mediated Correction of a CSF1R Mutation That Causes ALSP

Jasna Metovic[1], Yedda Li[1], Christiano R. R. Alves[1,2], David Rufino-Ramos[1], Leillani L. Ha[1], Natalie Golovanov[1], Yi Gong[1], Benjamin P. Kleinstiver[2,3], Florian Eichler[1]

[1]Department of Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA,[2]Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA,[3]Department of Pathology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Adult Onset Leukodystrophy with Neuroaxonal Spheroids and Pigmented Glia (ALSP) is a rare, neurodegenerative, autosomal dominant disease caused by loss-of-function mutations in the colony-stimulating factor 1 receptor (*CSF1R*) gene located at 5q32 chromosome. CSF1R is a tyrosine kinase receptor, essential for regulating the proliferation and activation of microglial cells. There are currently no disease-modifying therapies, and supportive treatment is used to control some of the ALSP symptoms. CRISPR-based engineered base editor (BE) technologies have proven to be effective at correcting pathogenic point mutations by precisely editing DNA sequences without intentionally inducing DNA double strand breaks. Cytosine base editors (CBE) enable the efficient conversion of C to T in human cells when programmed with a guide RNA (gRNA) designed to target a specific locus. Here we explored the use of CBEs to correct a recurrent *CSF1R* c.2381 T>C mutation that causes a non-synonymous amino acid substitution, I794T, that leads to loss of CSF1R function. We designed various gRNAs that would position the CBE edit window over top of the CSF1R mutation and explored various established and recently engineered CBE constructs. Using a patient-derived fibroblast cell line bearing the *CSF1R*-I794T mutation, we performed nucleofections (Lonza) with plasmids encoding the CBEs and gRNAs to identify optimal CBE-gRNA pairs capable of efficient and specific mutation correction. The fibroblasts maintained normal morphology post-nucleofection. Importantly, we observed approximately 90% *CSF1R*-I794T correction with an optimized CBE-gRNA pair (using TadA-CBEd), substantially exceeding correction levels of 70% observed with a more conventional BE4max CBE construct. Most editing events included only the intended C>T substitution to correct I794T, with minimal unwanted bystander editing of other nearby cytosine bases. We anticipate that the genome editing tools hold great potential for precise gene correction in ALSP patients and will eventually allow for targeted treatment of this currently incurable and fatal disease. We are currently evaluating the genome-wide specificity of this approach, to gain insight into the long-term safety of these therapies *in vivo*. Continued development of this efficient and safe editing approach should benefit ALSP patients, with hope for favorable clinical outcomes for disease control, prevention, and cure.

681. Unconstrained Mitochondrial DNA Editing with Evolved TALE Proteins

Santiago R. Castillo[1], Karl J. Clark[1], Stephen C. Ekker[2]

[1]Mayo Clinic, Rochester, MN,[2]University of Texas at Austin, Austin, TX

The human mitochondrial genome is a 16,569 bp long, multicopy, circular double-stranded DNA (dsDNA) molecule that encodes 37 genes essential for cellular energy metabolism. Pathogenic mitochondrial DNA (mtDNA) variants are prevalent in ~1 in 8,000 people and are causal in incurable metabolic disorders. Current mtDNA editing strategies rely on all-protein systems, such as transcription activator-like effector (TALE)-based technologies. In general, these technologies are composed of a TALE, which acts as a programmable DNA-binding protein, fused to an effector domain. In particular, dsDNA deaminase A (DddA)-derived cytosine base editors (DdCBEs) consist of TALE-$DddA_{tox}$ fusions. Given its preference for dsDNA, $DddA_{tox}$, the deaminase domain of DddA, is split into two inactive halves to avoid toxicity. Thus, a DdCBE monomer incorporates either the N- or C-terminus of split $DddA_{tox}$ downstream of a TALE. In the context of DdCBE pairs, binding of their respective DNA-binding domains to adjacent target sequences enables the reassembly of functional $DddA_{tox}$, followed by targeted cytidine deamination. This process leads to programmed C•G-to-T•A conversions in mtDNA. Despite their robustness, the versatility of canonical DdCBEs is thought to be limited by the requirement of a thymine immediately upstream of their respective TALE target sequences. Following this conventionally accepted double 5'-T constraint (one per DdCBE monomer), about 12% of the human mitochondrial genome is theorized to remain inaccessible to canonical DdCBEs. Here, aiming to elucidate the relevance of the 5'-T constraint in the context of DdCBE-mediated mitochondrial base editing, and enable access to 100% of the editable motifs in the human mitochondrial genome, we generated DdCBEs containing TALE proteins engineered to bypass the 5'-T constraints, herein referred to as αDdCBEs. First, seeking to characterize the activity and specificity profiles of αDdCBEs relative to DdCBEs, we compared pairs of each type of editor in both 5'-T-compliant and 5'-T-noncompliant formats across multiple mtDNA loci accessible to both types of editors. Unexpectedly, we observed that DdCBEs are active even when they are 5'-T-noncompliant. Nonetheless, as hypothesized, 5'-T-noncompliant αDdCBEs tend to be significantly more active than 5'-T-noncompliant DdCBEs, reaching the same levels

of activity as 5'-T-compliant DdCBEs. Subsequently, we compared αDdCBEs and DdCBEs at *MT-TC* and *MT-TL1*, two mitochondrial loci considered to be inaccessible to DdCBEs. Remarkably, DdCBEs were as active as αDdCBEs at *MT-TC*, reaching editing efficiencies of up to 50% in HEK293T cells 3 days post-transfection. Nevertheless, at *MT-TL1*, αDdCBEs were more active than DdCBEs. Finally, seeking to optimize a base editing strategy for the installation of the pathogenic m.3242G>A variant in *MT-TL1*, we screened an array of αDdCBEs at this locus. Notably, all editors in this approach contained DddA11, an engineered $DddA_{tox}$ variant known to be highly active. Interestingly, we observed that sliding either one or both arms of an αDdCBE pair even just a couple of nucleotides led to dramatically distinct editing profiles. This screening approach resulted in the installation of the m.3242G>A pathogenic variant at about 50% editing efficiency with low bystander editing in HEK293T cells. In summary, αDdCBEs are generally better editors than DdCBEs, successfully bypassing the 5'-T constraint, which rather than being an absolute barrier for DdCBE-mediated mtDNA editing, acts as a limiting factor in most target loci. These observations support unconstrained mitochondrial base editing as a strategy for disease modeling and potentially gene therapy applications.

682. *In Vivo* Gene Editing Treatment of Alpha1-Antitrypsin Deficiency

Zi Jun Emma Wang

YolTech Therapeutics, Shanghai, China

Alpha-1 antitrypsin deficiency (AATD) is a rare genetic disorder that causes liver disease in children and adults, as well as lung disease in adults, and is mainly manifested as serum α1-antitrypsin (AAT) deficiency. AATD is most commonly caused by Z mutation, which results in the substitution of glutamic acid with lysine (Glu342Lys) and produce mutant proteins that are prone to misfolding and aggregation. To address lung and liver disease associated with AATD, gene editing drugs have focused on correcting Z mutation. YOLT-202 is an in vivo gene-editing therapeutic agent that is designed to treat AATD by increasing the concentration of AAT in serum. It is based on adenine base editor (ABE) system and comprises a lipid nanoparticle encapsulating messenger RNA for ABE and a single guide RNA targeting Glu342Lys of *SERPINA1*. Delivery of YOLT-202 into HepG2 cells resulted in 60% editing efficiency at position A7 at a dose of 30ng,which can correct Glu342Lys mutation. AATD Mouse serum ELISA data indicated a significant increase in serum AAT to 25 mg/mL at 7 days after a single dose (0.5 mg per kilogram and 2 mg per kilogram). There was no significant increase in alanine aminotransferase (alt) and aspartate aminotransferase (ast) at day 1,3,7 after infusion, indicating that YOLT-202 did not cause significant liver injury. Taken together, our findings suggest that YOLT-202, which can correct the Z mutation and restore the expression level of AAT in serum, can be effectively applied to the treatment of AATD.

683. Rescue of AAT-Z Mutant Protein Aggregation in PiZ Mice After Treatment with an LNP Delivered RNA Editing Oligonucleotide Targeting the E342k Mutation

Melissa Pink

Pharmacology, Korro Bio, Cambridge, MA

Alpha-1 antitrypsin (AATD) is a rare genetic disorder that results in abnormal protein aggregate formation within hepatocytes. The most prevalent mutation in humans for AATD is the Glu342Lys (also known as the E342K or Z) point mutation. Korro Bio is using an RNA editing approach to correct the E342K (G>A) mutation to target the Z allele. RNA editing is a natural physiological process that occurs in cells where a specific single base edit is mediated by an enzyme called Adenosine Deaminase Acting on RNA ("ADAR"). Korro Bio's RNA editing approach involves co-opting this endogenous editing system via a proprietary engineered oligonucleotide to introduce precise edits to RNA. To study the pharmacological activity of Korro Bio's LNP delivered oligonucleotide *in vitro* and *in vivo*, the PiZ transgenic mouse model of AATD liver disease was used. The livers of these mice have significant Z protein aggregation and secrete the mutant human Z-AAT protein into circulation. Invitro data demonstrated that an LNP delivered oligonucleotide can edit *in vitro* hepatocytes derived from PiZ mice. *In vivo,* sub chronic dosing resulted in editing of the E342K mutation that led to newly repaired M-AAT protein. The function of this protein was assessed in a neutrophil elastase (NE) inhibition assay. Data demonstrated that elastase inhibition correlated with the percent editing observed in the livers of the mice. These data support utilizing RNA editing to correct the mutated protein to achieve functioning AAT protein levels in PiZ mice and the potential to translate to similar results in AATD patients.

684. Novel and Efficient Base Editors Engineered to Comprehensively Target the Human Genome

Cristina N. Butterfield, Cindy J. Castelle, Kartik Lakshmi Rallapalli, Steve J. Flammer, Morayma Temoche-Diaz, Jin Wen Tan, Liliana Gonzalez-Osorio, Chia-Yao Lee, Michael L. Spelman, Emily C. Suter, Jared Muysson, Lisa M. Alexander, Daniela S. A. Goltsman, Christopher T. Brown, Brian C. Thomas

Metagenomi, Inc., Emeryville, CA

Base editors can knock out genes and correct pathogenic mutations with single nucleotide precision, making them promising tools for treating human diseases. Base editing systems consist of a programmable nickase fused to either a cytosine (CBE) or adenine deaminase (ABE) to catalyze site-specific nucleotide transitions. However, current systems cannot adequately address many disease indications due to efficiency and targeting limitations. Here, we used modular engineering to develop a flexible toolbox of efficient base editing systems from novel metagenomics-derived components. Base editor targeting ability was expanded by replacing the PAM interacting domain with variants that have different sequence preferences. Compared with first generation SpCas9 base editors, this platform has improved ABE human genome targeting potential from 18% to

95%, and CBE targeting potential from 15% to 53%. We demonstrated that this system can be used to efficiently knock out several genes for therapeutically-relevant editing of liver cells, and validated the system in vivo using mRNA and LNP delivery. Furthermore, we achieved efficient multiplexed gene editing and protein knockdown in primary T cells for cell therapy ex vivo applications, without impacting cell viability. By leveraging an expansive metagenomics database and rational and evolutionary protein engineering, we have developed ABEs and CBEs that significantly improve human genome coverage over SpCas9-based BEs, are highly efficient with minimal toxicity, and have demonstrated success with LNP delivery in vivo. This suite of highly active base editors has the potential to expand the scope of diseases that can be addressed, and accelerate the development of next generation genetic medicines.

685. Prospects and Challenges of CRISPR-Based Gene Editing of Tuberous Sclerosis Complex 2 Gene in Human Mesenchymal Stem Cells

Abdallah Salemdawod[1,2], Brandon Cooper[3], Yajie Liang[1], Piotr Walczak[1], Jaroslaw Maciaczyk[2], Miroslaw Janowski[1]

[1]Diagnostic Radiology and Nuclear Medicine, University of Maryland School of Medicine, Baltimore, MD,[2]Diagnostic of Neurosurgery, University Hospital Bonn, Bonn, Germany,[3]University of Maryland Greenebaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore, MD

Introduction: Tuberous sclerosis complex (TSC) is an autosomal dominant genetic disorder that results from a mutation in either the TSC1 or TSC2 gene and is characterized by the presence of vascular hamartomatous tumors in various organs. While epilepsy is the most challenging symptom and our long-term interest, an increasing involvement of TSC2 mutation in cancerous tumors is being unfolded. Moreover, the aberrant morphogenic signals originating from mesenchymal progenitors with TSC2 mutations underscore their significant involvement in the pathomechanism of TSC. This emphasizes the suitability of mesenchymal stem cells (MSC) as an initial target for genome editing interventions. Therefore, we sought to test the ability of novel CRISPR-based gene editing tools to introduce a very frequent point mutation in the TSC2 gene to human MSCs (hMSCs), as a basis for a future attempt to correct it through genome editing. **Methods:** We targeted a frequently reported point mutation affecting the TSC2 gene (1864C>T (p. Arg622Trp)) in hMSCs *in vitro*. The guide RNA sequences were designed using AI-based tools with a high predicted editing efficiency of 98% and a low off-target editing yield of 1 potential unwanted SNP edit. Lipofectamine was used for co-transfection of gRNA with the base editor in the form of ribonucleoprotein (RNP) or mRNA. The editing efficiency was quantified using Sanger sequencing. **Results:** RNP scored an impressive 47% editing efficiency, while the performance of mRNA was three times lower but still satisfactory at 15%. In both cases, each on-target edit was consistently accompanied by one off-target edit within the site. **(Figure 1)**. **Conclusions:** Relatively high, double-digit efficacy of CRISPR-based editing of the TSC2 gene in hMSCs is feasible *in vitro* using clinically applicable strategies such as transfection. One unexpected and unpredicted off-target edit was observed within the PAM site but with very high consistency. Whole genome analysis is needed to detect all off-target edits. Furthermore, AI prediction of editing efficiency and off-target yield appears to be based on the genomic structure but does not consider the characteristics of the targeted cell population. In summary, CRISPR-based gene editing is a promising strategy for the treatment of tuberous sclerosis.

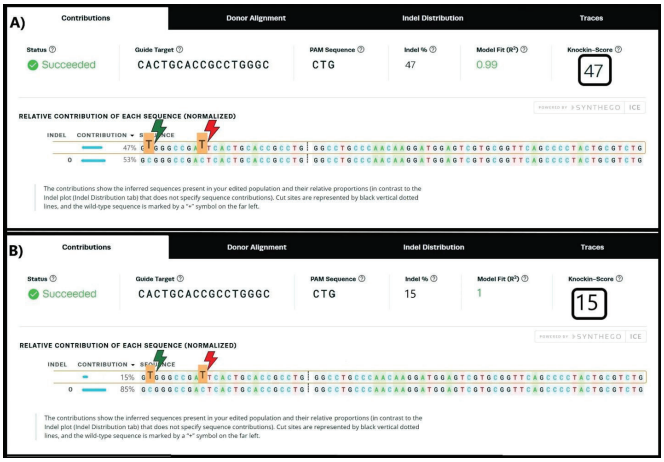

Figure1: A) ICE analysis of the sequenced amplicons form gene-edited MSCs using Cas9-RNP, showing an editing efficiency of 47% of C>T (Orange) for both on-target (green spark) and off-target (red spark) regions within the PAM-site. **B)** ICE analysis of the sequenced amplicons form gene-edited MSCs using Cas9-mRNA, showing a lower editing efficiency of 15% of C>T (Orange) for both on- target (green spark) and off-target (red spark) regions within the PAM-site.

686. Quantifying Prime Editing Kinetics - Timelapse Fluorescence Data and Model Inference

Nathalie Gabriele Schaeffler[1], Julian Geilenkeuser[2], Dong-Jiunn Jeffery Truong[2], Gil Westmeyer[2], Joachim Rädler[1]

[1]Faculty of Physics, Ludwig-Maximilians-Universität München, Munich, Germany,[2]Institute for Synthetic Biomedicine, Helmholtz Zentrum München, Oberschleißheim, Germany

Prime Editing (PE) enables a precise “search and replace” of gene elements to cure many gene and cell based diseases [1]. While current research focuses predominantly on enhancing its efficacy, the kinetics of PE remain underexplored. We study the kinetics of pDNA and mRNA based delivery of PE protein and pegRNA. As a reporter system, we use HEK293T cells, which constitutively express a blue-shifted mGreenLantern (bs-mGL) protein. Two proximal base edits on a single pegRNA are sufficient to revert it to the original mGreenLantern (mGL) sequence. Transfection of the PE system induces these edits, restoring the expression of the original mGL protein. Using automated single cell timelapse imaging (LISCA [2]), we record the time-to-edit and the onset distributions (see Fig. 1A) and model this edit process mathematically using the Julia programming language. We split the PE process into three steps: the delivery of the PE components, the expression of these and the editing process itself (see Fig. 1 B-D).

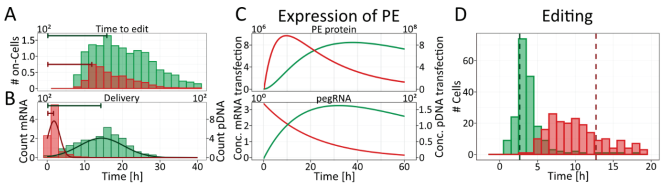

Fig 1: Graphical representation of PE kinetics (A) Time to edit: From transfection to onset of mGL fluorescence for pDNA(green) and mRNA(red) (B) Time from transfection till release of pDNA(green) and mRNA(red) based delivery (C) Concentration-Time courses inferred from the model for PE protein and pegRNA starting from either pDNA(green) or mRNA(red). (D) Editing time: Time between detected expression of PE protein and detected edit for different pegRNAs ($mean_{short}$ = 2.64h, $mean_{long}$ = 12.7h).

In order to estimate the parameters of the mathematical model, we performed additional, independent experiments. For the first step, delivery with mRNA or pDNA, we transfect the cells directly with mGL encoded in pDNA and mRNA and record a mean delivery delay of 14.5h (pDNA) and 1.4h (mRNA). For the second step, the expression of the PE protein and pegRNA, we simulate these with kinetic rate equations. The parameters for this were measured through experiments as explained in the literature [3]. These simulations show a slower onset for pDNA than mRNA, but higher end concentrations. Lastly, for measuring the third step, i.e. the editing time from expressed PE Protein to completed edit, we again use HEK293T cells with bs-mGL. In this iteration, a P2A-mScarlet3 region is added to the PE2 plasmid following a plasmid design from David Liu [4]. We now image the expression of both, PE2 via mScarlet and the edit via mGL, per cell and can therefore determine the time between mScarlet and mGL onset for pegRNAs. These pegRNAs target the same edit (bsmGL to mGL), but differ in edit length inside the Reverse Transcriptase template ($edit_{short}$ = 6bp, $edit_{long}$ = 21bp) . The mean editing time is 2.64h and 12.7h respectively. In summary, using experiments and modelling, we are able to extract the kinetics of single cell prime editing events. The time-to-edit consists of the delivery time, the protein expression and the editing time itself, which is influenced by the pegRNA design and can range from 2h for short edits up to several times that for longer edits. This matches with prior findings on DNA-strand replacement that showed how length and mismatches affect the duration of this process [5]. Our work shows that kinetic data combined with mathematical modelling can help to optimise pegRNAs and PE efficacy in silico, which may guide experimental screens in the future. 687. Highly Efficient Base Editing of Homozygous and Heterozygous COL7A1 Variants in RDEB Patients' Fibroblasts Using ABE8e mRNA System Delivered via Novel LNP Formulations

Joanna Jackow-Malinowska[1], Ina Guri[1], Imogen R. Brooks[1], Yara Alrokh[1], Aidin Kazamizadeh[1], Carina Graham[1], Stephen L. Hart[2], John McGrath[1]

[1]King's College London, London, United Kingdom,[2]UCL Great Ormond Street Institute of Child Health, London, United Kingdom

Introduction and aim: Adenine base editors (ABEs) present an attractive approach to gene editing in the inherited blistering disease, recessive dystrophic epidermolysis bullosa (RDEB), which results from pathogenic variants in *COL7A1*. We previously showed that ABE8e, a new variant of ABE, confers remarkable efficiency (94.6%) and a favourable safety profile in correcting variants and restoring collagen 7 (C7) expression when electroporated into RDEB fibroblasts. With a goal to develop topical base editing creams, we now explore use of lipid nanoparticle (LNP)-encapsulated ABE8e mRNA system to edit two distinct variants in RDEB fibroblasts. **Methods:** Primary patient fibroblasts harboring a homozygous G>A mutation (exon 42) or a heterozygous C>T mutation (exon 54) were gene edited using ABE8e mRNA, delivered via lipofectamine or six different LNPs. To assess the gene editing efficiency, Sanger Sequencing and NGS methods were employed. Cell viability was evaluated via an LDH cytotoxicity assay, while functional restoration of C7 expression was assessed via western blotting of cell lysate and supernatant. Finally, topical delivery was tested on normal human skin equivalents (HSEs). **Results:** We identified an optimal ratio of 1:7 for sgRNA:ABE8e, at which editing efficiency increases with ABE8e dosage, with 400ng being sufficient for 90% bi-allelic editing. Formulations containing DTDTMA (C14) and DHDTMA (C16) LNPs demonstrated ~90% and ~80% editing, with and without the peptide, respectively, as well as reduced cytotoxicity compared to lipofectamine. Depending on the nature of the mutation, the edit corresponded to an increase in C7 expression in supernatant only or cell lysate as well, whereby C14 LNPs enabled two-fold C7 restoration. Finally, our HSEs demonstrated viability of topical delivery of lipofectamine-encapsulated GFP mRNA. **Conclusions:** We demonstrated the potential value of base editing as a gene therapy for RDEB as well as of these LNPs for clinical translation of the therapy. Nonetheless, further safety and functionality tests are to be carried out.

688. Innovative Transformer Base Editor (tBE)-Mediated Undetected Off-Target Base Editing and Its Potential Clinical Applications for Unmet Medical Needs

Lijie Wang[1], Peixue Li[1], Lang Zhang[1], Yichuan Wang[1], Zhuoan Cheng[1], Yan Zhang[1], Runni Guo[1], Hongxia Ma[1], Kewei Lan[1], Huiming Zheng[1], Di Zhu[1], Jinyan Zuo[1], Yuchen Zhang[1], Jing He[1], Qing Su[1], Xiaodun Mou[1], Jia Chen[2]

[1]CorrectSequence Therapeutics Co., Ltd, Shanghai, China,[2]ShanghaiTech University, Shanghai, China

The fusion of CRISPR-Cas9 with cytidine deaminases leads to base editors (BEs) capable of programmable C-to-T editing without DNA double strand break (DSB), which has potential in clinical applications but suffers from off-target (OT) mutations. Here, we used a cleavable deoxycytidine deaminase inhibitor (dCDI) domain to construct a transformer BE (tBE) system. After the colocalization of paired hsgRNA and msgRNA on genomic DNA, the assembled TEV protease cleaves the mA3dCDI off and mA3CDA1 is activated, which induces efficient and precise base editing at the on-target site. The tBE system could induce efficient editing with no detected genome-wide and transcriptome-wide OT mutations and avoid cell apoptosis and chromosomal abnormalities triggered by DNA DSB. It holds great potential in therapeutic applications, including previously undruggable targets due to its highly efficient on-target editing and undetected off-target mutations. Hematopoietic stem cells (HSCs) and T cells can

be edited by tBE *ex vivo* for the treatment of hematological diseases. Here we show that tBE could edit *HBG1/2* promoter region in the CD34+HSCs to trigger the reactivation of fetal hemoglobin (HbF) to treat transfusion-dependent β-thalassemia (TDT) patients. Due to the safety advantages of tBE, it can edit the most potent target site to trigger the highest HbF expression when compared with other CRISPR-based gene editing therapies. And tBE could edit multiple sites simultaneously without causing off-target mutations or chromosomal translocation in T cells to enhance its efficacy or reduce its immunogenicity for the next generation Chimeric antigen receptor T-cell (CAR-T) therapies development. Besides, we have demonstrated LNP and AAV delivery of tBE to disrupt *PCSK9 in vivo* in mice via introducing a premature stop codon, indicating that tBE could flexibly adapt to various *in vivo* delivery vehicles for liver-targeted gene editing therapy, such as hypercholesterolemia. Furthermore, tBE could precisely introducing several nonsense mutations simultaneously to silence Hepatitis B viral genes, enabling sustained reduction of the three major Hepatitis B viral (HBV) markers, HBsAg, HBeAg and HBV DNA *in vitro*. The above data all demonstrate the great potential of tBE for the treatment of various disease including blood disorders, metabolic diseases, and infectious diseases. tBE could be a powerful tool in developing novel therapeutic approaches for unmet medical needs.

689. Prime Editing for Correction of GATA2 Deficiency in Human CD34+ Hematopoietic Stem Cells

Jonas H. Wolff[1], Thomas W. Skov[1], Sofie R. Dorset[1], Anne Louise S. Revenfeld[2], Didde Haslund[2], Mette Holm[3,4], Trine H. Mogensen[1,5], Bjarne K. Møller[2], Rasmus O. Bak[1], Jacob G. Mikkelsen[1]

[1]Department of Biomedicine, Aarhus University, Aarhus, Denmark,[2]Department of Clinical Immunology, Aarhus University Hospital, Aarhus, Denmark,[3]Department of Paediatrics and Adolescent Medicine, Aarhus University Hospital, Aarhus, Denmark,[4]Department of Clinical Medicine, Aarhus University Hospital, Aarhus, Denmark,[5]Department of Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark

Ex vivo gene editing of autologous human hematopoietic stem cells is being developed as a treatment for inborn errors of immunity (IEIs). However, the current gene editing platform relying on Cas9-directed DNA cleavage and the use of rAAV6 as a donor for homology-directed repair is challenged by indel formation, off-target DNA cleavage, and toxicity in hematopoietic stem cells. Thus, there is a need for improved genome editing strategies in hematopoietic stem cells that do not require delivery of a DNA donor template and act without generating DNA double-strand breaks (DSB). Here, we present work using the DSB-independent prime editing technology to correct a patient-derived 7 bp deletion in the *GATA2* gene causing GATA2 deficiency, which can cause immunodeficiency, bone marrow failure, and increased risk of leukemia. We screened several prime editing guide RNAs (pegRNAs) as well as nicking sgRNAs (ngRNAs) to efficiently correct the 7 bp deletion, and we found that editing efficiencies were highly dependent on the ngRNA, resulting in prime editing rates in model K562 cell lines that varied between 20% and 80%. We then aimed at establishing efficient prime editing in CD34+ hematopoietic stem and progenitor cells (HSPCs). Initial attempts using *in vitro*-transcribed PEmax mRNA in combination with synthetic pegRNAs and ngRNAs resulted in low editing efficacies. However, using enhanced pegRNAs (epegRNAs) as well as optimizing nucleofection conditions, mRNA structure and epegRNA:ngRNA ratios, we were able to achieve efficient prime editing of up to 60% of *GATA2* alleles in CD34+ HSPCs from healthy donors as well as in patient-derived HSPCs. Furthermore, we investigated the fitness of the CD34+ HSPCs following editing using either prime editors or conventional HDR-based gene editing. While prime editing generally resulted in less editing than conventional HDR-based gene editing, prime-edited HSPCs showed superior viability and proliferation. Furthermore, as opposed to RNP nucleofection and AAV transduction, which led to a 2-fold decrease in colony forming units (CFUs) compared to mock-treated HSPCs, prime-edited HSPCs showed no significant decrease in CFU potential. We are currently investigating the potential of prime-edited patient-derived CD34+ HSPCs to engraft in immunodeficient mice. We are also investigating off-target editing as well as potential adverse on-target genomic alterations using long-read sequencing. Together, our preliminary results indicate an increased fitness compared to traditional CRISPR-based gene editing approaches, supporting the further exploration of prime editing to treat IEIs.

690. Induction of HbF Using Improved CRISPR-Cas12a Base Editor

Stefano Stella[1], Haixia Wan[2], Alex Perez[1]

[1]Ensoma, Copenahgen, Denmark,[2]Ensoma, København N, Denmark

Base editing is a minimalist gene editing system that can induce precise base conversions within the target DNA. It includes a catalytically impaired Cas protein and a DNA-modifying enzyme. The most widely used base editors contain a nickase variant of Cas9 that binds and cleaves one strand of the target DNA and this nicking activity is necessary for efficient base editing. CRISPR-Cas12a is a type V CRISPR system containing a single DNA cleavage site where Cas12a undergoes protein rearrangement to sequentially bring each strand of the DNA target into the catalytic pocket to be cleaved. Thus, generating a highly efficient nickase enzyme with Cas12a scaffold can be challenging. However, given its multiplex capability and high specificity, Cas12a stands out as an appealing scaffold for developing a safe and easy-to-deliver gene editing system. At ENSOMA, using a structurally guided approach, we have generated and screened thousands of Cas12a variants to develop an Engenious™ base editing platform that induces high level of base editing, maintaining the multiplex ability and the high specificity of the Cas12a scaffold without cutting any strand of the DNA target. We have used our base editing approach to induce high level of fetal hemoglobin production.

691. Chemically Controlled Base Editors for Precise Gene Editing *In Vivo*

Xue Gao

University of Pennsylvania, Philadelphia, PA

DNA base editors use deaminases fused to a programmable DNA-binding protein for targeted nucleotide conversion. However, base editors often cause a broad range of off-targets, including the most widely used TadA deaminases. Here, we present two chemically controlled methods that utilize chemically induced dimerization (CID)

to control the catalytic activity of the deoxyadenosine deaminases. Our results show high on-target editing activity upon small molecule induction while maintaining low background activity without induction. Importantly, the chemically controlled base editing systems have reduced genomic and transcriptomic off-target effects. When delivered via dual adeno-associated virus vectors, we also efficiently convert a single A•T base pair to a G•C base pair on the *PCSK9* gene in mouse liver, demonstrating in vivo CID-controlled DNA base editing. Thus, our systems demonstrate precise control of base editing, which will have broad implications for basic research and in vivo therapeutic applications.

692. Developing a Novel Adenine Base Editor Tool for *In Vivo* Alpha-1 Antitrypsin Deficiency Gene Correction

Jenny Gao
RNA Therapeutics Institute, Worcester, MA

Background: Alpha-1 antitrypsin deficiency (AATD) is most commonly caused by a G-to-A mutation in the *SERPINA1* gene (PI*Z mutation), which encodes AAT protein, an abundant serum serine proteinase inhibitor. AAT is synthesized by hepatocytes and delivered via serum to the lung, where it neutralizes neutrophil elastase. Patients with AATD are at an increased risk of liver disease due to mutant protein aggregation and lung emphysema due to elastase overactivity. Adenine base editor (ABE) consists of an adenine deaminase (TadA) conjugated to a Cas9 nickase, mediating A to G base editing within a defined editing window. While ABEs based on *Streptococcus pyogenes* Cas9 (SpCas9) have been used to correct the PI*Z mutation, they were too large for efficient therapeutic delivery via a single adeno-associated virus (AAV) due to the SpCas9 protein size. Using a compact, evolved Cas9 nickase derived from *Neisseria meningitidis* (eNme2-C) that can be packaged using a single AAV, we assessed its editing efficiency at the PI*Z site. Not only was there high editing efficiency, but bystander editing rates can be decreased depending on the TadA deaminase used. **Methods:** The HEK293T PI*Z reporter cell line was generated by transduction of HEK293T cells with lentivirus carrying a plasmid encoding for the Z-AAT coding sequence followed by puromycin selection. To test the editing efficiency of ABEs in editing the AAT site, we transfected the PI*Z reporter cell line with plasmids and quantified editing efficiency by targeted amplicon deep-sequencing. The transgene was packaged into AAV8 and injected into PI*Z mice via tail vein at 9 x 10^{11} vg. Animals were sacrificed eight weeks after treatment. Five liver biopsies were taken per animal and the PI*Z site was sequenced using by targeted amplicon deep-sequencing. Two lobes were taken per animal to perform PAS-D staining. Sex-, age-, and weight- matched PI*Z mice were used as controls. **Results:** An all-in-one eNme2-C ABE8e/guide 2 plasmid achieved approximately 20% on target editing in HEK293T PI*Z cells, with bystander editing rates reaching as high as 12.83% depending on the adenine position (n=3). To minimize bystander editing, we used ABE9e, which has a narrower editing window than its predecessor, ABE8e. Indeed, eNme2-C ABE9e/guide 2 displayed lower bystander edits compared to ABE8e while maintaining high on-target editing. Its on-target editing rate averaged 21.08% while the highest bystander rate was 9.06% (n=3). An all-in-one eNme2-C ABE9e/guide 2 AAV was administered to PI*Z mice using AAV8 and showed approximately 30% editing efficiency after 8 weeks. PAS-D staining revealed a decrease in PAS-D^+ area and increase in PAS-D^- cells in treated mice compared to control mice. **Conclusions:** We demonstrated the feasibility of an eNme2-C based ABE in single AAV to edit the PI*Z site. ABE9e showed high on-target edits with low bystander edits. Moreover, it was able to decrease PAS-D^+ globules in PI*Z mice. Future work would focus on assessing the therapeutic threshold needed to prevent lung emphysema development.

693. *In Vivo* Dual AAV Split Prime Editing Mediated Correction of Pathogenic *Ppp2r5d* Mutations in Mouse Brain

Isaac J. Villegas, Rency Dhaduk, David L. Cameron, Julian Halmai, Kyle D. Fink
Department of Neurology, University of California Davis Health Systems, Sacramento, CA

PPP2 syndrome type R5D or Jordan's syndrome is a rare monogenic form of intellectual disability that arises from *de novo* missense mutations that occur within protein phosphatase 2, regulatory subunit B' delta (*PPP2R5D*, OMIM 601646). *PPP2R5D* encodes an isoform of the regulatory B subunit, B56δ, for the protein phosphatase 2A (PP2A) holoenzyme that is enriched within the brain. As an essential serine/threonine phosphatase, PP2A plays a significant role in regulating phosphorylation across many cell signaling pathways. Whole exome sequencing from patients has previously identified 16 unique pathogenic variants spanning *PPP2R5D*, with clusters of mutations identified in exons 5, 7, and 12. Within the current patient population, the two most prevalent variants that comprise ~50% of known cases, p.E198K and p.E200K respectively, are both caused by G>A transition mutations and reside in exon 5. To date, there are no disease-modifying treatments available for patients. Prime editing is a novel genome editing tool that offers a unique advantage over previous CRISPR/Cas9 technologies since it does not require the generation of double-strand breaks or the use of exogenous donor DNA templates. Additionally, previous work has demonstrated its ability to function in non-dividing cells, such as neurons. Therefore, we employed prime editing mediated gene correction as a novel therapeutic intervention for Jordan's syndrome. In our study, we designed enhanced prime editing guide RNAs (epegRNAs) that target and edit *Ppp2r5d*. Initial epegRNA screens using PE2max generated <1% editing. Incorporating an additional nicking gRNA (PE3max) generated a 28-fold increase in editing at the *Ppp2r5d* locus. We further optimized our epegRNAs by evaluating various reverse transcription templates and primer binding site lengths. Utilizing our optimized epegRNAs targeting *Ppp2r5d*, we demonstrate up to 20% editing efficiencies with minimal insertions or deletions (indels) detected in mouse Neuro2A cells. Moreover, a current drawback in utilizing prime editing systems for *in vivo* applications is the size of the prime editing components. With a minimum size of ~6.3 Kb, prime editors surpass the packaging capacity of gold-standard delivery vehicles such as adeno-associated virus (AAV). Therefore, to overcome the packaging capacity limitations of AAV and evaluate *in vivo* prime editing of *Ppp2r5d*, we developed an intein-split prime editing system that is within the packaging capacity of two AAV genomes. Utilizing novel murine models of Jordan syndrome that contain the human equivalent mutations, p.E198K and p.E200K respectively, we demonstrate in vivo correction of pathogenic *Ppp2r5d*

mutations in mouse brain. In summary, we establish prime editing as a corrective approach to target pathogenic disease-associated mutations within the central nervous system.

Wednesday Posters: Epigenetic Editing and RNA Editing

694. CasMINI-Mediated CRISPR Epigenome Editing for Cell Type-Specific Manipulation of Gene Expression

Mikah Green, Nikhil Hajirnis, Eric Choi, Ramesh Chandra, Shanmugasundaram Ganapathy, Mary Kay Lobo

Department of Neurobiology, University of Maryland School of Medicine, Baltimore, MD

CRISPR epigenome editing, using CRISPR-activation or CRISPR-interference (CRISPRa/i) allows for more physiologically relevant manipulation of gene expression. Previously, our lab has used Cas9 derived CRISPRa/i epigenome editing tools and light-inducible Opto-CRISPRa/i tools in Neuro2A cells to manipulate a transcriptional program that was altered in specific neuronal populations in the brain following exposure to an addictive substance. Recent advances in CRISPR have paved the way for using a Cas12f derived system (CasMINI) instead of Cas9. The advantages of this system are twofold - First, dead (d)CasMINI is less than half the size of dCas9 allowing for packaging in adeno-associated viruses (AAVs) instead of the previously used lentiviruses. Further, this smaller construct allows the possibility of including multiple guide constructs for manipulation of multiple genes at the same time. We are utilizing a CRISPRi system in which a KRAB domain is fused to dCasMINI, and a CRISPRa system in which VP64 is fused to dCasMINI. These constructs are paired with a dCasMINI-compatible guide RNA (gRNA) construct. With this system, we target hub genes previously found to be upregulated and downregulated in significant gene network modules in mouse brain neuron stubtypes following forced abstinence from fentanyl. We have validated for the first time in Neuro2a cells that the dCasMINI fusion genes can express at the mRNA and protein level. We have also shown that both the dCasMINI-KRAB & dCasMINI-VP64 constructs paired with gRNA can successfully downregulate and upregulate targeted gene expression levels, respectively. We are currently validating the light-inducible Opto-dCasMINI system for temporal-specific control of gene expression. For this platform, dCasMINI is fused to CIBN and KRAB or VP64 are fused to Cry2. Prior to light stiumation, the gRNA construct recruits dCasMINI-CIBN to the targeted gene locus and upon light stimulation, CIBN & Cry2 fuse, recruiting transcriptional regulator (VP64 or KRAB) to the promoter region of the target gene. The potential to use these tools to alter transcription of specific gene(s) in a cell type-specific manner in the brain will allow routine use of AAV CRISPR epigenome editing tools in vivo.

695. CRISPR-Mediated *Reln* Knockdown Disrupts Striatal Physiology and Cocaine Reward

Kasey Lynn Brida[1], Emily T. Jorgensen[1], Morgan E. Zipperly[1], Robert A. Pillips[1], Cathy E. Newman[1], Jennifer J. Tuscher[1], Kelsey Montgomery[2], Kristen R. Maynard[3], Keri Martinowich[2], Jeremy J. Day[1]

[1]Neurobiology, University of Alabama at Birmingham, Birmingham, AL,[2]Lieber Institute for Brain Development, Baltimore, MD,[3]Lieber Institute for Brian Development, Baltimore, MD

Reelin is a large, secreted glycoprotein with a well-characterized role in brain development and links to numerous neuropsychiatric disorders. While Reelin is abundant in the adult striatum, Reelin's functional role in this brain region remains poorly characterized. Using a recently generated cellular atlas of the rat nucleus accumbens (NAc) following cocaine experience, we identified *Reln* mRNA as a marker of cocaine-responsive *Drd1*+ medium spiny neurons (MSNs). Here, we sought to define Reelin's role in striatal functions, and to determine its contribution to cocaine behavioral response. We designed a CRISPR sgRNA targeting the *Reln*promoter to enable repression of *Reln* transcription with CRISPR interference (CRISPRi). We demonstrate minimal off-target effects in primary striatal neurons and efficacious *Reln* knockdown in vivo. To assess if *Reln* serves as a passive marker of cocaine-sensitive cells or facilitates cocaine response, we performed conditioned place preference following targeted *Reln* knockdown in the NAc. Compared to non-targeting gRNA controls, *Reln* knockdown animals had no preference for the cocaine-paired chamber. To understand Reelin's role in regulating activity in the NAc, we used whole-cell patch clamp following *Reln* knockdown. While we saw no changes in passive membrane properties or action potential properties, cells lacking *Reln* exhibited decreased intrinsic excitability and an inability to maintain sustained firing. Single-nucleus RNA-sequencing of the NAc following *Reln* knockdown reveals changes in the expression of genes important for maintaining calcium homeostasis and provide direction for future pharmacological assays. Together, these results reveal a key role for Reelin in striatal function and cocaine reward. Ongoing studies are modifying this CRISPRi strategy to be compatible with an adeno-associated virus delivery system for application in animal models and human-derived neuronal cultures.

696. The Integration of High-Resolution, Genome-Scale Epigenetic Mapping with Epigenetic Editing Technology Enables Precise Epigenetic Engineering of Cells

Rigel Joseph Kishton, Sam Gross, Pedro Mendez, Nien-Chen Wang, Nicholas P. Restifo, Justin Valley, Arash Jamshidi, Alex Aravanis

Moonwalk Biosciences, South San Francisco, CA

DNA methylation is prominent in determining cell type and is implicated in many disease processes. However, methylation states for most of the CpG sites in the human genome (~30 million sites) have never been measured for most cell-types. This has limited the field's ability to fully understand epigenetic biology and explore treatment modalities based on epigenome engineering. Here we describe for

the first time an epigenome engineering platform to enable complete, high-resolution single-cell mapping of the methylome in conjunction with targeted methylation modifications, a set of complementary technologies named EpiRead™ and EpiWrite™ respectively. The adoption of DNA sequence-targeted nucleases such as CRISPR/Cas, TALENS and ZFNs has mediated a new era of precise genome engineering, with novel therapeutic strategies for a variety of human diseases and disorders entering the clinic. Additional genome engineering strategies designed to confer higher degrees of editing specificity and limit the enzymatic cutting of DNA such as base editing, PRIME editing and epigenetic editing each exhibit great potential as therapeutic modalities. Epigenetic editing is a novel strategy to alter the phenotypic properties of cells or tissues through directed modifications of non-genetically encoded regulators of gene expression, such as histone acetylation and methylation or DNA methylation. Unlike traditional gene editing approaches which require cutting of DNA, epigenetic editing can be utilized to increase or decrease the expression of target genes, allowing for increased control over cell properties. Despite the considerable promise of epigenetic editing, current approaches often rely on targeting known genes through manipulation of gene promoters. The ability to both identify disease-specific epigenetic cell states and utilize targeted epigenetic editing techniques to modify cell epigenomes would have several advantages, including increased precision and specificity of epigenetic editing, the expansion of the target space for epigenetic editing to encompass regulatory regions of the genome such as enhancers and non-coding RNAs, and improvements to understanding the safety and off-target profile of epigenetically editing interventions. Further, enhanced understanding of the epigenetic biology of disease states may allow for rationally designed multiplex editing strategies to further enhance therapeutic benefit. Here we describe our development of dual, complementary technologies to enable high resolution epigenetic mapping in conjunction with targeted epigenetic editing. Our epigenetic mapping technology, referred to as EpiRead™, encompasses high resolution whole genome analysis of DNA methylation states, with the utilization of machine learning/artificial intelligence (ML/AI) to precisely identify and categorize cellular epigenetic states at single cell resolution. In parallel, we have developed EpiWrite™, a modular epigenetic editing technology that allows for the precision targeting of epigenetic edits to desired regions of the genome. We demonstrate the utilization of EpiRead™ and EpiWrite™ in the context of epigenetically editing primary human T cells, with epigenetic mapping-informed usage of EpiWrite™ to silence T cell genes in multiplex. We further show the increased utility of whole-genome epigenetic mapping of DNA methylation relative to commonly performed microarray based methylation platforms in characterizing the impact of epigenetic editing. Finally, we describe our utilization of EpiRead™ to create epigenetic maps of human T cell subsets, including the surprising finding that the in vitro differentiation of both CD8+ and CD4+ T cells does not recapitulate the epigenetic state of corresponding *in vivo*-derived subsets.

697. Tuned Upregulation of Diverse Gene Targets Using Programmable Epigenomic Controllers

Jeremiah Farelli, Chevaun Morrison-Smith, Marcus Gibson, Mayur Gurnani, Prachi Dhanania, Stephen Siecinski, Yaoyu Wang, Justin Chen, Adam Katz, Houda Belaghzal, Giuliana Coatti, Charles O'Donnell, Thomas McCauley

Omega Therapeutics, Cambridge, MA

Epigenetic mechanisms mediate DNA sequence and homeostatic gene expression, with dysregulation at this pre-transcriptional interface found at the root of myriad diseases. Therapeutic modulation of the epigenome presents a unique opportunity to leverage endogenous mechanisms for pre-transcriptional control of gene expression, avoiding biological and developmental hurdles inherent with existing modalities. Omega Therapeutics, a clinical-stage biotechnology company, has developed a modular platform for design of programmable mRNA therapeutics enabling precision epigenomic control of expression of single or multi-gene targets. Leveraging 3D chromatin architecture, we model cell-type- and context-specific epigenetic regulatory sites within conserved chromatin loop structures termed Insulated Genomic Domains (IGDs) to rationally design epigenomic controllers (ECs). ECs are mRNA-encoded proteins that target the epigenome with exquisite specificity for tunable and durable effect persisting after degradation of the mRNA product - decoupling pharmacokinetics (PK) and pharmacodynamics (PD) for an improved safety profile relative to existing modalities. ECs consist of one or more protein domains (effectors) selected from a validated library and tethered to custom, site-specific DNA-binding-domains to induce a desired regulatory effect. This fusion is optimally encoded in an mRNA therapeutic producing one or several effector-DBD fusion proteins, delivered tissue-specifically using custom lipid nanoparticles (LNPs). Complementing Omega platform ECs that have demonstrated durable gene downregulation for multiple months, here we demonstrate platform capabilities to up-regulate gene expression across a diverse set of gene types, spanning a broad spectrum of conditions. This includes (1) genes that have been inactivated in a cell type of interest, (2) activated but lowly-expressed genes whose augmented up-regulation would lead to therapeutic benefit, and (3) genes whose activation or further up-regulation is gated by regulatory processes awaiting stimuli or their cis regulatory elements (cRE). For cases (1) and (2), we have designed a library of effectors, rationally targeted these effectors to impact regulatory DNA sites within the IGDs of multiple genes, demonstrating expected epigenetic state change and resulting tunable increases in both transcription (fold-change) and duration of effect long after EC degradation. This includes the application of a human gene-targeting EC shown to maintain ≥2-fold upregulation through 55 days in K562 cells, while culture conditions could be maintained. In the context of case (3) we demonstrate the EC-driven epigenetic activation of distinct targets through modulation of cis-regulatory elements and by modulation of chromatin looping factors and IGD state change. Finally, we demonstrate the capability of an Omega EC to durably downregulate a gene of interest and then, using a different EC, to reverse the effect in the same cells, restoring expression of the gene.

Development of such a generalizable approach to epigenomic tuning and upregulation of a target gene enables broad application across a range of therapeutic targets and disease conditions.

698. Design and Characterization of Compact and Precise Cas Enzymes for Treating Diseases in Patients

[1]EpiC-BIO, South San Francisco, CA,[2]Department of Bioengineering, Stanford University, Stanford, CA,[3]ChEM-H, Stanford University, Stanford, CA,[4]Chan Zuckerberg Biohub, San Francisco, CA

Genome and epigenome editing each hold immense potential for making targeted, precise corrections to either our genes' sequences or how they are expressed, clearing new and accelerated paths toward therapies for previously untreatable diseases. However, there remain significant barriers to realizing this potential including the development of genome and epigenome editing tools that are both highly precise and have broad targeting scopes. By combining the precision and broad targeting potential of CRISPR-Cas enzymes with novel regulators of gene expression, Epic Bio's epigenetic editing platform is at the forefront of gene therapy to mitigate and reverse diseases that are beyond the reach of traditional genome editing. Our Cas engineering platform has led to the discovery of highly compact nuclease-deficient dCas enzymes, thus enabling efficient delivery by AAV due to their small sizes (one-third the size of SpyCas9), and avoiding double-strand breaks or permanent edits. All clinical applications of Cas-based genome engineering are constrained by the requirements for protospacer-adjacent motifs (PAM) in the target DNA. Importantly, our novel dCas enzymes display flexible PAM requirements and are easily programmed to target therapeutic genes, underlining their broad utility. Here we present a novel cellular assay for PAM characterization that comprehensively and quantitatively captures the PAM requirements of dCas enzymes in human cells. This assay enables accurate detection of greatly expanded PAM profiles for our lead dCas enzymes (dCasONYX, dCasRUBY, dCasTOPAZ), enabling the efficient targeting of disease-causing genes. This assay enables ongoing engineering and deep characterization of our novel dCas in relevant genomic contexts to facilitate their translation to therapeutics. Altogether, we present our work to optimize compact and precise Cas molecules at the core of our epigenetic editing platform and demonstrate their broad utility, representing a major advancement toward treating intractable diseases in patients.

699. Revolutionizing Safe Gene and Cell Therapy by Precise Epigenome Editing

Lei Stanley Qi

Bioengineering, Stanford University, Stanford, CA

The precise control of the epigenome is key to advancing gene and cell therapies for diseases beyond the scope of gene editing. While we have witnessed a rapid revolution in biotechnological advances towards gene therapy via gene editing, major challenges remain due to limited scope of disease indications and potential permanent editing side-effects. To address these critical challenges, we focus on the discovery of novel technologies that allow precise engineering of human epigenetics beyond gene editing. This effort is motivated first by the desire to bring the best tools to bear on human diseases of most need, and by the desire to do so in the safest and most efficacious manner. To address challenges in the field, we have developed highly compact nuclease-dead dCas systems (dCasMINI, 1/3 size of Cas9), as well as highly compact and potent epigenetic modulators (less than 200 bp). We have demonstrated their utility for the versatile control of gene transcription and epigenetic modifications and precisely targeting greatly expanded genomic contexts in living cells and in vivo. This platform is inherently safe, as it is designed to accomplish changes in gene expression without damaging or mutating genomic DNA. Recent studies have shown Cas9 nucleases or base editors can induce chromosomal translocation and genotoxicity. In comparison to gene editing-based approaches, we demonstrate epigenetic editing is safe without permanent off-targets or toxicities to cells. Additionally, the dCasMINI molecules we have developed have extremely low immunogenicity profiles, superior to larger and more immunogenic Cas9 or Cas12 proteins of bacterial origin. Although epigenetic editing has immense potential, we have addressed two critical challenges of applying epigenetic editing towards clinical applications: firstly we have generated a compact CRISPR-based epigenetic platform (reducing payload size by more than 2/3) capable of efficient delivery via either a single adeno-associated virus (AAV) or lipid nanoparticle (LNP) in vivo; secondly we have built a comprehensive library of epigenetic modulators, via both machine learning algorithms and large-scale screening, which allow us to activate and suppress multiple gene expression in a programmable way. We have developed an integrated platform based on these two major advances, termed Gene Expression Modulation System (GEMS), which realizes the full potential of epigenetic editing to precisely regulate gene expression. We demonstrate the clinical applications of our GEMS' persistent epigenetic editing platform to treat genetic disorders, including Facioscapulohumeral muscular dystrophy (FSHD), which are beyond the reach of conventional gene editing. Our FSHD program is poised to enter the clinic this year, potentially a first for epigenetic editing technologies. In a further demonstration of its utility, we can apply epigenetic editors to human T cells to enhance T cell functionality for better elimination of tumor malignancies. Notably, we have identified epigenetic modulators capable of durable and persistent target gene activation, opening the possibilities for novel therapeutic applications to address various haploinsufficiency diseases. In summary, precise epigenetic editing technologies hold great promises for developing next-generation gene therapies.

700. EPI-321: A Novel Epigenetic Gene Therapy for FSHD Targeting D4Z4 Epigenome

Alexandra Collin de L'Hortet, Abhinav Adhikari, Siddaraju Boregowda, Hao Zheng, Vishi Agarwal, Andrew Norton, Nalinda Wasala

Epic-Bio, South San Francisco, CA

Facioscapulohumeral muscular dystrophy (FSHD) is one of the most common types of adult muscular dystrophies with an annual incidence rate of about 1 in 10,000, affecting approximately 1 million people globally. With no cure available, current therapeutic strategies

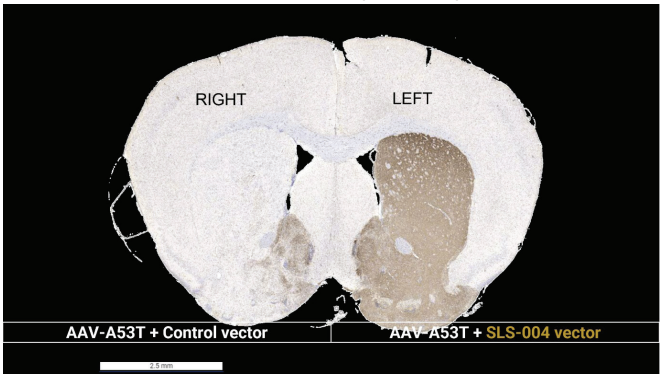
only involve managing symptoms to improve overall quality of life. Misexpression of disease-causing protein, DUX4, in muscle leads to slow and progressive muscle degeneration through activation of apoptotic and other downstream pathways. DUX4 gene is encoded at the distal region 4q35 chromosome from D4Z4 macrosatellite array. In FSHD patients, the D4Z4 marosatellite array is hypomethylated, leading to stochastic and transient DUX4 expression, which makes the development of cure challenging. At Epic-Bio, we leverage our proprietary Gene Expression Modulation System (GEMS) platform to develop a treatment for FSHD that targets the D4Z4 epigenome and permanently suppress DUX4 expression. Our product, EPI-321 is a single vector AAV serotype rh74 encoding an ultracompact, catalytically inactive Cas protein (effector) fused to gene-suppressing modulators, under the expression of the muscle specific promoter, CK8e, and a guide RNA targeting D4Z4 locus. Our preclinical studies showed that EPI-321 administration leads to robust and dose-dependent suppression of DUX4 and DUX4-downstream gene expression in ten different FSHD patient-derived immortalized and primary myoblasts in vitro, irrespective of the number of D4Z4 repeats, and showed antiapoptotic activity as measured by Caspase 3/7 staining. Mechanistically, EPI-321 showed re-methylation of the D4Z4 target locus leading to suppression of DUX4 expression. Further, in vivo evaluation of EPI-321 in humanized FSHD mouse model showed a dose-dependent suppression of DUX4-pathway at the mRNA and protein level, and antiapoptotic activity in muscle tissues. Additionally, 3D engineered human muscle tissue (3D EMT) using FSHD patient-derived immortalized myoblasts transduced by EPI-321 resulted in efficient suppression of DUX4 and DUX4-pathway genes up to 46 days and demonstrated significant dose dependent improvement in muscle contractility, shown by increased twitch and tetanic force post-treatment. Taken together, our findings provide robust evidence for EPI-321 as a potential single-administration gene therapy for treating FSHD by permanently suppressing the pathogenic DUX4 gene through epigenetic silencing. We intend to submit an Investigational New Drug (IND) application this year and are looking forward to commencing first-in-human trials in 2024.

701. ADAR Mediated RNA Editing for Treatment of Collagen VI Related Muscular Dystrophy

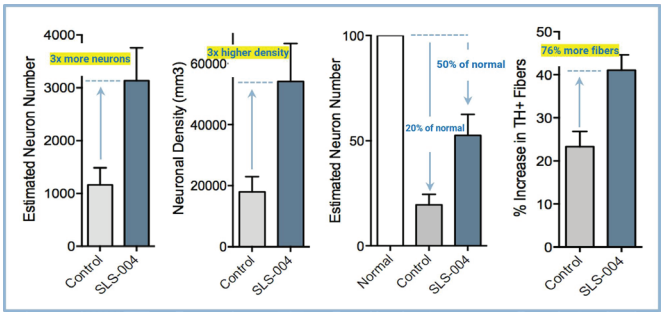
Russell J. Butterfield, Manshu Tang

Pediatric Neurology, Univeristy of Utah, Salt Lake City, UT

Introduction: The collagen VI related muscular dystrophies (COL6-RD) are inherited disorders of muscle characterized by progressive weakness and a combination of distal joint laxity and proximal joint contractures. There are no treatments beyond supportive care. Mutations in any of the three genes encoding collagen VI can result in COL6-RD. Missense mutations resulting in substitution of the glycine residue in the conserved Gly-x-y repeat of the triple helical (TH) domain allow incorporation of abnormal chains into secreted tetramers resulting in the dominant negative effect. Allele-specific gene silencing has been proposed as a therapeutic mechanism for COL6-RD and several different approaches using antisense oligonucleotide (ASO) or small interference RNA (siRNA) are in early stages of development. The goal for this project is to demonstrate feasibility of an alternative treatment strategy with an in-situ RNA-editing using adenosine deaminase acting on RNA (ADAR) to correct mutations in COL6-RD at the transcript level. ADAR is a site-specific RNA editor converting adenosine (A) to inosine (I) in RNA transcripts. Since 'I' in the mRNA sequence is read by the translation machinery as guanine (G), A-to-I edits of G-to-A transitions result in a correction of the mutation at the transcript level. In contrast to ASO and siRNA-based approaches to treatment of COL6-RD which are limited to specific targeted mutations, ADAR editing may allow targeting of multiple adjacent sites using the same guide-RNA. This is especially attractive for COL6-RD where dominant negative mutations are clustered in the N-terminal end of the triple helical domain and a single guide-RNA could be developed targeting multiple adjacent mutations. **Methods:** We used cultured fibroblasts from skin biopsy samples from patients with COL6-RD due to glycine missense mutations in the TH domain of the *COL6A1* gene. Since the c.850G>A (p.G284A) mutation in exon 9 is the most common cause of COL6-RD, our initial studies were performed on fibroblast samples with this mutation. Candidate guide-RNA sequences were cloned into plasmids and transfected into cultured using lipofectamine. ADAR editing was measured using RNA-seq to compare the read counts of wild type and mutant transcripts. In our first experiments, we first used linear synthetic RNA oligonucleotides or RNA transcribed from plasmid vectors specific to *COL6A1*, exon 9. Next, we designed two circularized guide-RNA's by flanking the sequences targeting either pre-mRNA or spliced mRNA, both of which centering exon9, with sequences from Twister ribozyme and stem-forming sequences from pre-tRNA. The Twister ribozyme sequences undergo rapid autocatalytic cleavage, leaving termini that are brought together by the stem-forming sequences and ligated by the ubiquitous endogenous RNA ligase RtcB resulting in a more stable guide-RNA with longer half-life. **Results:** Using linear synthetic RNA oligonucleotides or RNA transcribed from plasmid vectors specific to *COL6A1*, exon 9, we were unable to identify a significant amount of editing. Circular guide-RNAs showed improved stability and longer half-life than the linear counterparts with a clear rise in A-to-I editing. RNA-seq revealed that the editing efficiencies reached about 20% for both pre-mRNA and mRNA guide-RNA's without detectable bystander editing. Our best candidate guide-RNA to date shifted the A:G ratio from 0.88 in control samples to 0.56 in treated samples. **Conclusions:** We successfully demonstrated that the c.850G>A mutation in *COL6A1* can be edited *in vitro* in patient-derived fibroblasts with a circularized guide-RNA. These experiments support further development of this therapeutic candidate by optimization of the guide-RNA sequence and secondary structure to shift the ration of wild-type and mutant transcripts to a level that can reliably reverse the retention of collagen VI protein in the fibroblast cells and correct the defect in the matrix deposition.



702. One Year *In Vivo* Safety After CRISPR Based Parkinson's Disease Treatment



Krishna Subramanian[1], Raj Mehra[2]

[1]Seelos Therapeutics Inc., New York, VA,[2]Seelos Therapeutics Inc., New York, NY

Parkinson's disease (PD) is the second most common neurodegenerative disorder in the world after Alzheimer's disease. Neuronal α-synuclein disease defined by biology encompasses all α-synucleinopathies. These diseases include - incidental Lewy body disease, preclinical (without

clinical features), premotor, pure autonomic failure, idiopathic rapid eye movement-sleep behaviour disorder, prodromal (early signs or symptoms not yet fulfilling clinical diagnostic criteria), or as having a possible or probable clinical diagnosis of Parkinson's disease, Parkinson's disease dementia, or dementia with Lewy bodies. SLS-004 is a CRISPR based epigenetic modulator of α-synuclein gene expression. SLS-004 can be personalized individually for precision medicine application and can be tailored to be broadly used a therapeutic for downregulation of α-synuclein overexpression. SLS-004 utilizes a CRISPR based active epigenetic DNA methylation mechanism to restore homeostasis and reduce α-synuclein levels to normal physiological levels. SLS-004 can be applied across all neuronal α-synuclein diseases. In a humanized PD mouse model of A53T α-synuclein overexpression in vivo, SLS-004 was able to restore tyrosine hydroxylase (TH) levels in striatum in the treated hemisphere compared to control hemisphere. In the control hemisphere complete loss of TH-positive expression was observed, but in treated hemisphere TH-expression remained persistent, 76% more fibers. The stage of disease in control hemisphere is equivalent to the Stage 1A&1B of the newly coined neuronal α-synuclein disease integrated staging system (ND-ISS). TH-positive dopamine neurons in the substantia nigra pars compacta (SNpc) were recovered in the SLS-004 treated hemisphere compared to control hemisphere, 3X more dopamine neurons. Thus, dopaminergic dysfunction, but no evidence of clinical signs or symptoms (Stage 1b) was also recovered by treatment with SLS-004. SLS-004 was also administered directly into normal animals that were not induced with any targeted dopaminergic neuronal α-synuclein overexpression. In these animals the expression of TH levels in striatum in the treated hemisphere was retained. This was evident after one year of in vivo expression in mice. The animals were dosed with SLS-004 starting on Day 112 (Age) and were followed for one year up to at least 477 days. Thus, SLS-004 can be administered safely for a long duration of time in vivo using the novel CRISPR epigenetic modulation mechanism. The therapeutic lowering of α-synuclein with SLS-004 do not cause any adverse reactions in normal animals. This validates the broad application of SLS-004 across all neuronal α-synuclein diseases. No safety findings were observed both during in-life and at the extensive end-term necropsy in vivo. The safety and efficacy of SLS-004 are thus established in both normal and diseased animal models including in aged mice (>477 days). SLS-004 can be used to treat all neuronal α-synuclein diseases to restore the neurons back to normal physiological levels of α-synuclein through a safe and effective CRISPR based epigenetic regulation mechanism.

703. A Novel Rett Syndrome Patient-Derived Cerebral Organoid Model for Epigenetic Editing

Klaudia M. Braczyk[1,2], Julian Halmai[1,2], Casiana Gonzalez[1,2], Roy Ben-Shalom[2], Kyle D. Fink[1,2]

[1]Center for Interventional Genetics; Stem Cell Program; Gene Therapy Center; Institute for Regenerative Cures, Sacramento, CA,[2]MIND Institute; Department of Neurology, University of California, Davis, Health Systems, Sacramento, CA

Rett syndrome (RTT) is a rare neurodevelopmental disorder, primarily affecting girls, caused by loss-of-function mutations in *methyl CpG-binding protein 2* (*MECP2*). Mutations in *MECP2,* which is located on the X chromosome, lead to significant neurological deficits including speech and motor regression, cognitive impairment, and seizures. Currently, there is no cure for RTT and with only limited symptomatic treatments available, there's an urgent need for more therapeutic approaches targeting the underlying cause of this disease. Recent studies have shown that epigenetic reactivation of the endogenous, healthy copy of *MECP2* from the inactive X chromosome (Xi) can restore normal neurological functions in RTT-like neurons *in vitro* using two-dimensional (2D) ESC-derived neural cultures. However, the evaluation of this approach in a physiologically relevant brain microenvironment remains unexplored. Cerebral organoids formed from neuronal stem cells (NSC) derived from patient induced pluripotent stem cells (iPSC), grant close recapitulation of the human brain microenvironment due to cell three-dimensional organization, layer formation closely resembling brain architecture and increased neuronal maturation. Cerebral organoid model allows then for effective evaluation of epigenetic reactivation in a brain-like setting along with accurate assessment of viral-based delivery of therapeutics. **Methods**: RTT patient iPSCs were differentiated into NSCs and cerebral organoid cultures were established. Organoids were then investigated for RTT phenotype and neuronal maturation utilizing RT-qPCR and immunocytochemistry (ICC) to evaluate expression of neuronal molecular markers, and Microelectrode Arrays (MEA) for electrophysiological activity. Mature organoids were transduced with epigenetic editing tools to evaluate transduction efficiency and targeted reactivation. **Results:** RT-qPCR and ICC indicated that all established cerebral organoids indeed express various neuronal markers, and that RTT organoids successfully recapitulated RTT phenotype compared to healthy control organoids. MEA showed that all established organoids were capable of presenting electrophysiological activity with distinguishable firing pattern between RTT and control organoids. Viral transduction successfully delivered the CRISPR-dCas9 construct

to the mature, patient NSC-derived organoids with high efficiency. **Conclusions**: RTT patient iPSC NSC-derived cerebral organoids can serve as a brain-relevant model to investigate the epigenetic reactivation of the endogenous, healthy copy of *MECP2* gene. Future directions aim to rescue the RTT phenotype in RTT patient iPSC NSC-derived cerebral organoids, and to assess potential of the novel epigenetic editing therapy approach to treat Rett syndrome in patients.

704. Evaluation of CRISPR-CasRx Strategies for Targeted Gene Knockdown in Primary Hyperoxaluria Type 1: Unveiling Discrepancies between *In Vitro* & *In Vivo* Approaches

Laura Torella[1], Erwan Sallard[2], Jessica Del Campo Ayala[1], Mario Santafe-Méndez[1], Diego Herrero-Martínez[1], Guiomar Pérez-Otero[1], Cristina Gazquez[1], Cristina Olagüe[1], Africa Vales[1], Nerea Zabaleta[3], Gloria Gonzalez-Aseguinolaza[1]

[1]CIMA, University of Navarra, Pamplona, Spain,[2]University Witten/Herdecke, Witten-Annen, Germany,[3]Mass Eye and Ear/Harvard Medical School, Boston, MA

Primary hyperoxaluria type 1 (PH1) is a rare genetic disease characterized by oxalate overproduction in the liver and its toxic accumulation in the kidneys. CRISPR-Cas9-mediated *Hao1* gene disruption has been effective in reducing oxalate accumulation in a PH1 mouse model. However, permanent genome changes remain a safety concern. Here, we have investigated the use of CRISPR-RfxCasR13d (CasRx), a programmable RNA-guided, RNA-targeting technology that allows protein knockdown without modifying the DNA. First, we tested the efficacy of 11 guides that target different regions of the *Hao1* CDS and 3'UTR by analyzing the reduction in glycolate oxidase (GO) expression in transfected mammalian cells. GO expression was reduced to almost undetectable levels in all the conditions, interestingly, a reduction in expression of co-transfected reporter genes was also observed, reflecting the collateral cleavage of non-complementary bystander RNA. Despite a similar targeted knockdown efficiency, the gRNAs demonstrated different degrees of collateral activity and importantly, we did not detect evidence of this concerning activity in endogenous genes. Thus, we selected the most effective gRNAs with the lowest collateral cleavage effect to generate AAV8 vectors carrying single or multiple gRNAs in tandem to increase the knockdown efficiency and tested them *in vivo*. Mice were co-injected with an AAV expressing Luciferase to assess collateral activity *in vivo*. A reduction in Luciferase and CasRx expression confirmed collateral cleavage of exogenously expressed genes. While a reduction of *Hao1* mRNA levels was observed, it was insufficient to decrease GO protein expression. All-in-all, despite the promising *in vitro* results, we underscored the challenges and need for further optimization in applying CRISPR-CasRx for therapeutic purposes in the context of PH1.

705. Robust and Durable RNA Editing *In Vivo* with Axiomer™ Editing Oligonucleotides in Non-Human Primates

Nicole H. P. Cnubben, Katarzyna E. Kolodziej, Bruno Albuquerque, Saskia Crowe, Jim Swildens, Hans A. V. Kistemaker, Lenka van Sint Fiet, Peter de Visser, Sjef de Kimpe, Gerard Platenburg

ProQR Therapeutics B.V., Leiden, Netherlands

Axiomer, an RNA editing platform, uses chemically modified and complementary editing oligonucleotides (EONs) to recruit and guide endogenous Adenosine Deaminase Acting on RNA (ADAR) to perform A-to-I editing on double stranded RNA. To date, EONs have shown robust editing *in vitro* and *in vivo* (rodents), and we report here editing efficiency and tolerability of an EON targeting *ACTB* RNA in non-human primates (NHPs). In the primary experiment, cynomolgus monkeys were dosed with three intravenous infusions each at D1, D8, D15 with *ACTB* EON at a dose of 2mg/kg (N = 4) or control EON (N = 4). During this study animal welfare was closely monitored. Tolerability, including safety parameters, and *ACTB* editing efficiency in liver biopsies were assessed on D4, D18, D25, and D39. Editing efficiency of *ACTB* RNA, confirmed through RNAseq and dPCR, reached up to 70% in the *ACTB* EON group in comparison to 0.1% in the control group at D4 (1 dose) and showed an average of 61% and 62% editing efficiency observed at D4 and D18 (3 doses), respectively. Durable high double-digit editing was maintained within the *ACTB* EON group after the last dose. No significant off-target editing was observed in NHP liver upon treatment with EON targeting *ACTB* RNA. No abnormalities in animal welfare or signs of discomfort were noticed during treatment. Safety parameters did not show significant differences in the *ACTB* EON vs. EON control group, although some transient formulation-related changes compared to baseline were noted in circulating hepatic enzymes. Axiomer *ACTB* EON repeat dosing showed robust and durable editing efficiency at the RNA level in NHP *in vivo* with a similar safety profile known from other single-stranded oligonucleotides. These preliminary data confirm the potential of Axiomer EONs in preparation for clinical development and support discovery of new therapeutic applications.

706. Exon Editing of ABCA4 rNA in Human Retinal Explants and Non-Human Primate Retina for the Treatment of Stargardt Disease

Ting-Wen Cheng, Akiko Noma, John Bachmann, Tayla Cormier, Sangeetha Manokaran, Delaney Conor, Jim Faulkner, Justin Nelson, Brian Olshaw, Jason Thresher, Dennis Wu, Akiko Doi, Carrie Wager, Michael Ehlers, Robert Bell

Ascidian Therapeutics, Boston, MA

Exon editing is a promising strategy that utilizes RNA trans-splicing activity of endogenous spliceosomes to rewrite mutated RNA and thereby correct the underlying genetic causes of disease. Exon Editor RNA molecules can be designed to carry correct coding sequences of multiple exons, target a specific region of mutated pre-mRNA, and replace pathogenic mutations with the corrected sequence resulting in full-length, repaired mRNA molecules and wild-type proteins. Here we developed ACDN-01, an AAV-encoded RNA Exon Editor targeting

ABCA4, for the treatment of ABCA4-related retinopathies, including Stargardt disease. First, to model the Exon Editor expression and RNA replacement activity in the human retina, human retinal explants from 8 donors with no known ocular disease were treated with ACDN-01 *ex vivo,* to mimic bleb formation analogous to that seen following *in vivo* subretinal injection. The results demonstrated that ACDN-01 effectively transduced human retinal cells and efficiently replaced 22 exons in the 5' half of the 7 kb *ABCA4* coding sequence. Full-length ABCA4 protein expression levels in ACDN-01 treated human retinal explants were characterized by capillary electrophoresis. In addition, the full-length protein translated from ACDN-01 edited *ABCA4* mRNA was confirmed to retain functional ATPase activity. Next, durable and well-tolerated exon editing in non-human primate (NHP) retina were demonstrated following a single subretinal injection of ACDN-01 at therapeutically relevant doses. In an IND-enabling GLP toxicology study, ACDN-01 achieved stable vector transduction and Exon Editor RNA expression in NHP retina, mainly in the photoreceptor cells, at 3-months post-dosing and persisted up to 6-months post-dosing. Trans-splicing activity increased dose-dependently and effectively produced chimeric human/NHP ABCA4 mRNA and protein. ACDN-01 was well tolerated in the mid-dose group with minimal microscopic findings that did not affect eye function and therapeutically relevant levels of chimeric ABCA4 mRNA and protein were demonstrated. Retinal findings associated with the highest dose of ACDN-01 tested aligned with other previous reports that evaluated high doses of AAV in the eye. In summary, ACDN-01 can provide robust and durable *ABCA4* exon editing in *ex vivo* human retinal explants and NHP retina at well tolerated doses. These results support going forward with additional studies to fully understand the potential for ACDN-01 in the treatment of ABCA4-related retinopathies.

Wednesday Posters: Gene Targeting and Gene Correction New Technologies

707. A Novel Mutation-Agnostic Gene Therapy Using AAV-Delivered Heterologous Expression of Engineered Microbial Mechanosensitive Channel in Animal Model of Ocular Hypertension

Adnan Dibas, Lucero Garcia, Megan Aldape, Sanghoon Kim, Subrata Batabyal, Mohanty Samarendra
Nanoscope Technologies, Bedford, TX

Purpose Patient adherence to daily eye drop medications for control of ocular hypertension is a major challenge. The engineered mechanosensitive channels (EMC) derived from microbial systems can detect elevated pressure levels based on membrane tension. Introducing an AAV-carried EMC in the trabecular meshwork (TM) via intracameral injection offers an innovative approach for sustained reduction of intraocular pressure (IOP). In this study, we measure the aqueous humor (AH) outflow facility in an IOP-elevated TGFβ2 mouse model of glaucoma and assess the dose-dependent impact of EMC gene therapy in enhancing the outflow facility to lower IOP. **Methods** EMC was packaged in self-complementary (sc) AAV2 and produced using the triple transfection method. EMC expression in TM was driven by the MGP promoter upstream, while mCherry downstream served as a biomarker. Immortalized human TM cells were used for evaluating transduction by scAAV2-EMC. Since TGFβ (transforming growth factor beta) is known to increase intraocular pressure (IOP) by inducing changes in the TM, including extracellular matrix deposition and increased outflow resistance, intravitreal injection of Ad5-TGFβ-2 was carried out in adult C57BL/6J mice for IOP elevation. IOP was measured by TonoLab. Intracameral injection of scAAV2 was carried out to determine changes in the aqueous outflow (AH) facility and IOP due to EMC transduction of TM. The AH outflow measurement was conducted using manometry in EMC-treated and control groups. Visually evoked potential (VEP) measurement was conducted to evaluate the effect of EMC treatment on the health of retinal neurons. **Results** Our results show successful transduction of human TM cells by scAAV2-EMC, visualized by fluorescence microscopic imaging of mCherry reporter, and western blot. Intracameral delivery of scAAV2-EMC led to EMC expression in TM. Reduction of AH outflow through the conventional outflow pathway was observed in the IOP elevated TGFβ2 model. Intracameral scAAV2-EMC treatment led to a statistically significant increase in aqueous humor drainage in the TGFβ2 model along with a reduction in IOP. VEP measurement showed a 50% higher amplitude in the scAAV2-EMC treated group as compared to the control, which suggests protection of retinal neurons owing to the reduction of ocular hypertension. **Conclusions** Heterologous expression of EMC enables the reconstitution of innate pressure sensory and response capacity within tissues regulating pressure. When expressed in cells of the conventional drainage system of the eye, EMC gets activated by increased ocular pressure and modulates cellular changes that enhance the outflow facility and facilitate pressure relief through the conventional TM pathway. Ectopic expression of EMC represents a new therapeutic approach for the treatment of edema and hypertension in different organs.

708. B Cell Targeting by All-in-One Vectors for Cell Activation and Genome Engineering

Hsu-Yu Chen, Chun Huang, Atishay Mathur, Chan-Hua Chang, BingFei Yu, Paula M. Cannon
Molecular Microbiology and Immunology, University of Southern California, Los Angeles, CA

We have previously shown that genome editing at the Immunoglobulin Heavy chain locus can be used to reprogram human B cells to express custom antibodies, including broadly neutralizing antibodies that could provide an anti-HIV therapy. We typically edit B cells using the combination of CRISPR/Cas9 RNPs and AAV6-based homology donors, but we have now developed alternative 'all-in-one' integration-defective lentiviral vectors (All-IDLVs) that can also engineer IgH. These vectors package RNPs through an aptamer/ABP interaction, while the homology donor antibody cassette is encoded in the vector genome. Further adapting All-IDLVs for *in vivo* gene editing would provide significant advantages, especially as edited B cells can be amplified by immunization, suggesting that only a small number of edited cells may be necessary. However, this is made challenging by the lack of robust cell-type specific delivery systems, and the requirement for the cells to be cycling to support homology-directed genome editing. For example, VSV-G pseudotyped lentiviral vectors can only

transduce B cells *ex vivo* following incubation in activation media, which both upregulates the LDL receptor needed for vector entry, as well as driving the cell cycle changes that are necessary for homology-directed editing.To confer B cell targeting to All-IDLVs, we evaluated ligands directed against a series of B cell surface molecules. The ligands were displayed using either an engineered paramyxovirus system or in combination with a mutant VSV-G. As proof of principle, we inserted the broadly neutralizing nanobody, J3, into the IgG1 locus, where correct gene editing results in both secreted and membrane-anchored forms of a J3-Fc fusion antibody. The most effective combination was achieved by targeting a co-stimulatory molecule in the mutant VSV-G platform, which improved transduction of resting human B cells by more than 5-fold compared to wild-type VSV-G. Moreover, the vectors significantly activated the B cells, increasing expression of CD80 and CD86. As a result, All-IDLVs were able to engineer human tonsil B cells without pre-activation, detected by the surface expression of J3, and confirmed by specific PCR. Finally, these B cell targeted vectors were also able to transduce primary B cells from Rhesus macaques, supporting future investigations *in vivo* using this model. Taken together, we have developed a B cell targeted vector that can engineer B cells without requiring pre-activation, and which could therefore be compatible with *in vivo* engineering of B cells.

709. Expansion of *In Vivo* HDAd-Transduced HSCs by Constitutive Expression of tHMGA2 after Intravenous Vector Injection into Mobilized Mice without Additional Drug Selection

Hongjie Wang, Aphrodite Georgakopoulou, Sucheol Gil, Andre Lieber

University of Washington, Seattle, WA

We developed an *in vivo* hematopoietic stem cell (HSC) gene therapy approach that consists of HSC mobilization and intravenous injection of HSC-tropic HDAd vectors. To achieve therapeutically relevant numbers of corrected cells, the approach requires *in vivo* expansion of transduced HSCs. For *in vivo* HSC selection we are currently using a technique that involves an $mgmt^{P140K}$ mutant and treatment with low-dose chemotherapy drugs (O^6BG/BCNU). Clearly, a chemotherapy drug-free method for *in vivo* expansion would be desirable. We therefore generated a HDAd5/35++ vector system for stable integration of a transgene cassette consisting of the ubiquitously active EF1α promoter driving a 3′UTR truncated HMGA2 gene linked to GFP via a self-cleaving 2A peptide (HDAd-tHMGA2/GFP). In mice, HSCs were mobilized with G-CSF/AMD3100 and, at the peak of mobilization, intravenously injected with the vector (N=10). Twenty weeks after HDAd injection, GFP-positive PBMCs started increasing above the background of 1% in all the mice reaching an average of 50% (range 10-70%) by week 44. In mice that received a control HDAd-GFP vector, GFP marking in PBMCs was steady at <1%. During this time, in HDAd-tHMGA/GFP transduced mice, the number of white blood cells increased, mostly due to higher percentage of $GFP^+/CD19^+$ (B-lymphocytes) and $GFP^+/Gr1^+$ (granulocytes) cell fractions within PBMCs. The number of erythroid cells and erythroid parameters did not change. At week 44, the average GFP marking in bone marrow mononuclear cells (MNCs) was 4-fold lower than in PBMCs indicating that most of the tHMGA2-mediated expansion occurred after the cells exited the bone marrow. Within bone marrow cells, about 10% of LSK cells, a cell fraction that is enriched for HSCs, were GFP-positive. This is 10-fold higher than in mice that received the HDAd-GFP control vector, suggesting an expansion at the level of HSCs as well. In the spleen, on average 35% of LSK cells were GFP-positive in HDAd-tHMGA2/GFP mice. The vector copy number per cell was comparable in PBMCs, bone marrow, and spleen, implying that tHMGA2 did not increase vector integration, but only the number of transduced cells. Genomic DNA from bone marrow MNCs were subjected to genome-wide transgene integration site analysis. These studies showed random vector integration without signs of clonal dominance. Lineage-negative bone marrow cells from wk 44 HDAd-tHMGA2/GFP transduced mice were transplanted into lethally irradiated secondary recipients. Engraftments rates were nearly 100% and GFP marking in PBMCs was stable over 12 weeks at 40% on average. No hematological abnormalities were observed. Another *in vivo* HSC transduction study was performed in humanized mice, i.e. in mice that were transplanted with human HSCs and developed hematopoietic chimerism. These mice were mobilized and injected intravenously with HDAd-tHMGA2/GFP. GFP marking in peripheral human ($CD45^+$) leukocytes increased, starting at week 20, and reached on average 30% by week 24. Similar marking rates were found in the bone marrow in $CD34^+$ cells (HSCs), $CD33^+$ cells (myeloid), $CD19^+$ cells (B-lymphocytes) and $CD3^+$ cells (T-lymphocytes). The percentage of GFP^+ cells in these subfraction was 4-5 higher compared to mice that were *in vivo* transduced with the HDAd-GFP vector that did not express the tHMGA2 gene. In summary, we present an approach that mediated the autocatalytic, self-limiting expansion of *in vivo* transduced HSCs and myeloid/lymphoid progenitors without disturbance of hematopoiesis or neoplastic transformation. Considering concerns that increased HMGA2 expression is associated with certain cancers, safety and efficacy studies in non-human primate models are warranted.

710. Efficient and Precise Gene Editing by STAR (Seek-Tag-Amend-Release) Editing Enabled by Synergistic Actions of a Cas9 Nickase, a segNA (STAR Editing Guide Nucleic Acids) and a DNA Dependent Polymerase

Minghong Zhong[1], Qiong Zhao[2], Xiaoyun Lin[1], Ju-tao Guo[2]

[1]GeneLancet Biosciences, Inc., Doylestown, PA,[2]Baruch S. Blumberg Institute, Doylestown, PA

Clustered regularly interspaced short palindromic repeats (CRISPR)-associated protein (Cas) is a gene editing system directed by variants of small noncoding RNAs, each with a spacer sequence of approximately 20 nt long. CRISPR-Cas comprises one or two nucleic acid endonucleases, which cut one or both nucleic acid strands targeted by the spacer sequence. For precise gene editing, either a nucleic acid-templated editing synthesis, integration of exogenous DNA plasmids or viral vectors, or modifications of a nucleotide base by one or more protein domains are usually incorporated into actions of a naturally occurring system or a modified system with a chimeric guide RNA. Base-modifying protein effectors (base editors, BE) have bystander off-targets, which are guide-independent and rarely have

single-base resolutions, while templated gene editing (prime editing, PE) usually has decreased efficiency compared to wild-type enzymes. In particular, the guide RNA construct of a prime editor (pegRNA or epegRNA) is self-inhibitory because of its inner complementarity at the spacer region. In addition, plasmids and viral vectors are well known for integrating into the host genome. CRISPR editors utilizing base modifying protein effectors have a limited editing capacity, while gene editors based on a nucleic acid templated editing synthesis are greatly more versatile and capable of full-spectrum gene editing, including any single base change, short or long deletions, and insertions. Examples of such editors include prime editing, PASTE, and STAR editing. In contrast to a prime editor and PASTE, which use a reverse transcriptase that is error-prone and has low fidelity and low processivity, STAR editing (Fig 1) uses a single-strand DNA (ssDNA) template tethered to a guide RNA and either a cellular DNA-dependent DNA polymerase or a fusion protein comprising a Cas protein and a DNA-dependent DNA polymerase domain. DNA-dependent DNA polymerase is known to be precise and has high fidelity and processivity. STAR editing uses the nicked non-targeted DNA strand after single-strand nicking by a Cas protein as a DNA synthesis primer and an ssDNA template tethered to guide RNA, coined as a STAR editing guide nucleic acids (segNA), which is uniquely accessible by the chemically ligated guide RNA (LgRNA) technology. There is a potential self-inhibition in a segNA similar to a pegRNA or an epegRNA in prime editing; however, a double-stranded DNA/RNA is less stable than a double-stranded RNA/RNA, and thus the self-inhibition is decreased in comparison to a prime editor, and can be further reduced by structure optimization. To improve the editing efficiency and specificity of STAR editing, we have developed a screening platform for the optimization of segNAs (Fig. 2), consisting of a cleavage assay (by CRISPR-Cas9), an extension assay (by CRISPR-nCas9 and a DNA polymerase) and a confirmative cell assay. Various segNAs containing a committed stop codon were synthesized, and segNAs capable of efficient, precise anti-HBV gene inactivation have been identified. In addition, we observed cellular DNA polymerases are sufficient for DNA-templated precise gene editing. The screening platform is also useful for optimizing a chemically ligated epegRNA to improve prime editing.

711. Genome Editing Strategies for *In Vivo* Generation of Truncated EPO Receptors in HSCs to Expand Erythroid Progenitors Carrying Therapeutic Genetic Changes

Karthik V. Karuppusamy[1], Akshara S. Velmurugan[1], Chang Li[1], Hongjie Wang[1], Jack A. Queenan[2], Nouraiz Ahmed[3], David R. Liu[3], Robert Peters[4], Andre Lieber[1]

[1]University of Washington, Seattle, WA,[2]Harvard, Boston, MA,[3]Broad Institute, Boston, MA,[4]Ensoma, Boston, MA

Genome editing in hematopoietic stem cells (HSCs) has the potential to treat patients with β-thalassemia and sickle cell disease. We developed an *in vivo* HSC gene therapy approach that consists of HSC mobilization and intravenous injection of HSC-tropic HDAd vectors. To achieve therapeutically relevant gene correction levels, we are currently using an *in vivo* HSC expansion approach that is based on a mutant O^6-methylguanine-DNA methyltransferase ($mgmt^{P140K}$) gene that confers resistance to the low dose chemotherapy drugs O^6BG/BCNU. However, for non-oncological applications, especially for hemoglobinopathies, an *in vivo* selection approach that avoids chemotherapy or genotoxic agents would be preferrable. We have therefore been exploring a series of *in vivo* HSC selection/expansion methods that do not require chemotherapy drugs. One such approach is based on a truncation in the erythropoietin receptor (tEPOR), which causes benign congenital erythrocytosis—a condition marked by a non-pathogenic hyper-production of red blood cells. Others have shown that *ex vivo* tEPOR gene addition in HSCs or *ex vivo* editing to create a tEPOR can confer a selective advantage to the derived red blood cells, most likely due to mediating hypersensitivity to erythropoietin. Our goal is to create tEPORs in HSCs *in vivo* by base or prime editing together with the introduction of genetic changes that would cure hemoglobinopathies such as *in vivo* γ-globin gene addition, *in vivo* base editing to reactivate γ-globin, or *in vivo* prime editing to correct the sickle cell disease mutation. The approach would involve intravenous injections of mobilization agents and a therapeutic HDAd vector resulting in *in vivo* edited HSCs localized in the bone marrow. Upon differentiation into tEPOR-edited erythroid progenitors, an autocatalytic, (endogenous) EPO-mediated expansion would occur, resulting in corrected erythrocytes at levels that will be curative. For EPOR editing we used cytosine base editors that would introduce premature stop codons resulting in different C-terminal truncated EPORs. We have screened several single guide RNAs and found sgRNAs that result in the generation of a naturally occurring tEPOR variant, i.e. a stop codon at amino acid position 71 through converting TGG to TAA in HEK293T cells and found efficient editing at rates of ~30%. Next, we edited HUDEP-2 cells, an erythroid test cell line. and observed increased proliferation of cells with the desired modification up to 2.5-fold (within 5 days) with physiological concentration of erythropoietin. The second strategy involves prime editors that would create a tEPOR variant *in vivo* that was first reported by Harvey Lodish in 1990. Prime editing will replace the nucleotides for amino acids 467-Asp-Tyr-Ser-469 with nucleotides encoding Ala and Leu and creating a STOP codon, thereby removing the normal C-terminal 42 amino acids and adding alanine and leucine (for receptor stabilization). We used the latest prime editor enzyme PE6d and screened two nick-RNAs and eight pegRNAs. Preliminary screening in HEK293T cells showed desired prime editing with two of the pegRNA/nick-RNA

combinations. The generation of corresponding HDAd vectors is ongoing and results for *in vitro* and *in vivo* multiplex editing will be reported.

712. Highly Efficient Gene-Editing of *S. aureus* Cas9 in Patient Hematopoietic Stem and Progenitor Cells for Treating Sickle Cell Disease

ByoungYong Yoo[1], So Hyun Park[1], Vivien Sheehan[2], Gang Bao[1]

[1]Rice University, Houston, TX,[2]Emory University School of Medicine, Atlanta, GA

Introduction: Sickle cell disease (SCD) is a hemoglobinopathy caused by a single nucleotide mutation (A>T) in the sixth codon of the β-globin gene (*HBB*). Technologies based on CRISPR/Cas9 mediated gene-editing have been developed to provide a permanent cure for SCD by editing the *HBB* gene in hematopoietic stem and progenitor cells (HSPCs). Recently, Casgevy and Lyfgenia, *ex vivo* CRISPR/Cas9 gene-editing based therapies for SCD, have received FDA approval. However, the high cost of ~$2-3 million per treatment and the high-quality infrastructure needed for *ex vivo* editing limit access to these therapies, especially for patients in low-resource countries, such as Africa. Therefore, there is an unmet need for *in vivo* editing-based therapy that can significantly reduce the cost and eliminate the requirement of highly sophisticated infrastructure. One potential approach for *in vivo* gene-editing based therapy is to use adeno-associated virus (AAV) vector for delivery of the gene editing machinery to HSPCs in patients. However, the most widely used *S. pyogenes* Cas9 (SpCas9) cannot be packaged into a single AAV. Therefore in this study we systematically quantified the gene-editing outcomes of *S. aureus* Cas9 (SaCas9) which can be packaged into AAV to treat SCD, and compared the results with that of SpCas9. **Methods:** We edited two genes, *HBB* to correct the sickle mutation and *BCL11A* enhancer to induce fetal hemoglobin (HbF) with biological replicates in SCD HSPCs from different 2 donors. We delivered sgRNA with SpCas9 or sgRNA with SaCas9 as RNP, along with a corrective ssODN donor template to correct the sickle mutation in *HBB* and RNP of SpCas9 or SaCas9 to disrupt *BCL11A* enhancer by electroporation. *HBB* has a mutually permissive PAM sequence for both Cas9, and we screened 6 targetable sites for SaCas9 around the target site of SpCas9 and chose one with the highest editing efficiency. We analyzed the editing rate and small insertions and deletions (INDELs) profile by Next Generation Sequencing (NGS) and measured large deletions (> 61 bp) by ddPCR. We erythroid differentiated the edited SCD HSPCs for 14 days and measured % HbF by intracellular staining followed by flow cytometry. To evaluate the transduction efficiency of AAV in SCD HSPCs, we generated AAV6-GFP and transduced the SCD HSPCs, and measured % GFP^+ cells. **Results:** We found that SaCas9 is as highly efficient as SpCas9 in the sickle mutation correction (HDR rate by SpCas9: 42%, by SaCas9: 43%). With RNP only, the cutting efficiency of SaCas9 at *HBB* was comparable to that of SpCas9 (INDEL rate by SpCas9: 78%, by SaCas9: 80%). Large deletions, one of the unintended gene editing outcomes, were not significantly different (33% by SpCas9 RNP, 19% by SpCas9 RNP with the ssODN, 38% by SaCas9 RNP, and 18% by SaCas9 with the ssODN). SaCas9 was also as highly efficient as SpCas9 in *BCL11A* enhancer disruption (INDEL rate by SpCas9: 86%, by SaCas9: 88%). After erythroid differentiation, cells with *BCL11A* enhancer disruption by SaCas9 showed comparable HbF induction to SpCas9 (% HbF^+: 54% by SpCas9, 50% by SaCas9). The *in vitro* transduction efficiency of AAV6-GFP was 49% in SCD HSPCs. **Discussions:** In this work, we showed highly efficient gene-editing by SaCas9 and compared it with the highly optimized and widely used SpCas9 in sickle mutation correction and *BCL11A* enhancer disruption in SCD HSPCs. The results demonstrated the therapeutic potential of SaCas9 for treating SCD. We confirmed the high transduction efficiency of AAV6 in SCD HSPCs. Based on these results, we will generate AAV6-CRISPR with SaCas9 targeting *BCL11A* enhancer to investigate its potential for treating SCD by *in vivo* gene-editing.

713. Improving Therapeutic Homology Directed Repair Genome Editing Efficiency in Human Primary Cells through Optimal Guide RNA Selection

Sridhar Selvaraj, Nicole Marie Johnston, Ludwig Schmiderer, Nelson A. Amorin, Matthew H. Porteus

Pediatrics, Stanford University School of Medicine, Stanford, CA

Nuclease-based genome editing utilizing homology directed repair (HDR) pathway allows for precise integration of transgene sequences ranging from single nucleotide to multi kilobases in length. Genome editing platform employing Cas9/guide RNA (gRNA) ribonucleoprotein (RNP) and adeno-associated virus serotype 6 (AAV6) based HDR donor template delivery enables allelic HDR efficiency of 20-60% across different therapeutically relevant genomic loci in various human primary cell types, ex vivo. Further enhancement of HDR efficiency would greatly benefit both therapeutic and research applications of this technology. We have recently reported that transient treatment with a small molecule inhibitor of DNA-dependent protein kinase catalytic subunit (DNA-PKcs), AZD7648 during genome editing further improves the allelic HDR efficiency to about 50-90% through the inhibition of non-homologous end joining (NHEJ) DNA repair pathway. Since, NHEJ pathway plays a critical role in the maintenance of genomic integrity, there could be potential safety risks associated with this approach. Thus, it is essential to develop methods to enhance the HDR efficiency without modulating the endogenous DNA repair pathways. Recent studies have reported that gRNA selection could affect HDR efficiency due to the variability in DNA repair pathway choice between NHEJ, HDR and microhomology-mediated end joining (MMEJ). Here, we assessed whether alternate gRNA selection can affect HDR efficiency at previously characterized therapeutically relevant genomic loci in human primary cells. For this, we identified alternate gRNAs with PAM sites offset by 1 to 13 bases relative to the previously characterized gRNAs in the sense and antisense strands at *HBB, CCR5 and STING1* gene loci to allow for use of the same original HDR donor template. Following gene editing with RNPs of original/alternate gRNAs and AAV6 HDR donor in hematopoietic stem and progenitor cells (HSPC) and human pluripotent stem cells (PSC), we found the HDR efficiency to be variable between 10-90% across different gRNAs. The gRNAs with highest frequency of +1 INDELs (+1 gRNAs) post editing with RNP alone showed consistently lower HDR frequency of about 10-47% at all three loci upon editing with AAV6 template. The other gRNAs (var gRNAs) with variable INDEL patterns and lower +1 INDEL frequency showed higher HDR frequency of about 50-90%. Transient treatment with AZD7648 resulted in higher HDR

frequency across all gRNAs but the fold improvement was higher while using the +1 gRNAs indicating the preference for the NHEJ pathway (Fig. 1). Next, we assessed whether the kinetics of HDR and INDELs is affected by editing with +1 vs var gRNAs. In the samples edited with RNP only, we found that INDELs occur faster with the +1 gRNAs than the var gRNAs at all three loci starting at 4-8h. Upon editing with RNP and AAV6, we found that the HDR kinetics is faster with the var gRNAs than the +1 gRNAs from 4-8h which inversely correlated with the INDEL kinetics in the RNP only samples. Correspondingly, AZD7648 treatment normalized this difference in HDR kinetics. Thus, choosing gRNAs with lower +1 INDEL frequency could be ideal for achieving high HDR efficiencies by leveraging the alteration in choice of endogenous DNA repair pathways. In conclusion, optimal gRNA selection can aid in designing HDR-based high efficiency transgene integration strategies in human primary cells for therapeutic and research applications.

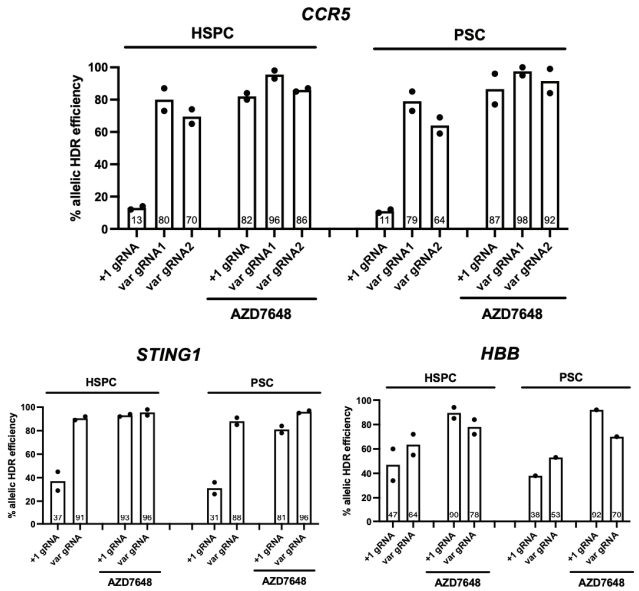

Fig 1: Improved HDR efficiency in HSPC and PSC with optimal gRNA selection. Allelic HDR efficiency in HSPC and PSC edited at the *CCR5, STING1 and HBB* loci with RNP/AAV6 gene editing using +1 or variable (var) INDEL gRNAs with and without AZD7648.

714. Making Change Possible: VLP-Mediated Editing in Primary Human Bronchial Epithelial Cells

Ariel Aspiras[1], Alisa Bell[2], Martin Mense[3], Calvin Cotton[1], Hillary Valley[1]

[1]Gene Editing, Cystic Fibrosis Foundation, Lexington, MA,[2]Cystic Fibrosis Foundation, Lexington, MA,[3]Cystic Fibrosis Foundation Therapeutics, Lexington, MA

Cystic fibrosis (CF) is a rare, life-shortening genetic disease caused by mutations in the *CFTR* gene. Gene editing strategies that can correct multiple CF-causing mutations are promising, as more than 2,000 genetic variants have been suggested to cause CF. Insertion of a partial cDNA (also known as a super exon (SE)) into the native *CFTR* genomic locus can restore the *CFTR* gene to a WT coding sequence for all mutations downstream of the insertion site. Targeted insertion of a super exon coding for exons (E) 2-27 into *CFTR* intron 1, could in theory benefit >99% of people with cystic fibrosis. Primary human bronchial epithelial cells (hBEs) are a frequently used model system for cystic fibrosis research, as they are derived from explanted lung tissue and differentiate into a pseudostratified epithelium over several weeks at air-liquid-interface (ALI) culture. However, delivery of gene editing reagents to well-differentiated hBE ALI cultures is difficult and hampers development of promising genetic correction strategies, such as the super exon. Virus like particles (VLP)s are composed of viral proteins to facilitate transduction but lack viral genomic material so are replication and integration incompetent. Here we show that in undifferentiated hBE cells, adenovirus with super exon donor DNA can be co-transduced with VLPs delivering complexed cas9 ribonucleoproteins (RNPs) without significant cytotoxicity and with 53% total editing efficiency. Additionally, we have demonstrated 17% editing of fully differentiated hBE cells in ALI cultures when RNPs were delivered via VLPs. These results suggest a way forward to genetically engineer primary hBE cells and to develop a durable cure for cystic fibrosis.

715. REMEDY Corrects Heterozygous Mutations Independent of Exogenous Donor Template with High Efficiency

Yasemin Sezgin[1], Noushin Saljoughian[1], Genesis Snyder[1], Colin Maguire[1], Ebru Erzurumluoglu Gokalp[2], Eleonora D'Ambrosio[1], Devi Jaganathan[1], Burcak Ozes[1], Zarife Sahenk[1], Sriram Vaidyanathan[1], Jerry R. Mendell[1], Nizar Y. Saad[3], Roshini S. Abraham[1], Juhi Bagaitkar[1], Susan D. Reynolds[1], Allison M. Bradbury[1], Meisam Naeimi Kararoudi[3]

[1]Nationwide Children's Hospital, Columbus, OH,[2]Eskisehir Osmangazi University, Eskisehir, Turkey,[3]Nationwide Children's Hospital and Ohio State University, Columbus, OH

One of the major limitations of the current gene correction approaches is the need of an exogenous donor template to introduce the desired changes in the targeted DNA. However, this donor template can have negative effects on cell viability and genome stability as it can be cytotoxic given the initiation of DNA sensing mechanisms and can cause unwanted integrations or recombination. Here we report the development of a novel genome editing strategy that allows REpair of Heterozygous Mutations Independent of Exogenous Donor Template with High EfficiencY efficient (REMEDY) in human and mouse cells. We hypothesized that CRISPR targeting of the mutant allele induces double strand break (DSB) and stimulates the movement of healthy homologous chromosome to serve itself as an endogenous DNA donor template. This initiates the correction of the CRISPR-targeted mutant allele via intra-homologous chromosome repair. To perform REMEDY, we designed mutant allele specific gRNAs (near-PAM or in-PAM) to introduce DSB. To test the idea, we designed multiple mutant specific gRNAs targeting the heterozygous phenylalanine 508 (F508del) mutations in CFTR gene to induce DSB. We electroporated the patient-derived human bronchial epithelial cells (HBEC) harboring one copy of the F508del variant with the Cas9/RNP. As the REMEDY correction is regulated by homology-directed repair (HDR), we treated the cells with HDR enhancers such as AZD7648, which further improved the efficiency of the correction. We observed a significant increase in the

frequency of wildtype allele in the cells treated with gRNA1 from 50% to 86%, and to 87% with gRNA2 measured with using Sanger sequencing and next generation sequencing (NGS). Data were analyzed by ICE (interference of CRISPR Edits) and CRISPResso2. We further demonstrated the utility of REMEDY in the context of other four different diseases with heterozygous mutations such as Hutchinson-Gilford progeria syndrome (correction of from 50% to 69% wild-type allele), inclusion body myopathy with early-onset Paget disease and frontotemporal dementia (IBMPFD) (correction of from 50% to 71% wild-type allele), inositol 1,4,5 triphosphate receptor 3 (ITPR3) (correction of from 50% to 62% wild-type allele), and tubulin folding cofactor D (TCBD) in human patient derived primary cells (correction of from 50% to 83% wild-type allele) and mouse model derived cells (correction of from 50% to 58% wild-type allele). REMEDY has immense potential to be used in basic science and pre-clinical studies to correct heterozygous mutations in vitro as well as to treat patients if corrections can be performed ex vivo for many cell therapy applications.

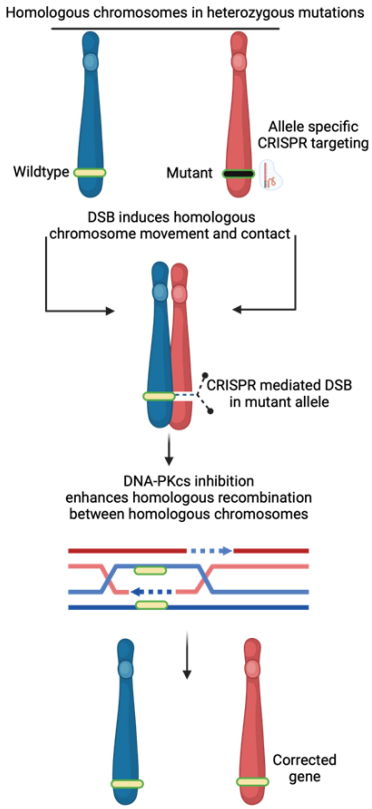

Figure 1. REMEDY results in highly efficient heterozygous mutation correction using HDR between homologous chromosomes and does not need an exogenous DNA template

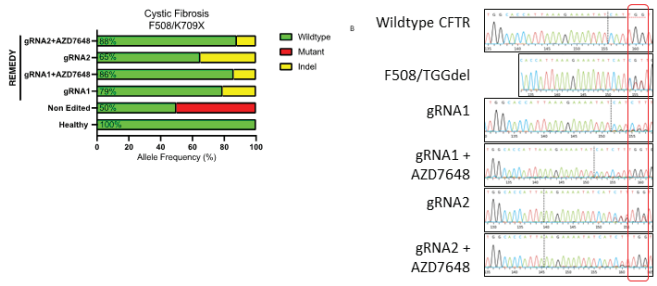

Figure 2. REMEDY corrects several heterozygous mutations in different cell types and diseases. REMEDY corrected heterozygous mutations in human airway epithelial cells with *CFTR* heterozygous mutation derived from a patient with CF.

716. A Catalogue of Novel Type II CRISPR Nucleases with Diverse PAM Preferences

Bang Wang[1], Yuanwei Cao[1], Miao Yu[2], Si Chai Liu[1], Lawrence Yuk Ting Ip[1], Ken Chau[1], Hoi Yee Keung[1], Zongli Zheng[2]

[1]GenEditBio Limited, Hong Kong, China,[2]Ming Wai Lau Centre for Reparative Medicine, Karolinska Institutet, Hong Kong, China

Clustered regularly interspaced short palindromic repeats and associated proteins (CRISPR-Cas) system holds great promise to revolutionize genome editing and therapy in basic and translational settings. Various CRISPR-Cas systems have been explored and engineered, such as CRISPR-Cas9 and CRISPR-Cas12a that belong to the Class 2 of CRISPR-Cas system. However, therapeutics applications of these tools can be limited due to the restriction of the protospacer adjacent motif (PAM)-related targetability and potential off-target effects. To address these challenges, we established and streamlined an efficient, fast, high-throughput platform for screening natural novel CRISPR Cas nucleases. With this new platform, we identified and characterized dozens of novel type II Cas nucleases with diverse PAM restrictions and protein sizes. We selected three representatives with A-rich, C-rich, and AC PAM recognitions for detailed optimization and engineering. The A-rich PAM nuclease (GEBxII108) showed generally comparable editing potency compared to the well-documented *Streptococcus pyogenes* (SpCas9) at over ten endogenous loci, and with higher fidelities at tested sites than SpCas9 as evaluated by GUIDE-seq. We engineered the sequences of Cas and single guide RNA (sgRNA), which remarkably enhanced the potency in primary cell using RNA format, enabling fully functioning. For the C-rich PAM nuclease (GEBxII920), we mutated key amino acids at the endonuclease domain to be used as a nickase. The results showed that it was functional when fused with an adenine base editor, with an expanded base editing window (A1 to A12), which might be useful for base editing at the *cis*-regulatory region (e.g. promoter) or splicing site. There are numerous scenarios where disease-causing mutations are not in an ideal distance to NGG - the PAM sequence of the most widely used SpCas9, making it necessary to use nucleases with alternative PAM recognitions. We identified a nuclease (GEBxII901) that recognizes a 5'-NRHACT-3' PAM, where the 'ACT' bases are highly restrictive. We utilized this restriction property for an allele-specific targeting application. The result showed a significant discriminative power on

editing mutation-containing allele than the WT allele. A base editor based on this GEBxII901-engineered nickase showed higher potencies compared to SpCas9-base editor at over ten tested target loci. Based on our novel type II Cas nuclease mining platform, we have identified a collection of type II Cas nucleases with diverse PAM restrictions that could be useful alternatives to SpCas9 in cell and genome editing therapy development.

717. Advanced Gene Editing with an Enhanced Site-Specific Nuclease for Knock-Out and Knock-In Applications

Oscar Alvarez, Lucas Homa, Khalid Hajj, Zhibo Ma, Cindy Negron, David Ebeid, Matthew Nitzahn, Mauricio Barajas-Mora, Arturo Barcenas, Alicia Davis, Mu Li, Nicholas Cam, Ming-Yue Lee, Blair B. Madison
Poseida Therapeutics, San Diego, CA

Our Cas-CLOVER™ Gene Editing System is a high-fidelity system that relies on the Clo051 nuclease domain and dCas9 RNA-guided DNA binding. Dual guide RNA targeting greatly restricts double-strand breaks (DSBs), conferring high specificity to the Cas-CLOVER nuclease, which is approximately 10-fold greater than Cas9, and thus significantly reduces the risk of unwanted off-target mutations. Across multiple candidate sites, the Cas-CLOVER nuclease delivers high on-target activity (84% average) and low off-target editing (<0.5%). Through efforts exploring the potential of the Cas-CLOVER nuclease, we pursued biased phylogeny-informed and structure-based mutagenesis of the Clo051 nuclease domain. One mutation (S44P) conferred a 2 to 3-fold enhancement of on-target activity, with confirmatory studies showing higher editing activity among multiple genomic targets. Notably, very low off-target editing (<0.2%) was maintained with the S44P variant, even with dose escalation, reflecting full preservation of Cas-CLOVER fidelity. The enhanced activity and fidelity were likewise observed in vivo following LNP-mediated delivery of Cas-CLOVER mRNA. We then investigated the ability of this 2nd generation Cas-CLOVER nuclease (CCv2) to yield site-specific knock-ins. Targeting an intron in the mouse *Alb* gene, a bi-directional promoterless and a uni-directional promoter-containing strategy were each evaluated for the integration of akaluciferase and phenylalanine hydroxylase (PAH) genes of interest (GOI). Each DNA donor cassette was delivered using an AAV vector. At a dose of 5E12 vector genomes per kg (vg/kg) and 1.5 mg/kg CCv2 LNP, akaluciferase bioluminescence imaging (BLI) yielded a >300-fold increase in signal relative to AAV-only controls. Liver immuno-staining indicated successful targeting of >67% of nucleated cells in the liver. For the PAH GOI delivery and integration, mRNA levels of hPAH reached 100 to 150% of normal mouse PAH levels. In the context of *Pah* knockout PKU animals, normal serum phenylalanine levels were achieved within 7 days of dosing. These data highlight the utility of the CCv2 nuclease for efficient knock-ins. In conclusion, the high-fidelity Cas-CLOVER nuclease system represents a key advancement in gene editing technology, boasting exceptional efficiency and specificity compared to conventional nucleases. The unique dimeric structure of the Cas-CLOVER high-fidelity nuclease provides the core foundation for its specificity, which greatly minimizes the occurrence of double-strand breaks at off-target sites. The S44P variant has proven to be a key enhancer of Cas-CLOVER activity, through modulation of Clo051 nuclease structure, yielding a 2 to 3-fold improvement in on-target editing. Moreover, this 2nd generation Cas-CLOVER nuclease exhibited remarkable capabilities for site-specific knock-ins, as evidenced by successful integration of a relevant GOI in mouse liver cells and phenotypical rescue in a PKU mouse model. The high fidelity coupled with the enhanced CCv2 activity could lead to greater safety and efficacy benefits for gene editing therapeutics compared to traditional Cas9.

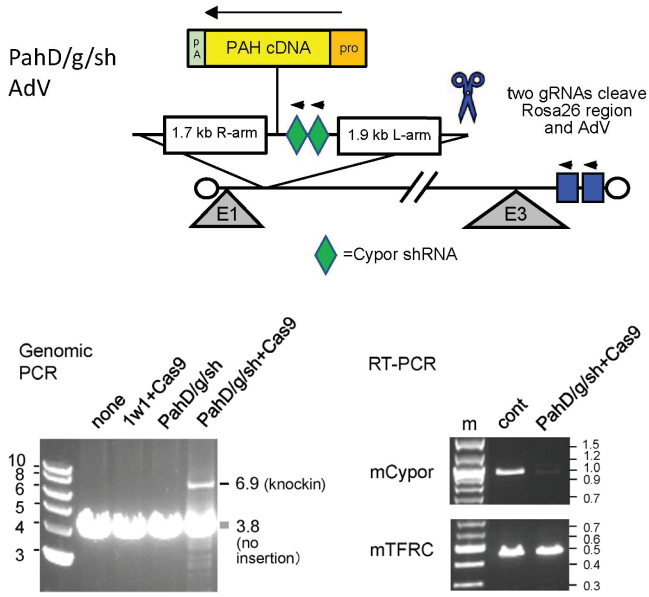
718. Domesticating Retron Reverse Transcriptases for Precise Genome Editing

Seth Shipman
Bioengineering and Therapeutic Sciences, UCSF & Gladstone Institutes, San Francisco, CA

The use of chemically synthesized DNA sequences has accelerated biomedical research. We now recode genomes, barcode molecular events, and modify cell proteomes using synthesized DNA. However, limitations in synthetic DNA delivery prevent us from realizing the full power of these approaches. Unlike engineered RNA or protein, which we may produce inside cells, synthetic DNA must be physically delivered to the cells that we aim to modify, using methods that are inefficient, lack specificity, and offer no temporal control. As a solution, my lab is harnessing components of a bacterial immune systems called a retron to produce designed DNA inside cells by reverse transcription. I will present work showing how we have domesticated and modified retrons for use as a platform biotechnology via high-throughput, quantitative assays. I will discuss implications of this technology for genomic medicine and also highlight new approaches for fundamental biology that the retron enables, including precise and trackable genome editing screens and molecular recording of transcriptional events.

719. CRISPR-Enabled Autonomous Transposable Element (CREATE) for RNA-Mediated Gene Editing and Delivery

Yuxiao Wang[1], Ruei-Zeng Lin[1], Bruce McCreedy[2], Meghan Harris[1], Bianca Lavayan[1], Daniel Getts[1]
[1]Myeloid Therapeutics, Cambridge, MA,[2]ONK, Durham, NC



To realize the potential of genome editing, tools that can achieve targeted delivery of multi-kilobase gene payloads without inducing double-stand breaks (DSB) are necessary. The combination of Prime Editing with a DNA transposase overcomes the size limitation but requires co-delivery of multiple components including a DNA donor plasmids. Here, we introduce the CRISPR-Enabled Autonomous Transposable Element (CREATE), an RNA-based genome editing system that merges CRISPR/Cas9 with the capabilities of the human L1 retrotransposon to insert gene-sized payloads without DNA donors or double strand breaks. This is achieved by endowing the L1 mRNA with features that enable Cas9-guided reverse transcription and specific integration of an RNA-encoded payload gene without size limits. To demonstrate targeted gene delivery in mammalian cells, we insert a 1.1 kb gene comprising a promoter and green fluorescent protein (GFP) into several loci in human genome. Mechanistic studies reveal that the CREATE system is highly specific with no observed off-target events. The fully RNA-based delivery of CREATE can achieve efficient payload integration in Huh7 liver cells. Together, these findings

establish CREATE system as a programmable gene delivery platform solely based on RNA components enabling large-scale in vivo genome engineering with broad therapeutic potential.

720. The Development of Knock-In Adenovirus Vectors Aiming for Safe *In Vivo* Genome-Editing Therapy of Genetic Diseases Using Multiplex CRISPR Guide RNAs and Short-Hairpin RNA

Tomoko Nakanishi, Megumi Yamaji, Nakamura Mariko, Izumu Saito, Sigeto Sato, Nobutaka Hattori
Juntendo University, Tokyo, Japan

Introduction: Phenylketonuria (PKU) is one of the most common metabolic diseases, which results in the accumulation of phenylalanine (Phe) caused by a deficiency of the hepatic enzyme phenylalanine hydroxylase (PAH). Currently, there is no cure for PKU. The prevailing treatment is predominantly through dietary restriction of Phe to the minimum required level for normal growth, supplemented with specifically designed medical foods. CRISPR/Cas9 genome editing system, the most popular and powerful tool for gene-editing technology, is expected for clinical application to therapies for genetic diseases such as PKU. We have developed adenovirus vectors (AdVs) expressing eight multiplex guide RNAs (gRNAs) and found that these AdVs can efficiently disrupt multiple genes of human papillomavirus and hepatitis B virus *in vitro* and *in vivo* by simultaneous expression with Cas9 nickase using double-nicking strategy. The strategy reduces unwanted off-target effects, and, in fact, off-target mutations decreased below the detection limit in our study. Here, we showed a novel approach aiming for efficient and safe knock-in therapy. **Results**: An animal model for PKU, the Pah^{enu2} mouse, has a missense mutation (F263S) in exon 7, which inactivates PAH. To treat these mice, we first constructed an AdV containing a 4-kb donor DNA, including the normal exon 7 sequence, together with eight multiplex gRNA expression units. The former six gRNAs cleave genomic DNA near the mutation site and the latter two cleave the AdV genome to excise the donor DNA from the backbone. When the AdV was infected to culture cells together with the AdV expressing native Cas9 or Cas9 nickase, the knock-in efficiency increased by excision of the donor DNA but was still 3% at maximum. By administration of the AdVs to Pah^{enu2} newborn mice, a 30% reduction of the serum Phe levels was observed after 5 weeks. However, knock-in efficiency was low in the liver cells, at less than 1%, and the treatment was not sufficient. Therefore, we tried to develop a novel, more efficient knock-in system where AdV delivers the entire expression unit into the Rosa26 safe-harbor region. This AdV carries the donor DNA consisting of the expression unit of normal Pah cDNA, homology arms of 1.7 and 1.9 kb, and two gRNAs targeting at Rosa26 and two shRNAs against Cypor mRNA (graphic1) (the cells successfully knocked-in lack Cypor mRNA and can be selected *in vivo* by high dose acetaminophen). The knock-in efficiency of this AdV was about 7% *in vitro*, and the level of Cypor mRNA decreased by more than 90% (graphic2). **Conclusion**: We developed AdVs simultaneously expressing multiplex gRNAs and shRNAs and carrying a large donor DNA, which can be selected in the knocked-in liver cells *in vivo*. Utilizing the method, we established an efficient system of "cDNA knock-in", in which the entire expression units of normal cDNA are inserted efficiently into the Rosa26 region. Our results suggest that the cDNA knock-in strategy using AdVs described here could be applied to the treatment of various inborn metabolic disorders by exchanging the cDNA in the expression unit.

721. Intron Editing of HSPC Enables Lineage-Specific Expression of Therapeutics

Eduardo Seclen[1], Aminah Lawal[1], Hana Cho[1], Alexandre Juillerat[1], Sylvain Pulicani[2], Philippe Duchateau[2], Julien Valton[2]
[1]Innovation, Cellectis, INC, New York City, NY,[2]Innovation, Cellectis, SA, Paris, France

Gene therapy on hematopoietic and progenitor stem cells (HSPC) has the potential to provide a lifelong supply of genetically encoded therapeutics. Gene editing strategies for supra-endogenous expression often rely on constitutive promoters resulting in transgene overexpression irrespective of cellular differentiation, which could be detrimental for HSPC function. We have developed a TALEN mediated promoter-less intron editing technology that relies on the endogenous cellular RNA splicing machinery to induce lineage-specific transgene expression exclusively after HSPC differentiation. By inserting a promoterless eGFP cassette into different intronic regions of the genome, we demonstrated a lineage-specific expression pattern for several hematopoietic lineages *in vitro* and *in vivo*. In addition, we modeled the potential translatability of this technology by inducing myeloid-specific expression of alpha-L-iduronidase (IDUA), the deficient enzyme in Mucopolysaccharidosis type I. Our *in vitro* data confirmed that editing the introns of B-cell, T-cell or myeloid/microglial lineage-specific genes did not lead to significant eGFP expression in HSPC prior to cell differentiation. For our myeloid gene candidate, *in vitro* differentiation of edited HSPC confirmed the expected myeloid-specific expression pattern of the transgene, while maintaining the endogenous expression of the targeted gene. For our B- and T-cell gene candidates, successful lineage-specific eGFP expression was confirmed after editing activated peripheral blood and

mononuclear cells (PBMCs). eGFP-edited HSPC were injected into a conditioned immunodeficient mouse model that recapitulates bone marrow transplantation including *in vivo* differentiation into myeloid, B cell, T cell and microglia lineages. Sixteen weeks after HSPC injection, animals were euthanized and eGFP expression was characterized in blood, brain and bone marrow. A thorough characterization of human cells engraftment, level of editing and transgene expression in multiple tissues will be presented. Lastly, we edited our myeloid gene candidate in HSPC to support IDUA expression after differentiation. *In vitro*, differentiated IDUA-edited HSPC displayed a 10-fold supra-endogenous IDUA expression in comparison with the endogenous IDUA expression of non-diseased cells, highlighting the high translational potential of this technology for therapeutic approaches based on cross-correction. *In vivo*, IDUA-edited HSPC effectively populated blood, spleen, bone marrow and brain of conditioned immunodeficient mice, and retained the capacity to secrete IDUA *ex vivo*. We believe this intron editing approach is an important addition to the HSPC gene editing toolbox that might unlock new strategies for the treatment of metabolic and neurological diseases.

722. Highly Specific Zinc Finger Proteins with Synthetic Target Sites Enable Self-Regulated Expression of Dosage-Sensitive Transgenes

Gillian Houlihan, Matthew Mendel, Qi Yu, Kimberly Marlen, Jisoo Lee, Yolanda Santiago, Mohammad Samie, Patrick Dunn, Amy Pooler, Bryan Zeitler

Sangamo Therapeutics, Inc., Richmond, CA

Limiting overexpression of AAV delivered cargo is an important safety consideration particularly for indications with dosage sensitive genes which require transgene expression in a precise therapeutic range to balance efficacy and potential toxicity. To address this therapeutic challenge, we developed a self-regulating expression technology using zinc transcriptional repressor (ZFRs) proteins that serve as vector elements to precisely control transgene expression. The combined ZFR and target site payload is <1kb, does not require exogenous components and should be compatible with any promoter and transgene construct in which fine control of expression is required. Highly specific orthogonal ZFs were engineered to bind unique target DNA sequences not found in preclinically or clinically relevant mammalian genomes. When tethered to a KRAB repressor domain, these (ZFRs) exhibited exquisite specificity with no detectable differentially expressed genes identified in mouse or human neurons transduced with AAVs encoding the engineered ZFRs. Top candidate ZFRs were assessed for tolerability in vivo. AAV mediated ZFR delivery to wild type mice revealed these proteins were well tolerated with no neuronal loss or neuroinflammation observed in brain or spinal cord. Next, we developed a gene circuit regulated by a ZFR feed-forward loop using ZF target sites engineered into a promoter to tune the level of transgene expression. A panel of self-regulated expression cassettes controlling the expression of GFP were evaluated by flow cytometry and microscopy in transfected cells and AAV transduced neurons. A reduction in the population of cells with the highest levels of GFP expression was observed compared to unregulated expression cassettes. Transgene levels in AAV transduced neurons were measured by RT-qPCR which demonstrated the magnitude of ZF mediated self-regulation directly correlated with the number of ZFR target binding sites in the expression cassette. Furthermore, modulating ZF affinity for a given target site directly influenced transcriptional output. ZFR cooperativity should reduce expression proportionally to the level of delivered transgene cells thus enabling uniform transgene expression on a per cell basis. Further development and in vivo validation will be performed to evaluate this ZF platform as a solution for safe and effective gene therapies with dose-sensitive transgenes.

Wednesday Posters: Oligonucleotide Therapeutics

723. Enhancing Antisense Oligonucleotide Efficacy with Small Molecule Oligonucleotide Activity Enhancers

Saeed Anwar[1], Scott David-Bittner[2], Annie Tang[1], Rika Maruyama[1], Hong M. Moulton[2], Toshifumi Yokota[1]

[1]Medical Genetics, University of Alberta, Edmonton, AB, Canada,[2]Biomedical Sciences, Oregon State University, Corvallis, OR

Antisense oligonucleotides (ASOs) are synthetic oligomers that are adept at binding to RNA and modulating gene expression through various mechanisms, including mechanisms include RNase H-mediated cleavage, direct steric blockage, splicing modulation, non-coding RNA inhibition, and gene activation. These oligomers show promise for treating a range of complex genetic and rare diseases. However, their suboptimal activity in targeted cells and organs, particularly *in vivo*, represents a significant challenge. Following systemic administration, ASOs predominantly accumulate in the liver and kidneys, with markedly reduced accumulation in other tissues. Moreover, ASOs often become sequestered in nonproductive intracellular sinks, e.g., endosomal compartments, impeding effective gene expression modulation. This study investigates the hypothesis that small molecule oligonucleotide activity enhancers (OAEs) can significantly amplify ASO efficacy and safety. We have developed a mini-library of OAEs by repurposing molecules already approved by the FDA or extensively researched for other indications. These molecules are hypothesized to aid ASO escape from endosomal entrapment and enhance ASO activity in a non-toxic manner upon co-administration. We demonstrate the impact of OAEs on ASOs' therapeutic potential in three distinct *in vitro* disease models. Our findings include a significant (~3-fold) increase in exon-skipping efficiency of phosphorodiamidate morpholino oligomers (PMOs) targeting exon 27 of the *DYSF* gene in dysferlin-deficient limb-girdle muscular dystrophy recessive type 2 (LGMDR2) patient-derived myoblasts, restoring an out-of-frame transcript to in-frame and indicating potential functional improvements as evidenced by an enhanced myotube fusion index. Additionally, we observed that OAEs markedly increased the efficacy of *DUX4* transcript knockdown (71-97%) by locked nucleic acid (LNA) and 2′-O-methoxyethylribose (MOE) gapmers in facioscapulohumeral muscular dystrophy (FSHD) patient-derived myotubes. This was accompanied by a significant reduction in the expression of *DUX4* downstream genes, including *ZSCAN4*, *TRIM43*, and *MBD3L2*. Furthermore, we demonstrate OAEs' capacity to improve allele-selective LNA and MOE gapmer ASOs targeting the $ACVR1^{R206H}$ allele (15-25%) in fibrodysplasia ossificans

progressiva (FOP) patient-derived fibroblasts. Across these cell-based disease models and ASO chemistries, OAE co-administration resulted in highly significant enhancements in ASO activity. OAEs thus emerge as a practical tool for intensifying the activity of diverse ASO chemistries, potentially broadening the therapeutic applicability of ASO-based strategies. Ongoing research focuses on the *in vivo* efficacy and safety of these OAEs in relevant mouse models, with the aim of translating these findings into clinically viable treatments.

724. Optimization and Application of the Endosomal Escape Vehicle (EEV™) Platform for Enhanced Delivery of Oligonucleotides to Skeletal and Cardiac Muscle

Xiang Li[1], Patrick G. Dougherty[1], Mah Kheirabadi[1], Nelsa L. Estrella[1], Ajay Kumar[1], Amy N. Hicks[1], Ashweta Sahni[1], Mark Wysk[1], Kimberli J. Kamer[1], Wenlong Lian[1], Nanjun Liu[1], Ning Li[1], Matthew Streeter[1], Kyle Totaro[1], Ming Zhou[1], Christopher M. Brennan[1], Anushree Pathak[1], Alison Burman[1], Sara L. Blake[1], Mohanraj Dhanabal[1], Andy Stadheim[1], Mahasweta Girgenrath[1], Ziqing Leo Qian[2]

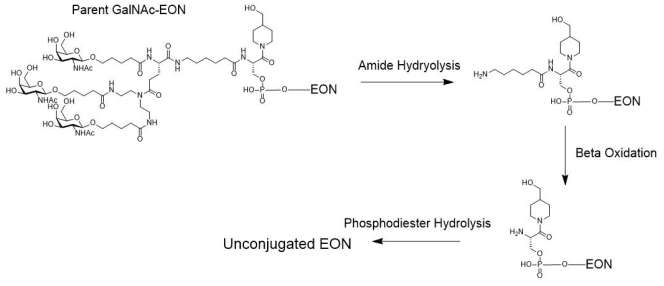
[1]Entrada Therapeutics Inc, Boston, MA,[2]Entrada Therapeutics, Boston, MA

Intracellular delivery of oligonucleotide therapeutics is challenging because of poor cell entry and limited escape from the endosome in the target cell. These limitations often necessitate high therapeutic doses and can be associated with less-than-optimal therapeutic activity. One strategy to overcome these limitations is conjugation of oligonucleotides to cell-penetrating peptides (CPPs). Compared with linear CPPs, cyclic CPPs have been shown to efficiently penetrate the cell membrane and are more resistant to proteolytic degradation. We have designed a family of proprietary cyclic CPPs that form the core of our Endosomal Escape Vehicle (EEV™) technology, which is capable of delivering covalently conjugated cargo to several tissue types. First generation EEV cyclic CPPs underwent several specific chemical modifications to optimize their ability to deliver antisense oligonucleotides. Notably, potentially cytotoxic residues were substituted, and nuclear localization signal was added to improve the delivery of oligonucleotides. These studies demonstrate that the medicinal chemistry underlying the structure of cyclic CPPs are integral in their ability to efficiently deliver therapeutic cargo. The therapeutic potential of EEV-oligonucleotide conjugates has been confirmed in preclinical models of Duchenne muscular dystrophy (DMD) with enhanced exon skipping and broad dystrophin protein expression in skeletal and cardiac muscles of mice and nonhuman primates. These results demonstrate the ability of the EEV platform to efficiently deliver exon skipping oligonucleotides to skeletal and cardiac muscle in preclinical models of DMD and support the potential for further study in patients with DMD. The first-in-human, phase 1 clinical trial of ENTR-601-44 in healthy male subjects is ongoing in the United Kingdom, with study results anticipated in the second half of 2024.

725. S10 Peptide Conjugated to Phosphorodiamidate Morpholino Oligomer Mediates Exon Switching in Mouse Airway Epithelial Cells

Luis Sorroza Martinez[1], Maud Auger[1], Nadine Brahiti[2], Carole-Ann Huppé[3], Laurence Faucher-Giguère[4], Imen Arbi[4], Maxime Hervault[4], Xue Cheng[4], Bruno Gaillet[5], Frédéric Couture[6], David Guay[4], Soultan Al-Halifa[4]

[1]Chemical Engineering, Université Laval, Quebec, QC, Canada,[2]Fledan Therapeutics, Quebec, QC, Canada,[3]TreansBIOTech, Quebec, QC, Canada,[4]Feldan Therapeutics, Quebec, QC, Canada,[5]Chemical Engineering, Université Laval, Québec, QC, Canada,[6]TransBIOTech, Quebec, QC, Canada



Among the various inhaled biomolecules investigated to treat lung diseases, antisense oligonucleotides (ASOs) are attractive due to their ability to mediate RNA degradation, alternative splicing, or suppress translation of targeted RNA sequences without affecting genomic DNA. Several ASOs have shown promising results in treating respiratory diseases such as asthma and cystic fibrosis (CF). Among the different ASO derivatives, phosphorodiamidate morpholino oligomers (PMOs) have great potential as therapeutic biomolecules. PMOs are ASOs in which the phosphodiester is replaced by a phosphorodiamidate backbone and the ribose by a morpholino subunit. PMOs have been successfully approved by the FDA to restore dystrophin protein expression in muscles of Duchenne muscular dystrophy (DMD) patients after systemic administration. Nevertheless, except in the case of altered tissues such as deteriorated muscle membranes in DMD, *in vitro* and *in vivo* studies show that PMOs are internalized into cells but remain mostly trapped in endosomes, preventing them from reaching intracellular RNA molecules. S10 is a peptide-based delivery agent that enables the intracellular delivery of biomolecules such as GFP, CRISPR-associated nucleases, base editor ribonucleoproteins (RNPs), and a fluorescent peptide into lung cells after intranasal or intratracheal administrations to mice, ferrets, and rhesus monkeys. Herein, we demonstrate that covalently attaching S10 to a labeled peptide or a functional splice-switching PMO improved their intracellular delivery to airway epithelia in mice after a single intranasal instillation. Data revealed a homogenous delivery from the trachea to the distal region of the lungs, specifically into the cells lining the airway. Quantitative measurements further highlighted that S10-PMO conjugation via a cleavable bond strategy was the most beneficial compared to conjugation via a non-releasable bond. We believe that S10-based conjugates bring new opportunities to enable the intracellular delivery of peptides and ASOs with therapeutic properties to the lungs.

726. Complex Metabolism and Prolonged PK/PD of a GalNAc-Conjugated Editing Oligonucleotide (EON) in Mice

Everett J. Perkins[1], Ryan Hill[1], Ellese Carmona[2], Shrutokirti De[1], Simone Bigler[3], Nicole Cnubben[3], Wouter Beumer[3], Cherie Kemmel[3], Christian van't Hekke[3], Lenka van Sint Fiet[3]

[1]Eli Lilly and Company, Indianapolis, IN,[2]Eli Lilly, Cambridge, MA,[3]ProQR Therapeutics, Leiden, Netherlands

Background: Editing oligonucleotides (EONs) are single stranded oligonucleotides designed to utilize ADAR (Adenosine Deaminase Acting on RNA) to induce single nucleotide (A to I) changes in mRNA. GalNAc-EON11 is a triantennary N-acetylgalactosamine-conjugated EON being explored for the treatment of a liver metabolic disorder. EON11 has demonstrated effective editing of the target mRNA *in vitro* and *in vivo* in mice. **Methods:** To assess the relationships between EON concentrations and pharmacological effect, a PK/PD study was conducted with GalNAc-EON11 in a mouse disease model. The drug was administered subcutaneously at a single dose of 30 mg/kg. Plasma, liver, spleen, and kidney were collected from 4 mice at time points ranging from 0.5 hr to 28 days post-dose. Parent drug and its metabolites were assessed in plasma and tissues by high resolution LC-MS and hybridization-HPLC. Additional study arms assessed liver concentrations and pharmacodynamic effects after repeat dose paradigms. Pharmacodynamics were determined by measuring the target enzyme activity in liver. **Results:** The EON11 oligonucleotide was rapidly cleared from plasma by extensive liver and kidney uptake. The EON was stable *in vivo*, with a long tissue half-life and no *in vivo* metabolites of the nucleic acid moiety observed. However, 10 metabolites of the GalNAc linker still attached to EON11 were observed. Very low levels of fully unconjugated EON11 were present in all tissues. The metabolic pathway of the GalNAc portion was generally consistent with previous reports of triatennary GalNAc molecules, with rapid initial loss of the sugars after tissue uptake and sequential cleavage of the amide bonds (Figure 1). But the predominant and long-lived metabolites in tissues were full-length EON11 with an intact portion of the alkyl heterocycle-based linker, in addition to sequential oxidation products of the 6-carbon alkyl chain. These metabolites are all presumed to retain editing activity, based on preliminary *in vitro* studies with GalNAc and non-GalNAc EONs. Further analysis was conducted by hybridization-HPLC to increase sensitivity and simplify the evaluation of PK/PD relative to total EON, assuming all GalNAc metabolites will be detected equally. Plasma concentrations of total oligo were low relative to liver but were reflective of the liver elimination profile. Spleen concentrations of total EON increased over the course of the study, suggesting redistribution from other tissues. The resulting PK profile of total EON indicates a terminal half-life that exceeds 28 days in mice, which coincided with prolonged durability of effect and accumulation with repeated dosing. Enzyme activity in liver increased over the 4-week period and was further increased with repeated dosing, indicating potential utility of this GalNac-conjugated EON approach in the treatment of metabolic genetic disorders.

727. *In Vitro* Assessment of GalNAc-Conjugated siRNA Cellular Uptake and Target Knockdown in Primary Human Hepatocyte Culture Models

Karissa E. Cottier[1], Jeannemarie Gaffney[2], Devika Bhalerao[1], Candice Lewis[1], John Griffith[1], Scott Heyward[1]

[1]BioIVT, Halethorpe, MD,[2]BioIVT, Medford, MA

New therapeutic modalities, including oligonucleotide therapies, comprise a growing share of drugs in development due to their improved target affinity and selectivity, and a longer duration of action as compared to small molecules. For liver diseases, additional site selectivity can be achieved using N-Acetylgalactosamine (GalNAc)-conjugated to therapeutic RNA to direct liver delivery by its strong affinity for the hepatocyte-specific asiaglycoprotein receptor (ASGPR). In these studies we characterized the time, ASGPR expression, and hepatocyte donor-dependent cellular uptake and knockdown efficiency of a GalNAc conjugated siRNA in standard plated hepatocytes as well as in the HEPATOPAC ® model, a micropatterned co-culture for long-term primary human hepatocyte culture. This model retains hepatic functions for up to 28 days including high levels of albumin, urea, and stable metabolic enzyme activity. To observe treatment time-dependent differences in GalNAc-siRNA efficiency, standard plated hepatocytes were treated with 50nM of Cy-3 GalNAc-siRNA targeting GAPDH for 24 hours on day 0, 1, and 2 of plating. In standard plated cultures, the greatest siRNA uptake and percent knockdown was seen when cells were treated on the day of plating (day 0). A significant difference in siRNA uptake was observed between the hepatocyte lots. Previous HEPATOPAC studies assessing ASGPR expression, siRNA uptake as measured by Cy3 signal, and target knockdown (KD) showed a strong linear correlation between these variables. To confirm ASGPR dependent uptake in HEPATOPAC, ASGPR was knocked down prior to GalNAc siRNA treatment. ASGPR siRNA transfection knocked down ASGPR mRNA by >80%. ASGPR KD reduced GalNAc-siRNA uptake by approximately 2-fold and target KD by approximately 3-fold. When HEPATOPAC cultures were exposed to GalNAc siRNA for increasing durations (0.25, 1, 4, 24, 48, or 72 hours), GalNAc-siRNA uptake and target KD peaked after 48 hours of exposure. No toxicity was observed in the hepatocytes as measured by urea output. A significant difference in both maximal uptake and KD was observed between hepatocyte lots. In this study, siRNA uptake and knockdown kinetics were similar within the hepatocyte lots tested, however the magnitude of effect varied significantly between donors. This suggests that the use of multiple lots may be important when assessing GalNAc-siRNA *in vitro*. Together, these data demonstrate the suitability of both standard cultures for short term assays, as well as HEPATOPAC cultures for longer term assays including extended incubations or repeat dosing, knockdown of multiple targets, and assessment of toxicity.

728. Oligonucleotide-Based AML Immunotherapy through Targeted STAT3/DNMT1 Inhibition Combined with TLR9/IRF8 Activation

Dongfang Wang[1], Karol Jacek[2], Damian Kaniowski[3], Yu-Lin Su[4], Haiqing Li[1], Tomasz Adamus[3], Susanta Hui[5], Bozena Kaminska[2], Vittorio DeFranciscis[6], Carla Esposito[6], Annalisa DiRuscio[7], Bin Zhang[8], Guido Marcucci[8], Ya-Huei Kuo[8], Marcin Kortylewski[1]

[1]Immuno-Oncology, Beckman Research Institute at City of Hope Comprehensive Cancer Center, Duarte, CA,[2]Nencki Institute of Experimental Biology, Warsaw, Poland,[3]Beckman Research Institute at City of Hope, Duarte, CA,[4]Beckman Research Institute City of Hope, Duarte, CA,[5]City of Hope Comprehensive Cancer Center, Duarte, CA,[6]Institute for Experimental Endocrinology and Oncology "Gaetano Salvatore" (IEOS), Naples, Italy,[7]Harvard Medical School Initiative for RNA Medicine, Harvard Medical School, Boston, MA,[8]Beckman Research Institute at City of Hope Comprehensive Cancer Center, Duarte, CA

Acute myeloid leukemia (AML) cells resist differentiation stimuli despite high expression of innate immune receptors, such as Toll-like Receptor 9 (TLR9). We previously demonstrated that targeting STAT3 using TLR9-targeted decoy (CpG-STAT3d) oligodeoxynucleotide increases immunogenicity of human and mouse AML cells. Here, we elucidated molecular mechanisms of AML cell reprogramming driven by STAT3-inhibition/TLR9-activation. The transcriptional profiling of AML cells isolated from mice after intravenous administration of CpG-STAT3dODN or leukemia-targeted *Stat3* silencing with TLR9 co-stimulation, upregulated similar sets of myeloid cell differentiation (*Irf8, Cebpa, Itgam*) and antigen-presentation (*Ciita, Il12a, B2m*) related genes while downregulating leukemia-promoting *Runx1*. Single cell transcriptomics revealed that CpG-STAT3d induced multilineage differentiation of leukemic cells into monocytes/macrophages, erythroblastic and B cell subsets. As shown by an inducible *Irf8* silencing in AML cells in mice, IRF8 upregulation was critical for monocyte-macrophage differentiation of leukemic cells. TLR9-driven AML cell reprogramming was likely enabled by downregulation of STAT3-controlled methylation regulators, such as DNMT1 and DNMT3a/b. In fact, the combination of DNMT inhibition using a combination of DNMT1 aptamer inhibitor (AptaDiR) or hypomethylating agent (azacytidine) with CpG immunostimulation mimicked CpG-STAT3d effects, resulting in AML cell differentiation, T cell activation and systemic leukemia regression. These findings highlight immunotherapeutic potential of bi-functional oligonucleotides to unleash TLR9-driven differentiation of leukemic cells by concurrent STAT3 and/or DNMT inhibition.

729. Antisense Oligonucleotide Targeting FUS-DDIT3 Oncogene for RNase H Degradation

Erin F. Hall[1], Simon Wentworth[2], Jillian Gallagher[1], Toloo Taghian[1], Yvette Diaz Lopez[1], Abigail W. McElroy[1], Hector Ribeiro Benatti[1], Sarah Nath[1], Neeta Somaiah[3], Gina D'Amato[4], Jonathan K. Watts[5], Miguel Sena-Esteves[6], Heather L. Gray-Edwards[1]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Department of Neurology, University of Massachusetts Medical School, Worcester, MA,[3]Department of Sarcoma Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX,[4]Sylvester Comprehensive Cancer Center, University of Miami Health System, Miami, FL,[5]RNA Therapeutics Institute, UMass Chan Medical School, Worcester, MA, Canada,[6]Department of Neurology, UMass Chan Medical School, Worcester, MA

Introduction: Myxoid Liposarcoma (MLSc) is soft-tissue sarcoma caused by a translocation between the FUS and DDIT3 genes on chromosomes 12 and 16 respectively (96% of cases) or more rarely between the EWSR1 and DDIT3 genes (4% of cases). The aberrant fusion protein FUS-DDIT3 is thought to act as a transcription factor inhibiting adipocyte differentiation. Tumor growth is slow in MLSc and prognosis is typically good for patients with low grade MLSc, however the disease often becomes chemotherapy resistant upon metastasis. Primary tumors typically occur in the limbs. There are 11 documented fusion transcript variants of myxoid liposarcoma, with most transcripts consisting of the N-terminus of FUS and the entire coding sequence of DDIT3. Type 1 and 2 are the most common fusion transcripts, with breakpoints at FUS exon 7 and 5 respectively. Our lab has been working to develop antisense oligonucleotides (ASO) for type 1 and type 2 MLSc chimeric FUS-DDIT3 mRNA that will target the transcript for RNase H degradation, resulting in terminal differentiation of MLSc tumor cells. **Methods:** To screen ASOs for knockdown efficiency, we acquired the tumor-derived MLSc type 1 DL221 cell line. To model the type 2 MLSc cell line, we generated a stable HEK-293T cell line expressing the type 2 FUS-DDIT3 fusion by infecting cells with a lentivirus expressing the type 2 fusion transcript. ASOs were designed by tiling across the type 1 and type 2 breakpoints between FUS and DDIT3 sequences in the chimeric mRNA to engage specifically the chimeric mRNA without affecting the normal transcripts. We screened several different ASO chemistries in our cell lines, including 2'O-Methoxyethyl (2'-MOE) and Locked Nucleic Acid (LNA) using lipid transfection. **Results:** We have identified a top 2'-MOE and candidate in our type 2 cell line. The 2'-MOE ASO resulted in 37% average knockdown compared to a non-targeting control. We have experiments ongoing to identify a top LNA ASO in our type 2 cell line. We also have experiments ongoing in NSG mice to select the lead ASO candidate for type 1 MLSc using the DL221 cell line. Looking towards the clinic, we are planning future human clinical trials for both type 1 and type 2 patients.

Wednesday Posters: Nonviral Therapeutic Gene Delivery and Synthetic/Molecular Conjugates

731. AmplifyBio Non-Viral Gene Editing (NVGE™) Platform

Andrew Conroy, Benjamin J. Meckiff, Craig Fett, Diana Nguyen, Evelyn Vilchez, Hemi Shah, John Greer, Justin Win, Kevin Shao, Marcela Briones, Zheng Pan, Eric J. Kunkel, Theresa R. Stueve

AmplifyBio, LLC, South San Francisco, CA

Adoptive T cell therapies have achieved unprecedented response rates for hematological malignancies, and multiple trials are recruiting for solid tumors. While many therapies are manufactured using viral vectors, the benefits of targeted non-viral approaches are clear: improved insertional specificity; a better understood safety profile; reduced cost of manufacturing; and greater flexibility in simultaneous knock-in and knock-out strategies. AmplifyBio has developed an industry-leading, CRISPR-based Non-viral Gene Editing Platform[1], NVGE™, to support the cell therapy industry from discovery through commercialization. *Targeted engineering for improved genomic safety:* Viral editing produces cells with variable transgene copy numbers and unknown insertion sites, and reductions in integrating vector copy number are recommended by the FDA to reduce risk of insertional mutagenesis. For TCR-T therapies, AmplifyBio's targeted knock-in of TCR payloads of known copy number (2 copies/diploid cell) results in transgenic TCR expression at physiologic levels, without reliance on foreign promoters. Further, simultaneous knock-out of endogenous TCR undercuts competition for CD3 molecules requisite for surface TCR expression and minimizes wildtype and transgenic TCR α and β chain mispairing, enhancing TCR-T function and safety. *Multiplexed edits for increased therapy function:* The modular NVGE™ Platform can be leveraged to multiplex edits including addition of co-receptors and selection markers to the payload. Further, we show the flexibility of the NVGE™ Platform allows for simultaneous knock-out of endogenous TCR and one of six immunosuppressive targets in TCR-T cells. Moreover, the platform can accommodate payloads up to 5.3 kB and potentially larger with modifications to the backbone plasmid used for homology-directed repair. *Rapid cycling time for product selection:* The versatility and speed afforded by single-step NVGE™ produces TCR-T cells with features that can be iterated, vetted, and prioritized in a battery of functional and phenotypic assays we offer clients to inform product selection decisions. *Superior genomics safety profile and testing services:* NVGE™ allows for precision genome engineering with minimal off-target events, as evidenced by FDA-responsive genomic safety assays on offer with AmplifyBio. *cGMP cell therapy manufacturing and lot release testing:* The NVGE™ Platform has been optimized for clinical-scale cGMP manufacturing, and this process has generated materials tested in humans. In addition, AmplifyBio offers comprehensive lot release testing services responsive to FDA guidance to support regulatory filings and clinical trials. *Conclusion:* AmplifyBio offers the advanced cell therapy community a portfolio of solutions from TCR discovery to product release rooted in its CRISPR-based, NVGE™ precision engineering platform. Relative to non-targeted editing, NVGE™ produces TCR-T cells with more predictable phenotypes and superior safety profiles, critical for clinical success and lower-cost manufacturing at scale. 1. Foy *et al*. Non-viral precision T cell receptor replacement for personalized cell therapy. *Nature* (2023); PMID: 3635659.

732. *In Situ* Modification of Macrophages for Targeting PDL-1 in Triple Negative Breast Cancer

Armaan Siddiqui[1], Hemavathi Dhandapani[1], Aijaz Rather[1], Arvind Ingle[2], Deepak Sharma[3], Prakriti Tayalia[1]

[1]Biosciences and Bioengineering, Indian Institute of Technology Bombay, Mumbai, India,[2]Tata Memorial Centre Advanced Centre for Treatment, Research and Education in Cancer, Mumbai, India,[3]Bhabha Atomic Research Centre, Mumbai, India

Background: Chimeric Antigen Receptor (CAR) T-cells have demonstrated remarkable success in treating hematological malignancies. However, hindrance in the ability to infiltrate the solid tumor and exhaustion by tumor microenvironment has impeded their success in treating solid tumor. On the other hand, circulating macrophages and monocytes form a substantial part of the tumor milieu and efficiently infiltrate solid tumor masses. This unique capability of circulating monocytes and macrophages has gained significant interest in extending CAR therapy to macrophages for the treatment of solid tumor. **Aim:** The clinical scaling of chimeric antigen receptor therapy poses challenges related to the maintenance of high quality, logistical complexities, and substantial financial investments. To address these issues, we propose the utilization of a non-viral approach for in situ modification of peritoneal macrophages to express CAR for targeting Triple negative breast cancer (TNBC). This approach will facilitate development of a cost-effective approach to target solid tumor using immunotherapy and will also help avoid the risk of tumorigenic potential of virus-modified cells. **Method:** Chitosan, a biocompatible and biodegradable cationic polymer was modified with mannose to make it specific to monocytes and macrophages. Mannosylated chitosan, a cationic moiety was utilized as a carrier of plasmid DNA (Polyplex system) encoding CAR against PDL-1 which is highly expressed in TNBC. Macrophages were modified using the polyplex system and evaluated for their anti-tumor activity against murine and human triple negative breast cancer tumor models both in vitro and in vivo. STING agonist was used along with the polyplex based CAR macrophage therapy to enhance the efficacy of the study. **Results:** Mannosylated chitosan based polyplex was prepared at different weight ratios of mannosylated chitosan (Mannosylated chitosan: pDNA expressing CAR) and the size was well below 200 nm and had zeta potential of +30mV at higher weight ratios. These polyplexes were analysed for their ability to transfect both murine macrophage and human macrophage. Phagocytic ability of these modified macrophages was evaluated upon co-culture of transfected macrophages with murine and human breast cancer cell lines and the modified macrophages displayed PDL-1 specific phagocytosis. Further, the polyplex system was tested in immunocompetent murine triple negative breast cancer model and the polyplex system showed a potent anti-tumor activity when used along with STING agonist. The anti-tumor activity was further supported by the elevation in the levels of pro-inflammatory cytokines in the tumor microenviroment. **Conclusion:** The study

presents significant advancements in gene and cell therapy, showcasing an effective *in situ* immunotherapeutic approach for cancer treatment. These findings contribute substantially to the field and propose a promising candidate for advanced therapeutic strategies.

733. Internalization of a Peptide-Based Nanoplatform for Cas9 Ribonucleoprotein Delivery and Gene Editing

Alyson Schwartz[1], Joey LaValla[1], Audrey Wessinger[1], Jessica Larsen[1,2], Angela Alexander-Bryant[1]

[1]Department of Bioengineering, Clemson University, Clemson, SC,[2]Department of Chemical and Molecular Engineering, Clemson University, Clemson, SC

Introduction: The CRISPR/Cas9 system is a rapidly evolving gene editing tool for treating genetic diseases. Ribonucleoprotein (RNP) complexes eliminate the need for transcription or translation once internalized within the cell, reduce off-target effects, and have a higher delivery efficiency compared to plasmid and mRNA delivery. However, due to their large size, negative charge, and susceptibility to degradation within the endosome, RNP complexes require a delivery vehicle for successful internalization. Peptides have emerged as a promising delivery system due to their low immunogenic response, high versatility, and self-assembling properties. The fusogenic peptide, DIV3W, is able to electrostatically bind with the negatively charged RNP due to a large cationic tail. Our lab has previously demonstrated that DIV3W is biocompatible, able to facilitate endosomal escape, and protect RNA cargo. The objective of this project is to evaluate the ability of the DIV3W peptides to deliver bioactive Cas9 RNP complexes and induce knockout of green fluorescent protein (GFP) in HEK293 cells. Methods: The RNP:DIV3W system is formed by spontaneous complexation of Cas9 and gRNA at equimolar ratios, and then adding DIV3W at increasing molar ratios. The complexation of the RNPs and peptides was observed using an agarose gel electrophoresis assay. To analyze cytocompatibility, RNP:DIV3W complexes were formed and incubated with HEK293 human embryonic kidney cells for 48 hours, after which, an MTS assay was performed. The internalization of the complexes was visualized by forming RNP complexes using Cy5-labeled non-targeting siRNA (siNT) and Cas9 at equimolar ratios, and then adding DIV3W at varying molar ratios. The complexes were added to HEK293 cells and incubated for 4 and 24 hours, before analyzing using fluorescence imaging and flow cytometry. Results and Discussion: We observed that the RNP/DIV3W complexes successfully self-assembled at a minimum molar ratio of 1:1:20 (gRNA:Cas9:DIV3W) as shown in the agarose gel shift (Figure 1A). The RNP/DIV3W complexes were cytocompatible with HEK293 cells, demonstrating over 90% viability when analyzed via MTS (Figure 1B). Fluorescent imaging revealed that the RNP/DIV3W complexes were efficiently internalized into HEK293 cells at 4 and 24 hours. Flow cytometry quantified this data as shown in Figure 2. Conclusions: The results demonstrate that the DIV3W peptide is able to successfully self-assemble with RNP and the complex is cytocompatible with HEK293 cells. Furthermore, the DIV3W peptide facilitates internalization of RNP into HEK293 cells. The initial studies have shown the promise of the DIV3W peptide delivery system for gene editing. Future studies for the project include quantification of GFP knockout, identifying indel mutations, and evaluating various routes of internalization.

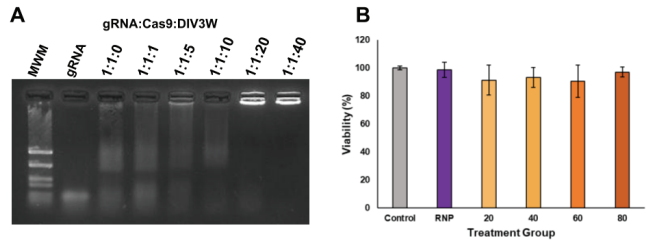


Figure 1: RNP:DIV3W Complex Characterization. Equimolar RNPs were complexed with increasing concentrations of DIV3W and electrophoresed in an agarose gel (A). HEK293 cells were treated with equimolar RNPs complexed with increasing concentrations of DIV3W and incubated for 48 hours before assessing biocompatibility using MTS (B). N=3. Data are mean ± SEM.

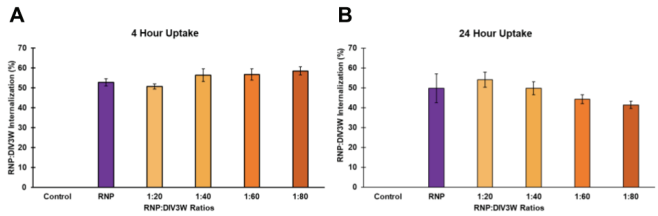

Figure 2: Uptake Flow Cytometry. HEK293 cells were treated with equimolar Cas9 and Cy5 siRNA RNPs complexed with increasing concentrations of DIV3W. (A) 4 hour flow cytometry. Data are mean SEM± (N=2). (B) 24 hour flow cytometry. Data are mean SEM± (N=3).

734. Comparing the Performance of Different Double-Stranded DNA Donor Templates in CRISPR-Cas9 Genome Editing Applications

Vaughn Thada[1], Tyler Kozisek[2], Karthik Murugan[1], Jim Williams[2], Rolf Turk[1], Garrett Rettig[1]

[1]Integrated DNA Technologies, Coralville, IA,[2]Aldevron, Fargo, ND

Genome editing using the CRISPR-Cas9 system can be harnessed to disrupt gene function, correct a pathogenic mutation, or insert an exogenous sequence into the genome. To facilitate insertion, a donor template with homology arms that flank the guide RNA (gRNA) target site must be introduced into cells along with the genome editing machinery. While synthetic oligonucleotides affecting SNP changes for small insertions can be quite efficient in mediating 'perfect' repair, knock-in of long (> 500 base pairs) double-stranded DNA (dsDNA) donor templates is generally inefficient. However, through innovations in donor DNA design, donor DNA modifications, and inhibition of proteins in competing double-strand break (DSB) repair pathways, we have observed additive and incremental improvement of dsDNA donor knock-in efficiencies via homology-directed repair (HDR). To this end, knock-in rates can be increased up to ten-fold by treating cells with small molecules and/or peptides that enhance HDR. Within the Danaher Life Sciences operating companies, IDT Alt-R™ HDR donor blocks are end-modified linear dsDNA templates for research use only (RUO), and Aldevron's Nanoplasmid™ is an RUO through cGMP-grade circular dsDNA template. In CRISPR knock-in experiments in K562, HEK293, and U2OS cells, Alt-R™ HDR donor blocks and the Nanoplasmid vector achieve similar knock-in rates in the absence of HDR enhancers, but in the presence of HDR enhancers, higher knock-in percentages are achieved with Alt-R™ HDR donor blocks, demonstrating up to 35% knock-in efficiency (with a 2 kb insert) in HEK293 cells with Cas9 mRNA and donor

delivery achieved via electroporation in the presence of multiple HDR enhancers. However, in induced pluripotent stem cells (iPSCs), Cas9 mRNA and Nanoplasmid vector delivery by electroporation in the presence of a single HDR enhancer results in 35% knock-in efficiency of a 2 kb insert, indicating donor template performance may be cell-type specific. As such, due to the scalability and cGMP manufacturing capabilities of Aldevron's Nanoplasmid vectors, we are interested in developing methods to improve Nanoplasmid vector knock-in efficiencies in the presence of multiple HDR enhancers in all cell types. To do this, we designed a "Nanoplasmid vector derivative" for use in CRISPR knock-in experiments. In K562, HEK293, and U2OS cells, use of the Nanoplasmid vector derivative results in knock-in rates similar to those observed with the original Nanoplasmid vector and Alt-R™ HDR donor blocks in the absence of HDR enhancers, but in the presence of HDR enhancers, knock-in percentages achieved with the Nanoplasmid vector derivative are comparable to those achieved with Alt-R™ HDR donor blocks and are more than double those achieved with the Nanoplasmid vector. Thus, future cGMP manufacturing of the Nanoplasmid vector derivative may allow for the large-scale production of a donor template that exhibits increased performance in CRISPR knock-in applications in a multitude of cell types, including the production of non-viral CAR T-cells. In this poster, we assess how different gRNA target sites, donor template insert sizes, and donor template homology arm lengths affect knock-in efficiencies of the aforementioned dsDNA templates in both immortalized and therapeutically-relevant cell types.

735. Highly Efficient Genome Editing of Human Primary Immune Cells Using Scalable Microfluidic Droplet-Enabled Cell Mechanoporator

Byeongju Joo[1], You-Jeong Kim[2,3], Dayoung Yun[1,4], Sungbin Im[1], Cheulhee Jung[4], Aram Chung[1,2,3]

[1]MxT Biotech, Seoul, Korea, Republic of,[2]School of Biomedical Engineering, Korea University, Seoul, Korea, Republic of,[3]Interdisciplinary Program in Precision Public Health, Korea University, Seoul, Korea, Republic of,[4]Department of Biotechnology, Korea University, Seoul, Korea, Republic of

Gene and cell therapy have emerged as pivotal modalities in clinical practice, marking transformative advancements in the disease treatment paradigm. Representative examples, including CAR-T, CAR-NK, and CRISPR treatment, underscore the shift towards genetically modified therapeutic approaches. The efficacy of these interventions relies on the precise delivery of external genetic molecules such as mRNA, plasmid DNA, and/or CRISPR into target cells. Current methods for ex vivo gene modification predominantly employ established techniques such as viral vectors and electroporation. However, these widely adopted methods encounter limitations related to high cost, low scalability, high cytotoxicity, and/or loss of cell functionality. This study introduces a novel genome delivery platform characterized by high efficiency and high scalability, facilitated by our microfluidic droplet-enabled cell mechanoporator. Cells and target genetic materials are co-encapsulated within droplets in the microfluidic platform. As these droplets pass through a narrow constriction, mechanical cell stretching leads to the transient discontinuity of the cell membrane and nuclear envelope. The recirculation flows generated within the droplets facilitate the internalization of external cargos through the generated membrane discontinuities, enabling highly efficient delivery of macromolecules, which is limited to viral transduction. Also, the permeabilization of cell membrane and nuclear envelope is recovered within droplets, which minimizes cell death. Leveraging our platform, we successfully achieved the internalization of GFP-expressed mRNA (996-nt) and plasmid DNA (9.1 kbp), demonstrating a highly effective cell transfection. Furthermore, through the delivery of CRISPR-Cas9 ribonucleoproteins (RNPs) for non-homologous end joining (NHEJ), double NHEJ, and homology-directed repair (HDR), we demonstrated a significantly improved genome editing efficiency in comparison to conventional methods such as electroporation and lipofection. Also, employing a parallelized microfluidic platform enabled a rapid and high cell processing capability which is challenging to achieve with electroporation and viral vectors. Compared to a single-channel platform, the parallelized channel showed equivalent gene delivery efficiency and cell viability while proving a high throughput process. This underscores the applicability of our system in the production of cell therapies, which typically require processing on the order of 10^8 cells. In summary, this study highlights the platform's capability for achieving high delivery efficiency, scalability, low analyte consumption, and cost-effective operation in the context of CRISPR-based genome editing. These findings affirm its significant potential for applications in genome editing and cell engineering-based therapies.

736. Manufacturing Off-the-Shelf Allogeneic NK Cell-Based Immunotherapy via Hydroporator®

Hyelee Kim[1,2], Mujin Lee[3], Bohwa Han[3], Jinho Kim[4], Duck Cho[4], Junsang Doh[3], Aram Chung[1,2]

[1]Korea University, Seoul, Korea, Republic of,[2]MxT Biotech, Seoul, Korea, Republic of,[3]Seoul National University, Seoul, Korea, Republic of,[4]Sungkyunkwan University, Seoul, Korea, Republic of

CAR-T cell therapy, characterized by its efficient therapeutic effects, has received six approvals from the Food and Drug Administration (FDA) for the treatment of blood cancer. However, as autologous T cells from patients frequently exhibit functional deficiencies due to lymphopenia, there is a substantial demand for allogeneic off-the-shelf CAR immunotherapies. Therefore, the focus has shifted to natural killer (NK) cells exhibiting high cytotoxicity against tumor cells, independent of antigen specific TCRs. As a result, allogeneic off-the-shelf CAR-NK cells have the potential to yield an equivalent or more effective therapeutic outcome than autologous CAR-T cells. To manufacture CAR-NK cells, successful transfer of CAR-encoding genes is imperative. However, conventional viral transduction is impeded by genotoxic off-targeting. Furthermore, non-viral approaches such as electroporation and lipofection are limited by low cell stability after the process and suboptimal transfection efficiency. In response to these limitations, we present a novel microfluidic intracellular delivery platform named Hydroporator® to address the drawbacks associated with current methods and enhance the manufacture of highly efficient NK cell-based immunotherapy. Hydroporator® demonstrated high transfection efficiency in delivering GFP mRNA of primary NK cells without compromising their viability and phenotype. Therefore, we employed this approach to manufacture anti-CD19 CAR-NK cells by transfecting CAR mRNA. These CAR-NK cells showed highly enhanced

cytotoxicity against CD19-positive lymphoma cells. To further validate the capability of Hydroporator® to produce next-generation NK cell-based immunotherapy, CRISPR-Cas9 ribonucleoprotein (RNP) targeting an inhibitory receptor was introduced into primary NK cells. The successful knockout of inhibitory receptors in processed NK cells resulted in enhanced killing capacity against solid cancerous cells. These results suggest that Hydroporator® can deliver various types of cargo without affecting the stability of hard-to-transfect primary NK cells. In conclusion, our study introduces a novel microfluidic intracellular delivery platform that may set a new standard for manufacturing highly stable and efficient NK cell-based immunotherapy.

737. The JL Transposon System: A Novel, Efficient, and Safe Tool for Gene and Cell Therapy with Lower Cytotoxicity and Enhanced Transposition Efficiency

Pingjing Zhang[1], Kejia Kan[2], Chengyi Song[3], Tao Liu[1], Bo Gao[3], Yan Sun[1], Ning Wu[2], Qijun Qian[1], Wei Wang[2]

[1]Shanghai Cell Therapy Group, Shanghai, China,[2]Shanghai Waker Bioscience Co., Ltd., Shanghai, China,[3]College of Animal Science and Technology, Yangzhou University, Yanghzou, China

Effective gene therapy requires robust delivery of the desired genes into relevant target cells, long-term gene expression, and minimal risks of secondary effects. The challenges of the DNA transposon-based gene delivery with respect to integration efficiency and insertional mutagenesis facilitate the development of a novel hyperactive JL transposon system through a large-scale genetic screening within the genome of the Three-Spined Stickleback (Gasterosteus aculeatus). The JL system includes the Tiniplasmid, a minimized antibiotic-free transposon plasmid with backbone DNA of less than 500bp for efficient cell nucleus entry. It also has the JL Transposase, an mRNA-based engineered transposase that produces over 10-fold transposition integration levels with significantly lower mRNA dosage and reduced safety concerns. To better understand the JL transposon system, we conducted a comprehensive assessment of its biological properties of CAR-T cell manufacturing. Our findings demonstrate that the JL transposon system has more efficient transposition than classical systems such as PiggyBac (PB) and Sleeping Beauty (SB). It achieves comparable efficiency with significantly lower plasmid doses and less cytotoxicity to T cells. As a result, it substantially increases CAR-T proliferation. To investigate the potential genotoxicity, we compared the terminal inverted repeat (TIR) non-specific promoter activity between the JL and conventional transposon systems using luciferase assay. The results showed that the 28bp TIR of the JL system has lower non-specific promoter activity. Moreover, we performed a genome-wide integration site analysis (ISA) using ligation target amplification PCR (LTA-PCR), next-generation sequencing, and in-house developed bioinformatics tools to analyze the integration sites of JL transposon-based system in transfected primary T cells. More than 10,000 unique integration sites (UISs) were retrieved from 5 samples on day 10 post-transfection. The results showed that UISs were randomly distributed throughout the genome, and no clustering on a particular genome was observed. On average, 69.14% of the UISs occurred within genes (79.67% in genes ± 10 kb). Interestingly, the relative count ratio of all sites related to cancer-associated genes was below 0.5%, and no genes related to known adverse events of cell and gene therapy were found within the integration sites. Furthermore, no clustered hotspot was found from the above results. These findings suggest the JL transposon system could be an effective and safe delivery method for human gene and cell therapy, and a promising tool for future research and clinical applications.

738. Precision T Cell Engineering through a Non-Viral Microfluidic Gene Delivery Platform, Hydroporator®

Seohyun Kim[1], Eunji Kwon[1], Dayoung Yun[1], Aram Chung[1,2]

[1]MxT biotech, Seoul, Korea, Republic of,[2]Bioengineering, Korea University, Seoul, Korea, Republic of

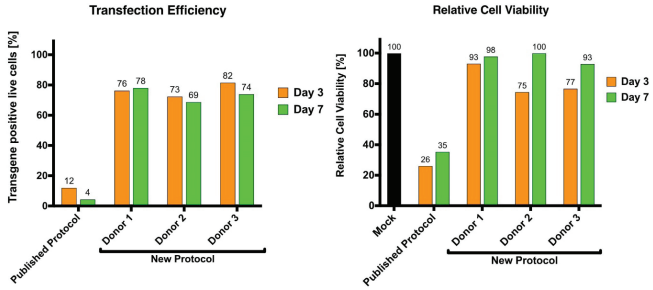
For decades, the cornerstone of cancer treatment has been surgery, chemotherapy, and radiation therapy. Nevertheless, there is a rapid paradigm shift in the therapeutic landscape, moving away from conventional methods to the realms of gene and cell therapies. One notable breakthrough is CAR (chimeric antigen receptor)-T cell therapy, demonstrating extremely high efficacy, especially for patients with hematological malignancy. Despite its success, they face challenges in safety, scalability, and cost due to the use of viruses as a gene delivery carrier, limiting the widespread accessibility of the therapy. In this study, we present our novel non-viral microfluidic gene delivery platform, named Hydroporator®. Through this platform, we achieved the efficient production of CD19 targeted CAR-T cells with high scalability. These CAR-T cells have been substantiated to exhibit potent cytotoxicity against CD19-positive lymphoma cells, while preserving innate cell functionality. To further demonstrate the capability of Hydroporator® in facilitating the production of CAR-T cells with enhanced cytotoxicity, we employed CRISPR-Cas9 ribonucleoprotein (RNP) to target an inhibitory receptor PD-1. Successful knockout of PD-1 in processed T cells was achieved. Additionally, to validate the potential use of Hydroporator® for allogenic T cell production, we demonstrate efficient TRAC knockout. In summary, our findings suggest that our novel gene delivery platform holds promise as a new tool for developing diverse cell therapies.

739. Potent and Metabolically Fit CAR T Cell Manufacture Enabled with Novel Solupore® Non-Viral Transfection

Jamie Frankish

Avectas, Maynooth, Ireland

Background and aim: Retention of cell health and function following the delivery of cargo is of pivotal importance in the advancement of next generation gene-modified cell therapies. Current gene delivery technologies for cell therapy applications rely on mechanical or electrical mechanisms which can negatively impact cell quality and result in wide-spread unregulated gene expression. Solupore is an automated, reproducible closed physicochemical transfection system for the delivery of a wide variety of cargo (RNA, DNA, protein) to primary immune cells as well as CD34+ cells for use in the development of clinical cell therapies. The aim of this work was to assess Solupore and another standard technology, electroporation, in the manufacturing of gene modified T cells by analysing the effect cargo delivery has on



the health and functionality of those cells post-transfection. **Methods, Results, & Conclusion:** To determine the impact transfection has on the cell quality, function, and ultimately the therapeutic potential, Solupore and electroporation were assessed in several in vitro and in vivo assays, such as metabolic fitness, surface marker analysis for T cell phenotype, cytokine secretion, apoptosis response, the immunological synapse with target cells, and tumor burden reduction. Using CRISPR-Cas9 RNP based knockout of TRAC, β2M, and CD7 as proof of concept, we demonstrate that Solupore efficiently delivers cargo for multiplexed editing of primary T cells. Transduction of the clinically approved anti-CD19 CAR was used to benchmark functionality of transfected and edited cell populations. The measured metabolic profile, OXPHOS, is higher in both basal and maximal respiration for Solupore transfected populations. Solupore retains 16% more TSCM cells, IFN-γ is increased 1.45x fold more per cell and apoptosis is reduced from 25% to 12% when compared to electroporation. Significant improvement in cellular avidity is observed, demonstrating over 70% of cells binding to target cancer cells for Solupore transfected cells, compared to just 37% for electroporation. This leads to enhanced cytotoxicity of target cancer cells in vitro and performs as a more potent and significantly more effective therapy in vivo, with more than a 30x fold enhanced tumour growth inhibition (pval = <0.0001). Solupore transfected cells engrafted 5.4x fold more compared to electroporation in NSG mice and retained their gene KO profile at terminal endpoint. Taking the in vitro data together with the in vivo data highlights that the Solupore technology retains a more metabolic fit, functional, and potent cell compared to an electroporation standard.

740. Persistent Genetic Modification of K562 and Human Hematopoietic Stem and Progenitor Cells Using S/MAR DNA Nanovectors

Patrick Derigs[1], Malte Thomas[1], Alicia Roig-Merino[2], Julia Denise Peterson[1], Luisa Burger[1], Toros Tasgin[1], Anna Hartley[1], Michael Schmitt[3], Carsten Müller-Tidow[3], Richard P. Harbottle[1]

[1]DNA Vector Lab, German Cancer Research Center, Heidelberg, Germany,[2]MaxCyte, Gaithersburg, MD,[3]Department of Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany

Transplantation of hematopoietic stem and progenitor cells (HSPCs) electroporated with cytotoxic drug resistance inducing genes would ensure effective tumor suppression by applying respective anticancer therapy while maintaining sufficient hematopoiesis in cancer patients. Effective strategies for the persistent genetic modification of HSPCs are needed for this treatment approach. Recombinant integrating viruses are a potent and widely used tool. However, their random integration into the genome introduces a risk of insertional mutagenesis. Their innate immunogenicity presents another impediment to clinical application. To achieve the goal of an efficient and safe generation of stably transfected cells of a variety of cell types, we have developed a non-viral DNA vector platform based on Scaffold/Matrix-Associated Regions (S/MAR). The episomal maintenance of S/MAR DNA nanovectors (nS/MAR) eradicates the risk of insertional mutagenesis, providing a major advantage compared to already clinically applied approaches using CRISPR/Cas9 systems or viral vectors. Additionally, with its unlimited capacity, even large therapeutic transgenes or other sophisticated genetic elements can be delivered with nS/MAR. Furthermore, genetic engineering based on n/SMAR with its inherent mitotic stability should minimize costs for the manufacturing of genetically modified HSPCs. In this study, we have evaluated the efficiency and persistence of reporter transgene expression in the K562 cell line and HSPCs using nS/MAR. Additionally, we have cloned nS/MAR containing a mutant human dihydrofolate reductase transgene (*hDHFR*) to facilitate resistance against methotrexate (MTX) and tested them in K562 cells. For electroporation the MaxCyte ExPERT® platform was used. Transfection efficiency and cell viability were analyzed by flow cytometry. Our study demonstrates the feasibility of using nS/MAR for persistent genetic modification of K562 and HSPCs. Using nS/MAR containing reporter transgenes, initial transfection efficiencies of primary human HSPCs of three different donors were high with up to 82% positive cells. Cell viability was sufficient ranging from 75 to 93 % three days after electroporation (**Figure 1**). Transfected HSPCs retained reporter transgene expression for at least 21 days in culture. In K562 nS/MAR containing double-mutant *hDHFR* facilitated resistance against MTX successfully. Further studies are ongoing to modify primary HSPCs with these nS/MARs and to characterize engraftment potential and MTX resistance. These findings provide a promising first step towards the persistent genetic modification of HSPCs with nS/MAR and their usage in hematopoietic cell transplantation for the treatment of cancer patients or monogenic hematological disorders.

741. One Stop Solution for Circular RNA Synthesis and Lipid Nanoparticle Delivery

Xiaofei Long, Youshang Zhao, Zhen Sun, Kangming Chen, Qingwei Meng, Fengmei Pi

GenScript Biotech Corporation, Nanjing, China

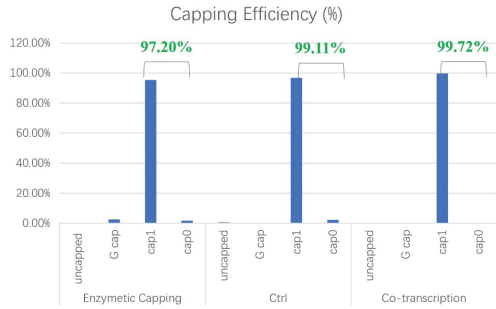
The approval of messenger RNA (mRNA) based COVID-19 vaccines was a scientific turning point, establishing mRNA as a new drug modality with great therapeutic potential. However, linear mRNAs have short half-life and require base modification to reduce their immunogenicity, imposing a limitation to the broad application. Circular RNAs (CircRNAs) are single-stranded, covalently closed RNA molecules with non-modified base that presents a better alternative for prolonged expression of the proteins. Here we developed a new in vitro self-splicing intron system to efficiently produce circRNAs by screening and rationally designing sequences that aid in splicing. Not only that, we also screened for highly effective expression elements, the circRNAs we synthesized are quite stable and highly expressed, with low immunogenicity and fewer exogenous sequence residues, enabling higher safety and extended protein translation in cell-based assays in vitro. In addition, the circRNA encoding a CCR9 antigen,

a transmembrane protein, was encapsulated in lipid nanoparticles (LNP) and intramuscularly injected into mice without adjuvant in a single immunization. The in vivo result showed that strong antibody productions were induced and detected in serums by flow cytometry using a CHO-CCR9 stable cell line. In summary, Genscript developed a one-stop solution for circular RNA including sequence design, RNA synthesis & purification, and LNP encapsulation.

742. Nanoparticle Immunoadjuvant Complexes Augment Antigen-Specific Germinal Center Responses to Enhance Humoral Immunity

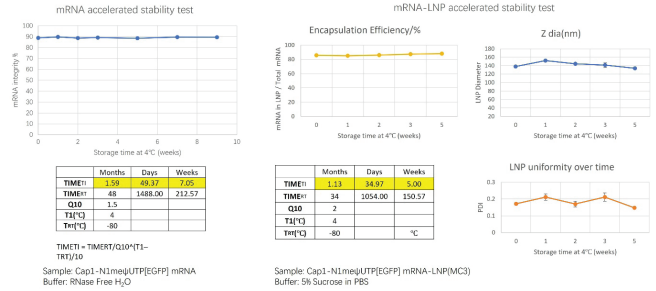
Nicholas J. Tursi[1,2], Toshitha Kannan[1], Jennifer Londregan[2], Katlyn Lederer[2], Michaela Helble[1], Ebony Gary[1], Nicole Bedanova[1], Ivan Maillard[2], David Allman[2], David Allman[2], Amelia Escolano[1], Andrew Kossenkov[1], Daniel W. Kulp[1], David B. Weiner[1]

[1]Vaccine and Immunotherapy Center, The Wistar Institute, Philadelphia, PA,[2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA



An alluring strategy for improving protective humoral immunity against infectious diseases would be to directly target the germinal center (GC). Robust GC responses are associated with high titer and high affinity antibody responses. Despite advances in formulation strategies and vaccine design, there remains a critical need for next generation approaches to elicit potent humoral immunity. Multimeric nanoparticles offer enhanced immunogenicity compared with monomeric antigen partially due to potent B cell activation and increased antigen density on the nanoparticle. Here, we investigated whether GC cytokine IL-21 could be displayed on nanoparticles to further enhance immune responses. We designed a chimeric nanoparticle using the GT8-60mer, a germline targeting HIV immunogen, as a model to scaffold IL-21. GT8 and IL-21 scaffolded nanoparticles, termed GT8 IL-21 nanoparticle immunoadjuvant complexes (GT8 IL-21 NIC), increased antigen-specific GC B cells, functional Tfh cell responses, and serum antibody titers relative to the antigen-only GT8-60mer. Additionally, GT8 IL-21 NICs reorganized antigen-specific GC B cell responses to the light zone (LZ) of the GC, the canonical site of antigen-driven selection. Single-cell RNA sequencing of antigen-specific GC B cells from GT8 IL-21 NIC immunized mice demonstrated upregulation of selection-associated gene signatures and a shift in the clonal repertoire. Thus, GC targeting NICs may provide value to drive improved humoral immunity.

743. Early-Stage Considerations for mRNA Drug Development: Addressing Production Technologies, Stability, and Safety



Zhiming Yang[1], Ye Bu[1], Qifan Liu[1], Xinfa Shi[1], Irene Song[1], Luyan He[1], Xin Swanson[1], Paul Li[2]

[1]PackGene Biotech INC, Houston, TX,[2]PackGene Biotech, Houston, TX

mRNA serves as a versatile platform for vaccine, gene, and cellular therapy, offering advantages in quick production, easy delivery, scalability, and native post-translational modification. However, before scaling up production, considerations of technology, cost, quality, stability, and safety are crucial. Our study explores key aspects in the early stages of mRNA drug development, focusing on later production processes. In choosing capping technology, the ownership of co-transcription technology by Trilink prompts consideration of licensing fees for CleanCap. A comparison with enzymatic capping reveals comparable efficiency, making enzymatic capping a viable, potentially fee-avoiding alternative. Addressing stability, purified mRNA from in vitro transcription (IVT) exhibits a shelf life of 5 years, while mRNA-LNP, susceptible to freeze-thaw cycles, remains stable at -80°C for over 2 years, maintaining size, uniformity, and encapsulation efficiency. Stable mRNA expression persists even after 2 years. Concerning dsRNA-induced immunogenicity, HPLC purification is suggested to reduce the dsRNA : mRNA ratio. Our optimized IVT system consistently achieves <0.1% dsRNA : mRNA ratio, with ongoing exploration into further reduction through additional HPLC purification. These insights provide crucial considerations for mRNA drug development, guiding informed decisions for successful and safe production processes.

Wednesday Posters: Other Nonviral Delivery

744. Engineered Virus-Like Particle to Deliver CRISPR-Cas9 Ribonucleoprotein *In Vivo* with Saturated Efficacy and Minimal Off-Target Effects

Zihua Jiang[1], Hua Lu[2], Martin Chan[2], Bang Wang[2], Zongli Zheng[1]

[1]Ming Wai Lau Centre for Reparative Medicine, Karolinska Institutet, Hong Kong, China,[2]GenEditBio Limited, Hong Kong, China

The revolutionary CRISPR-Cas9 system offers a glimmer of hope for treating a vast array of genetic diseases that currently have no effective treatments. Delivery of the CRISPR-Cas9 system should be transient and prompt to minimize off-target effects, especially when delivered in vivo systemically. To achieve this, an engineered virus-like particle (eVLP) system that delivers Cas9 ribonucleoprotein (RNP) is under development. This system can enable rapid targeting of the genome and degradation of the Cas9 protein, thereby minimizing the off-target effects of CRISPR-Cas editing systems. Here we engineered a highly efficient VLP containing the wildtype SpCas9 and sgRNA. We conducted an evaluation of the off-target effect of the SpCas9-sgRNA RNP eVLP in various targeting sites. We compared its performance at a saturated dosage with that of the liposome-based CRISPR RNA, both *in vitro* and *in vivo*. Two methods were utilized to assess genome-wide off-target effects, namely the GUIDE-Seq and a novel method for editing event detection (EDITED-Seq). Our team developed the EDITED-Seq method to enable concurrent identification and verification of potential off-target sites, which is compatible with regular gene editing protocols and does not require additional cell manipulations. To produce the eVLP, four plasmids (VSV-G, MMLV gag-pol, MMLV gag-SpCas9 and sgRNA plasmids) were co-transfected into LentiX-293T cells. At 48h post-transfection, the supernatant was harvested, purified, and concentrated 100-fold for cell transduction or 1000-fold for animal administration. The optimized eVLP after purification and concentration can easily achieve over 90% editing efficacy at several targeting sites (HEK3, TTR, PD-1, *Pcsk9, Dnmt1*) in different species cell lines (HEK293T, HepG2, Jurkat, Vero, Hepa1-6, Neuro-2a). The eVLP targeting mouse *Ttr* gene was utilized to do liver gene editing on the C57BL/6 mice by tail vein injection, achieving a 60% indels in the bulk liver with a 95% reduction of serum *Ttr* protein at day 7 post-administration, which performed compatible with that of the method based on liposome delivered CRISPR RNA. we also assessed SpCas9 editing efficiencies in other tissues and observed 2.9% indels in the spleen, 1.5% indels in the lung, and minimal indels in the muscle, tail and heart. In the off-targets profiling results, the eVLP method had no detectable off-targets in cell lines, while the liposome-based RNA method showed several off-target sites according to GUIDE-Seq and EDITED-Seq results. Furthermore, EDITED-Seq results of *in vivo* edited liver samples showed that the eVLP method had significantly less off-targeting editing compared to the liposome-based RNA method. The data suggests that using eVLP to deliver CRISPR-Cas9 ribonucleoprotein can significantly reduce off-target effects compared to liposome-based RNA delivery both *in vitro* and *in vivo*.

745. High-Throughput Screening Powers the Discovery of Tissue-Specific Lipid Nanoparticles *In Vivo*

Qing Xia[1], Zhixiong Zhou[1], Bang Wang[1], Zongli Zheng[2]

[1]GenEditBio Limited, Hong Kong, China,[2]Karolinska Institutet, Shatin, Hong Kong

Efficient and safe delivery of CRISPR/Cas9 gene editing agents to the target tissue/cells is in high demand. Lipid nanoparticles (LNPs) have become a popular nonviral delivery tool in the nucleic acid-based therapies due to their low immunogenicity and modularity. Developing LNPs to enable tissue-specific delivery is desperately needed and extremely challenging. To rationally design highly effective LNP and pinpoint its optimal formulation has been proven difficult. Cell-based evaluations do not necessarily predict in vivo performance. Therefore, to effectively evaluate a large amount of LNP candidates in vivo is highly desirable. We herein present a high-throughput screening platform that simultaneously evaluates delivery efficiencies of up to 96 barcoded LNPs for in vivo gene editing. The delivery efficiencies of different LNPs were tracked and quantified by their corresponding barcodes. The barcode sequence *per se* has no effect on delivery and can only be detected when both *Cas9* mRNA and sgRNA are co-delivered and functional. We show that the barcoding system works effectively in both small and large animals, as well as in cells. Particularly, delivery efficiencies in small animals do not correlate well with large animals, highlighting the importance of direct evaluation in non-human primates for potential clinical applications. Using the barcoding technology, we were able to identify highly performatively LNPs for hepatic delivery in NHPs, with industry-leading dose-dependent efficacy. Moreover, we were able to expand our LNP discovery for extrahepatic delivery.

746. Optimization of Lipid Nanoparticles for Gene Editing of the Liver via Intraduodenal Delivery

Christine Wei[1], Yining Zhu[1], Shuting S. Cai[2], Jingyao Ma[1], Leonardo Cheng[1], Kam W. Leong[2], Hai-Quan Mao[1]

[1]Johns Hopkins University, Baltimore, MD,[2]Columbia University, New York, NY

Introduction: Lipid nanoparticles (LNPs) have emerged as a promising non-viral gene delivery vehicle for diverse therapeutic strategies, including *in vivo* gene editing. Despite notable progress in gene delivery research, the predominant focus remains on optimizing traditional administration modes, such as intravenous and intramuscular injections. The potential of oral delivery to enhance the quality of life for patients is constrained by challenges associated with physiological barriers. In this study, we explore the feasibility of gene editing in the liver using pDNA LNPs through intraduodenal injection as an indicative route for oral administration. Our optimized LNP-based all-in-one CRISPR-Cas9 pDNA gene-editing tool demonstrated targeted liver delivery, efficient gene editing, therapeutic efficacy, and safety in a hypercholesterolemia-related mouse model following intraduodenal injection, underscoring the potential for an oral gene editing approach in the treatment of familial hypercholesterolemia and other genetic diseases. **Methods:** By employing a multi-step screening approach that

addresses various physiological barriers and a machine learning-guided framework, we systematically assessed a diverse library of ca. 1,000 pDNA LNP formulations and optimized the type of helper lipid and component ratios for liver-targeted gene delivery via intraduodenal injection. Using the optimized LNP encapsulating a pDNA construct encoding both *Strep. pyogenes* Cas9 and gRNAs targeting loxP sites, we demonstrated successful non-viral *in vivo* gene editing of the liver post intraduodenal injection in an Ai9 reporter mouse model. Utilizing an all-in-one SpCas9 pDNA construct containing gRNAs targeting *PCSK9* and *ANGPTL3*, we evaluated the therapeutic efficacy of the optimized pDNA LNP formulation in a hypercholesterolemia-related mouse model. **Results:** The top-performing LNPs from the library screening achieved highly preferential liver transfection one week post intraduodenal injection, with over 87% of the bioluminescent flux localized in the liver (**Fig. 1a**). At a dose of 1 mg/500 µL, CII-β3, a DOPE-based LNP with over 95% liver accumulation one week after intraduodenal administration, achieved the highest transfection efficiency in the liver among all formulations and doses, and demonstrated efficient gene editing capability in the liver in the Ai9 model (**Fig. 1b-c**). In the hypercholesterolemia-related mouse model, mice with elevated serum cholesterol levels (> 300 ng/µL) experienced a significant reduction in serum cholesterol following treatment with CII-β3 pDNA LNPs, with no significant change in serum ALT (a liver toxicity marker) compared to the untreated group (**Fig. 1d**). Notably, there was an average of 27% decrease in serum cholesterol ($p < 0.01$) one week post intraduodenal LNP administration in comparison to the untreated group (**Fig. 1e**). **Conclusion:** Our optimized pDNA LNP formulation, CII-β3, demonstrated efficient gene editing capability in the liver and therapeutic efficacy in lowering serum cholesterol levels post intraduodenal administration. This all-in-one LNP-based pDNA-mediated gene editing strategy via intraduodenal administration not only showcases its potential as an oral therapeutic solution for familial hypercholesterolemia, but also unveils new possibilities for DNA-based medicine.

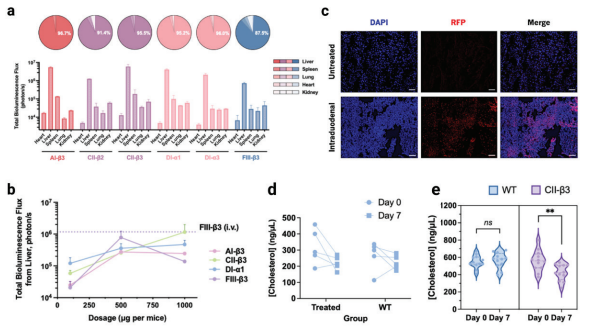

Fig. 1 | **a**, Expression percentage by organ and *ex vivo* bioluminescence flux of top six individual LNP formulations one week after intraduodenal injection (n = 4). **b**, Dosage response curve of top performing LNPs. **c**, Fluorescence confocal microscopy images of liver sections collected one week following CII-β3 pDNA LNP administration. Scale bar = 200 µm. **d-e**, Paired serum cholesterol concentrations before and one week after intraduodenal administration of CII-β3 pDNA LNP (n = 12).

747. Development of Self-Assembled Functional RNA Nanoparticle for CRISPR-Cas9 System Delivery

Yeochan Yun, Chang-yun Lee, Hyeon-Yeol Cho
Kookmin University, Seoul, Korea, Republic of

Recently, the CRISPR-Cas9 system has been extensively researched in genetic research, biotechnology, and medicine. It allows for precise gene editing and has potential applications in the development of novel therapies, the study of gene function, and the treatment of genetic diseases. Various approaches, including DNA, RNA, and ribonucleoproteins, have been developed to improve intracellular delivery of the CRISPR-Cas9 system. In this study, we proposed self-assembled functional RNA nanoparticles for mRNA delivery of the CRISPR-Cas9 system. Magnetic nanoparticles (MNPs) have been widely used in the biomedical field, with applications in bioimaging, biomolecule extraction, cancer treatment, and targeted drug delivery systems. The introduction of T7 polymerase conjugation to the MNP surface has significantly enhanced mRNA delivery via rolling circle transcription (RCT). The 10 nm zinc-doped MNPs that were synthesized exhibit strong magnetic properties and a significant surface area. A cationic polymer coating was applied to provide amine groups on the MNP surface, which allowed for conjugation with the carboxyl group of T7 polymerase. These functionalized MNPs played a crucial role in the synthesis of mRNA by replacing T7 polymerase in RCT and forming an RNA layer. Significantly, by displaying T7 polymerase on the surface of magnetic nanoparticles, we enhanced the encapsulation efficiency of mRNA creating an RNA shell that envelops the magnetic core. Successful mRNA delivery and expression were demonstrated through the observation of green fluorescent protein expression inside the cells using confocal laser scanning microscopy. In addition, self-assembled functional RNA nanoparticles enables the co-delivery of Cas9 mRNA and target gene sgRNA into cells, resulting in an efficient knockout of the target gene. This mRNA delivery system has potential for advanced gene editing and therapeutic applications.

748. A Fiber Based Adsorbent to Address Purification Requirements in the Delivery of mRNA Therapies via Extracellular Vesicles

Ian Scanlon, Christie Childers, Daniella Steel, Marc Hummersone
Research and Development, Astrea Bioseparations, Cambridge, United Kingdom

Introduction/ Background: Extracellular vesicles (EVs) and exosomes are currently being investigated as useful tools for the delivery of various C> therapeutics across several areas. Particularly, in oncology and areas where their native tropism, stability, and lack of inherent immunogenicity can deliver therapeutic payloads with increased efficacy. mRNA sequences such as CRISPR cas 9 can be delivered using EVs as an alternative to the systemic delivery using Lipid nanoparticles (LNPs). This avoids the potential issues with LNP instability, toxicity, and the limits around their low drug load efficiency. Purification of

the raw materials used to produce both the payload and the vector in these new systems can be challenging since both modalities are larger than can be dealt with easily by most chromatographic adsorbents. We present a study showing that the AstreAdept fiber adsorbent can be used to produce pure linearised plasmid for mRNA production and can be used to isolate EVs from their biological sources to support early process development in quickly accomplishing the critical quality attributes required for clinical use. **Experimental:** A fiber mat functionalised with ion exchange or hydrophobic ligands was encapsulated in a disposable housing which was sanitized, and used to purify raw material components for the non-viral vector gene therapy delivery. **Results and Discussion:** Hydrophobic material was used to purify linearised plasmid DNA produced from E Coli lysate. Anion exchange material was used to purify EVs expressed in a biological system. Processes were evaluated by capacity, recovery, and removal of product and process related impurities.

749. Novel Immune Tropic LNP-Based mRNA Delivery in Non-Human Primates

Juliet N. Crabtree, Ganapathy S. Sankaran, Karolina Kosakowska, Grace Chen, Shinu John, Muthusamy Jayaraman

ReNAgade Therapeutics, Cambridge, MA

mRNA therapies have emerged as the new frontier of genetic medicines and have shown early clinical promise in treating pathologies with established genetic targets in oncology and autoimmunity. Lipid nanoparticles (LNPs) are a clinically validated and effective delivery platform for mRNA *in vivo*. The promise of LNP-mediated RNA delivery has been demonstrated for vaccines and liver-directed therapies. Despite recent clinical success, RNA medicines are limited by insufficient delivery to extra-hepatic tissues, and cell-specific delivery remains a large unmet need in the field. Here we describe a high-throughput LNP discovery engine capable of unlocking LNP-mediated RNA delivery to extra-hepatic tissues. We utilized >300 unique lipids which further resulted in the development of >200 LNPs across multiple structural and chemically distinct classes of ionizable lipids, helper lipids, structural lipids, and hydrophilic lipids, utilizing various LNP formulation ratios. We employed a systematic barcoding screening approach to evaluate the engineered LNP libraries, alongside performing functional mRNA delivery assessments in mice and non-human primates (NHPs). Using this approach, we identified a suite of novel immune tropic LNPs. One of the lead LNPs identified by our barcoding efforts, when evaluated individually in an NHP model, demonstrated ~60% delivery in total splenic T cells and ~50% in peripheral blood T cells. Our data opens opportunities for exploration of *in vivo* chimeric antigen receptor (CAR) T cell therapies in both oncology and autoimmune disease settings.

750. Ligand-Conjugated Poly (Beta-Amino Ester) Nanoparticles for Targeted mRNA Delivery to Primary T Cells

Manav Jain, Savannah Est-Witte, Stephany Tzeng, Sarah Neshat, Sydney Shannon, Francis Yu, Leo Cheng, Jonathan Schneck, Jordan Green

Johns Hopkins University, Baltimore, MD

Introduction: Despite the promise of adoptive T cell therapies, the translational potential of these treatments is hindered by a long and expensive ex vivo manufacturing process whereby patient T cells are isolated, genetically engineered using a viral vector, expanded for several days, and then reinfused into the patient. In contrast, non-viral gene delivery approaches can be used to transfect endogenous T cells and generate therapeutic cells in situ, thereby addressing these manufacturing concerns. Poly(beta-amino ester)s (PBAEs) are biodegradable cationic polymers that can be complexed with nucleic acids like mRNA to form polymeric nanoparticles for efficient non-viral gene delivery *in vitro* and *in vivo*. Although PBAE nanoparticles have demonstrated robust transfection across different cancer cell lines and certain myeloid cells, this class of materials has had limited efficacy in transfecting primary T cells. Here, we outline the generation of polymeric nanoparticles comprised of a novel, hybrid lipophilic PBAE formulation and conjugated to several T cell targeting ligands. These targeted PBAE nanoparticles demonstrate higher T cell transfection than standard PBAEs, highlighting the potential of this non-viral gene delivery platform for T cell engineering.**Materials and Methods:** Nanoparticles were formed by self-assembly by mixing the PBAE polymer with GFP-encoding mRNA and a functional PEG linker. Different T cell targeting ligands were then conjugated to the functional PEG, thereby generating ligand-targeted nanoparticles. The targeting ligands investigated in this study were aCD3 and aCD28, which are the canonical "Signal 1" and "Signal 2" required for T cell activation. Moreover, CD3-TCR engagement has previously been implicated in T cell endocytosis, which informed our choice of aCD3 as the primary T cell targeting moiety used with our particles. Nanoparticle size and polydispersity was characterized use dynamic light scattering (DLS) and transmission electron microscopy (TEM). An overview of this nanoparticle fabrication process can be seen in Figure 1A.Primary murine T cells were co-incubated with polymeric nanoparticles that were conjugated to either aCD3 and aCD28, aCD3 alone, or no ligand. After 24 hours, transfection (as measured by GFP expression) and cell viability were measured using flow cytometry.**Results and Conclusions:** As shown in Figure 1B, nanoparticle size, as measured by DLS and TEM is consistent across the three different conditions with all particles being ~200 nm in size. Despite the uniformity in size between conditions, particles with multiple targeting ligands (aCD3 and aCD28) achieved significantly higher T cell transfection than particles with only one or no targeting ligands, as seen in Figure 1C. This trend was seen to be consistent in a dose dependent manner. Moreover, there were no significant differences in T cell viability across these conditions (Figure 1D), suggesting that PBAE NPs with multiple targeting ligands can achieve robust mRNA delivery with minimal toxicity. While previous studies have investigated the use of targeted PBAE NPs for T cell engineering, this is the first demonstration that particle functionalization with multiple ligands, namely the two key signals needed for T cell activation, significantly enhances transfection. The ability of these targeted polymeric nanoparticles to transfect endogenous T cells are currently being evaluated in vivo.

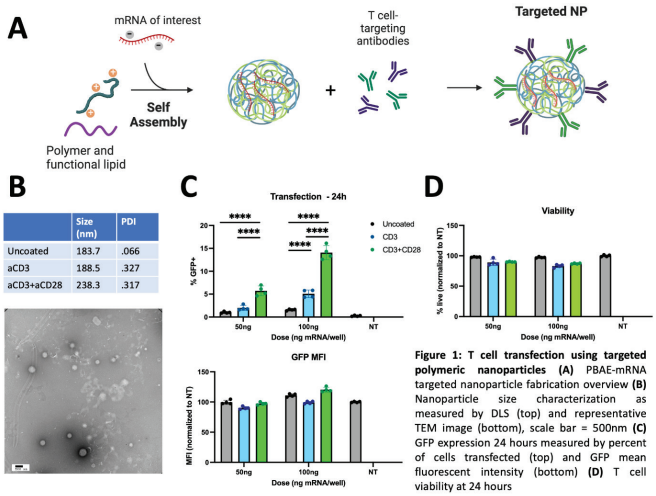

Figure 1: T cell transfection using targeted polymeric nanoparticles (A) PBAE-mRNA targeted nanoparticle fabrication overview **(B)** Nanoparticle size characterization as measured by DLS (top) and representative TEM image (bottom), scale bar = 500nm **(C)** GFP expression 24 hours measured by percent of cells transfected (top) and GFP mean fluorescent intensity (bottom) **(D)** T cell viability at 24 hours

751. Ionizable Lipid Selection and Targeted LNP Formulation Development for *In Vivo* CAR-T Therapy

Mir Mukkaram Ali

Non-Viral Gene Therapy and Genome Engineering, Mir Mukkaram Ali, Cambridge, MA

CAR-T (chimeric antigen receptor - T cell) therapy has shown significant clinical benefit to patients with hematologic malignancies such as leukemia and lymphoma. However, the treatment is currently performed ex vivo with a complex manufacturing process that results in barriers to patient access. To obviate the complexities of ex vivo manufacturing, we are developing therapeutics that enable *in vivo* specific cell reprogramming to provide re-dosable, off-the-shelf gene therapies to patients without the need for pre-conditioning treatments. We have developed a novel ionizable lipid series for *in vivo* reprogramming of T-cells via targeted delivery of mRNA using lipid nanoparticles (LNPs). αCD3 and αCD8 targeted LNPs were developed via post-insertion of an antibody (Fab/VHH) PEG-lipid conjugate into pre-made "parent" LNPs based on novel ionizable lipids. We found that targeted LNP performance was dependent on lipid chemistry including head group and tail group structure. Specifically, the hydrophobic chain length, branching, structural isomerism, and/or degree of saturation within the lipid head group and tail group impacted LNP potency. We selected ionizable lipid based on a combination of LNP physiochemical properties (size, polydispersity, RNA encapsulation and freeze-thaw stability) and the efficiency of reporter protein (GFP or mCherry) expression in primary human T cells transfected ex vivo and optimized LNP performance via ionizable lipid structure. We evaluated a subset of lead lipids for *in vitro* potency using mRNA encoding αCD20 Chimeric Antigen Receptor (CAR) protein assessing potency based on the level of membrane bound αCD20 CAR protein expression in transfected T cells and by T cell cytotoxicity towards CD20+ Raji B-cells in Raji/CAR-T cell co-culture experiments. Additionally, we demonstrated the specificity of the αCD8 targeted LNPs to the CD8+ T cell population in human whole blood and *in vivo* in a human T cell engrafted NSG mouse model. The targeted LNP compositions exhibited promising *in vivo* T cell reprogramming and tolerability, supporting further development towards the clinic.

752. Bioanalytical Development and *In Vitro* Characterization of mRNA LNP Formulation for *In Vivo* CAR-T Therapy

Allison Caron[1], Aaron Griset[1], Mir Ali[1], Viktor Lemgart[1], Austin Boesch[1], Ulrik Nielson[1], Daryl Drummond[1], Christian Mueller[2], William Kuhlman[1], Christopher Borges[2]

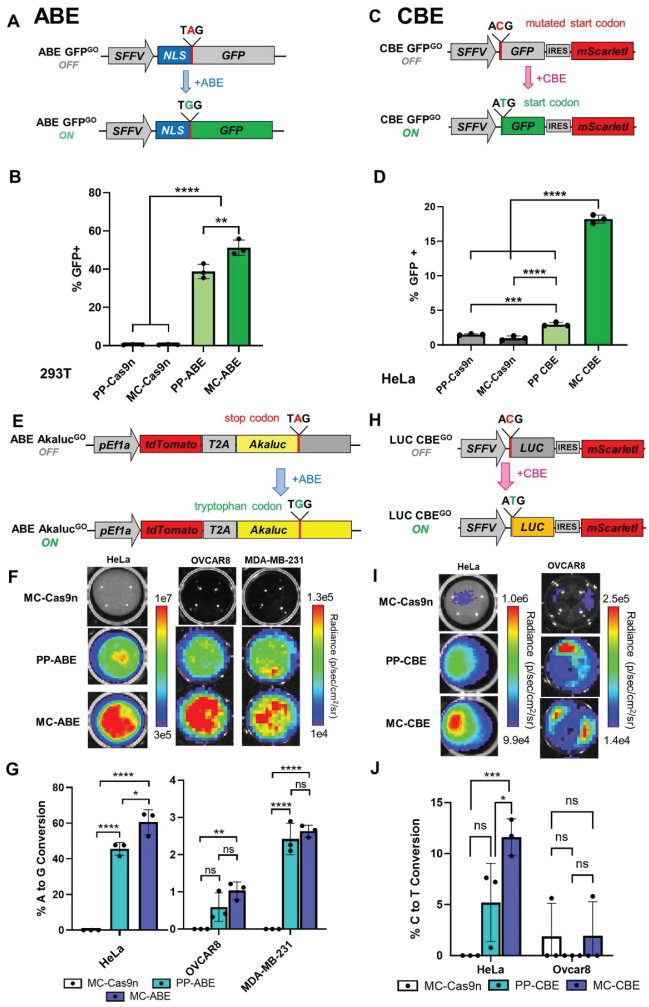
CAR-T (chimeric antigen receptor - T cell) therapy has shown significant clinical benefit to patients with hematologic malignancies such as leukemia and lymphoma. However, the treatment is currently performed ex vivo and requires a complex manufacturing process that results in barriers to patient access. To obviate the complexities of ex vivo manufacturing, we are developing therapeutics that enable *in vivo* specific cell reprogramming, providing redosable, off-the-shelf gene therapies to patients while eliminating the need for pre-conditioning treatments. We developed several analytical methods to characterize and optimize the final lipid nanoparticle (LNP) formulation. To determine the effect of various lipid compositions and the association, specificity, and functionality of different moieties for CD3, CD4, and CD8 targeting, we incubated fluorescently labeled (DiI) LNPs containing reporter (GFP and mCherry) mRNAs with primary human T cells *in vitro*. Transfection of LNPs composed with ionizable lipids DLn-KC3-DMA maintained T-cell viability at various concentrations and displayed >60% GFP+ CD8+ cells and <5% GFP+ CD4+ cells when conjugated with an αCD8 (e.g., TRX2) targeting moiety. We observed similar trends in specificity for CD4+ T cells with αCD4 (e.g., Ibalizumab Fab) moieties. Additionally, we verified transfection, translation, and subsequent surface expression of a functional aCD20 CAR protein by incubating T cells with LNPs encapsulating functional mRNA cargo and using an anti-FLAG antibody to detect a FLAG-tag sequence. Finally, we assessed the cytotoxic potential of CAR-LNPs by co-culturing CAR-LNP transfected T cells with a Raji cell line expressing the antigen of interest and found CAR-LNPs that transfected 20% of CD8+ T-cells with a detectable level of αCD20 CAR resulted in 3-fold higher Raji killing than the same LNP formulation with a non-functional mCherry mRNA. In summary, our suite of in vitro characterization assays enables us to assess the impact of many modifications to a LNP formulation thus supporting the further development of these candidates towards the clinic.

753. Evaluation of Lipopolymers as Therapeutic Sirna Delivery Agents in Non-Malignant and Malignant Primary Cells

Aysha S. Ansari[1], Cezary Kucharski[1], Mahsa Mohseni[1], Daniel N. M. Sundaram[1], Joseph M. Brandwein[1], Xiaoyan Jiang[2], Hasan Uludag[1]

[1]University of Alberta, Edmonton, AB, Canada,[2]University of British Columbia and BC Cancer Research Institute, Vancouver, BC, Canada

Targeting leukemia-driving oncogenes via short interfering RNA (siRNA) offers an alternative approach to leukemia treatment that can overcome the limitations of conventional chemotherapy as well as specific small molecule inhibitors. Low molecular weight polyethyleneimine (PEI) grafted with lipid substituents (lipopolymers) have emerged as promising carriers for siRNA delivery to leukemia



cells (Valencia-Serna J. et. al. J. Control. Release. 2019, Landry B. et. al. J. Control. Release. 2016). Lipopolymers harboring select aliphatic lipids were recently shown to downregulate target oncogene leading to significant anti-leukemic activity in both *in vitro* and *in vivo* cell line-based leukemia models (Ansari A. et. al. Blood. 2022). The goal of this study was to evaluate these lipopolymers in (i) peripheral blood mononuclear cells (PBMCs) obtained from healthy donors to determine the potential impact on non-malignant cells, and (ii) primary leukemia patient cells to assess therapeutic efficacy. The direct effect of lipopolymer/siRNA complex treatment on normal PBMCs was examined by quantifying the target gene (FLT3) transcript levels by RT-qPCR. At day 1 post-treatment, no changes in target mRNA levels were observed in all six PBMC samples with the two candidate lipopolymers (LeuFect B and LeuFect C) tested. Among 11 PBMC samples evaluated at day 2, only one sample showed a significant reduction in oncogene transcript levels on treatment with LeuFect B. The impact of lipopolymer/siRNA complex treatment on progenitor cells in the PBMC population was assessed by measuring changes in their colony forming ability. Of the seven PBMC samples tested, significant reduction in colony numbers was observed in one sample with LeuFect B and two samples with LeuFect C. On an average, the lipopolymer/siRNA complexes were well tolerated by normal healthy cells as changes observed in oncogene expression and colony forming ability were not consistent across the whole pool**.** Primary acute lymphoblastic leukemia (ALL) patient cells treated with complexes targeting STAT5A showed marked reduction in STAT5A transcript levels in four out of seven samples with both the lipopolymers tested. The subsequent impact of STAT5A downregulation on the clonogenicity of leukemia stem cells was observed in the significant decrease in colony numbers seen in three samples (out of eight) with LeuFects. Additionally, combined downregulation of STAT5A and BCR-ABL genes in BCR-ABL positive ALL patient samples led to a notable decrease in cell proliferation and viability. Moreover, 2 out of 3 acute myeloid leukemia (AML) patient samples harboring the FLT3-ITD mutation showed significant retardation in their colony forming ability on treatment with FLT3-targeting siRNA complexes. Collectively, the ALL and AML primary samples demonstrated promising preliminary results, suggesting a therapeutic effect on the stem cell population which is critical for mitigating relapse or prolonging remission. These findings provide further proof-of-concept for clinical translation of lipopolymer mediated siRNA therapy of leukemia, showing relative safety and selectivity of these complexes formed by lipopolymer/siRNA combinations.

754. Non-Viral Pathways to Precision: Utilizing DNA Minicircles to Deliver Adenine and Cytosine Base Editors in Cancer Cells

Melissa M. Evans[1,2], Shirley Liu[1,2], Joshua S. Krautner[1,2], Caroline Seguin[2], Rajan Leung[1], John Ronald[1,2,3]

[1]Medical Biophysics, Western University, London, ON, Canada,[2]Robarts Research Institute, London, ON, Canada,[3]Lawson Health Research Institute, London, ON, Canada

Introduction: Curing genetic diseases hinges on our ability to modify DNA precisely. CRISPR-Cas9 has revolutionized this field, enabling exact RNA-guided DNA targeting but also reveals challenges, like unintended genetic changes and safety concerns. A critical aspect is safely delivering editing tools into cells. We explore non-viral DNA minicircles (MCs) for this purpose. Smaller and lacking prokaryotic backbone elements, MCs are safer alternatives to traditional viral vectors. Our study examines MCs for delivering adenine and cytosine base editors (ABEs and CBEs) to cancer cells, employing the innovative 'Gene On' (GO) activatable reporter system and development of a new bioluminescent GO reporter with the sensitive luciferase Akaluciferase (Akaluc), to precisely monitor edited cells in vitro. **Methods:** We engineered 293T, HeLa, OVCAR8 and MDA-MB-231 cells for ABE and CBE studies to express GFP^{GO} (Fig 1 A, C), $Akaluc^{GO}$, or LUC^{GO} (Fig 1 E,H). These cells were transfected with MCs or plasmids (PPs) containing ABE/CBE/Cas9n. 48 hours post-transfection, GFP^{GO} expression was assessed via flow cytometry (Fig 1 B, D), and LUC^{GO}/$Akaluc^{GO}$ activation was measured using bioluminescence imaging (Fig 1 F, I). DNA was extracted for PCR and Sanger sequencing to analyze editing efficiency (Fig 1 G, J). **Results:** MC-ABE or MC-CBE transfected cells showed significantly higher GFP^{GO} expression compared to PP-ABE/CBE or PP and MC Cas9n control-transfected ones at 48 hours (Fig 1B, D). $Akaluc^{GO}$ or LUC^{GO} cells receiving MC-ABE or MC-CBE displayed significantly stronger signal than MC-Cas9n controls ($p < 0.0001$, Fig 1F, $p<0.001$, 1I). All MC-ABE cells had significantly higher bioluminescence than PP-ABE ($p < 0.05$). The delivery efficiency and percent editing varied across cell lines (Fig 1G, J). In some lines, it was difficult to detect editing with Sanger sequencing, but we were still able to detect an increase in bioluminescence over controls. **Conclusions:** Our findings demonstrate the effective use of DNA MCs in delivering ABEs and CBEs to cancer cells, tracked by the activation of the reporter gene GO systems. As the first study to use MCs for base editor delivery, we show their advantage over traditional plasmids but look to advance beyond this single comparison in the future, as well as employ inducible promoters to better control base editor expression. The flexibility of this system also allows for the assessment of newer base editor versions and tracking their activation as well as comparing them to MCs.

756. Multiplex CRISPR/Cas9 Knockout Utilizing Sequential Delivery via Microfluidics Transfection System

Melis Keceli, Sewoon Han, Alla Zamarayeva, Todd Sulchek, Chih-Wen Ni

CellFE, Alameda, CA

Introduction: Multiplex genome editing is an emerging technology that can broaden the application of gene therapies to perform multiple gene edits within therapeutic cells. However, targeting multiple loci using CRISPR/Cas9 ribonucleoprotein (RNP) complexes can result in chromosomal translocations. The aim of this study is to address the potential of cell genotoxicity by establishing a cGMP manufacturing workflow for sequential gene editing. Our platform uses a microfluidics-based cell process that enables rapid cell compressions to deliver gene-modifying payloads intracellularly in native cell medium. Using this technology, we have demonstrated a process to sequentially deliver payloads at different time intervals to prevent genotoxicity. The benefit of the workflow is to achieve multiple genetic edits while maintaining cell viability. **Methods:** Human primary T-cells were transfected at multiple timepoints to evaluate transfection and damage to cells. Human primary T cells, isolated from fresh leukopak and subsequently frozen, were thawed and activated for the indicated time points. We tested two major applications: transient gene expression using mRNA (eGFP and mCherry for different reporters) and CRISPR/Cas9 knockout using RNP complex targeting TRAC and B2M loci. The transfection efficiency and cell viability were measured after sequential editing. Different time intervals (1hr and 24hr) were also tested for use in specific applications. To establish a baseline, a single transfection of one payload or co-delivery of both payloads was performed as a control. **Results:** Our platform effectively conducted two mRNA transfections sequentially in one hour interval without causing extra damage to cells comparing to single transfection. Using 48hr activated T-cells, cell viability post transfection ranged from 40% to 60% both for single and sequential transfections. Transfection efficiency was also comparable between single and double transfections in a range of 60% to 80%. Similar results were observed for CRISPR knockouts. Importantly, cells from both single and double transfections recovered fully 5 days post transfection to equivalent viability and cell numbers, suggesting this workflow is feasible for multiple gene editing in T-cell manufacturing. We further developed a workflow for 24hr transfection interval between gene knockouts to address the risk of chromosomal translocations. **Conclusion:** Our microfluidic platform demonstrated a capacity to perform multiplex transfections in a sequential manner for multiple payload delivery. The efficiency of such sequential transfections is comparable to single transfection while maintaining similar cell viability. Our platform and workflow provide a solution for T-cell manufacturing to address the challenges of complex gene editing.

757. Machine Learning-Design of mRNA Delivery Vehicles for *In Vivo* T Cell Therapies

Shashi Murthy

Nanite, Inc., Boston, MA

A major challenge in the design of in vivo T cell therapies is the delivery of nucleic acid payloads, such as chimeric antigen receptor-encoding mRNAs, to T cells with high specificity. While lipid nanoparticles (LNPs) have shown potential in addressing this challenge, there exists a need for alternatives capable of minimal concurrent delivery to the liver and other organs, and lower toxicity. Polymers offer appealing attributes that directly address the limitations of current LNP as well as viral vector gene delivery vehicles. While there have been sporadic attempts to exploit polymeric delivery vehicles, the field has thus far been severely hindered by the vast chemical design space that must be navigated, ranging from atomic level design of repeating units, identification of optimal molecular weights, and structural considerations such as branching and crosslinking. Additional challenges include control of polymer-cargo interactions for effective packaging and ultimately, demonstration of effective delivery in vivo. Advances in machine learning, materials informatics, and accurate, high throughput chemical synthesis techniques now make it possible to not only cover this vast design space but also generate new predictions of previously unknown delivery vehicle candidates. We report how this approach can be applied to delivery of mRNA payloads to T cells. Candidate delivery vehicles are identified through an iterative process that consists of generating a small number of predictions from an established model, testing the predicted set for delivery to T cells, feeding that data back into the model, and generating a new set

of predictions. Effective candidates can be identified with only a few such cycles. An additional attribute of the predicted vehicles is the ability to engineer different types of polymer backbone breakdown characteristics. Such characteristics play an important role the design of therapies that need to be redosable without concerns of immunogenicity or bioaccumulation.

758. Designing Programmable Nanotechnologies for *In Vivo* CAR T Cell Generation

Diego Sergio Banuet Gonzalez[1], Ruby A. Sims[2], Anya Yakimenko[3], Ruth A. Foley[4], Suwen Li[5], Jigar Patel[3], Christopher S. Seet[5], Satiro N. DeOliveira[2], Steven J. Jonas[2]

[1]California Nanosystems Institute, University of California, Los Angeles, Los Angeles, CA,[2]Department of Pediatrics, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA,[3]University of California, Los Angeles, Los Angeles, CA,[4]Bioengineering, University of California, Los Angeles, Los Angeles, CA,[5]Department of Medicine, Division of Hematology-Oncology, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA

Cell-based immunotherapies are transforming the treatment of relapsed and/or refractory pediatric cancers, with next generation approaches exploring non-viral methods for engineering T cells with chimeric antigen receptors (CARs) *in vivo*. While the delivery of CAR expression constructs *via* lipid nanoparticles (LNPs) has emerged as a promising technology to mediate CAR expression in human T cells, a key barrier to their clinical, *in vivo* translation lies in their non-specific delivery. Here we report the design of a modular, antibody conjugated LNP platform for direct targeting, activation, and engineering of immune cell populations. Optimization of our non-targeting platform was achieved through microfluidic synthesis of several LNP formulations integrating different ionizable lipids for mRNA delivery. Our highest performing LNP configurations contained the ionizable lipid SM-102, with nanoparticle diameters <200 nm measured by dynamic light scattering and green fluorescence protein (GFP)-encoding mRNA cargo encapsulation efficiencies >80% by Ribogreen fluorescence-based assay. The surface of the LNPs were then decorated with αCD3 monoclonal antibodies utilizing a bioorthogonal conjugation approach. Live cell imaging and flow cytometry analysis of activated T cell populations revealed GFP expression in as little as 4 h post LNP treatment. At least 80% of treated cells went on to express GFP for up to 72 h during active T cell proliferation. Addition of αCD3 monoclonal antibodies showed comparable transfection to that of optimized, non-targeting LNP platforms; while, in addition, our preliminary studies indicate the potential of our αCD3-modified LNPs to both stimulate and transfect naïve T cells. These nanotechnologies serve as a modular, foundational platform for T cell engineering, enabling target specificity to empower next generation cellular immunotherapeutic approaches with logic-gating and other advanced capabilities.

759. Teaching Old Lipids New Tricks: Engineering LNP Composition for Extrahepatic Delivery of DNA for Lung Cancer Imaging and Treatment

Badriprasad Ananthanarayanan, Blaine McCarthy, Sushil Lathwal, Suthara Ramachandran, Anderson Lee, Christine Pedersen, Xiaobin Wu, Robby Chandra, Nadege Morisot, David Suhy

Earli, Inc, Redwood City, CA

Early detection of lung cancer significantly improves survival rates. Yet only 27% of all lung cancers are diagnosed at Stages 1-2. This is partly due to the lack of highly accurate, non-invasive diagnostic imaging methods that can differentiate malignant cancers from benign lesions. To overcome this limitation, Earli's platform uses cancer-activated DNA vectors to force tumors to produce synthetic biomarkers. Unlike most gene therapy applications, transfection of a tiny fraction of tumor cells often can produce sufficient biomarker expression for diagnostic imaging, provided there is minimal expression in normal cells. This necessitates the development of nanoparticles that can deliver DNA to lung tumors. While lipid nanoparticles (LNPs) have achieved clinical success for the delivery of RNA to hepatocytes, delivering DNA to lung tumors entails solving two fundamental challenges: preventing rapid clearance of intravenously injected LNPs by phagocytes in the liver and spleen, and delivering DNA into the nucleus of tumor cells for gene expression. Comprehensive bioengineering of the LNP surface and core lipid components were used to address these challenges. To model DNA delivery to the nucleus, we developed an *in vitro* assay based on serum-starved, slowly dividing cell lines, including H1299 cells derived from lung tumors, and screened LNP formulations encapsulating dye-labeled nanoplasmid DNA expressing GFP. We then applied high-throughput, Design-of-Experiments methodologies to screen a library of sterol and helper lipid variants to optimize expression for each ionizable lipid tested. We also evaluated a library of 30 lipid-polymer variants to define LNP surfaces that could minimize serum opsonization and concomitant cell uptake while retaining high cell transfection rates. Through these engineering approaches, we identified LNPs that increased GFP expression by 40-fold while exhibiting lower uptake into cells compared with a canonical composition based on the FDA-approved drug Patisiran. In murine models, preliminary pharmacokinetic studies established that our lead LNP formulations exhibited strikingly longer circulation, achieving up to 15-fold higher DNA copies in serum at 48 hr post injection compared to canonical liver-directed LNPs. In a subcutaneous H1299 xenograft model, this resulted in up to 4-fold greater tumor exposure. LNPs encapsulating DNA encoding firefly luciferase driven by a constitutive CAG promoter were evaluated by *ex vivo* bioluminescence imaging (BLI) of the tumor and other major organs 24-48 hr post administration. The lead LNP formulations produced high levels of expression and achieved 17-fold higher BLI in the tumor, and 50-fold greater tumor-to-liver BLI ratio, than Patisiran-like formulations of the same ionizable lipid. In an orthotopic lung xenograft model, these formulations produced BLI 220-fold higher than PBS-dosed mice, whereas non-tumor-bearing mice produced no BLI above background, verifying the ability of these LNPs to selectively express DNA in lung tumors. Thus, comprehensive engineering of LNP composition enables extrahepatic delivery of DNA to lung tumors. When combined with cancer-activated expression of

PET reporter genes and further validation in preclinical mouse models and toxicology studies, this represents a promising diagnostic imaging platform for early detection of lung cancer.

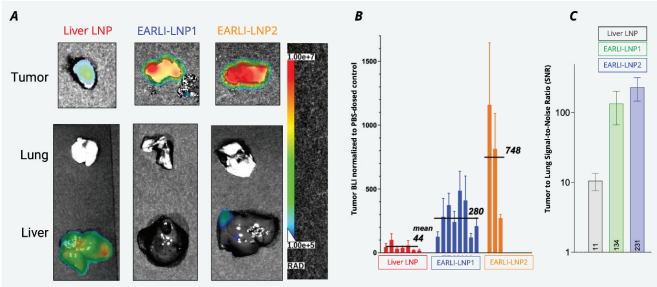


Figure 1. Extrahepatic delivery and expression of DNA by engineered LNPs. (A) Representative images of tumors, lungs, and livers from mice dosed intravenously with indicated LNPs encoding firefly luciferase and imaged 48 hr after administration. (B) Tumor BLI for indicated LNPs normalized to background in PBS-dosed mice. Each bar represents a distinct study. (C) Signal-to-Noise Ratio of average tumor to lung BLI for indicated LNPs. For (B) and (C), n=5 mice per group, error bars represent S.E.M.

760. Rapid Screening of Exosomal RNA Cargo for Therapeutic Research Applications

Chris DJamoos

Promega Corporation - Madison, WI, Brighton, MI

Aim: Exosome RNA therapy is emerging as a pivotal tool in cell and gene therapy, offering several advantages over traditional cell-based methods. Exosomes, as naturally occurring nanocarriers, provide a non-immunogenic, stable, and efficient means of delivering therapeutic nucleic acids. In addition, there are significant advantages in their manufacture, storage and distribution. Exosomes, when engineered through host cell transfection, can effectively deliver therapeutic nucleic acids such as mRNA, miRNA, siRNA, and circRNA. A crucial element in harnessing the full therapeutic potential of exosomes is the development of rapid, efficient methods for their isolation and the characterization of their RNA payload. The aim of this study was to validate a rapid and scalable exosomal miRNA isolation platform for characterizing nucleic acid payloads. **Methods:** Fully automated exosomal miRNA isolated from 500 µl of plasma (n=60) was performed using a magnetic bead-based affinity capture system (EXO-NET®, Inoviq Ltd) and a high-throughput miRNA extraction t chemistry (Maxwell® HT miRNA Plasma and Serum, Promega Corporation) on an automated platform (KingFisher APEX, ThermoFisher). Western blot analysis was used to confirm the presence of canonical protein biomarkers. The EV-RNA content was assessed by RNA seq using NovaSeq X Plus system (Illumina) and then targeted miRNAs were validated by RT-PCR. **Results:** Exosomal miRNA isolation from 60 plasma samples was performed in less than 2 hours. Western blot analysis confirmed the presence of exosomal protein biomarkers (CD9 and flotillin-1). Small RNA seq analysis identified more than 400 miRNAs in plasma derived exosomes. Further targeted miRNA analysis by RT-PCR showed abundancy and consistent expression of miR191 (Ct: 22.43±1.87), miR-21 (Ct: 21.98±1.96) and miR-186 (Ct: 24.59±2.03) in all plasma samples. **Conclusion:** We have established and validated a rapid, scalable and automated platform for exosomal RNA isolation for downstream analysis and characterization. The platform holds great promise for facilitating the development and translation of exosome-based companion diagnostics and therapeutics into routine clinical practice.

761. Peptide Based Nanoparticle-Platform for Extrahepatic Delivery of Functional mRNAs

Gilles Di Vita[1,2], Audrey Grunenberger[1,2], Elodie Czuba[1], Léa Cabrera[1], Veronique Josserand[3], Melanie Guidetti[3], Neil Desai[2]

[1]DIVINCELL, Nimes, France,[2]AADIGEN, Pacific Palisades, CA,[3]IAB, Grenoble, France

Therapeutic mRNAs constitute a new generation treatments to restore functional version of mutated or missing proteins in patients. We have developed a unique RNA Therapeutic platform that leverages novel peptide technology able to systemically target and deliver the RNA therapeutic into the pathologic cell to fight or prevent diseases. ADGN technology is based on short amphipathic peptides that form stable nanoparticles with mRNAs. The molecular composition and sequences of ADGN nanoparticles have been rationally designed for selective organ targeting of functional mRNAs, to overcome hepatic accumulation and to induce robust mRNA expression in the targeted tissue. ADGN/mRNA nanoparticles are stable both in solution and in dry powder formulations, with an average size of 100 nm and a high encapsulation efficiency (>90%). ADGN nanoparticles have been successfully used for the rescue of lost function of tumor suppressor functions resulting from mutations or alterations as a potential therapeutic approach in cancers. Tumor suppressors p53 and BRCA-1 play essential roles in tumorigenesis. Indeed, p53 or BRCA-1 mutations resulting loss of function are common across variety of tumors and influence tumor cell proliferation and metastasis in more than 50% of cancers. ADGN-531 combines proprietary P53 derived mRNA with a tumor selective peptide nanocarrier to rescue of p53 tumor suppressor function in p53 mutated cancers. ADGN-531 markedly inhibits the growth of a large panel of cancer cells harboring p53-missense or nonsense mutations or p53-deletion, by rescuing p53 transcriptional activity and subsequent expression of its target proteins. Systemic IV-administration of ADGN-531 resulted in dose responsive tumor growth inhibition in SaOs2 (osteosarcoma), SW403 (colorectal cancer) and H358 (lung cancer) xenografts with strong tumor growth inhibition when administered weekly at a dose of 1 mg/kg. [nd1] ADGN-903 combines a proprietary BRCA-1 derived mRNA complexed with a tumor selective peptide nanocarrier to rescue of BRCA-1 tumor suppressor function in BRCA-1 mutated cancers. ADGN-903 markedly inhibits the proliferation of BRCA-1 deficient cell lines depending on the type of BRCA-1 alterations. Systemic IV-administration ADGN-903 (2.0 mg/kg) prevented HCC-1937 breast cancer tumor growth. and resulted in strong tumor regressions. ADGN-903 was also highly effective, on large tumors of about 500-600 mm^3, in preventing further progression and achieving shrinkage of large tumors. Rescue of lost function of mutated tumor suppressors p53 or BRCA-1 by ADGN-531 and ADGN-903 respectively were well tolerated, with no sign of clinical toxicity detected after single or repeated administrations. ADGN nanoparticles constitute a safe and effective platform for tissue-specific delivery of functional mRNAs with potential clinical applications. Our study provides a proof-of-concept that restoration of tumor suppressor function by ADGN-531 or ADGN-903 could be used as a single agent therapy in P53 or BRCA-1 altered tumors independent of other driver mutations or with other therapies for potent combinatorial cancer treatment.

762. Exosomes as a Stromal-Targeting Extension of Oncolytic Virus Therapeutics

Kate R. J. Friesen[1], Dhanu Gupta[2,3], Kerry D. Fisher[1], Matthew J. Wood[2], Leonard W. Seymour[1]

[1]Oncology, University of Oxford, Oxford, United Kingdom,[2]Paediatrics, University of Oxford, Oxford, United Kingdom,[3]Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Oncolytic viruses (OVs) selectively replicate in and kill cancer cells. OVs can be used as a gene delivery vector for selective expression of therapeutics in the tumour microenvironment (TME). One current barrier of OV-mediated therapy in solid tumours is the poor viral spread due to the extracellular matrix produced from stromal cells such as cancer-associated fibroblasts (CAFs). Exosomes are naturally derived lipid-coated nanoparticles that transport various molecular payloads between donor and recipient cells. They range between 30 nm - 150 nm, are secreted by most cell types, have the same topology as the plasma membrane, and are generated from the inward budding of late endosome membranes forming multivesicular bodies (MVBs). Additionally, exosomes can be engineered to transport therapeutics between donor and recipient cells. This property makes them a promising nanoparticle-based delivery system for targeted drug and gene therapy. Aim: To enhance the spread of therapeutics *in situ*, we are developing an exosome-targeting system where DNA coding for a tripartite fusion protein (consisting of a targeting protein (anti-FAP scFv), a scaffold protein, and a therapeutic protein (cytosine deaminase)) is delivered by an oncolytic adenovirus. The fusion protein is synthesized and loaded into exosomes for delivery to surrounding potentially non-infected tumour and stromal cells such as CAFs.

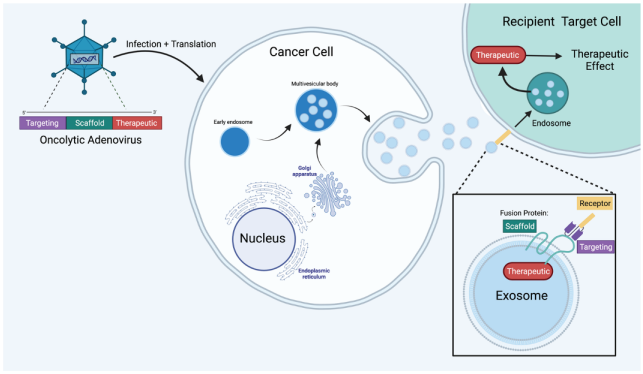

Figure 1. Project hypothesis: An oncolytic adenovirus can be used to deliver DNA coding for a tripartite fusion protein (consisting of a receptor-binding targeting protein, a scaffold protein, and a therapeutic protein) that will be synthesized and packaged into exosomes which will deliver the cargo to uninfected cancer and stromal cells.

Methods: Exosomes were isolated via size exclusion chromatography from adenocarcinoma cells stably transduced with the tripartite fusion protein and characterized according to MISEV guidelines. Real-time exosome uptake into cancer cells and CAFs was monitored using a split nanoluciferase reporter system. Nano-flow cytometry and a FlipGFP-reporter system were used to evaluate the functionality and targeting potential of the anti-FAP scFv exosmes. Cell viability assays were used to quantify the ability of exosomes to deliver cytosine deaminase to cancer cells and CAFs. Results: Exosomes containing a subunit of split nanoluciferase were capable of being taken up in real-time and delivering functional cargo into the cytoplasm of recipient tumour cells expressing the other subunit. A functional anti-FAP scFv was capable of being expressed on exosomes, and treatment with exosomes armed with cytosine deaminase resulted in a significant decrease in tumour cell viability following the addition of 5-fluorocytosine. Conclusions: Exosomes can be engineered to selectively package therapeutics and deliver cargo to recipient cells resulting in target cell death. The cytotoxicity of the oncolytic virus expressing the tripartite fusion protein is currently being evaluated using these methods *in vitro* and *ex vivo*. Concentrating the production of bioengineered EVs directly in the TME provides a novel approach to overcome the biodistribution and rapid EV clearance challenges that limit the clinical potential of therapeutic exosomes/EVs.

763. *In Vivo* Gene Editing of Non-Small Cell Lung Tumors Directed by CRISPR/Cas Reduces Tumor Growth and Extends Survival

Katelynn Owens[1], Kelly Banas[1], Nicole Haas[1], Emily Gielda[1], Kristen Pisarcik[1], Komal Khan[1], Hannah Pachalis[1], Laura Flanagan[2], Eric B. Kmiec[1]

[1]Gene Editing Institute, Christiana Care, Newark, DE,[2]Office of Laboratory Animal Medicine, University of Delaware, Newark, DE

Lung cancer is the leading cause of cancer-related mortality in the United States, with chemotherapies serving as the main line of treatment. While chemotherapies sometimes halt tumor progression, repeated or prolonged treatments often cause patients to become resistant. One gene that has been implicated in this resistance pathway is nuclear factor erythroid 2-related factor (NRF2). We hypothesized that targeting NRF2 with CRISPR Cas9 in patients with non-small cell lung cancer, will reverse chemo-resistance and allow the current standard of care to work better. To do this, we used athymic nude mice implanted with either an engineered H1703 cell line or patient derived tumor fragment as a model. Subcutaneous tumors were directly injected with lipid nano particles (LNP) encapsulating CRISPR Cas9 mRNA and gRNA. Data show high editing in tumors injected with LNP. Additionally, data show little to no biodistribution of the mRNA after injection, suggesting that delivery of the drug remains in the tumor after injection. Knockdown of NRF2 with CRISPR Cas9 at the genomic level is sufficient to affect the protein's function, as shown by altered target gene expression. LNP delivery of CRISPR Cas9 intra-tumorally, combined with chemotherapy, showed delayed tumor growth and increased survival when compared to controls. These data hold promise for overcoming chemotherapy resistance in patients with NSCLC and other diseases.

764. Engineered Ribonucleoproteins (eRNPs) for Non-Viral *In Vivo* Delivery of Gene Editors to Treat Ophthalmic Disorders

Rina Mepani[1], Aaron Cantor[1], Pawan Shahi[2,3], Spencer Wei[1], Vihasi Jani[1], Kory Melton[1], Prachi Khekare[1], Suhani Gupta[1], Jonathan Wang[1], Peter Otoupal[1], Jack Walleshauser[1], Benjamin Gowen[1], Weng In Leong[1], Krishanu Saha[2,4], Adam Silverman[1], Bikash Pattnaik[2,3], Mary Haak-Frendscho[1]

[1]Spotlight Therapeutics, Hayward, CA,[2]McPherson Eye Research Institute, University of Wisconsin-Madison, Madison, WI,[3]Department of Pediatrics, University of Wisconsin-Madison, Madison, WI,[4]Wisconsin Institute for Discovery, University of Wisconsin-Madison, Madison, WI

Genome editing technologies offer great potential as durable therapies for a myriad of diseases, including many inherited disorders previously deemed untreatable. The recent approval of ex vivo gene editing therapy for blood disorders showcases the immense promise of this transformative technology while underscoring the need to develop in vivo gene editors to enable application expansion. Current in vivo delivery approaches for gene editors, such as AAV, face multiple challenges, including pre-existing immunity, capsid-induced inflammation, persistent expression of nucleases, and complexity of manufacturing. Here we describe a new class of single administration genomic medicine, engineered RNPs (eRNPs). eRNPs are non-viral, non-encapsulated biologics designed for safe localized in vivo gene editing. These protein-RNA constructs are a scaffold of Cas nuclease fused with cell-penetrating and nuclear-localizing peptide sequences, with or without a deaminase domain, and complexed with a single guide RNA. Highlighting the modular nature of the protein scaffold, we illustrate the ability to generate bespoke eRNPs tailored to introduce indels, excise exons, or perform base editing for selected genetic lesions. Inherited retinal disorders (IRDs) represent a class of genetic disorders with high unmet need. eRNPs are particularly well suited for subretinal administration, which enables direct delivery to retinal pigmented epithelial (RPE) cells or photoreceptors. We demonstrate that eRNPs delivered by subretinal injection are highly efficient at introducing indels in RPE and retina in wild-type, transgenic reporter, and functional mouse models. In an Ai14 tdTomato reporter model we observed high focal tdTomato signal in the retinal pigment epithelium (RPE). We demonstrate editing efficiencies are biologically functional by targeting the wild-type allele in KCNJ13+/W53X mice, which resulted in near complete ablation of electroretinogram c-wave. We further show that eRNPs with engineered adenine deaminase domains mediate efficient base editing in the retina and RPE of wild-type mice. Taken together, these data suggest the highly modular biologic approach of eRNPs opens a new path for treating a wide range of IRDs and ocular diseases with tremendous unmet medical need.

765. Optimization of Fusogenix Proteolipid Vehicles for Extra-Hepatic Delivery of mRNA

Douglas Brown[1], Arun Raturi[1], Ping Wee[1], Prakash Bhandari[2], Amirali Bukhari[2], Maryam Hejazi[3], Jitendra Kumar[4], John Lewis[2]

[1]Entos Pharmaceuticals, Edmonton, AB, Canada,[2]Entos Pharmaceuticals, San Diego, CA,[3]Entos, Edmonton, AB, Canada,[4]Entos Pharmaceuticals Inc, San Diego, CA

The promise of genetic medicines for the treatment of a wide range of diseases remains limited by viral and non-viral delivery platforms. These legacy platforms face challenges in the effective and tolerable delivery of nucleic acids. While non-viral lipid nanoparticle (LNP) delivery platforms have undergone incremental improvements, they still suffer from a narrow biodistribution profile, predominantly hepatic cells, and substantial dose-limiting toxicities. To overcome these issues, we developed an alternative all-encompassing platform capable of body wide delivery of nucleic acids including mRNA, called Fusogenix. The Fusogenix proteolipid vehicle (PLV) platform leverages a proprietary fusion-associated small transmembrane (FAST) protein incorporated into well-tolerated lipid formulations. The Fusogenix platform achieves extra-hepatic delivery and tropism through manipulation of manufacturing parameters such as charge ratio, PEGylation, microfluidic flow rate, and lipid composition. Using this approach, we achieved dramatic shifts in surface properties of the PLVs, independent of the encapsulated cargo. Modulating these parameters altered the affinity of FAST-PLVs to a wide array of extra-hepatic tissues, such as muscle, lungs, and kidneys and increased the efficacy of mRNA-mediated gene expression in target tissues as well. Direct comparison of FAST-PLV mediated delivery of mRNA-FLuc to three conventional clinical LNP formulations (MC3-LNPs, Pfizer-LNPs, and Moderna-LNPs) via intramuscular, intrathecal, intracerebroventricular, and intravitreal injection show the dramatically improved biodistribution of FAST-PLVs. Intramuscular, intracerebroventricular, and intravitreal injection of FAST-PLVs resulted in robust localized expression of FLuc in the intended tissue. Intrathecally administered FAST-PLVs distribute throughout the central nervous system and achieved robust FLuc expression in multiple brain regions. All three clinical LNP formulations displayed predominant liver-tropism, resulting in saturating levels of FLuc expression in the liver regardless of the injection route. Conversely, no off-target FLuc expression was detected with FAST-PLVs by any route of injection. Precise delivery of nucleic acid cargoes associated with a favorable safety profile, as circulating cytokine levels were lower in mice administered FAST-PLVs, and histological analysis indicated no signs of pathology. Intravenous administration of FAST-PLVs yielded notable mRNA expression in the lung, with a subsequent profile analysis confirming expression in both type I and type II alveolar cells. To assess therapeutic gene expression, we administered mRNA encoding erythropoietin (mRNA-EPO) through both intravenous and intramuscular routes, leading to a rapid increase in circulating erythropoietin levels in the hours following injection. These findings collectively underscore the feasibility and optimization of extra-hepatic mRNA delivery achieved by fine-tuning the biophysical attributes of FAST-PLVs. Importantly, the ability to target extra-hepatic tissues and reduced liver tropism establishes FAST-PLVs as a promising platform for advancing the clinical development of mRNA-based genetic medicines.

766. Development of *In Vitro* Transcribed mRNA Therapeutics for Cystic Fibrosis

Yiman Li[1], Ruhina Maeshima[1], Claire Smith[2], Stephen L. Hart[1]

[1]Department of Genetics and Genomic Medicine, UCL Great Ormond Street Institute of Child Health, London, United Kingdom,[2]Department of Infection, Immunity and Inflammation, UCL Great Ormond Street Institute of Child Health, London, United Kingdom

Introduction: Cystic fibrosis (CF) is an autosomal recessive disorder caused by a mutation in the cystic fibrosis transmembrane conductance regulator (CFTR) gene. The dysfunctional CFTR protein leads to production of a thick sticky mucus, chronic bacterial infection and loss of lung function. Modulator drugs provide effective therapies for some CFTR genotypes but approximately 20% of patients remain untreatable. **Aim**: We propose to develop in vitro transcribed CFTR messenger RNA (mRNA) as a novel therapy, which has the potential to work in any CF patient. The aim of this study was to first optimize the structural elements of in vitro transcribed mRNA, including the design of the 5' and 3' untranslated regions (UTRs), regulating luciferase activity in epithelial cell models, as well as a novel non-viral nanoparticle formulation for their delivery. **Methods**: We have developed an epithelial cell targeting nanoparticle to improve mRNA delivery comprising targeting peptides and lipids. Different lipids and peptides were compared. The in vitro transcription protocol was optimized with the CleanCap cap analog added during in vitro transcription to allow co-transcriptional capping. Unmodified uridine-5'-triphosphates (UTPs) were replaced by modified UTPs, N1-methylpseudouridine-5'-triphosphate. Double-stranded RNA contaminants were removed by cellulose-base purification. The mRNA structural elements were optimized with various 5' Untranslated regions (UTR) and 3'UTRs cloned into the DNA template including known UTRs and novel UTRs from transcripts highly expressed in the airway epithelium. **Results**: The optimal design for transfection of 16HBE epithelial cells and CF bronchial epithelial cells comprised the cationic lipid, ditetradecyl trimethyl ammonium propane (DTDTMA), the neutral helper lipid, 1,2-dioleoyl-sn-glycero-3-phosphoethanolamine (DOPE), and the epithelial targeting peptide Y (K_{16}GACYGLPHKFCG) with luciferase mRNA which led to high transfection efficiency. According to the optimised in vitro transcription protocol, up to 280 micrograms (μg) of RNA could be produced from 1 μg of DNA. The luciferase mRNA produced transfected 16HBE and CFBE cells with similar efficiency to commercially available luciferase mRNA. The presence of certain UTRs from genes that are expected to give high epithelial expression further increased the translation efficiency. Compared to mRNA with no UTR, messenger RNAs with either individual UTR (5' or 3' UTR) or double UTRs (5' and 3'UTR) showed improved translation efficiency. Both human-derived and viral UTRs were involved in this study. While the optimal UTRs were cell type-dependent, mRNA with optimal UTRs showed a two-fold increase in translation efficiency over mRNA with no UTR in both 16HBE and CFBE. **Conclusions**: The in vitro transcription process and mRNA structural elements were optimized to produce synthetic mRNA with high translation efficiency, stability, and low inflammatory potential. Novel non-viral nanoparticle formulation was developed specific for mRNA delivery to epithelial cells. Taken together, this work provides the basis for the development of targeted gene therapy for cystic fibrosis that precisely delivers mRNA to epithelial cells in the lung.

767. A Platform Approach for Producing Engineered Extracellular Vesicles

Lisa Prendergast[1], Ali Navaei[2], Davide Zocco[3], Devarshi Kapadia[4]

[1]Licensing, Lonza Cell and Gene, Slough, United Kingdom,[2]R&D, Lonza Cell and Gene, Rockville, MD,[3]R&D, Lonza Cell and Gene, Sienna, Italy,[4]Commercial Development, Lonza Cell and Gene, Houston, TX

Extracellular Vesicles (EVs), including exosomes, are emerging as promising natural nano-scale platforms for delivering nucleic acids, proteins, and small molecules. However, precision EV engineering has been challenging to date. Such technologies have also been largely inaccessible for a broader community due to technical complexities. Here, we discuss materials and methods to express biomolecules on EVs. Protein scaffolds were developed and clinically proven to effectively load therapeutic proteins on the surface or lumen of EVs. Chemical linkers were developed to link nucleic acids or small molecules to the EV membrane while preserving their bioactivity and potency. Case studies and clinical data for each EV loading and linking technology will be presented. Technologies described here will be available to Pharma, Biotech and Academic communities under a Research License for broader access. They will also be available to therapeutics companies via contract development and manufacturing services for producing their engineered EVs.

768. Implementing Custom Particle Swarm-Differential Evolution Optimization (PSODE) for GFP Plasmid DNA Transfection in Jurkat and Primary T Cells

Devin Reslow, Andrew Hallinan, John Zhao, Ta-Chun Hang

Kytopen, Cambridge, MA

Optimization of transfection processes is critical to successful cellular drug product manufacturing. A key requirement for efficient transfection is utilization of an optimized buffer. Transfection buffer formulation is a convoluted problem that can benefit from sophisticated optimization methods. After defining a base formulation via traditional experimental design principles (DOE), we implemented a custom, hybrid particle swarm optimization and differential evolution (PSODE) algorithm with archived memory was used to simultaneously screen and optimize efficacy of numerous buffer additives and transfection parameters. PSODE was implemented with adaptive social and cognitive parameters to balance design exploration and exploitation of information. Mutation and crossover of designs further leveraged the information gained from successful formulations. In this approach, additives were evaluated to improve delivery of plasmid DNA. Traditional DOE methods with 22 unique additives (i.e., 3^k factorial design) results in a high-dimension space requiring >300E6 experimental iterations to characterize. PSODE identified optimal formulations after 5 iterations when combined with multi-objective optimization (MOO) of transfection efficiency and

cell viability. PSODE formulations demonstrated >75% transfection efficiency with >80% viability in Jurkats, a 3-fold increase over base formulation alone. PSODE formulations were subsequently tested in primary T cells, demonstrating >75% viability and >50% transfection efficiency. Transfections with various Flowfect® profiles identified synergistic buffer and energy effects, indicating further optimization is possible. PSODE implementation in Jurkats and T cells demonstrate the valuable coaction of Flowfect® technology and algorithm-based study designs, yielding high-throughput discovery capabilities to screen, optimize, and characterize transfection processes and parameters. In tandem, algorithmic buffer optimization methods can benefit cell and gene therapy applications, enhancing future development of specialized, optimal transfection processes for other cell type and payload combinations.

769. Improving Endotoxin Determination in Complex Gene Delivery Systems: Challenges and Novel Workflow Modifications

Andrew Dix, Alexia Bachir, Sneh Ringwala
Thermo Fisher Scientific, Eugene, OR

Endotoxin contamination, a common problem with recombinant proteins and nucleic acids used in cell and gene therapy, can trigger toxic shock, activation of nonspecific immune responses, or premature cell death. While tools for endotoxin quantification are not new, the techniques used for gene delivery are becoming increasingly complex and can interfere with the assay readout. Specifically, lipid nanoparticles (LNPs) and adeno-associated virus particles (AAVs) are known to scatter light, which is the reporting mechanism for commonly used chromogenic Limulus amebocyte lysate (LAL) assays. These challenges lead to inaccurate endotoxin measurements, which can have negative impacts on downstream experiments and applications. Here, we utilize spike-testing of a control endotoxin amount into the AAV and LNP samples to demonstrate challenges with the current state of endotoxin testing. Additionally, we detail best practices on how different endotoxin quantification assays can be used to determine contamination levels in these sample types. Overall, the highlighted data seeks to enable proper endotoxin determination and preserve the integrity of downstream applications.

Wednesday Posters: Cancer - Immunotherapy and Cancer Vaccines

770. Tumor Vaccination by HAdV5 and HC-HAdV5 and Its Targeting *In Vitro* and *In Vivo* to APCs by Engineered Modular Adapters

Fabian Weiss[1], Jonas Kolibius[2], Patrick Freitag[1], Andreas Plückthun[1]
[1]University Zürich, Zürich, Switzerland,[2]University of Zürich, Zürich, Switzerland

The clinical significance of B- and T-cell vaccines is undisputed, with adenoviral vectors demonstrating encouraging outcomes. Nevertheless, the commonly used human adenoviral vector serotype C5 (HAdV5) exhibits limited transduction efficiency in dendritic cells (DC), necessitating therefore very high viral loads. Thereby, gene-based therapy in APCs (antigen presenting cells) remains challenging. In response, we have developed a versatile platform that employs modular retargeting adapters to enhance transduction into specific cell types, including traditionally challenging host cells. By rational design we demonstrate successful targeting of HAdV5 to human and murine DCs through DC-SIGN and CD11c receptors. Our *in vivo* characterization highlights the potential for improved and specific transduction of DCs in draining lymph nodes without off-targeting to B-, T-cell, nor macrophages. Moreover, a tumor vaccination efficacy study showcases the advantageous co-expression of T cell stimulatory cytokines (IL-2v or IL-21) locally in lymph nodes alongside a potent tumor antigen. Lymph node directed gene-therapy at significantly reduced viral loads circumvents potential systemic toxicity of stimulating payloads. Our proposed low dosage DC-targeted therapy not only offers a cost-effective solution for patients but also minimizes potential adenoviral related side-effects. The robust immunogenicity of HC-HAdV5, with its expansive encoding capacity up to 37 kbp DNA, opens up exciting possibilities for future therapeutic combination strategies. This approach has significant potential to advance the field of combination immunotherapy by enhancing the precision of safe and low-cost DC based gene-therapies

771. The Strategy to Reduce Vector Doses by AAV-Extracellular Vesicles Composite

Ester Molina[1], Marcos Tejero Ambrosio[1], Ozgun Firat Duzenli[2], Hisae Kuoch[1], Colin Caine[1], Karina Krotova[1], Michael Paulaitis[3], George Aslanidi[4]
[1]The Hormel Institute, Austin, MN,[2]The Hormel Institute, University of Minnesota, Austin, MN,[3]Johns Hopkins University School of Medicine, Baltimore, MD,[4]University of Minnesota, Austin, MN

We recently showed advantages of using capsid and payload modified AAV vectors to generate protective antigen specific immune response in animal model of melanoma. However, one of the biggest challenges remaining in the field is the production of high yield and highly efficient vaccines. Extracellular vesicles or EVs have been used for years as a delivery platform since they are natural nanoparticles skilled in delivering their content between cells and tissues. Several studies have proposed the encapsulation of AAV vectors during common packaging process inside EVs to increase therapeutical performance. The advantage of such production method will be a one-step purification process. The aim of this work is to increase the efficacy of treatment using AAV-based cancer vaccine inside EVs. First, we comprehensively characterized EV-AAV vesicles by their concentration, average diameter, size distribution, vesicle morphology and EV biomarkers, as well as by AAV titers. Second, we showed that mice vaccinated with EV-opt-OVA antigen showed an increased in cellular immune response measured by flow cytometry of OVA-specific $CD8^+$ T cell, compared with those animals injected with opt-OVA at the same vector dose. We also showed that the dose EV-opt-OVA can be reduced by 100 to 1000 times to achieve the similar number of IFN-γ produced OVA tetramers positive $CD8^+$ T cell compare with opt-AAV-OVA. Additionally, mice injected with B16F10-OVA melanoma cells were protected against metastatic nodules in the lungs with 100-times less dose of EV-opt-OVA compared with opt-OVA alone, 10^8 vg/mice vs.

10^{10} vg/mice correspondingly. Finally, we used a therapeutic tumor self-antigen to assess the effectivity of EV-AAV vaccine with a less immunogenic payload. We observed the effective dose for EV-opt-TRP-1 is 10-times less compared with opt-TRP-1 alone, 10^{9} vg/mice vs. 10^{10} vg/mice correspondingly, to generate $CD8^{+}$ T cell and protect animals from B16F10 metastatic cells spreading in the lungs. The results of our study showed that EV associated AAVs can elicit a stronger immune response in mice compare with AAV vaccine alone. More importantly, EV-AAV vaccine have demonstrated a stronger protection against metastatic melanoma tumors in mice lungs at much lower doses used in previous experiments. Additionally, we have observed that the reduction of the vaccine dose is dependent on the antigen carried by AAV which underlines necessity to identify appropriate unmodified or neo-antigen(s) for effective cancer treatment. The natural ability of exosomes to deliver their cargo to cells particularly immune cells, together with AAV vectors highly efficient transduction of the antigen they carry is an attractive combination that has potential to be explored for the future cancer vaccine design.

772. Interplay Between Local Irradiation and AAV-Based Gene Delivery for Cancer Therapy

Juan Dubrot[1,2], Sonia Marco[1], Nerea Juanarena[1], Beatriz Honorato[1], Myriam Fernandez[1], Jesus Prieto[1]

[1]Cima-Universidad de Navarra, Pamplona, Spain,[2]Cancer Center Clinica Universidad de Navarra (CCUN), Pamplona, Spain

Radiotherapy (RT) is a pilar of cancer treatment. More than half of all cancer patients receive one modality of RT throughout the course of the disease. Originally, the rationale for its use relied on the direct cytotoxic effects that ionizing radiation (IR) causes in tumor cells. It is now recognized the importance of the host immune system in mediating and modulating the therapeutic effects of IR. Radiation causes immunogenic cell death that release tumor-associated antigens and damage-associated molecules which activate the innate immune system, triggering cytokine production and immune cell recruitment. These inflammatory signals are able to induce effective anti-tumor responses. At the same time IR initiates immune-resistance mechanisms such as IR-induced expression of PD-L1 in cancer and stromal cells and increased influx of immune-inhibitory populations. Thus, combination of RT with local delivery of cytokines that enhance antitumor responses or revert immunosuppressive mechanisms represents a reasonable strategy. Adeno-associated virus (AAV) vectors have been engineered for its use as gene delivery vectors has been used for the treatment of a variety of human diseases. Yet, the value of AAV vectors for cancer treatment has not been explored in depth. To interrogate the therapeutic potential of the combination of RT and AAV-based gene therapy, we designed an AAV vector encoding interleukin-12 (IL12), a multifunctional cytokine that plays a pivotal role in the immune system particularly in the context of anti-tumor responses. Due to its strong and diverse immunomodulatory properties, systemic expression of IL-12 can lead to toxicity with fatal consequences. Therefore, we designed an AAV vector that contains two critical safety elements. First, we have included micro-RNA 122 binding sites within the vector genome to prevent expression in the liver. Second, IR is known to induce type I IFN production through cGAS-STING pathway. Thus, we have designed an expression cassette encoding IL12 under the control of an IFN-inducible promoter that restricts its expression to inflamed tissue. These regulatory elements restrain the expression of IL12 within the tumor microenvironment (TME). We found that RT could be used not only as an initiator of the immune response and activator of IL-12 expression, but also as facilitator of AAV-mediated gene transfer, as we found that IR enhanced transduction of murine and human cancer cell lines by AAV vectors both *in vitro* and *in vivo*. In a constitutive promoter system, irradiated tumor cells infected with an AAV-GFP expressed higher levels of the transgene and retained GFP expression for longer periods of time. Similarly, expression of IL12 was detected at higher levels in irradiated in a dose-dependent manner. Importantly, expression of IL12 was restricted to the TME and no significant levels of the cytokine were observed in serum of treated animals. Local RT and intratumor injection of AAV-IL12 cooperate to induce a strong remodeling of the TME with remarkable presence of proinflammatory and effector populations. Consequently, the combination led to complete tumor rejections in several preclinical cancer models. Notably, elimination of the treated tumor is accompanied by a robust abscopal effect in distal untreated tumors. Overall, our work demonstrates the potential of an unexplored strategy for cancer treatment. We have designed a therapeutic combination that exploits the multiple benefits of local IR and safely delivers IL12 to unleash the full capacity of the immune system, which has been demonstrated to be the best way to obtain durable antitumor responses. The combination of RT and AAV-based immunotherapy represents a novel strategy that can impact a large number of cancer patients and improve the clinical results of current therapies.

773. Adenovirus Mediated HSP70 Combined with GM-CSF Enhances HPV E6/E7 Antigen Immunotherapy for HPV Infection Related Diseases

Philip C. Sin[1], Dingyue Tang[2], Wei Jiang[2], Xia Wu[2], Xiao Xiao[2]

[1]Belief BioMed Limited, Hong Kong, Hong Kong,[2]Belief BioMed Limited, Shanghai, China

Introduction: In recent years, with the application of various immune activating factors, immunotherapy has developed rapidly, especially in the field of tumor treatment. HPV infection related diseases are common diseases that pose a serious threat to women's health, persistent HPV infection is the main cause of most cervical cancers1, with E6 and E7 being the main oncogenic genes of HPV2. The prevention and treatment of E6 and E7 targets have always been a focus of research on HPV infection related diseases3. In order to enhance the efficacy of therapeutic vaccines targeting E6/E7 for HPV related diseases, we used a combination of HSP70 from mycobacterium tuberculosis4 and human GM-CSF, and used adenovirus vectors to mediate the expression of GM-CSF and HPV antigens fused with HSP70 to enhance the efficacy of immunotherapy. The research results indicated that the combination of HSP70 and GM-CSF could induce stronger T cell immunity and had a good synergistic effect. On this basis, after multiple efficacy studies and toxicological safety evaluations, the BBM-C101 adenovirus product was finally developed, demonstrating good preventive and therapeutic advantages for HPV positive diseases. **Methods and Materials:** Constructed relevant plasmids using adenovirus vectors, and obtained different adenovirus

products through transfection, cell culture, and purification. Evaluated the efficacy of different carriers through immunological experiments such as ELISPOT detection of splenic CTL lymphocyte production. After completing vector screening, further design optimization was carried out on the expression box and vector, and large-scale cell fermentation production and purification were carried out to obtain the BBM-C101 adenovirus drug product. Its effectiveness and safety were further verified in tumor monitoring experiments on TC-1 cell line tumor bearing mice and monkey toxicology experiments. (The final genetic basis of BBM-C101 product is Promoter-HPV E6/E7-HSP70-Promoter-GM-CSF). **Conclusions:** BBM-C101 is a novel immunotherapy drug for HPV infected diseases. It delivered the HPV 16/18 antigens, E6 and E7, into tissues and tumors by adenovirus 5, and activated T cell and B cell immuno-response of anti-HPV 16/18.BBM-C101 could inhibit the HPV 16/18 induced tumors, and established long-term immune memory.BBM-C101 specifically targeted the HPV 16/18 infected tissues and tumors, but it did not affect the tissues and tumors that were infected by other types of HPVDuring toxicology study, BBM-C101 did not induce the evident toxicity in rodent and non-human primatesIn clinic, BBM-C101 could clear away the cells that was infected with HPV 16/18, and turned subjects negative for HPV.In clinic, BBM-C101 did not induce SAE. Fever was common AE after BBM-C101 infusion.

774. INTASYL PH-762: PD-1 Intratumoral Immunotherapy

Melissa Maxwell, Dingxue Yan, Andrew Boone, Brianna Rivest, Linda Mahoney, Mary Spellman

Phio Pharmaceuticals, Marlborough, MA

PH-762 is an INTASYL compound designed to precisely silence PD-1 mRNA. INTASYL™ is a patented, self-delivering RNAi technology platform designed to impart specific properties to small interfering RNAs, providing extremely efficient delivery to a broad range of cell types and tissues without the need for specialized formulations or drug delivery systems. INTASYL's innovative approach features a simplified chemical composition, potentially reducing toxicity and enhancing tolerability and efficacy. PH-762 can be administered via intratumoral (IT) injection, which is anticipated to diminish the systemic side effects associated with conventional systemic antibody treatments. PH-762's unique structural and chemical modifications ensure an optimized cell and tissue uptake profile with IT administration. In vitro investigations have demonstrated efficient uptake of PH-762 by human T cells, silencing of PD-1 mRNA and subsequent protein reduction. Preclinical studies have shown that IT injections of murine targeted PH-762 (mPH-762) can silence the PD-1 mRNA in the T cells within the tumor and increase the secretion of IFN-γ. mPH-762 was well tolerated at the maximum administered dose and treatment with mPH-762 provided robust and statistically significant inhibition of tumor growth. Toxicokinetic studies conducted in marmoset monkeys demonstrated that PH-762, when administered intravenously at doses of up to 147 mg/kg, is well-tolerated. Importantly, no detectable cytokine-release associated cytokines were found in the plasma of treated monkeys at this dose. PH-762 is currently being investigated in an open-label clinical study (NCT 06014086) to evaluate the safety and tolerability of neoadjuvant use of IT PH-762 in cutaneous squamous cell carcinoma (cSCC), melanoma, or Merkel cell carcinoma, to determine the pharmacokinetic profile of PH-762 after IT injection, to observe pathologic and immunologic tumor responses, and to determine the recommended dose for continued clinical development. Tumor changes are evaluated per iRECIST criteria and pathological response. Immunological response in tumor tissue and blood samples are assessed as secondary endpoints. This clinical study will establish the basis for continued clinical development of PH-762.

776. Sequence-Optimized Circular RNA E7 Cancer Vaccine Mediates Robust Protective T-Cell Immunity and Profound HPV+ Mouse Tumor Regression

Edo Kon[1], Xiaoliang Shi[2], Zhihao Chen[2], Fei Lin[2], Yang He[2], Xiaowen Zou[2], Jian Ye[2], Mengyao Zheng[2], Siqi Li[2], Roi Mashiach[1], Emma Pan[2], Weiyi Zhang[2]

[1]RiboX Therapeutics (Israel) Ltd, Ness Ziona, Israel,[2]RiboX Therapeutics, Shanghai, China

Human Papilloma Virus (HPV)-related cancers are estimated to account for 5% of all global cancer cases worldwide, including the majority of cervical and oropharyngeal cancers. "High-Risk" HPV infections can cause cancer by disrupting basic cellular mechanisms responsible for proliferation and communication. The E6 and E7 viral oncoproteins are consistently expressed in tumors and are required for both their initiation and maintenance. Therefore, vaccines targeting E6 and E7 as antigens represent a promising option for HPV positive tumors and have been explored using different modalities including mRNA, and have advanced to various stages of clinical studies. Different from mRNA, the covalently-closed structure of circular RNA (circRNA) prevents the degradation by exoribonucleases, therefore, leading to intrinsic stability. In addition, the translation of circRNA is in a cap-independent mechanism where the internal ribosome entry site (IRES) drives protein translation. To explore the potential of circRNA as a therapeutic vaccine, circular E7 RNA (circ-E7) constructs have been generated and evaluated for their *in vitro* antigen expression, *in vivo* immunogenicity and anti-tumor efficacy. Growing evidence shows that durable and specific cellular immunity against HPV antigens including E7 is key to achieving long-term disease control. Therefore, the optimization of circ-E7 was centered around tuning the expression

level of E7 to establish an understanding of the relationship between antigen expression and anti-tumor immunity driven by circular RNA vaccines. A library of 406 IRESs has been screened and 10 selected IRESs were constructed with an E7 antigen coding sequence. The circE7 RNAs were formulated in proprietary lipid nanoparticles (LNP) and the antigen expression was determined by the percentage of E7 positive cells, measured by FACS. To measure the antigen-specific immunity, the 10 formulated circ-E7 vaccines were intramuscularly administered into C57BL/6 mice, weekly, for 3 weeks. The percentage of E7 specific $CD8^+$ T cells in PBMCs was determined and ranged from 3.14% to 24.48%. In addition, the E7-specific $CD8^+$ T cells entered various stages of differentiation, including robustly expanded $KLRG1^+CD127^-$ short-lived effector cells (SLEC) and a pronounced portion of $KLRG1^-CD127^+$ memory precursor cell (MPEC) phenotypes. This indicates that a specific and durable immune response is elicited by the circ-E7 vaccine. The two circ-E7 vaccines that elicited the most antigen-specific responses were further evaluated in a subcutaneous E7 expressing TC-1 tumor bearing model. When tumors reached a mean volume of ~23 mm^3, mice were treated intramuscularly with 3 weekly doses. The immunization led to a strong infiltration of $CD8^+$ T cell into the tumor, with over 80% being specific for E7. Furthermore, this led to a profound tumor regression in 9/12 and 12/12 of circ-E7 vaccines treated animals. In conclusion, we demonstrate that optimized circRNA has the potential to be harnessed as therapeutic cancer vaccines. The circRNA vaccines elicit a robust antigen-specific immunogenicity with a significant portion of memory cytotoxic $CD8^+$ T-cells and a pronounced anti-tumor efficacy.

777. Identification of a Novel Antigen Presenting Cell Targeted Lipid Nanoparticle for mRNA Cancer Vaccine Therapies

Xi Zhu[1], Chenxi Hou[1], Jingwei Sun[2], Zhao Xu[2], Hong Chen[1], Shin-Shay Tian[1], Yarong Liu[2], Xiaoping Zhao[1]

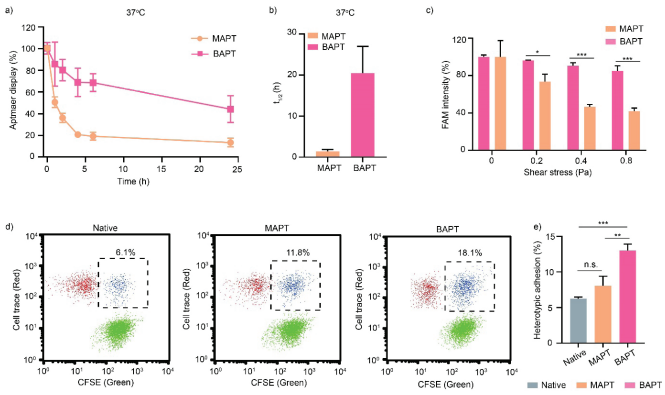
[1]Shanghai Vitalgen Biopharma, Shanghai, China,[2]Shanghai Grit Biotechnology Co Ltd., Shanghai, China

Current lipid nanoparticle (LNP) based mRNA vaccines have been reported to induce side effects in the liver, such as reversible hepatic damages and T cell-mediated hepatitis, which are likely caused by the strong expression of the mRNA payload in hepatocytes following intravenous (IV) or intramuscular (IM) administration. Therefore, developing an antigen presenting cell (APC)-specific LNP formulation could be a promising strategy for next-generation mRNA cancer vaccines with better efficacy and fewer side effects. Targeted delivery and expression of mRNA-encoding tumor antigens in APCs could facilitate the processing and presentation of antigens to the major histocompatibility complex (MHC), particularly MHC class I, thereby achieving higher activation of specific CD8+ T cells and better anti-tumor effects. Through iterative *in vitro* and *in vivo* screening, we have identified an APC-specific targeting LNP (APC-LNP) formulation. In *in vitro* transfection studies, when human peripheral blood mononuclear cells (PBMCs) were exposed to APC-LNP carrying GFP mRNA at a concentration of 1 μg/mL, 45% of DCs and 73% of monocytes were positive, while T cells and NK cells had positive rates of less than 0.1%. To evaluate in vivo tropism, C57BL/6 mice were intravenously injected with APC-LNP loaded with tdTomato mRNA. Flow cytometry analysis of different cell subsets in various organs 24 hours later showed high and specific tdTomato expression in DCs and macrophages. The positivity for DCs and macrophages ranged from 13% to 47% in the blood and spleen, and 5% to 43% in the liver, lung, and lymph nodes. Importantly, no expression was detected in the parenchymal cells of the liver and lung. Next, immune activation and antigen-specific responses were evaluated by intravenous administration of APC-LNP encapsulating mRNA expressing a tumor-associated antigen, TRP-1 (APC-LNP-TRP-1) in C57BL/6 mice. Significant upregulation of activation markers on DC and macrophages, T cells, B cells, and NK cells was observed in the spleen, lymph nodes, liver and peripheral blood following vaccination. In contrast, no obvious immune activation was observed with empty APC-LNP. Finally, the anti-tumor efficacy was evaluated in a B16F10 melanoma model. Compared to the control group, the APC-LNP-TRP-1 group showed significantly enhanced anti-tumor effects with specific T cell response confirmed by TRP-1 tetramer staining. The above data collectively indicate that our novel APC-LNP can achieve specific delivery and robust mRNA expression in APC cells in different tissues, leading to specific immune activation and potent anti-tumor effects, demonstrating the immense potential of this novel APC-LNP for the development of next-generation mRNA cancer vaccines.

778. Refining Chimeric Antigen Receptors via Barcoded Protein Domain Combination Pooled Screening

Xavier Rios, Osmay Pardias, Marc A. Morales, Pradyot Bhattacharya, Yibin Chen, Linjie Guo, Chunchao Zhang, Erica J. Di Pierro, Gengwen Tian, Gabriel A. Barragan, Pavel Sumazin, Leonid S. Metelitsa

Department of Pediatrics, Baylor College of Medicine, Houston, TX



Chimeric antigen receptor (CAR)-T cells represent a promising frontier in cancer immunotherapy. However, the current process for developing new CAR constructs is time-consuming and inefficient. To address this challenge and expedite the evaluation and comparison of full-length CAR designs, we have devised a novel cloning strategy. This strategy involves the sequential assembly of individual CAR domains using blunt ligation, with each domain being assigned a unique DNA barcode. Applying this method, we successfully generated 360 CAR constructs that specifically target clinically validated tumor antigens CD19 and GD2. By quantifying changes in barcode frequencies through next-generation sequencing, we characterize CARs that best mediate proliferation and expansion of transduced T cells. The screening revealed a crucial role for the hinge domain in CAR functionality, with CD8a and IgG4 hinges having opposite effects in the surface expression, cytokine production and antitumor activity in CD19- versus GD2-based CARs. Importantly, we discovered two novel CD19-CAR architectures containing the IgG4 hinge domain that mediate superior in vivo antitumor activity compared to the construct used in Kymriah, an FDA approved therapy. This novel screening approach represents a major advance in CAR engineering, enabling accelerated development of cell-based cancer immunotherapies.

779. Biomimetic Surface Coating of Living Cells for Enhanced Aptamer Display and Cell Recognition

Xuelin Wang, Yong Wang

Department of Biomedical Engineering, The Pennsylvania State University, State College, PA

Introduction: Cell surface engineering with aptamers holds great promise for various applications ranging from cancer immunotherapy to tissue engineering. Traditional methods for aptamer modification primarily rely on lipid insertion. However, this approach suffers from the low stability of aptamers. The purpose of this study is to develop a surface coating for enhanced aptamer display. In this study, NK cells were used as a model. The surface of NK cells was functionalized with a DNA-alginate template. Aptamers were immobilized within this template via molecular interactions. Aptamer stability and cell recognition were evaluated via numerous assays such as flow cytometry. **Methods:** Cholesterol-conjugated DNA initiator (DI) was incorporated into the cell membrane through the incubation of cells in the DI solution. DNA monomer (DM) 1 and DM2-alginate were added to form DNA-alginate template via hybridization chain reaction (HCR). The template was sequentially treated with biotinylated-polylysine (PLL-bio), biotinylated-alginate (Alg-bio), streptavidin, and biotinylated-aptamer (aptamer-bio) to form an aptamer-functionalized polymer matrix (BAPT). Cholesterol-conjugated complementary DNA (cDNA) was inserted into the cell membrane for displaying monovalent aptamers (MAPT, used as control). For stability assessment, the coated cells were incubated at 37°C with or without shear stress. At predetermined timepoints, DNA molecules remaining on cell surface were labeled with FAM-cDNA and the fluorescence intensity of the cells was measured using flow cytometry. For the binding analysis, a model aptamer (i.e., Sgc8c) was used to treat CCRF cells. The CellTrace Far Red prelabeled coated cells were mixed with CFSE prelabeled target cancer (CCRF) cells to examine cell recognition. The binding percentage was measured via flow cytometry. **Results:** The kinetic analysis revealed that the half-life ($t_{1/2}$) of the aptamer on MAPT-engineered cells was approximately 1.4 h, while the $t_{1/2}$ of the aptamer on BAPT-coated cells was approximately 20 h. When coated cells were subjected to shear flow, over 85% of the aptamers remained attached to the cell surface at a shear stress of 0.8 Pa. These data demonstrate that BAPT exhibited a high stability on the cell surface. For binding assay, at a NK to CCRF ratio of 1 to 3, the percentages of NK-CCRF complexes were 6.1%, 11.8%, and 18.1% in the native NK group, the MAPT-engineered NK group, and the BAPT-coated NK group, respectively. This difference can be attributed to the increased density of aptamers on the surface of BAPT-coated cells. The binding of BAPT-coated cells to CCRF cells remained strong 4 h after the coating formation. The percentages of NK-CCRF complexes in the native NK, MAPT-engineered NK, and BAPT-coated NK groups were 6.2%, 8.3%, and 13.1% respectively. These results reveal that BAPT-coated cells exhibited a high ability to bind target cells. **Conclusions:** The biomimetic coating can enhance the efficiency and stability of aptamer display on the cell surface. The coated cells can acquire an enhanced ability to recognize target cells. This work has demonstrated a promising method for the display of ligands on the cell surface for targeted cell-cell recognition.

Wednesday Posters: Cancer - Targeted Gene and Cell Therapy

780. Development and Preclinical Characterization of an Engineered T-Cell Therapy Targeting PRAME-Expressing Solid Tumors

George Reyner Pope[1], Rebecca Burton[1], Sebastian Laycock[1], Chloe Tayler[1], Terri Cornforth[1], Karolina Wikiert[1], Guy Wiedermann[1], Vera Kmonickova[1], Agata Patel[1], Philip Simister[1], Rachel Abbott[1], Sarah Loftus[1], Sofie Van Rossom[2], Robert Connacher[3], Marco Della Peruta[1], Phillip Debnam[1], Joseph Sanderson[1], Barbara Tavano[1]

[1]Adaptimmune, Abingdon, United Kingdom,[2]CellCarta, Antwerp, Belgium,[3]Adaptimmune, Philadelphia, PA

Introduction PRAME (PReferentially expressed Antigen in MElanoma) is a cancer testis antigen (CTA) expressed in many cancers, including solid tumors and leukemia, but has restricted expression in somatic tissues, making it an attractive target for immunotherapy.[1] Here, we describe the development of ADP-600, a preclinical autologous T-cell product targeting PRAME for use in the treatment of solid tumors. ADP-600 comprises T cells transduced to express an affinity-enhanced, human leukocyte antigen (HLA)restricted T-cell receptor (TCR) engineered to specifically target a PRAME antigen (peptide: SLLQHLIGL) presented on the surface of tumor cells by HLA-A*02:01. ***Methods and Results*** In agreement with the literature,[1, 2] our own target validation studies confirmed that protein expression of PRAME is limited outside of the reproductive tissues but is upregulated with high frequency in a range of solid tumors, including melanoma, endometrial cancer, ovarian cancer, synovial sarcoma, lung squamous cell carcinoma, and triple-negative breast cancer. To develop a target-specific TCR, two parental TCR candidates were selected for engineering to enhance their affinity for the PRAME antigen. From the resulting panel of mutants generated, the ADP-600 TCR was ultimately selected for preclinical testing based on its potency and specificity. ADP-600 showed good potency toward a panel of PRAME-positive cell lines, as determined by interferon gamma (IFNγ)

and granzyme B ELISA, with cytokine levels broadly in keeping with the level of expression of PRAME protein in HLA-A*02-positive target cells. ADP-600 also displayed cytotoxic behavior towards primary melanoma tumor, non-small cell lung carcinoma patient-derived xenograft tissue, and PRAME-positive 3D spheroids, both in terms of IFNγ and granzyme B production and cytotoxicity. ADP-600 has demonstrated good target specificity in a variety of in vitro assays, including screening of a panel of primary cell lines (selected for their optimal coverage of the protein coding transcriptome), an alloscreen in which potential cross-reactivity toward off-target HLA allelic variants was assessed, and an evaluation of the cytokine response following addition of ADP-600 to whole blood. ***Conclusions*** PRAME is an attractive target for adoptive T-cell therapy using affinity-enhanced TCRs. We have generated and characterized an affinity-enhanced TCR and subjected it to our extensive preclinical testing package, where it demonstrated potency toward PRAME-positive tumor targets while maintaining stringent specificity. These data describing ADP-600 may be used to support an investigational new drug application to enable the use of this product in clinical trials. 1. 781. Engineering Chimeric Antigen Receptor T Cells Against Protease-Activated Receptor 1 for Treating Pancreatic Cancer

Chao Lien Liu[1,2], Hao-Chien Hung[3], Ming-Huei Fan[1], Daniel Wang[1], Carol H. Miao[4], Pong Su[1]

[1]School of Medical Laboratory Science and Biotechnology, Taipei Medical University, New Taipei, Taiwan,[2]Ph.D. Program in Medical Biotechnology, Taipei Medical University, New Taipei, Taiwan,[3]Department of General Surgery, Chang-Gung Memorial Hospital, Linkou, Taoyuan, Taiwan,[4]Seattle Children's Research Institute, Seattle, WA

Background Pancreatic ductal adenocarcinoma (PDAC) is a devastating malignancy with a 5-year survival rate of 6% following a diagnosis, and novel therapeutic modalities are needed. Protease-activated receptor 1 (PAR1) is abundantly overexpressed by both tumor cells and multiple stroma cell subsets in the tumor microenvironment (TME), thereby offering a suitable immunotherapy target. **Methods** A chimeric antigen receptor (CAR) strategy was applied to target PAR1 using a human anti-PAR1 scFv antibody fused to the transmembrane region with two co-stimulatory intracellular signaling domains of cluster of differentiation 28 (CD28) and CD137 (4-1BB), added to CD3ζ in tandem. **Results** The engineered PAR1CAR-T cells eliminated PAR1 overexpression and transforming growth factor (TGF)-β-mediated PAR1-upregulated cancer cells by approximately 80% in vitro. The adoptive transfer of PAR1CAR-T cells was persistently enhanced and induced the specific regression of established MIA PaCa-2 cancer cells by > 80% in xenograft models. Accordingly, proinflammatory cytokines/chemokines increased in CAR-T-cell-treated mouse sera, whereas Ki67 expression in tumors decreased. Furthermore, the targeted elimination of PAR1-expressing tumors reduced matrix metalloproteinase 1 (MMP1) levels, suggesting that the blocking of the PAR1/MMP1 pathway constitutes a new therapeutic option for PDAC treatment. **Conclusions** Third-generation PAR1CAR-T cells have antitumor activity in the TME, providing innovative CAR-T-cell immunotherapy against PDAC.

782. Development of a Microscopy-Based IF/ISH Assay for Detection of ICT Cells in Patients Treated with AB-1015

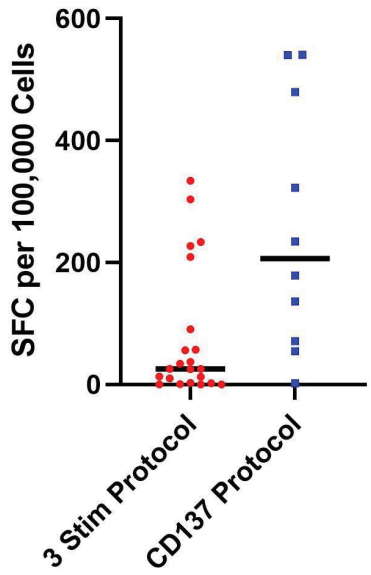
Nickolas Attanasio, Xinyan Tang, Hongruo Yun, Lionel Berthoin, Muamong Y., Amanda Fearon, Ryan Fong, Samuel A. Williams, W. Nicholas Haining, Stephen Santoro

Arsenal Biosciences, South San Francisco, CA

AB-1015 is an autologous, genetically modified integrated circuit T (ICT) cell product in clinical development for the treatment of ovarian cancer. AB-1015 integrates an "AND" logic gate designed to limit off-tumor toxicity through the requirement for dual tumor antigen recognition. It is also engineered with a dual shRNA-miR to resist TME suppression and improve ICT cell function and persistence. The AB-1015 logic gate consists of a synthetic priming receptor that, upon engagement of its target ALPG/P (alkaline phosphatase germ-line/placental), induces expression of an anti-mesothelin (MSLN) CAR that mediates tumor-cell killing. Methods to enable the detection of CAR and PrimeR in primary tumor specimens would be useful to examine the performance of various features of the AB-1015 logic gate. In order to visually identify AB-1015 ICT cells in human tissue independent of host immune cells, and understand the presence of ICTs in patient tumor samples, a custom multiplex immunofluorescence (mIF) assay was developed using the RNAScope(™) platform. The mIF panel was developed to detect CD3 protein by immunofluorescence (IF) and mRNA transcripts for both the PrimeR and CAR portion of the circuit by in situ hybridization (ISH), enabling detection of AB-1015 engineered T cells and PrimeR/CAR expression status. PrimeR and CAR probe specificity was established with positive and negative control cell lines under brightfield IHC as single stains, and additionally in multiplexed IF format. Further, probeset utility was demonstrated in a xenograft model to verify the usability of the mIF assay in solid tissues, incorporating an additional marker in order to visualize tumor cells. To date, the assay has been used to detect ICTs in one on-trial tumor biopsy sample of an AB-1015-101 patient. In conclusion, a mIF panel capable of detecting AB-1015 product in tissue was developed, with the intention of deploying this assay in future on-treatment samples for the AB-1015-101 clinical trial in ovarian cancer.

783. Optimizing the Generation of Antigen-Specific T Cells for the Treatment of High-Risk Malignancies

Samantha Murphy[1], Samuel Couto[1], Gage Paul[1], Monica Gerber[2], Kajal Chaudhry[1], Nethaji Muniraj[1], Christopher A. Lazarski[1], Sandeep Kumar Srivastava[1], Conrad Russell Y. Cruz[1], Catherine M. Bollard[1], Amy Hont[1]



[1]Children's National Hospital, Washington, DC,[2]Virginia Tech Carilion School of Medicine, Roanoke, VA

Background: Tumor-associated antigen-specific cytotoxic T cells (TAA-Ts) have therapeutic potential in high-risk cancer patients. However, products can be difficult to manufacture, with widely variable specificity and phenotype that can be donor- and technician-dependent. Standard protocols for TAA-T generation use peptide-pulsed antigen presenting cells (APCs) to stimulate peripheral blood mononuclear

cells (PBMCs) in multiple cycles, a time consuming and inconsistent method. This has been previously addressed through isolation and culture of cells positive for CD137, a surface receptor expressed on T cells after antigen-induced activation, with a CD4+ predominant product. Utilizing CD137 selection with standard cytokines and APCs may optimize the generation of antigen-specific T cells for clinical use. **Objective:** This study aims to characterize TAA-Ts generated via an optimized protocol utilizing CD137 selection in terms of specificity and phenotype, comparing them to those generated by the standard protocol. **Methods:** Peripheral blood mononuclear cells (PBMCs) were pulsed with PRAME and anti-CD28 antibody and incubated for 16-24 hours. CD137+ cells were isolated via magnetic bead selection and plated with irradiated CD137- cells in the presence of cytokines. Cells were restimulated on day 11 with PRAME-pulsed PHA blasts and cytokines and harvested on day 18 for characterization. Specificity was measured via IFNy ELISpot and phenotype via flow cytometry. Final results for specificity were compared to those generated using a traditional 3 stim protocol. **Results:** Using this CD137 protocol, we generated 10 distinct products. Phenotypically, products generated using the CD137 protocol were CD3/CD45RO enriched with variable proportions of CD4+ (3.2% - 88.1%) and CD8+ (3.1% - 91.8%) T cells. CD137 products demonstrated higher median PRAME specificity (Figure 1) compared to the standard protocol (206.5 vs 25.5 spot forming cells above background (SFCs); $p<0.05$). 90% of CD137 products were specific (≥20 SFCs above background) and 70% exceptionally specific (≥100 SFCs above background) as compared to only 57% and 24% of standard products. Preliminary data suggests that these specific CD137 products demonstrate cytolytic activity against pediatric tumor lines in vitro. **Conclusion:** Overall, this modified CD137 selection protocol enhanced antigen specificity and phenotype in shorter culture time compared to the standard method. Future directions will further investigate cytotoxicity, alternative targets, and genetic modifications.

Median Prame Specificity Between Protocols

784. Metabolic Conditioning During *Ex Vivo* Stimulation of Naïve Tumor Antigen-Specific CD8 T Cells

Joseph Choy, Sydney Shannon, Si-Sim Kang, Shuyi Li, Kenneth Adusei, Shaelyn R. Marx, Hai-Quan Mao, Jonathan Schneck

Johns Hopkins University, Baltimore, MD

Enrichment and expansion of antigen-specific cytotoxic T lymphocytes from a naïve population offers the ability to generate allogeneic cell therapies capable of treating malignancies. This approach is amenable to the current state-of-art cell therapies, as it can be produced without genetic manipulation, mobilizes a broad polyclonal response, and is derived from functional, non-exhausted naïve precursors. Further, seminal work in computational prediction of neoepitopes and antigen immunogenicity has made this strategy increasingly feasible for a broader range of cancers. However, current expansion processes to generate a relevant number of antigen-specific cells results an effector-dominant phenotype, which are suboptimal compared to less-differentiated counterparts. To address this, we characterized the effect of the broad glutamine antagonist 6-diazo-5-oxo-L- norleucine (DON) during ex vivo expansion of tumor-antigen specific CD8 T cells from healthy C57BL/6J mice. We conjugated recombinant MHC-Ig fusion proteins and co-stimulatory agonist antibodies onto magnetic nanoparticles as artificial antigen-presenting cells (aAPCs) to facilitate enrichment and expansion of cells in a dendritic cell-free manner. aAPCs were used to expand for cells recognizing H-2Kb:SIY or H-2Kb:Trp2, antigens from the B16SIY melanoma line. Our results show that the proportion of antigen-specific T cells is not significantly

reduced in the presence of DON, despite glutaminolysis being an integral part of metabolic reprogramming during T cell activation. In addition, DON skews these cells towards a central-memory like CD44+CD62L+ phenotype, while reducing the expression of PD-1 and TIM3. These results were accompanied by a shift towards a naïve CD25-CD44-CD62L+ signature in the non-cognate population. Next, we probed the activity of DON to influence phenotype and cytokine production upon restimulation by performing dose-response experiments and found that initial dosing in the first 24 h of activation is essential, while sustained exposure is beneficial but non- critical. We further mechanistically studied early activation events across a range of antigen affinities and doses by using H-2Kb-restricted SIINFEKL altered peptide ligands SIIQFEKL and SIIVFEKL conjugated on aAPCs to stimulate OT-I transgenic TCR cells. We observed that DON restrains TCR downregulation and CD25 expression, while upregulating CD45RB levels in high- affinity primed cells but does not demonstrate differences in intermediate or low affinity primed cells. Overall, we demonstrate that expansion of rare, tumor-antigen specific CD8 T cells from healthy, naïve T cells with DON generates a cell product with a memory-like, less exhausted phenotype. Early application of DON during high-affinity priming show the most potent effect compared to vehicle controls, where the pharmacological agent leads to changes in the kinetics of activation events. We show that phenotypical conditional with DON is homologous in an endogenous-like settings beyond previous TCR transgenic or CAR studies. This study highlights that metabolic conditioning of T cells is best suited to take advantage of the broad glutamine antagonism to inform development of future ACT products.

785. Loss of Heterozygosity is Low for Specific HLA Alleles in Cancer Patients with Driver Mutations

Christian Roy[1], Tomasz Sewastianik[1], Patrick Halvey[1], Meagan Montesion[2], Aastha Jindal[1], Markus Vallaster[1], Hubert Lam[1], Sean Garrity[1], Gary Shapiro[1], Christopher A. Klebanoff[3], Loic Vincent[1], Greg Opiteck[1], Dirk Nagorsen[1]

[1]Affini-T Therapeutics, Watertown, MA,[2]Foundation Medicine, Cambridge, MA,[3]Memorial Sloan Kettering Cancer Center, New York, NY

Immunotherapies have revolutionized cancer treatment, yet the limited predictability of response and/or resistance mechanisms continues to present novel therapeutic developmental challenges, especially for solid tumors. Many of these use a sensitive and specific T cell receptor (TCR)-HLA:peptide complex interaction as a mechanism of action and can be impacted by HLA loss of heterozygosity (LOH). Allele-agnostic HLA LOH analyses assessing loss of any MHC class I allele are relevant for HLA-agnostic approaches such as immune checkpoint inhibitors; however, studies in the context of specific HLA alleles, mutations, and indications remain limited. Such context-specific HLA LOH frequencies are especially relevant to adoptive T cell therapies engineered with TCRs and bispecific TCR T cell engagers targeting neoantigen peptides derived from oncogenic driver mutations, such as those of KRAS and TP53, which are presented by a specific HLA allele. Thus, existing allele-agnostic analyses may overestimate the frequency and relevance of HLA LOH for allele-specific modalities. A comprehensive genomic profiling dataset consisting of 78,418 cancer patient samples (Montesion M. et al., PMID: 33127846), germline heterozygous for one or more HLA class I locus, was analyzed for HLA LOH in the context of frequent driver mutations (KRAS G12C, G12D, G12V and TP53 R175H), corresponding HLA alleles (HLA-A*02:01, HLA-A*03:01, and HLA-A*11:01) and within specific tumor subtypes. Allele-agnostic HLA LOH was observed in 16.6% of all samples and varied between indications and HLA alleles (Montesion 2021). However, allele-specific loss of HLAs A*02:01, A*03:01, and A*11:01 across all samples was much lower than allele-agnostic loss (6.3%, 6.6%, and 6.3%, respectively). Although, a trend for increased allele-specific HLA LOH was observed when analyzed by driver mutation, the frequency remained low. Specifically, across all cases, A*02:01, A*03:01, and A*11:01 allele-specific LOH ranged between 5.9%-9.7% in relation to KRAS G12C, G12D, and G12V compared to 5.9%-6.2% for wild-type (WT). Moreover, it did not achieve statistical significance for any HLA-KRAS mutation pairs in colorectal (CRC), non-small cell lung (NSCLC), and pancreatic (PDAC) cancers, except for HLA-A*11:01 and KRAS G12C in NSCLC, which was lower in mutated cases (5.3% for G12C vs 10.1% for WT KRAS, p=0.045). Both allele-agnostic and A*02:01-specific HLA LOH in TP53 WT samples were lower than average which may be related to the role of TP53 in genomic stability. The TP53 R175H mutation was associated with limited increase in HLA-A*02:01 LOH (from 4.4% for WT to 8.1% for TP53 R175H) and varied between indications, e.g. no significant increase was observed in R175H-positive breast cancer and NSCLC cases contrary to CRC and PDAC. Based on this real-world dataset, over 90% of cases retain the TCR-targeted allele and, therefore, preserve the molecular complex necessary for HLA/driver mutation-based therapies. Notably, the analyzed database is enriched for advanced cancer patients. Further studies are warranted to test the hypothesis whether tumors in earlier lines of treatment have an even lower rate of HLA LOH and if correlations with treatments change longitudinally.

786. Pooled *In Vivo* Screening of Hundreds of T Cell Therapy Designs Using Spatial Multi-Omics Identifies Novel Designs with Superior TME Performance

Cassandra Kontur, Gundula Povysil, Megha Sah, Mariya London, Nan Chen, Annie Dyatel, Stephen Pu, David Phizicky, Xinchen Wang

Waypoint Bio, New York, NY

Background: Adoptive cell therapies such as CAR T have been curative for many liquid tumors, yet this success has struggled to translate to solid tumors due to the challenges posed by the solid tumor microenvironment (TME). Pooled CAR screens (e.g. CAR-POOLING) have recently emerged as a powerful approach for testing many designs for improving CAR T cell performance. However, these screens are typically restricted to univariate readouts (e.g. abundance) and cannot measure the cell-cell and cell-TME interactions that are critical for CAR T success in solid tumors. Here, we present a platform for performing pooled screens in vivo using spatial biology, facilitating simultaneous measurement of cell autonomous phenotypes, cell-cell interactions, and cell-environment interactions for hundreds of distinct cell therapy designs in a single mouse. **Methods:** We developed a custom spatial biology workflow to determine the identity of specific CAR constructs, armorings, or combinations in specific individual cells

from a microscope image ("design deconvolution"). We combined this design deconvolution with simultaneous multiplexed spatial biology phenotyping in the same cells & samples, followed by computer vision interpretation to quantify each design's performance across functional categories important for efficacy in solid tumors such as: tumor infiltration, tumor cell killing, proliferation, response to antigen heterogeneity & escape, exhaustion, persistence, and activity in immunosuppressive tumor microenvironments. In multiple mouse cancer models, we quantified the performance of hundreds of different cell therapy designs. **Results:** Using our pooled screens, we identified designs with superior performance in solid tumors across one or more key functional categories (e.g. infiltration, activity in immunosuppressive TMEs, etc.). We also mapped the landscape of cell therapy design principles by comparing dozens of existing designs derived from the literature head-to-head in the same animal, and we compared these benchmarked designs to novel cell therapies designed to improve CAR T function. We used these data to identify common rules that govern the design-phenotype relationship for CAR Ts in solid tumors and to identify CAR T designs with desired properties in solid tumors. **Conclusions:** Using a pooled in vivo screening platform, we discovered cell therapies that outperform existing designs across a variety of clinically-relevant metrics. Our spatial multi-omics measurements are critical for identifying designs that can effectively traffic to, infiltrate, and function in the solid tumor microenvironment. We are now using our pooled in vivo screens to identify highly efficacious designs in multiple solid tumor models.

787. Fueling Immunotherapy- Selective Targeting of Glutamine Metabolism to Enhance Metabolically Engineered iPSC-NK Cell Resilience Against Solid Tumors

Shambhavi S. Borde

Purdue University, West Lafayette, IN

Natural Killer (NK) cells, characterized by their intrinsic recognition and targeting capabilities against aberrant cells, have emerged as promising candidates for safe and effective cancer immunotherapies. Essential to the effector responses of NK cells are nutrients such as glucose and glutamine. Notably, glutamine and its metabolic enzyme, glutaminase, play pivotal roles in NK cell proliferation, expansion, and anti-tumor activity. However, the heightened glutamine consumption by tumor cells results in a glutamine-deprived tumor microenvironment (TME), challenging the survival of NK cells. In this study, we investigated the dependency of NK cells on glutamine in supporting effector functions and found its uptake indispensable for NK cell activity. The application of glutaminase inhibitors significantly diminished the proliferation and anti-tumor activity of NK cells. Inhibitors targeting glutamine metabolism exhibited a considerable impact on NK cell viability, anti-tumor cytotoxicity, activation marker expression, and mitochondrial functions. Notably, the blockade of glutamine transporters, including SLC1A5, significantly impaired NK cell cytotoxicity, proliferation, and mitochondrial functions against glioblastoma (GBM) targets, emphasizing the critical role of glutamine in sustaining NK cell processes within the TME. To address the need for targeted inhibition of glutamine in GBM while sustaining NK cell metabolic activity, we are genetically engineering NK cells to selectively enhance their metabolic resilience, by enabling normal function even in the absence of glutamine. Critical to immunotherapeutic responses is the availability of functionally mature and metabolically active NK cells. Previous findings underscore the clinical utility of induced pluripotent stem cell-derived NK cells (iPSC-NK cells) within the context of glutamine modulation. To do so, we have used genetic modifications aiming to elevate the expression of glutamine transporters (SLC1A5) on iPSC-NK cells, amplifying their glutamine uptake within the TME. The functions of modified NK cells are assessed using phenotypic and cytotoxicity analyses, as well as metabolic assays for mitochondrial activity. Transcriptional gene expression analysis further elucidates the impact of targeting glutamine metabolism on the genotype of NK cells in the TME. The goal is to generate metabolically resilient and functionally robust engineered iPSC-NK cells, thus enabling targeted and selective depletion of the metabolic behavior of cancer cells.

788. TGFβ-Conditioned K-NK Cells Exhibit Strong Cytotoxicity and Tumor Organoid Infiltration Against a Wide Range of Tumor Types

Anna Oja, Ieva Cesonyte, Robert Igarashi, Andre Kunert

Oncology Research, Sanofi, Amsterdam, Netherlands

NK cells possess multiple attributes that make them suitable as an "off-the-shelf" product for adoptive cell therapy (ACT) in oncology. The use of ACT for solid tumor settings face challenges due to the immunosuppressive tumor microenvironment, in particular impeded migratory capacity to the tumor site. TGFβ-conditioned (TGFβ-c) K-NK cells, NK cells expanded using plasma membrane particles (PM21) from K562-mb21-41BBL cell line in the presence of TGFβ, display features of resistance to TGFβ-mediated immunosuppression. To increase our understanding of the functionality of TGFβ-c K-NK cells in a physiologically relevant model, TGFβ-c K-NK cells were co-cultured with 60 unique, patient-derived tumor organoids from a range of cancer settings. TGFβ-c K-NK cells show dose-dependent killing of tumor organoids and production of cytotoxic molecules that can manipulate the TME and other immune cells, such as dendritic cells and T cells. Interestingly, while the degree of tumor organoid infiltration differs between the unique organoids, TGFβ-c K-NK cells display infiltration into all organoids. Furthermore, there was a strong positive correlation between the level of organoid infiltration and organoid killing. To discern functional properties between tumor infiltrating and non-infiltrating TGFβ-c K-NK cells, we developed tumor cell line spheroid models, enabling us to isolate these population of cells and differentially characterize them. In conclusion, TGFβ-c K-NK cells display several advantageous features making them a promising platform for ACT against a range of solid tumor malignancies.

789. Efficacy of B7H3-Targeting CAR T Cells Derived from Novel Monoclonal Antibodies in Solid Tumor Treatment

Thananya Inthanachai[1], Chatikorn Boonkrai[2], Tanapati Phakham[2], Trairak Pisitkun[2], Norihiro Watanabe[3], Nattiya Hirankarn[4,5], Koramit Suppipat[5,6,7], Supannikar Tawinwung[5,6,8]

[1]Medical Microbiology, Interdisciplinary and International Program, Graduate School, Chulalongkorn University, Bangkok, Thailand,[2]Center of Excellence in Systems Biology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand,[3]Baylor College of Medicine, Houston, TX,[4]Cancer Immunotherapy Excellence Center, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand,[5]Thailand Hub of Talents in Cancer Immunotherapy (TTCI), Bangkok, Thailand,[6]Cellular Immunotherapy Research Unit, Chulalongkorn University, Bangkok, Thailand,[7]Department of Research Affairs, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand,[8]Department of Pharmacology and Physiology, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand

B7 homolog 3 (B7H3) is overexpressed across multiple cancers with restricted expression on normal tissues, rendering it a potential target for CAR T therapy. To redirect T cells response against common solid cancers, we developed B7H3-targeting CAR T cells from monoclonal antibodies (mAbs) generated in-house. These mAbs were produced by immunizing mice with human B7H3 protein. Their binding kinetics were determined using surface plasmon resonance. Among the candidates, mAb clones 12G5 (K_D 6.01×10^{-9}), 11G5 (K_D 1.28×10^{-9}) and A2H4 (K_D 9.23×10^{-10}) were confirmed to be specific to recombinant human B7H3 protein and B7H3$^+$ cancer cell lines. Subsequently, we constructed second-generation CARs using these clones. These B7H3. CAR Ts exhibited dose-dependent cytotoxicity and cytokine response specifically against B7H3$^+$ targets (MDA-MB-231 and LN229). We next investigated their anti-tumor activity in a spheroid co-culture assay to simulate the tumor microenvironment. On day 7 of co-culture, B7H3 CAR T cells from all clones effectively eliminated the tumor spheroids. Notably, the clone 12G5, possessing the lowest affinity, demonstrated rapid tumor engagement. To verify the anti-tumor activity of our B7H3 CAR T cells *in vivo*, NOD-*scid* IL2Rg^{null} (NSG) mice subcutaneously engrafted with LN229 were treated with the CAR T cells. All B7H3 CAR T cells effectively eliminated and controlled the primary tumors, with a durable response observed in B7H3 CAR T clone 11G5 which has the intermediate affinity among the three clones. In summary, our B7H3 CAR T cells derived from novel mAbs demonstrated efficacy against B7H3$^+$ tumors. The study underscores the importance of selecting an scFv with optimal affinity for achieving durable anti-tumor efficacy.

790. Driving a Novel Platform of Cancer-Activated Genetic Expression for the Diagnosis and Treatment of Non-Small Cell Lung Cancer (NSCLC) Using Highly Selective and Active Transcription Factors

Elizabeth Stroebele, Dariusz Wodziak, Wendy Zhang, Ishan Podar, Ajda Rojc, Chloe Xia, Maggie Louie, David Suhy

Earli, Inc, Redwood City, CA

Early detection of cancer is an important for increased survival, quality of life and reduced healthcare costs. Earli is developing a highly sensitive, orthogonal approach that uses a genetic construct to usurp dysregulated molecular pathways and actively force cancer cells to drive the expression of a detectable 'synthetic' biomarker for the purposes of diagnostic imaging or expression of an engineered therapeutic protein. Identification of transcription factors (TFs) with abnormally elevated activity in cancer is crucial when developing a cancer-activated expression platform. Evaluating TF function in a genome-wide scale is challenging, especially since TF activity is not solely reflected by just its RNA expression or even by protein abundance, but also its post-translational modification including phosphorylation. Multi-omics Factor Analysis (MOFA) was performed on publicly available datasets from Clinical Proteomic Tumor Analysis Consortium (CPTAC) which includes RNA-seq based transcriptional profiling, MS based protein abundance and phosphorylation from 211 paired tumor and normal adjacent NSCLC samples. We identified 34 dysregulated TFs in NSCLC that displayed high expression levels in at least two of the three -omics platforms compared to normal adjacent tissues, and six exhibited high levels across all three. Expanding our TF analysis to benign lung lesions, we generated independent datasets for RNA-seq and protein abundance. Our findings revealed a distinct genetic signature that can be leveraged for the differentiation of malignant from benign and normal adjacent tissue. This suggests that differential activation of transcription could be used for selective gene expression in the context of diagnostics or therapeutics. Using the dysregulated TFs identified by the MOFA, we designed more than 2,000 unique synthetic promoter sequences containing arrays of homotypic or heterotypic TF binding sites with diverse motifs and spacing. We use a Massively Parallel Reporter Assay (MPRA) high-throughput pooled screening (HTS) method to assess cancer-specific activity in 8 NSCLC cell lines. We identified 30 strong candidate sequences for validation and found that 28 of 30 induced the expected expression, with the majority of response elements (n=20) showing expression 5-10X higher than background. Many of the tested synthetic promoters drove expression levels significantly higher than the activity of the constitutively active CAG promoter. In order to ensure sensitivity across a broad genetic background, the synthetic promoter sequences were empirically tested against 4 dozen primary tumor models - collected from individual NSCLC patients - that have been adapted for growth in vitro. Thus each primary tumor model exhibits a unique genetic background and a distinct dysregulated gene expression program responsible for the cancer development. Data from the first generation construct, with expression driven by sequences from the endogenous Survivin promoter, was only able to detect 5 of the 40 of the human primary tumors or a sensitivity of 13% when using 10% of CAG expression levels as a benchmark for expression. Conversely, one of our 4th

generation cancer-activated synthetic promoters produced signal against the same CAG benchmark, in 42 of the 43 samples or nearly 98% sensitivity, remarkable considering the different genetic background of each sample. Continued work towards clinical development is under way to use these synthetically engineered promoters in conjunction with a wide variety of expressed proteins and proprietary non-viral LNPs for application ofthe platform for therapeutics and diagnostic programs. These novel combinations being evaluated in a number of in vivo models including murine lung tumor models and larger animal models such as oncopigs.

791. Applification of CRISPR/Cas9-Mediated Gene Editing and Patient-Derived Organoids for Target Validation

Jinkyu Park

Gradiant Bioconvergence, Seoul, Korea, Republic of

Non-small cell lung cancer (NSCLC) is a major contributor to cancer-related deaths globally, with adenocarcinoma being the most prevalent subtype. Somatic mutations in the epidermal growth factor receptor (EGFR) are found in a significant proportion of lung adenocarcinomas. EGFR tyrosine kinase inhibitors (TKIs) have shown improved patient outcomes compared to conventional chemotherapy. However, tumors inevitably acquire resistance to TKIs, underscoring the imperative for a more profound comprehension of resistance mechanisms and the exploration of advanced combination therapies. In this study, we aimed to identify targets associated with drug resistance using patient-derived organoids (PDOs) and gene editing. We generated two sets of PDOs from pleural effusion at distinct time points for a patient with NSCLC. The divergent drug-responsive outcomes observed in these two organoids sets were consistent with the clinically observed resistance to the TKIs. Moreover, we identified genes correlated with drug resistance via transcriptome analysis. To validate their functional relevance, we conducted CRISPR/Cas9-mediated knockouts. Our results revealed a notable reduction in the IC_{50}, signifying a discernible alteration in drug response. Through these outcomes, the combined approach of PDOs and CRISPR/Cas9 not only elucidates molecular mechanisms underlying drug resistance but also provides valuable insights for developing targeted therapeutics.

792. Genomic Mechanisms of Interspecies Differences in Stromal Invasibility: Implications for Placental Invasion and Cancer Dissemination Using Gene-Edited Fibroblasts

Ashkan Novin, Yasir Suhail, Kshitiz .

UConn Health Center, Farmington, CT

Cellular invasion into surrounding tissues is crucial in both pregnancy and cancer metastasis. Placental invasion varies widely among eutherian mammals, from deep invasion in humans to noninvasiveness in cattle, and correlates with cancer malignancy. We previously demonstrated that fibroblasts from different species exhibit varying resistance to invasion by trophoblasts and cancer cells. In this study, we identified elements responsible for interspecies differences in invasibility and the key transcription factors governing proinvasibility and antiinvasibility genes in stromal cells. Using CRISPR-Cas9 gene editing, we found a set of genes significantly influences the invasibility of endometrial and skin fibroblasts. These findings provide insights into genomic mechanisms explaining species-specific disparities in stromal invasibility, with potential applications in regulating placental invasion, wound healing, and cancer dissemination. Additionally, we established a direct link between human vulnerability to placental invasion and the low resistance of human fibroblasts to cancer cell invasion, shedding light on therapeutic targets for modulating these processes.

793. NRF2 Functional Domains Dictate the Tolerance of Exon Skipping as a Result of CRISPR-Directed Gene Editing on the Phenotypic Outcomes

Natalia Rivera-Torres[1], John Anthony Rogowskyj[1], Guadalaupe Aguilar[2], Pawel Bialk[1], Eric B. Kmiec[1]

[1]Gene Editing Institute, ChristianaCare, Newark, DE,[2]Medical and Molecular Sciences, University of Delaware, Newark, DE

We are advancing a novel strategy for the treatment of solid tumors by employing CRISPR-directed gene editing to reduce levels of standard of care required to halt or reverse the progression of tumor growth. Our laboratory has been advancing a CRISPR-directed gene-editing platform technology as an augmentative therapeutic strategy for squamous cell carcinoma of the lung with follow-on applications to esophageal and head and neck cancer. Treatment for patients with these cancers remains diverse and can become ineffective over time due to the side effects of chemotherapy and the development of resistance for which both remain a serious barrier to successful treatment. Our genetic target is NRF2 a global transcription factor that regulates genes involved in response to cellular stress. It has been linked to chemo-resistance since its expression is regularly elevated in response to chemotherapy. Our objective has been to use CRISPR-directed gene editing to disable NRF2 functions so that the cancer cell becomes sensitive to the standard of care therapy. We have demonstrated that partial and complete knockout of this gene in human lung cancer cells increases chemo-sensitivity in cell systems and demonstrably retards tumor growth in animal models. We have successfully extended the approach to esophageal (KYSE 410) and head and neck (FADU) cancer cell lines. We have also identified two parameters that are crucial points to take into consideration when designing gene editing therapeutics. (1) The effect of exon skipping as a result of CRISPR-directed gene editing and (2) the effect of targeting specific functional domains of a gene. These parameters affect the phenotypic outcome that is intended to be achieved as a therapeutic effect. When these parameters are coupled and paired properly, we achieve an optimal gain of chemosensitivity and reduced cell proliferation. We have once again demonstrated that this gene is a viable target for gene editing to be used in therapeutic critical endpoints in solid tumors including halting the progression of tumor growth, inducing tumor cell death, and reducing tumor size to facilitate surgical resection. It is possible that gene editing and chemotherapy will act synergistically to reduce tumor growth. This treatment strategy could be used effectively in patients with locally advanced or even metastatic cancer or patients who have developed resistance to chemotherapy.

794. Living Anticancer *Clostridium Sporogenes* Colonizes *In Vitro* 3D Necrotic Spheroids

Merve Yildiz[1], Jella van de Laak[1], Alexandra M. Mowday[2], Ludwig J. Dubois[1], Jan Theys[3]

[1]Precision Medicine, University Maastricht, Maastricht, Netherlands,[2]Maastrict University, Maastricht, Netherlands,[3]University Maastricht, Maastricht, Netherlands

Background: Most solid cancers contain areas of necrosis resulting from chronic hypoxic injury. These high-risk tumour characteristics are associated with poor prognosis due to increased risk of metastasis and resistance to chemotherapy and radiotherapy. Strikingly, this necrotic environment also provides an opportunity for targeted therapy, such as our alternative anti-cancer approach that uses the harmless anaerobic bacteria *Clostridium sporogenes (C. sporogenes)*. Upon injection as spores, this species selectively penetrates necrotic areas and germinates into metabolically active vegetative bacteria that can produce anticancer effects inside the tumour. We have developed innovative genetic tools to further enhance these effects by "arming" *C. sporogenes* with therapeutic genes such as immune checkpoint inhibitors and cytokines. Novel therapeutic strains can be generated effectively in a short period of time. Therefore, it would be essential to evaluate and validate them in robust systems prior to in vivo studies because considering the Three Rs principle of animal research, the use of animals should be reduced or replaced if possible. It would thereby be beneficial to develop an in vitro validation method that can mimic tumour necrosis as an intermediate step.Methods: The Lewis Lung Carcinoma (LLC) cell line was used to generate 3D spheroids. Spheroids were first investigated on the development of necrotic fractions. Next, 5,000 colony-forming unit per millilitre (CFU/mL) of spores were added on different days to determine and optimize the experimental time frame of our spheroid model. The CFU/mL in spheroids was determined for each time point. Microscopic images were taken every day to follow-up spheroid growth. Furthermore, a *C. sporogenes* strain expressing the fluorescent reporter gene unaG was investigated as a live imaging tool in the spheroids.Results: LLC spheroids developed a necrotic core on day 5 after seeding. When spores were added on this day, *C. sporogenes* colonized the spheroids for 24, 48, and 72 hours, with 48 and 72 hours showing the highest number of bacteria inside the spheroids. Colonized spheroids started to disintegrate around 96 hours due to the antitumour effects of *C. sporogenes*. The fluorescent unaG strain was live imaged in the spheroid model. Fluorescent intensity positively correlated to CFU/mL and fluorescent signal was diminished after spheroid disintegration.Conclusion: These promising results show the high potential of 3D *in vitro* models that can potentially serve as important intermediate validation step before embarking in vivo studies. These models will be applied for testing therapeutic efficacy and antibiotic sensitivity of our *C. sporogenes* strains.

796. Enhancing the Efficacy of Retroviral Replicating Vectors-Mediated Suicide Gene Therapy in a Peritoneal Dissemination Cancer Model through Mesenchymal Stem Cell-Mediated Delivery

Shuji Kubo[1], Yuya Takeuchi[1,2], Nao Ogawa[1,2], Noriyuki Kasahara[3], Emiko Sonoda-Fukuda[1]

[1]Laboratory of Molecular and Genetic Therapeutics, Institute for Advanced Medical Sciences, Hyogo Medical University, Nishinomiya, Japan,[2]Departments of Biomedical Chemistry, School of Science and Technology, Kwansei Gakuin University, Sanda, Japan,[3]Departments of Neurological Surgery and Radiation Oncology, University of California, San Francisco, San Francisco, CA

Retroviral replicating vectors (RRVs) have demonstrated significant promise in cancer gene therapy through preclinical and clinical studies. Since retrovirus-based vectors are produced only a low titer in vitro, direct injection into local tumor tissue has been the preferred route of administration. However, inaccessible or metastatic tumors make this in vivo delivery feasible, necessitating the development of alternative methods for efficient delivery of RRV to tumor sites in vivo. To address this challenge, we are developing a novel technology that utilizes mesenchymal stem cells (MSCs) as carrier cells for RRV transport, leveraging their migratory and accumulative capabilities in cancer tissues. Previous investigations have established the ability of MSCs to acquire an RRV infection, to produce RRVs, to migrate toward tumor cells, and to transmit RRVs to tumor cells. In this study, we assessed the transmission efficacy and antitumor effect of RRV in peritoneally disseminated tumor models. First, RRV transmission efficacy was evaluated by in vivo imaging using a peritoneally disseminated tumor model in which nude mice were inoculated with humanMSTO-211H mesothelioma cells. In the non-ascites model, higher RRV transmission to tumors was observed in the RRV-infected MSC group (MSC/RRV group) than in the RRV-alone group (RRV group). On the other hand, in the ascites model prepared using human serum, the RRV group showed no RRV transmission to tumors, whereas the MSC/RRV group showed high RRV tumor-transmitting ability. Next, we evaluated the anti-tumor effect in the peritoneal disseminated tumor model and found that both the RRV and MSC/RRV groups showed a high anti-tumor effect in the non-ascites model. On the other hand, in the ascites model, the MSC/RRV group showed significantly higher efficacy than the RRV group in terms of tumor growth and survival. These findings suggest that using MSCs as carrier cells, RRV-mediated suicide gene therapy may be a novel treatment for peritoneally disseminated cancer, especially in cases of ascites.

Wednesday Posters: Challenges to Immunological Responses to Therapeutic Interventions

797. The Impact of Pre-Existing Antibodies and Complement on Immunological Safety of Adenoviral Vector Gene Therapy

Svetlana Atasheva, Jia Yao, Dmitry M. Shayakhmetov
Emory University, Atlanta, GA

Immunological safety is a one of the major concerns with the systemic intravascular administration of viral vectors in gene therapy. Targeting specific organs and cell types while surpassing uptake by the liver requires infusion of substantial doses of viral vectors. Introducing large quantities of viral vectors into the bloodstream poses the risk of eliciting severe and potentially fatal cytokine responses in some patients. The unpredictability and severity of systemic inflammatory response, coupled with a limited understanding of the molecular mechanisms behind the innate immune and cytokine responses to viral vectors, present significant obstacles to the development of new treatments, pushing the field to consider non-viral delivery methods. Nevertheless, viruses have evolved mechanisms allowing for a highly efficient gene transfer and can further be rationally engineered to provide targeted, safe, and efficient platforms for therapeutic gene delivery to patients. We hypothesize that in response to systemic administration of viral vectors, pre-existing neutralizing and non-neutralizing antibodies, together with the complement system, influence the activation of phagocytic myeloid cells, potentially inducing a hyperactivation state and the release of pro-inflammatory cytokines. To test this hypothesis, we immunized groups of mice with human adenovirus serotypes from species B (HAdv-B3, HAdv-B11), C (HAdv-C2, HAdv-C6), and D (HAdv-D28), followed by intravenous administration of HAdv-C5-based adenovirus vectors. Whereas the antibodies generated in these mice did not have any direct neutralizing activity to HAdv-C5, the amounts of inflammatory cytokines released into the blood 6 hours post HAdv-C5 vector administration varied dramatically between mouse groups pre-immunized with different virus serotypes. Further, mice immunized with adenoviruses phylogenetically distant from HAdv-C5 produced antibodies that could bind to HAdv-C5 viral particles and trigger C3 complement fixation. We termed these antibodies cryptic non-neutralizing opsonizing antibodies (CON-Abs). Importantly, CON-Abs-mediated C3 opsonization of HAdv-C5 viral particles potentiated inflammatory cytokine release from human PBMCs in vitro. While immunization with HAdv-C5 led to the generation of virus-specific neutralizing immunity in both wild-type and C3-KO mice, the intensity of the cytokine storm following HAdv-C5 vector administration was markedly greater in C3-KO mice, indicating that complement C3 in vivo plays a role in suppressing the inflammatory response. We found that in the absence of C3 the virus is accumulating in larger quantities in CD169 positive macrophages in the spleen, suggesting that C3 opsonization targets adenovirus-immune complexes away from immune phagocytic cells to non-responding cell compartments. Our findings underscore the unanticipated role of CON-Abs in potentiating the severity of cytokine storm responses and highlight the need for novel approaches to pre-screen patients for pre-existing humoral factors that could amplify inflammatory reactions to therapeutic vectors.Conflict of interest: DSH is a founder and a shareholder of AdCure Bio, which develops adenovirus technologies for therapeutic use.

798. Immune Silent Circular RNA (oRNA™) in TLR7 and TLR8 Expressing Transdifferentiated Monocytes

Blake Cohen[1], Yessica Wiryawan[1], Dovile Strimaityte[1], Justin Lee[1], Tobi Wuraola[1], Corey Ciullo[1], Subiksha Parthasarathy[1], Subiksha Parthasarathy[1], Ian Langer[1], Tracy DiMezzo[1], Genevive Bondaryk[1], Dylan Hoots[1], R. Alexander Wesselhoeft[2], Isin Dalkilic[1], Allen Horhota[1], Nelson Chau[1], Robert Mabry[1], Thomas M. Barnes[1], Thomas Lee[1]
[1]Orna Therapeutics, Watertown, MA,[2]Gene and Cell Therapy Institute, Mass General Brigham, Cambridge, MA

Orna Therapeutics is developing circular RNA (oRNA™) therapies offering advantages in magnitude and duration of protein expression over linear mRNA. Orna's proprietary autocatalytic circularization procedure and purification processes provide a simple, yet robust, method to generate immunoquiescent oRNA. Nucleobase modification is traditionally required to mask impurity driven immunostimulatory effects of delivered mRNA therapies. Absent modification, mRNA impurities trigger multiple immunostimulatory pathways (RIG-I, MDA5, TLR3, TLR7, TLR8), resulting in cytokine secretion and tolerability limitations. Orna's circular RNA architecture, coupled with optimized production r processes render oRNA immunoquiescent, abrogating the need for modified nucleotides. In vitro transcription and purification processes significantly impact RNA therapeutic immunostimulatory impurity levels. Optimized oRNA processing conditions generating highly translated with greatly reducing the immunostimulation properties. Efficient co-transcriptional circularization, elimination of capping reagents and steps, coupled with optimized purification processes, generate highly pure circular RNA. Demonstrating oRNA purity and translation to the human setting have been limited by available assays. Traditional ELISA, cell-based assays (A549), and in vivo murine models do not entirely recapitulate the suite of RNA sensing immune receptors reported to play key roles in human responses to mRNA , specifically TLR-7 and TLR-8. These TLR receptors sense single strand RNA degradation products in the endolysosome and are essential for detecting conserved RNAs from pathogens. Immortalized myeloid cell lines are widely utilized to investigate human innate immune pathways. Transdifferentiated BlaER1 cells have been shown to closely resemble primary human monocytes based on their PRR signaling pathways, from TLRs to inflammasomes. By inducing the myeloid transcription factor C/EBPα supplemented with IL-3 and M-CSF, the Blaer1 B cell precursors can transdifferentiate into a non-proliferative monocytic state. Phenotypic changes are observed where CD19, a canonical B cell marker, is reduced, while CD11b and CD14 expression upregulate during the differentiation process. Furthermore, transdifferentiated monocytic BlaER1s respond to agonist that stimulate TLR7, TLR8, and the RLR pathway, supporting the expression & functionality of their RNA-sensing PRRs. Functional TLR7 & TLR8 were validated by the R848 agonist in transdifferentiated BlaER1s cells which were reactogenic to unmodified mRNA controls. High levels of IL-6 and TNFα secretion,

cytokines associated with RNA-induced reactogenicity were observed. Utilizing the standard production process for oRNAs (Process A), we observed stepwise reduction of reactogenic responses at 200 to 50 ng of oRNA transfection per 100k BlaER1s, but undetectable levels at 10 ng. Cytokine responses observed with the standard oRNA process were not comparable to that of unmodified mRNA, demonstrating the improved purity and immunoquiescence afforded by circular oRNA, even in the absence of nucleotide modifications. Additional improvements to oRNA processing (Process B) removed immunostimulatory elements to levels that were not stimulatory to Blaer1s at any concentration. oRNA's high protein expression and purity, longer duration than mRNA, and simple manufacturing procedure, make it an ideal protein coding modality. Minimal reactogenicity in cells expressing both TLR7 and TLR8 further support oRNA's therapeutic potential.

799. Quantifying Alloreactive T-Cells in Recipients of Allogeneic Cell Therapies

Saida G. Wiltz, Rafael Fracasso, Sandhya Sharma, Mariana Mazzi, Lisa A. Rollins, David H. Quach, Cliona M. Rooney

Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX

Banked therapeutic T-cells derived from healthy donors for use in allogeneic recipients could overcome many of the problems associated with the use of customized autologous cell therapies. However, alloreactive T-cells (ARTs) in both the donor cell product and in the recipient cause graft versus host disease and rapid graft rejection respectively. We have used banked EBV-specific T-cells (EBVSTs) modified with a chimeric antigen receptor for CD30 (CD30.CAR) as a solution to both problems in patients with multiply relapsed CD30+ lymphoma. With their limited TCR repertoire, EBVSTs have not caused GVHD in hundreds of allogeneic recipients, while CD30 is upregulated on activated ARTs that then become susceptible to killing via the CAR *in vitro*. We have treated 20 lymphoma patients with CD30.CAR-EBVSTs with promising clinical results. No patients developed GVHD and CD30.CAR EBVSTs produced objective tumor responses in 78% of patients, and complete responses in 39%. However, tumor responses were of short duration and after a brief expansion, circulating CD30.CAR EBVSTs were almost undetectable by day 7. To test the hypothesis that ARTs, which comprise up to 10% of all T-cells, overwhelm the infused CD30.CAR EBVSTs, and to determine if the CD30.CAR is able to prevent allorejection, we are developing quantitative assays to measure ARTs in patients. This will allow us to compare the pre- and post- infusion frequencies of ARTs in patients that received allogeneic EBVSTs alone or expressing the CD30.CAR. Since there is no means to identify or quantify ARTs, we have used a stimulation assay to identify T-cells that proliferate in response to irradiated CD3- and CD28-activated allogeneic activated T-cells (ATCs) that upregulate costimulatory molecules after activation and are effective alloantigen presenting cells. We then quantified responder T-cells using CFSE assays, TCR Vbeta family analysis, TCR sequencing and cell cycle profiling before and after 7 days of stimulation. Since most ARTs reside in the naïve fraction of PBMCs, we expect to see an increased frequency of ARTs in the memory population in patients that received unmodified EBVSTs. So far, we are validating our quantitative assays in healthy donors. Alloactivated "recipient" T-cells showed 4 to 9 fold bulk expansion over 6 to 7 days of stimulation. We observed no marked changes in TCR Vbeta usage after stimulation, indicating that the response was polyclonal. TCR analysis identified clonotypes that proliferated in response to stimulation. To confirm that the expanded cells are alloreactive, we will sort the CFSE-negative fraction and evaluate their ability to kill "donor" ATCs and 3rd party HLA-mismatched allogeneic ATCs. We now plan to quantify alloreactive T-cells in patients that received allogeneic cell therapy products. A quantitative assay for ARTs will be useful for the evaluation of strategies designed to prevent rejection in recipients of allogeneic cell therapies.

800. Use of Immunological Adjuvants in Combination with Multiple Modes of Vaccination: Next-Generation Boosting of RNA and Protein Vaccines

Jiho Kim, Jenn Davis, Sean Gray, Darrick Carter

PAI Life Sciences, Seattle, WA

Immunological adjuvants are often included with vaccinations to boost the response of the various components of the immune system to raise an enhanced response against the target antigen. While certain adjuvants have been used since the advent of modern vaccines, recent RNA vaccines do not typically include adjuvants as RNA molecules are perceived to be self-adjuvanting. However, traditional immunological adjuvants such as those targeting TLR-4 are still powerful, relatively cheap additions to vaccines resulting in a clear boost in response. A next generation of TLR4 targeting adjuvants in differing formulations (EmT4; Oil-in-water emulsion, LiT4Q; Liposomal, MiT4; Micellar, AlT4; Alum-adsorbed) were developed to be alternatives and successors to some of the already approved adjuvants available for use in commercial vaccines, such as alum, AS-01, AS-04, or MF59. We have tested these adjuvants in boosting the immune response in multiple vaccines including those against influenza, tuberculosis, other diseases of global significance. Recently, these adjuvants were tested in combination with an RNA vaccine against SARS-CoV2. The adjuvants boosted the strength and breadth of the immune response against several variants of SARS-CoV2 such as D614G, Delta and Omicron. An interesting finding was that the duration of the response was also increased, with a significantly higher titer being maintained up to day 56 post-immunization. This addresses a common problem with mRNA vaccines: a quickly fading immunity which necessitates the frequent use of booster doses. These indicate that the combination of immunological adjuvants in combination with RNA vaccines holds much potential in enhancing a relatively novel mode of immunization. In addition, the adjuvant Em-T4 is currently being tested for use in combination with a vaccine against schistosomiasis, a neglected tropical disease prevalent in much of the tropics. The combination of the Sm-P80 antigen and Em-T4 has been previously tested in multiple animal models including mice, baboons, resulting in an elevated immune response and enhanced worm egg killing, thus reducing disease burden. We present recent results of using these next-generation adjuvants in the context of both new and old modes of vaccination, RNA and protein respectively. The adjuvants boost the responses in both modalities, resulting in gains in strength and breadth of response. The use of these adjuvants represents a rapidly deployable, economical option to implement in future vaccines, for use in emergency pandemic situations or conventional vaccine design and trials.

801. Fc-Modification of Anti-PcrV Gene-Encoded Antibodies Modulates Complement-Mediated Killing of *Pseudomonas aeruginosa*

Jillian Eisenhauer[1,2], Abigail Tracthman[2], Spencer Dublin[3], Jihae Choi[2], William T. Witt[3], Suman Bharti[2], Maria de la Paz Gutierrez[3], Sarah Miller[3], Elizabeth Parzych[2], Jacqueline D. Chu[2], Kaitlyn Flowers[2], Michaela Helble[1], Daniel Kulp[2], Trevor Smith[4], Mariette Barbier[3], David B. Weiner[2], Ami Patel[2]

[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[2]Vaccine & Immunotherapy Center, Wistar Institue, Philadelphia, PA,[3]Microbiology, Immunology, and Cell Biology, West Virginia University, Morgantown, WV,[4]Inovio Pharmaceuticals, Plymouth, PA

Prior to the SARS-CoV-2 pandemic, growing antimicrobial resistance (AMR) was a critical global health concern due to a rise in broad-spectrum antibiotic usage. During the pandemic, majority of COVD-19 patients received one or more antibiotics at the time of hospital admission which has led to an increase in multi-drug resistant *Pseudomonas aeruginosa*. With a lack of new antibiotic therapeutics or successful vaccine candidates, monoclonal antibody (mAb) approaches are emerging as potential strategies to combat AMR pathogens. Synthetic DNA plasmid vectors can be engineered to encode immunoglobulin heavy and light chains, followed by direct delivery *in vivo* by IM injection and electroporation. DNA-encoded antibodies (DMAb) enable transient expression and secretion of mAb directly by skeletal muscles resulting in biologically relevant levels for months. Previously, we described both protection and long-term expression of anti-type IIII secretion system component PcrV DMAb-V2L2. It has been shown that control and clearance of *P. aeruginosa* depends on phagocyte recognition, engulfment, and degradation of bacteria. Here we extend this work to hypothesize that *P. aeruginosa* mAb-mediated protection in high-risk patients like those with Cystic Fibrosis could benefit from enhanced recruitment of immune components that trigger the classical complement system to augment bacteria clearance. Building on previous work evaluating Fc-modified DMAbs in a vaginal *Neisseria gonorrhoeae* challenge, we designed 7 V2L2 DMAb variants encoding modifications in the human IgG1 heavy chain constant region with the goal of modulating binding to complement protein C1q and complement deposition. BALB/c mice (n=5/group) administered Fc-complement variant V2L2 DMAbs transiently express antibody for months post-administration. Mice (n=10/group) were either administered WT-fc or Fc-mod DMAb-V2L2 and infected after 28 days in an acute *Pseudomonas aeruginosa* PAO1 infection model. Here significantly lower bacterial load was detected in the lung and nasal washes in the mice administered complement enhanced Fc-DMAb compared with WT-Fc DMAb. Overall, we demonstrated that gene-encoded antibodies can be sequence modified to modulate complement engagement as a strategy to increase antibody potency as determined by bacterial clearance. To date, we have also expanded on this work to modulate the potency of DMAbs targeting both *Streptococcus pneumoniae* and *MRSA*. Overall, we have demonstrated an advantage of plasmid engineering and sequencing optimization to improve downstream complement engagement for improved bacterial clearance. Together these studies show implications for gene-delivered antibody development as a potential strategy for the treatment or prevention of AMR infections in larger animals and humans.

802. Delivery of an Fc-Modified DNA-Encoded Monoclonal Antibody Targeting the Pneumococcal Histidine Triad Protein D (PhtD) Improves Protection During Fatal Pneumococcal Infection via Engagement with Complement Proteins

Jillian Eisenhauer[1,2], Aaron D. Gingerich[3], Elizabeth Parzych[2], Anna L. McCormick[3], Yue Li[2], Bhavya Bhardwaj[2], Jarrod J. Mousa[3], David B. Weiner[2]

[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[2]Vaccine & Immunotherapy Center, Wistar Institue, Philadelphia, PA,[3]Center for Vaccines and Immunology, University of Georgia, Athens, GA

Streptococcus pneumoniae (pneumococcus, *Spn*) infection remains a leading cause of death globally despite widespread use of current capsular polysaccharide vaccines. Despite a reduction of pneumococcal disease, these vaccines are limited by serotype specificity with disease persisting for some vaccine serotypes due to immune system evasion capability (i.e., capsule shedding, electronegative cell surface). Therefore, there is a growing need for serotype-independent approaches to combat *Spn* infection. One promising approach is utilizing antibodies targeting conserved surface antigens thereby bypassing serotype limitations of current vaccines. We have previously characterized a candidate human monoclonal antibody against the conserved surface antigen, pneumococcal histidine triad protein D (PhtD), and demonstrated protective efficacy in pneumococcal pneumonia challenge model. While recombinant antibody therapies are constrained by cold storage and high dose requirements, we have utilized DNA-delivered monoclonal antibodies (DMAbs), produced by muscle cells, for long-term systemic circulation of fully functional Abs by a single injection. Furthermore, pneumococcal vaccines are reported to be protective via opsonophagocytosis, which involves the complement system. To build on this prior work, we developed DMAb variants for direct *in vivo* expression to drive improved antibody durability, and secondly, we engineered an Fc-point mutation to enhance complement binding activity to improve the *in vivo* potency of these antibodies compared to DNA-derived mAb without the Fc-complement mutation and recombinant mAb control. Importantly, *in vivo* expressed anti-PhtD DMAbs retain binding to recombinant antigen and serotype 3 pneumococci. We compared, positive control protein mAb delivered at the time of challenge to IM delivered WT-Fc DMAb, spanning 25 ug to 200 ug, at day 28-post administration. At the lowest dose of 25 ug, mice showed 50-58% survival while protection by higher dose groups maxed out at 75% survival which was not statistically significant from recombinant PhtD mAb control. We hypothesized that single point mutations within the Fc-region may improve binding efficacy for effector proteins, like complement, to improve antibody potency and decrease protective dose. We then compared complement enhanced anti-PhtD DMAb (200 ug, 10 ug) versus non-complement enhanced DMAb (200 ug, 10 ug) and protein control (as above). Mice administered low dose (10 ug, 30-fold lower) of the complement enhanced anti-PhtD DMAb exhibit similar protection to mice administered high dose WT-Fc DMAb or recombinant PhtD mAb control in pneumococcal pneumonia challenge model. Furthermore, mice administered anti-PhtD DMAbs show persistent expression at protective levels suggesting the application of our DMAbs

as a single dose injection for protection lasting over one year. Overall, these studies support our previous work on enhanced complement-mediated membrane attack complex (MAC) anti-*N. gonorrhea* DMAbs and show further application of Fc-engineering to enhance complement mediated phagocytosis by anti-*S. pneumoniae* DMAbs at the lung mucosa in a pneumococcal pneumonia challenge model.

803. Impaired Anti-Toxin Memory B Cell and Serum Anti-Toxin B IgG Responses to *C. difficile* Vaccination Increase Susceptibility to CD196 Spore Challenge in Aged Mice

Emily Konopka, Matthew Bell, Elias Haddad, Michele A. Kutzler

Drexel University College of Medicine, Philadelphia, PA

Clostridioides difficile is a spore-forming gastrointestinal pathogen responsible for nearly half a million infections and up to 30,000 deaths in the U.S. annually. Aged individuals (>65) are among those with the highest susceptibility to severe infection, recurrence, and death. Current treatments for primary *C. difficile* infection (CDI) predominantly involve antibiotic use, but these may increase the risk for recurrent infection. To further understand the age-associated impairments in the immune response to *C. difficile* for the development of effective therapeutics, aging mouse models of CDI are critical. We hypothesized that immune dysfunction in the elderly will make them more susceptible to infection with *C. difficile*. To test this, we first established the lethal CD196 spore dose in aged (72-80 weeks) mice. After identification of this lethal dose, vaccination followed by challenge was performed to determine vaccine efficacy and impairments in immune response associated with elevated mortality in young versus aged mice. Mice were immunized twice over 30 days with a DNA vaccine expressing the receptor binding domain of toxin A (RBDA) and B(RBDB) (5ug/plasmid/mouse) followed by orogastric challenge with 200 CD196 spores at thirty days post boost. Serum analyses showed that while young and aged mice developed similar anti-toxin (TcdA/B) IgG responses following two doses of the RBDA/RBDB vaccine, aged mice that succumbed to CD196 infection trended to lower anti-toxin B IgG responses. Additionally, post-challenge, aged mice developed significantly less toxin A-specific memory B cells compared to young unvaccinated mice and significantly lower toxin B-specific memory B cells compared to young RBD vaccinated mice. While these age-related defects in the humoral response are associated with increased morbidity and mortality following CDI, we also show that these defects can be restored with the addition of the molecular adjuvant Adenosine Deaminase -1 (ADA-1) during vaccination of aged mice with RBDA/RBDB-encoding DNA. When ADA-1 is used as an adjuvant in aged mice, the anti-TcdA/B antibody response is restored to levels observed in young adult mice. Additionally, the use of ADA-1 as an adjuvant boosts the frequency of T follicular helper cells in aged mice following vaccination, suggesting that ADA-1 targets the germinal center and restores the development of protective immunity following vaccination. Together, these results indicate that increased susceptibility to CDI in the aged is associated with reduced vaccine-specific anti-toxin B IgG in sera and lower frequencies of toxin-specific memory B cells suggesting the necessity for adjuvanted vaccine formulations for improvement of aged immune responses to *C. difficile* infection.

804. A Genetically Engineered, Stem-Cell-Derived Cellular Vaccine

Tom Henley

Intima Bioscience, Cambridge, United Kingdom

Despite rapid clinical translation of COVID-19 vaccines in response to the global pandemic, an opportunity remains for vaccine technology innovation to address current limitations and meet challenges of inevitable future pandemics. We describe a universal vaccine cell (UVC) genetically engineered to mimic natural physiological immunity induced upon viral infection of host cells. Cells engineered to express the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) spike as a representative viral antigen induce robust neutralizing antibodies in immunized non-human primates. Similar titers generated in this established nonhuman primate (NHP) model have translated into protective human neutralizing antibody levels in SARS-CoV-2-vaccinated individuals. Animals vaccinated with ancestral spike antigens and subsequently challenged with SARS-CoV-2 Delta variant in a heterologous challenge have an approximately 3 log decrease in viral subgenomic RNA in the lungs. The universal vaccine cell has been improved further to not only release protein antigen upon lysis post-vaccination, but to also deliver a payload of antigen-encoding, self-amplifying mRNA, through microvesicle release into the immune microenvironment. CRISPR engineering of the UVC enables the tethering of mRNA molecules to the structural proteins of microvesicles that are formed within the cells and released upon vaccination, thus protecting the mRNA within these living nanoparticles. These microvesicles are additionally modified via genetic engineering to specifically target immune cells to promote delivery of the antigen-encoding mRNA to the adaptive immune system. This cellular vaccine is designed as a scalable cell line with a modular poly-antigenic payload, allowing for rapid, large-scale clinical manufacturing and use in an evolving viral variant environment.

805. T Cell Predominant Response to AAV-Spike Protects hACE2 Mice from SARS-CoV-2 Pneumonia

Coral M. Kasden[1], Christopher D. Greer[1], Tanvi Singh[1], Leon Morales[1], Cristhian Salas-Quinchucua[2], Benjamin Kozyak[3], Paul Bates[1], Jean Bennett[1], Hansell H. Stedman[4]

[1]University of Pennsylvania, Philadelphia, PA,[2]University of Wisconsin, Madison, WI,[3]University of Pennsylvania School of Medicine, Philadelphia, PA,[4]University of Pennsylvania Medical Center, Philadelphia, PA

Prevention of COVID-19 has been predominantly based on neutralization of SARS-CoV-2 by vaccine-induced humoral immunity, leading to emerging escape variants that have perpetuated the pandemic. Here we show that a single intramuscular injection of Adeno-Associated Virus-6 (AAV6) or AAV9 encoding a modified, N-terminal domain deleted (^NTD) spike protein induces robust cellular immunity and provides long-term protection in k18-hACE2 transgenic mice from lethal SARS-CoV-2 challenge, associated weight loss and pneumonia independent of vaccine-induced neutralizing humoral immunity. In both mice and macaques, vaccine-induced cellular immunity results in the clearance of transduced muscle fibers coincident with macrophage and CD8+ cytotoxic T cell infiltration

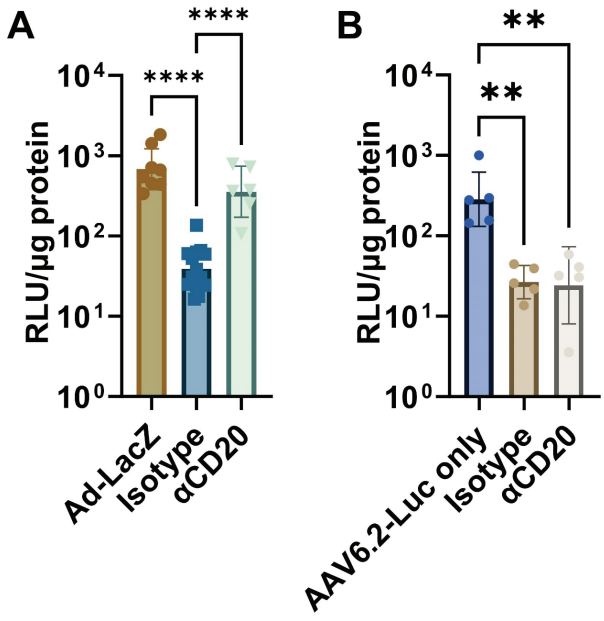
at the site of immunization. Additionally, mice demonstrate a strong Type-1 polarized cellular immunophenotype and equivalent *ex vivo* T cell reactivity to peptides of wildtype and alpha (B.1.1.7) variant spike. These studies demonstrate not only that AAV6 and AAV9 can function as effective vaccine platforms, but also that persistent antigen expression in muscle is associated with robust and long-term T cell immunity, and the immunobiological properties of skeletal muscle may be contributing to both the sustained expression of our Spike-M8B transgene product near the injection site 29 days post-immunization and the long-term T cell-mediated immunity induced by a single injection of our non-adjuvanted intramuscular AAV-Spike-M8B platform. These results may also be compatible with the retracted nature of the myositis seen in dystrophin-deficient patients receiving gene therapy for DMD. Taken together, these findings may have broader implications for the development of variant-agnostic universal vaccines against a wider range of pathogens, and demonstrate the critical transgene-dependent balance between immunogenic vaccine and non-immunogenic gene therapy on the AAV platform.

806. STING and Type-I Interferon Signaling Do Not Contribute to AAV Immunogenicity in Mice

Robert Junkins, Kelsey Higgins, Layth Awartani, Dylan Sourthers, Alan Curtis, Rachel Hedinger, Erik Wielechowski, Yash Shah, Audry Fernandez, Rohini Sheth, Ricardo Rodriguez, Angela Mote, Anna Tretiakova, Sherif Gabriel, Shari N. Gordon, R. Jude Samulski

Asklepios BioPharmaceutical, Inc., Morrisville, NC

Introduction: The host immune response remains a significant hurdle to adeno-associated virus (AAV) gene delivery, redosing, and long-term transgene expression. Efforts in the field have been heavily biased towards understanding the acquired immune mechanisms that limit AAV transduction such as neutralizing antibodies and T cell responses. However, generation of these acquired responses first requires viral sensing and induction of innate immune pathways. In contrast to the well-defined mechanisms of acquired immunity against AAV, the innate immune sensors and signaling pathways involved in viral sensing remain poorly defined. One such example is the cyclic GMP-AMP Synthase (cGAS) and Stimulator of Interferon Genes (STING) pathway, which is critical for antiviral immunity and is the focus of this study. It is a key regulator of anti-viral immunity that senses cytosolic DNA to initiate a potent type-I interferon response. **Methods:** Wild-type, Sting-deficient ($Sting^{-/-}$) and type-I interferon receptor-deficient ($Ifnar^{-/-}$) mice were injected with 1E11 vg/mouse of AAV-rh32.33 intramuscular (IM) or AAV8 intravenous (IV) expressing luciferase transgene or formulation buffer and monitored for 30 days. Acute inflammatory responses were assessed in the serum by cytokine bead array. T cell responses were assessed by interferon-γ enzyme-linked immunosorbent spot (ELISPOT) and flow cytometry (AAV capsid specific-dextramer). Binding antibodies were assessed in serum by enzyme-linked immunosorbent assay (ELISA). Transgene activity was assessed by *in vivo* imaging, while transgene expression and viral genomes were assessed by reverse transcription digital polymerase chain reaction (RT-dPCR). **Results:** No acute systemic inflammatory responses were detected at 2 hours post IV administration or 14 hours post IM administration of AAV. Intramuscular administration of AAV-rh32.33 induced significant capsid specific T cell responses in wild-type and Sting-deficient mice as assessed by both dextramer staining and ELISPOT compared to buffer controls. Interestingly, no significant differences in AAV specific T cell responses were observed between knockout strains. Both AAV8 and AAV-rh32.33 induced high titer antibody responses across all strains on day 30 relative to buffer controls. However, no significant differences in the magnitude of binding antibodies were observed between strains. Transgene activity peaked on day 8 and was maintained in all strains for the duration of the study. For IM delivered AAV-rh32.33, no differences in transgene activity, expression or vector genome copies in the tibialis anterior muscle were observed across knockout strains *in vivo* or *ex vivo*. For IV delivered AAV8, a moderate but significant increase in transgene activity in the liver was observed in Sting and Ifnar-deficient mice relative to wild-type controls in vivo and increased AAV genome copies were measured in the livers of type-I interferon receptor deficient animals. **Conclusions:** This study used a clinically relevant AAV8 capsid (frequently used for liver directed gene therapies) and the highly immunogenic T cell inducing AAV-rh32.33 capsid to investigate the contributions of the Sting/type-I interferon pathways on anti-AAV immunity in mice. Neither the frequency or functional capacity of the anti-AAV T cell response nor the magnitude of the antibody response was different in wild-type vs Sting/type1 interferon receptor deficient mice suggesting that these innate pathways are not major contributors to the development of the adaptive response in these murine models.



807. Evaluation of αCD20 for Repeated Delivery of Inhaled Gene Therapy Vectors

Robert David Edward Clark, Dora Pungan, Felix Rabito, Ferris Munyonho, T. Parks Remcho, Jay K. Kolls

Center for Translational Research in Infection and Inflammation, Tulane University Health Science Center, New Orleans, LA

RATIONALE Host immune responses to viral gene therapy vectors such as adenovirus (Ad) and adeno-associated viruses (AAV) have emerged as a primary impediment to effective treatment. While extensive work has been published on the nature of immune responses to systemically delivered gene therapy vectors, our understanding of immune responses to inhaled gene therapy vectors is less well-developed. In the systemic context, anti-AAV neutralizing antibodies and CD8+ T-cell responses have been observed to block repeated vector transduction and reduce the duration of transgene expression, respectively. However, the lung is a unique mucosal niche and site of frequent pathogen encounter that has evolved mechanisms such as resident memory B (B_{RM})- and T (T_{RM})- cells which may present unique challenges for gene therapy vector delivery. Furthermore, in addition to promoting mucosal humoral responses, B-cells in the lung also play critical roles as antigen-presenting cells to prime memory T-cell responses and promote the formation of T_{RM}. Therefore, we reasoned immunomodulation with depleting αCD20 might permit redelivery of inhaled viral vectors. **METHODS** We first studied Adenoviral (HAdV) vectors due to their well-known ability to elicit potent immune responses, and later sought to extend our results to clinically relevant adeno-associated viruses (AAV6.2). Mice were dosed with a depleting αCD20 antibody or isotype control 2 days before primary HAdV or AAV6.2 vector delivery. 4 weeks later, 6-week old female C57BL/6 (HAdV and AAV6.2) or BALB/c (AAV6.2) mice received a second

dose of a LacZ- (HAdV) or luciferase- (AAV6.2) expressing vector, followed by euthanasia after 3 days (HAdV) or 3 weeks (AAV6.2) to assess second-round gene transfer and anti-vector immune responses. Intravascular staining of lymphocytes and flow cytometry was used to evaluate the development of lung-resident memory cells, and ELISPOT and MHC-I tetramer staining were used to enumerate the number of vector-specific B- and T-cells. Second-round gene transfer was assessed by chemiluminescent activity assay and anti-vector antibody responses were evaluated by ELISA. **RESULTS** Delivery of HAdV and AAV6.2 vectors leads to the development of anti-vector humoral responses in serum and bronchoalveolar lavage fluid (BALF). For both vectors, pretreatment with αCD20 depletes both circulating and intraparenchymal B-cells but did not reduce the number of antigen-specific IFNy-secreting T-cells. However, αCD20 did reduce the number of airway infiltrating T-resident memory (T_{RM}) cells in BALF one month after HAdV delivery. As anticipated, HAdV delivery elicited substantially more T_{RM} and B_{RM} compared with AAV6.2. For HAdV, αCD20 treatment before first round gene transfer completely abrogated mucosal humoral and B-resident memory (B_{RM}) responses and rescued second-round gene transfer (figure 1A). For AAV, αCD20 similarly abrogated mucosal humoral responses; however, there was no benefit to transgene expression 3 weeks after second vector delivery (figure 1B). **CONCLUSIONS** Mucosal humoral immunity is critical in preventing re-administration of HAdV vectors, and αCD20 treatment before vector delivery rescues re-administration. However, for AAV6.2, despite a reduction in anti-vector humoral immune responses, transgene expression was not rescued by αCD20. Future work will elucidate the possible role of CD8+ T-cell mediated immunity in limiting AAV6.2 gene expression in the lung.

Wednesday Posters: Immune Targeting and Approaches with Genetically-Modified Cells and Cell Therapies

808. Fully Human B7-H3 CAR T Cells Exhibit Potent Preclinical Activity Against Solid Tumors

Pradip Bajgain
National Cancer Institute (NIH), Frederick, MD

B7-H3, a cell surface protein overexpressed in multiple types of solid tumors, has emerged as an attractive target for cancer immunotherapy. T cell therapies employing B7-H3 chimeric antigen receptors (CARs) are currently being tested against various cancer types in phase I/II clinical trials. To date, B7-H3 CARs predominantly utilize mouse derived monoclonal antibodies (mAbs) obtained from hybridomas. For instance, all B7-H3 CAR trials underway in the U.S. utilize CARs with scFvs derived from mAbs 376.96 or MGA271, both of murine origin. While humanization of the variable domain framework regions helps reduce the potential immunogenicity of these CARs, they still maintain murine complementarity-determining regions (CDRs) that can potentially elicit host mediated immunorejection. This obstacle can be evaded by constructing CARs using scFvs isolated from phase display libraries of human scFvs. In this study, we investigated if human scFv library derived "binders" can be used to generate potent fully human B7-H3 CARs with strong anti-tumor activity against aggressive solid tumors like pancreatic cancer and neuroblastoma. To accomplish this, we screened a human scFv library and identified ten unique binders that were then used to generate CARs with the same architecture including - CD28 derived hinge and transmembrane regions, a 4-1BB costimulatory domain, and a CD3ζ cytoplasmic tail. Based on superior *in vitro* performance in assays comparing CAR expression on T cell surface, antigen binding, and tumor-killing capacity, three CARs - Y111, Y117, and Y868 were selected for further evaluation *in vivo*. In orthotopic pancreatic ductal adenocarcinoma and metastatic neuroblastoma tumor models, the Y111 CAR consistently demonstrated the most robust and durable anti-tumor responses. To determine how the Y111 CAR activity compares to the B7-H3 CARs being pursued clinically, for a head-to-head assessment, we also constructed 376.96 and MGA271 CARs with architecture identical to that of Y111. While the tumor-killing ability of all three CARs was similar *in vitro*, the Y111 CAR exhibited similar or better anti-tumor efficacy compared to 376.96 and MGA271 derived CARs in mouse studies. Our data demonstrate that highly effective CARs against B7-H3 can be developed using scFvs obtained from human scFv phage display libraries. Additionally, fully human B7-H3 CARs like the Y111 CAR harbor the lowest potential for immunogenicity, eliminate the need for humanization, and help streamline the path to effective clinical translation.

809. Synthetic Gene Expression Regulatory Switches for CAR T Cells to Cure Solid Tumors

Leidy Diana Caraballo Galva

Pediatrics, Baylor College of Medicine, Houston, TX

Chimeric antigen receptor (CAR) T cells induce response rates of up to 90% and durable complete remission rates of ~50% in patients with lymphoid malignancies but have had limited efficacy in patients with solid tumors. The inhibitory tumor microenvironment (TME) of solid neoplasms lacks most survival factors needed for T cell homeostasis, contains inhibitory mediators, and together with chronic tumor antigen exposure induces CAR T cell dysfunction, ultimately leading to treatment failure. Our group and others have shown that modulation of positive, or knock out of negative, regulators of T cell function can improve the antitumor activity of CAR T cells against solid tumors. We hypothesize that simultaneous overexpression of T cell survival-related genes (*IL15, JUN, BACH2*, and *TCF7*) and downregulation of T cell dysfunction-associated genes (*TOX, BLIMP1, BTG1, RASA2*, and *REGNASE1*) using cell state-specific regulatory switches will be both safe and effective in improving CAR T cell expansion, persistence, and anti-tumor activity. We developed Synthetic Gene Expression Regulatory Switches (SynGERS) for tumor antigen-specific and cell state dependent bi-directional regulation of genes in CAR T cells. SynGERS contain a cell-state specific sensor unit acting on a minimal promoter that drives overexpression of genes associated with T cell survival (enhancer unit), and an RNA interference-based unit to repress T cell dysfunction-related genes (repressor unit). We developed a novel activation-specific sensor responding to nuclear receptor 4A2 (NR4A2) that outperformed previously described NFAT sensor unit by 10-fold (**Fig 1**). Furthermore, we generated a library of 50 SynGERS and controls and tested them in a bicistronic vector constitutively co-expressing our clinically validated glypican-3 (GPC3)-specific CAR. We targeted GPC3 as it is expressed in several pediatric solid tumors but not in non-malignant tissues. We screened the library of SynGERS-CAR for optimal combinations of positive and negative regulator genes resulting in superior expansion, persistence and killing function in repeat tumor challenge assays against GPC3+ tumor cells. Compared to T cells expressing the GPC3-CAR alone, eight SynGERS had increased cytotoxicity and/or proliferation. The top four performing SynGERS (IL15-TOX, IL15-BTG1, IL15-RASA2, and IL15-REGNASE1 had increased tumor killing capacity (fold change: 1.43, 1.27, 1.08, and 1.23, respectively), and had superior expansion (fold change: 2.75, 1.97, 1.88, and 1.58, respectively) at round four after repeat killing assay (**Fig 2**). These results demonstrate the potential for SynGERS to induce potent anti-tumor function by CAR T cells with improved persistence and proliferation in solid tumors.

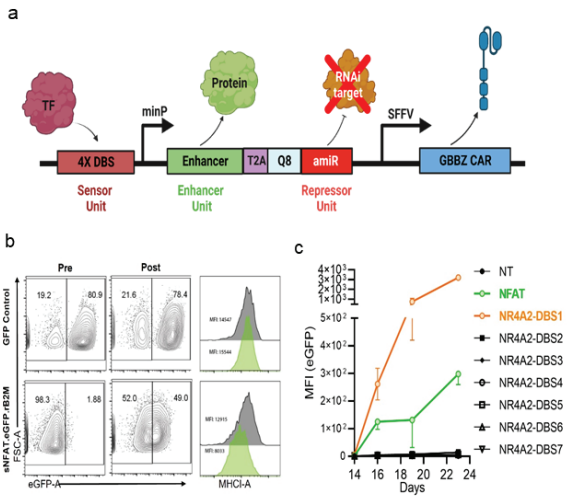


Figure 1. Development of SynGERS. a) Schematic of SynGERS: The expression cassette consists of a 5' sensor cell state specific sensor; acting on a minimal promoter (minP) followed by the enhancer and repressor units. An independent promoter (SFFV) drives the GPC3-CAR (GBBz, GPC3-specific second-generation CAR incorporating the 41BB endodomain). The enhancer unit incorporates the Q8 tag for induction detection, which is translated into a separate peptide with the use of a T2A sequence. b) Activation dependent induction and repression of target genes. T cells were transduced with indicated SynGERS and pre- and post- activation gene expression induction (eGFP) and repression (MHC Class I) was measured by FACS. One representative of three independent experiments. c) Generation of NR4a2 sensors. Transduced cells were stimulated via TCR and FACS measured induction of GFP expression. Combined results from three independent experiments.

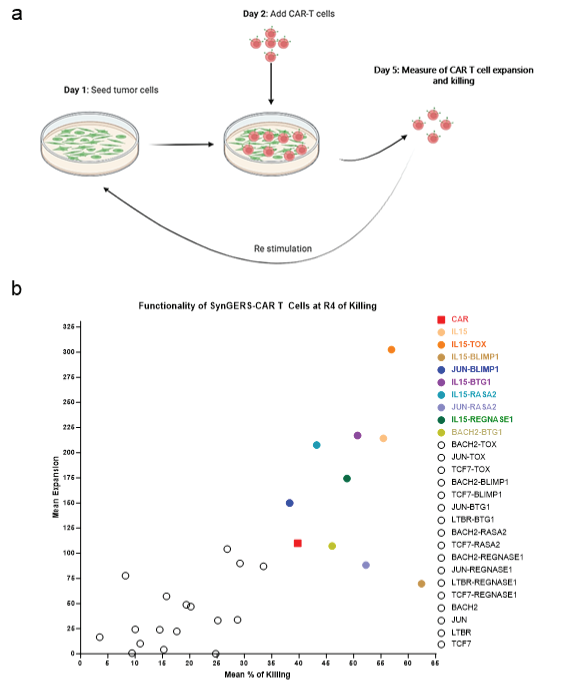

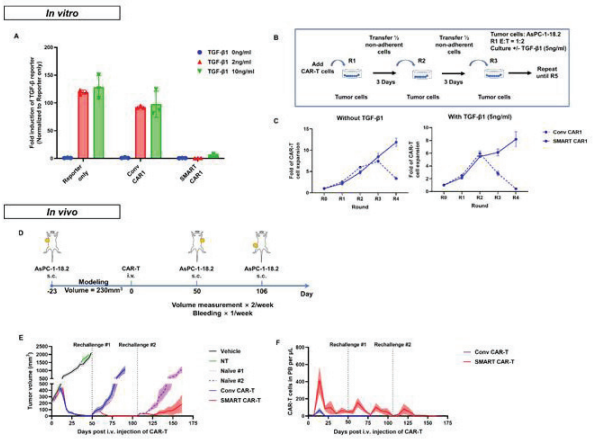

Figure 2. Figure 2. Unbiased screening of SynGERS-CAR T Cells. SynGERS-CAR T cells were evaluated in repeat tumor cell killing assay (a) in which SynGERS- CAR T cells were co-cultured with Huh7-eGFP cells at a 1:1 effector to target ratio. Cells were analyzed at the end of each round for expansion and killing. Functionality of SynGERS-CAR T Cells, based on ability to repeatedly kill tumor cells and proliferate, was assed at round four of repeat killing (b). Cell expansion was measured by flow cytometry using counting beads, and tumor cell killing was determined by IncuCyte. Data are presented as mean of two donors.

810. A Nanobody-Based and TGF-β-Resistant Claudin 18.2-Specific CAR-T Generates Effective and Durable Anti-Tumor Response: A Preclinical Study

Qi Dong, Wenjie Yin, Tao Wang, Manli Yin, Di Wu, Xinxin Wang, Wei William Cao, Lianjun Shen
Gracell Biotechnologies, Shanghai, China

Introduction: Claudin 18.2 (CLDN18.2), a member of the tight junction protein family with limited expression in normal tissues, is selectively overexpressed in solid tumors, such as gastric cancer/gastroesophageal junction cancer (GC/GEJ) and pancreatic cancer. CAR-T therapies targeting CLDN18.2 have been actively investigated in clinical trials. However, due to the immunosuppressive tumor microenvironment (TME), the overall efficacy of CAR-T therapy for solid tumor still needs improvement. Here, we generated nanobody-based CLDN18.2-targeted CAR-T cells armed with a SMART (Suppressive Molecule Activated and Rejuvenated T cells) module that combines the ectodomain of the dominant-negative TGF-β receptor 2 and a cytokine signaling domain. By converting immunosuppressive signals into pro-T cell signaling, SMART CAR-T cells can resist and persist in the TME with enhanced efficacy and prolonged durability. **Methods:** Candidate CLDN18.2-specific binders were screened from a camelid nanobody phage display library that was constructed from PBMCs isolated from an alpaca immunized with CLDN18.2 peptides and CLDN18.2-expressing cells. Binders that showed specificity to CLDN18.1 were eliminated during the initial screening process. Selected binders were further tested with membrane proteome array (MPA) to verify their specificity. Second-generation CAR-T cells expressing the CLDN18.2 binders with and without SMART were generated. CLDN18.2-targeted SMART CAR-T cells were compared with conventional CAR-T cells in terms of cell activation status, memory phenotype, short-term cytotoxicity and cytokine levels when co-cultured with tumor cells. Repeated antigen stimulation assays assessing long-term expansion and cytotoxicity in in the presence or absence of TGF-β were also performed. Immunodeficient mice bearing xenografts derived from CLDN18.2-expressing cell lines were used to study the *in vivo* potency and safety of CLDN18.2-targeted CAR-T cells. Tumor volumes, mouse body weights and survival, and CAR-T cell expansion were assessed. **Results:** Three binders (1, 2, 3) demonstrated high specificity to CLDN18.2 without any detectable off-target binding, as evidenced by MPA and/or toxicity to human primary cells in the form of CAR-T cells (CAR1, CAR2, CAR3). CAR1 cells displayed a higher proportion of naïve or stem-like memory T cells and non-activated ($CD69^{-}CD25^{-}$) cells compared to CAR2 and CAR3 cells. The short-term cytotoxicity to target cells, including those with low antigen densities, was similar among the three CARs, with CAR1 secreting the highest amount of IL-2. When armed with the SMART module, although all CARs showed elevated frequencies of T cells of a younger phenotype and enhanced resistance to TGF-β in long-term cytotoxicity assays by reducing Smad-mediated signaling, SMART CAR1 outperformed the others by effectively eradicating established TGF-β-expressing CLDN18.2-positive tumor xenografts and suppressing tumor rechallenges *in vivo* without causing significant toxicity. Significant amount of tumor infiltrating and peripheral CAR-T cells were detected. **Conclusions:** These data indicate that the camelid nanobody-derived, CLDN18.2-targeted SMART CAR-T cells are a promising immunotherapeutic approach to overcome the TGF-β-rich TME and elicit a deeper and more durable response. This CAR-T therapy warrants further clinical studies in patients with CLDN18.2-positive solid tumors, including GC/GEJ and pancreatic cancer.

Representative results of *in vitro* and *in vivo* studies. (A) Responsiveness to TGF-β1 by SMART or conventional (conv) CAR-expressing TGF-β reporter cell lines. (B) Schema of multi-round antigen stimulation assay. (C) Expansion of SMART or conv CAR-T cells in the presence or absence of TGF-β1. (D) Schema of *in vivo* rechallenge study. (E) Tumor volumes. (F) Peripheral blood CAR-T cells.

811. Development of AB-2100, a PSMA-Inducible Anti-CA9 Car T Cell Therapy Intended for the Treatment of ccRCC

Irene Scarfo, Mark Landon, Rakesh Sudhakah, Michelle Nguyen, Suchismita Mohanty, Jeremy Chen, Alma Gomez, Nickolas Attanasio, Amanda Fearon, Ivan Chan, Christine Nelson, Thomas J. Gardner, Darrian Moskowitz, Vince Thomas, Stanley Zhou, Angela Boroughs, Jennesa Smith, Jennifer McDevitt, Levi Gray-Rupp
ArsenalBio, South San Francisco, CA

Relapsed/refractory clear cell renal cell carcinoma (ccRCC) progressing after treatment with CPI and VEGF inhibitor remains an area of unmet need. We have developed AB-2100, an autologous integrated circuit T (ICT) cell product, generated via CRISPR-mediated site-specific integration of a single DNA cassette into a safe-harbor locus. AB-2100 is composed of three modules: a sequential "AND" logic gate that requires the presence of two antigens in the tumor microenvironment (TME) to trigger T cell killing; an shRNA-miR module to enhance resistance to suppressive TME via constitutive knockdown of FAS and TGFBR2; and a constitutive synthetic pathway activator (SPA) that enhances antitumor activity. The sequential "AND" logic gate consists of a priming receptor (PrimeR) targeting PSMA, and a CA9-targeted CAR that is upregulated upon PrimeR engagement with PSMA expressed on the tumor neovasculature. This design is intended to minimize the potential risk of on-target, off-tumor toxicity and to improve therapeutic index relative to a constitutive CA9 CAR T cell therapy. The dual-antigen specificity of the logic gate was tested in vitro and in vivo against CA9+ and PSMA+CA9+ tumors, showing that AB-2100 selectively kills tumors that express both antigens, and not tumors that express CA9 alone. Furthermore, we confirmed that co-culturing AB-2100 cells with PSMA-expressing endothelial cells was sufficient to upregulate CA9 CAR expression and enable tumor cell killing. Finally,

AB-2100 containing both shRNA-miR and SPA modules demonstrated enhanced anti-tumor activity in xenograft RCC models. These data demonstrate that AB-2100 selectively targets tumors expressing both PSMA and CA9, and can overcome multiple suppressive mechanisms in the TME. Based on these promising preclinical data, AB-2100 is being evaluated in a phase 1/2 clinical trial for the treatment of advanced or metastatic ccRCC.

812. Redirected Soluble Modulators (RSM) - A Novel Engineering Strategy to Enhance Immune Receptor Signaling

Nicholas G. Minutolo, Lauren C. Shaw, Kerri Ciccaglione, Tierra S. Tobin, Robert J. Saporito, Thomas Condamine, Michael Klichinsky

Carisma Therapeutics Inc, Philadelphia, PA

Immune cells require activation of primary and secondary signaling pathways to achieve maximum effect. To harness secondary signals in the design of synthetic immune receptors such as chimeric antigen receptors (CARs), costimulatory domains have been grafted directly into the membrane proximal intracellular space of these receptors. While direct incorporation of co-stimulatory domains such as 4-1BB and CD28 has been a successful strategy in CAR-T cell design, there are certain signaling domains for which membrane localization can lead to constitutive (tonic) signal propagation. This challenge is particularly notable for macrophages which signal through innate immune pathways such as MyD88 which activate from membrane proximity. To overcome the hurdle of tonic signaling from costimulatory domains, we developed redirected soluble modulators (RSMs). These chimeric soluble proteins combine the phospho-tyrosine binding capabilities of Src Homology 2 (SH2) domains from one protein with signal-transducing portions of another. Here we demonstrate an RSM that combines the phospho-ITAM binding SH2 domains from Syk with the signaling death domain of MyD88. The Syk-MyD88 RSM is capable of localizing to an ITAM domain that endogenously recruits Syk, but upon recruitment drives MyD88 signaling alongside endogenous Syk signaling. We co-expressed an ITAM-containing CAR together with the Syk-MyD88 RSM in macrophages. Upon antigen-induced CAR activation, the Syk-MyD88 RSM greatly enhanced proinflammatory cytokine output while simultaneously driving an expansion of the proinflammatory cytokine profile and enhancing M1 polarization compared to CAR activation alone. When the Syk SH2 domains of the RSM were mutated, the effect was lost, confirming the necessity for recruitment of the RSM to the ITAM to drive function. Additionally, the Syk-MyD88 RSM abrogated the tonic, antigen-independent release of proinflammatory cytokines seen with CARs that contain MyD88 death domain directly in the CAR construct. Syk-MyD88 RSMs enhanced the anti-tumor activity of CAR macrophages (CAR-M). Macrophages are critical effector cells of monoclonal antibodies. We evaluated the ability of Syk-MyD88 RSM to redirect endogenous Fc receptors to activate MyD88 in response to antibody signaling as a strategy to endow antibodies with multi-pronged innate immune signaling. When activated with antigen-specific monoclonal antibodies such as trastuzumab, macrophages expressing the Syk-MyD88 RSM exhibited a marked increase in antigen specific cytokine release, an expanded proinflammatory cytokine/chemokine output profile, and enhanced M1 polarization. RSM macrophages stimulated with antibodies activated MyD88 signaling, and thus offer a universal strategy to enhance monoclonal antibody-based therapy. In summary, these results demonstrate the development of a novel method to provide costimulation to macrophages. RSMs allow for the decoupling of costimulatory domains from the CAR construct, helping alleviate issues with constitutive signaling, while maintaining the antigen-dependent activation of costimulatory signals. Additionally, Syk-MyD88 RSMs provide a universal method to rewire monoclonal antibody Fc receptor signaling to boost macrophage activation and anti-tumor function. RSMs have cell type agnostic potential to rewire signaling downstream of TCRs, FcRs, CARs, and other immunoreceptors.

813. Development of Tunable Microenvironment-Responsive CAR T Cells Using Synthetic Genetic Circuits

Yannick Schreiber[1], Joshua N. Leonard[2]

[1]Chemical and Biological Engineering, Northwestern University, Chicago, IL,[2]Chemical and Biological Engineering, Northwestern University, Evanston, IL

Engineered cell therapies expressing a chimeric antigen receptor (CAR) in human T cells have demonstrated great promise for the treatment of hematological malignancies. However, unique challenges remain in translating the success of CAR T cell therapies to solid tumors, namely: (1) *specificity*: there are few truly unique antigens present on solid tumors, leading to off-target effects that damage normal tissue and pose safety risks; and (2) *suppression:* solid tumors develop microenvironments that are immunosuppressive and decrease T cell survival and tumor-directed cytotoxicity. To address these challenges and improve the safety and potency of solid tumor cell therapy, we engineered cells with synthetic genetic circuits containing a previously validated hypoxia biosensor (HBS) that responds to upregulation of the native HIF1α and HIF2α transcription factors by hypoxia, enabling the cells to sense and respond to the hypoxic tumor microenvironment ubiquitous among solid tumors. We evaluated CAR expression from circuit architectures containing the HBS promoter driving expression of both CAR and native HIF1α or HIF2α, as well as from circuit architectures containing the HBS promoter and our previously described toolkit of synthetic transcription factors and promoters, under normoxic and hypoxic conditions in HEK cells. We identified novel circuits providing fast reporter output with minimal background signal, and elucidated design rules that enable or restrict amplification of transgene in native HIF1α and HIF2α-containing circuits. We observed differences in CAR transgene expression between HIF1α and HIF2α-containing circuits, suggesting mechanistic differences in regulation of HIF1α and HIF2α when overexpressed. Additionally, we observed greatly amplified transgene expression in certain circuit topologies containing our synthetic transcription factor and promoter toolkit compared to native HIF1α and HIF2α-containing circuits. Ultimately, this project will provide a new therapeutic technology that enables the development of safer, more effective cell therapies for solid tumors, as well as provide new biological and mechanistic insights that can inform the future development of hypoxia-responsive cell therapies.

814. Development of Logic-Gated "Payload" Module in CAR T Cells; Aimed at Increasing Local Concentration of a Secreted Pro-Inflammatory Molecule in an Antigen-Dependent Manner

Gavin E. Shavey, Joseph H. Choe, Audrey Fung, Luke Cassereau, Marian Sandoval, Emily Ng, Suchi Mohanty, Jeremy Chen, Alma Gomez, Sofia Kyriazopoulou Panagiotopoulou, Alba Gonzalez, Aaron Cooper, Nick Haining

ArsenalBio, South San Francisco, CA

Background: CAR T cell therapies may require genetic modifications that enhance expansion and persistence in order to be clinically effective against solid tumors. We have previously deployed several modules in Integrated Circuit T cells (ICTs): engineered T cells that express a logic gate and are generated via non-viral, CRISPR-mediated transgene knock-in. The previous modules include ICT-intrinsic enhancements that provide increased antigen specificity (logic-gated CAR), resistance to the immunosuppressive tumor microenvironment (shRNA to FAS, TGFBR2), and constitutive signaling through the Janus-kinase signal transducer and activator of transcription (JAK/STAT) pathway (SPA: synthetic pathway activator) within each ICT cell. We hypothesized that logic-gated secretion of a pro-inflammatory molecule (or "Payload") could provide an ICT-extrinsic enhancement by supporting activation of the endogenous immune system to aid in the anti-tumor response. **Methods:** We evaluated the ability of a variety of supplemented cytokines to enhance both ICT and bystander immune cell anti-tumor function in vitro. From the top cytokine hits, we used synthetic biology approaches to engineer a library of over 30 cytokine variants (including tethered cytokines, muteins, and fusion proteins) to be secreted as a logic-gated Payload by ICT cells. We funneled down our library of cytokine variants by analyzing enhancements to desired anti-tumor activity in an assay modeling chronic antigen stimulation and by monitoring undesired antigen-independent T cell outgrowth in an assay modeling engineered T cell transformation potential. Payload leads were evaluated for antigen-dependent cytokine secretion, ability to induce activation of a bystander immune cell subset, and potency in a subcutaneous MSTO-211H in vivo model. **Results:** Incorporation of many distinct Payload designs into ICT cells resulted in significant augmentation of ICT anti-tumor activity without increasing cytokine-independent outgrowth. Additionally, we showed that incorporation of the Payload module into ICTs can boost bystander immune cell anti-tumor activity and is secreted from ICT cells in an antigen-dependent manner. Most importantly, incorporation of Payload into ICT cells resulted in a significantly lower required dose for maintained clearance in a MSTO-211H in vivo model, and desired ICT contraction after tumor clearance. **Conclusions:** We have developed an ICT-based Payload platform that allows for antigen-dependent expression of a user-defined secreted protein. The Payload module can enhance function of both ICT and bystander immune cells without signs of increased transformation risk in preclinical assays, and can increase capacity for tumor clearance in vivo at significantly lower dosage. Several lead Payload designs are being considered for inclusion in future ICT products.

815. Unleashing the Potential of NK Cell Therapy by Genetic Disruption of Key Immunoregulators Identified via ImmuT Finder® Platform

Jingwei Sun[1], Yiyang Tan[1], Jiahui Jin[1], Jingman Wang[1], Lingyun Chen[1], Ke Liu[1], Pin Wang[2], Yarong Liu[1]

[1]Grit Biotechnology, Shanghai, China,[2]University of Southern California, Los Angeles, CA

Natural killer (NK) cells, a distinct subset of innate lymphoid cells, play a pivotal role in cancer immunity. With multiple cytotoxicity mechanisms against tumors and a unique advantage for allogeneic therapeutic applications, NK cells have emerged as an attractive candidate for adoptive cellular therapy in recent years. Since early clinical trials have demonstrated a favorable safety profile and promising efficacy, strategies aimed at enhancing persistence and potency, as well as overcoming the immunosuppressive tumor microenvironment (TME), may lead to increased clinical benefits and expand the application of NK cells to solid tumors. To identify key immunoregulatory targets that could maximize the efficacy of NK cell therapy, we established a CRISPR/Cas9 screening platform, ImmuT Finder®, to pinpoint functional gene targets in primary human NK cells. NK cells transduced with a CAR construct carrying a designed sgRNA library were repeatedly stimulated by tumor cells, leading to an exhaustion profile and significantly diminished cytotoxicity by the end of the screening assay. Importantly, we achieved high and stable gene editing efficiency with subsequent rapid expansion in primary NK cells. Multiple quality control parameters were implemented to ensure the reliability of the screening system. Following several rounds of screening, we selected the top 25 targets and validated their function. Subsequently, the top targets that exhibited significantly enhanced cytotoxicity and/or persistence in CAR-NK cells were further subjected to comprehensive functional evaluation, resulting in the validation of several key functional targets that showed significantly improved cytotoxicity during tumor serial killing, cytokine release, proliferation and/or cytokine-independent long-term survival compared with CISH used as a benchmark in primary NK cells. In summary, the findings from our ImmuT Finder® platform demonstrates its capability to identify crucial immunoregulatory targets within primary NK cells. This underscores the potential of unleashing the power of NK cells through genetic engineering of identified targets, paving the way for the development of next-generation NK cell therapies for solid tumors.

816. Harnessing Single Cell Multiparametric Analysis for nS/MAR DNA Vector Based TCR-T Cell Therapy

Silvia Rizzato[1], Alice De Roia[1], Laura Rocchi[2], Paola Poggi[2], Rita Ruggiano[2], Silvia Bocchi[2], Andrea Faenza[2], Massimo Bocchi[2], Richard P. Harbottle[1]

[1]German Cancer Research Centre (DKFZ), Heidelberg, Germany,[2]Cellply S.r.l., Bologna, Italy

The potential of T cell therapies, which employ the use of transgenic T cell receptors (TCRs), hold great promise for advancing cancer treatment. Our research focuses on overcoming key challenges associated with TCR-T cell therapies while simultaneously developing

potent treatments utilizing high-potency TCR-T cells. TCR-T cells are modified with a novel S/MAR DNA NanoVector platform which offers a safe, efficient and fast system for generating recombinant T cells. nS/MAR vectors, in contrast to integrating systems, remain episomal, minimizing the risk of insertional mutagenesis and the potential for secondary malignancies. Moreover, they streamline the manufacturing process, offering a cost-effective and practical timeframe for the treatment of cancer patients. The identification of TCR-T cell products with enhanced potency and low exhaustion is crucial for prolonged and effective treatment. To characterize the effectiveness of our transgenic nS/MAR anti-MART-1 TCR-T cells we employed a novel automated single-cell level analysis platform, the VivaCyte®. This allows us to categorize TCR-T cells based on function and specific marker expression, providing a comprehensive understanding of the product's potency. In this study, nS/MAR vector features were refined, and the most efficient promoter for driving TCR expression (strong sEF1-α and weak hTCR) was investigated. Utilizing the novel VivaCyte® platform, we assessed single-cell cytotoxicity, focusing on the identification and frequency of serial killer cells capable of killing three or more target cells. Simultaneously, the expression of exhaustion markers (PD-1, LAG-3) and activation marker (CD137) was determined. To test functionality and fitness of the anti-MART-1 nS/MAR TCR-T cells, a 24-hour co-culture was performed with the K562 target cell line genetically modified to express HLA-A2, MelanA/MART-1 target epitope, and GFP reporter gene. High-throughput, multi-parametric analysis determined cytotoxicity and phenotype of individual T cells. Interestingly, an increase in serial killer cell frequency was observed after transfection. TCR-T cells consistently displayed a Potency Score higher than 1, suggesting each cell's capability to eliminate more than one target cell. Exhaustion and activation markers provided insights into serial killer population kinetics; an increase in CD137 marker expression occurred, while no signs of exhaustion were observed during the assay. In conclusion, we assessed the effectiveness of recombinant TCR-T cells genetically modified with the novel nS/MAR DNA vector platform, employing conventional assays and the innovative VivaCyte® system. Single-cell analysis underscored the capacity of the (nS/MAR) DNA Vector to increase the frequency of serial killer cells, linking this to specific phenotypic characteristics.

817. Investigating the Role of Immunological Synapse in Chimeric Antigen Receptor (CAR) Immunotherapy

Jong Hyun Cho, Xuening Wang, Maeve Byrne, Dongfang Liu

Rutgers University-NJMS, Newark, NJ

Chimeric antigen receptor (CAR) immunotherapy utilizes genetically engineered immune cells that express a unique cell surface receptor which combines tumor antigen specificity with immune cell activation in a single receptor. CAR immunotherapy has shown remarkable success in improving the overall survival of patients with hematological malignancies, yielding 70-90% complete remission rates for treatment of relapsed/refractory B-cell acute lymphoblastic leukemia using CD19-CAR-T cells. However, long-term follow-up revealed that 33%-50% of patients who achieved remission ultimately relapsed. With ongoing clinical trials, CARs with different target specificities and sequence modifications are being developed and tested by many laboratories to target different tumor antigens and to improve the safety and efficacy of the treatment. Despite the impressive progress, conventional ways to identify optimal CAR constructs are limited by costly, time-consuming, and labor-intensive tools. Furthermore, precisely predicting the efficacy of different CAR products and selecting clinical responders to the therapy remain a key challenge in clinical settings. Recently, our lab has developed novel CAR-natural killer (NK) cells expressing anti-CD147 against hepatocellular carcinoma (HCC), showing promising results in reducing HCC burden in vitro and in a xenograft mouse model. However, the CAR-NK cell cytotoxicity mechanisms and the ways to determine its efficacy in the tumor microenvironment are still under investigation. Our lab has also identified that the quality of immunological synapse (IS) between CAR-T or CAR-NK cells and tumor cells is important for optimal CAR-modified cell antitumor function. The IS is a highly organized interface between lymphocytes and their target cells and includes multiple adhesion, signaling, regulatory, and structural molecules. Previous studies have demonstrated that T or NK cell efficacy is not only controlled by the specificity and avidity to the tumor antigen, but also it depends on the spatially and temporally organized IS formation. Recognizing the limitations of conventional tools and the importance of IS in immune cell functions, we investigate a new strategy for assessing CAR-NK cell efficacy by quantifying CAR IS quality. Here, we evaluate CAR-NK IS quality by quantitation of F-actin, clustering of tumor antigen, polarization of lytic granules, and distribution of key signaling molecules within the IS using immunofluorescence confocal microscopy. We propose to address the basic biology of CAR-modified cell immunological synapse and its application to develop novel means to predict CAR-modified cell efficacy.

818. Persistent Genetic Modification of NK cells Using Non-Integrating S/MAR DNA Vectors for Cancer Immunotherapy

Luisa Burger[1], João S. Cardoso[1], Julia D. Peterson[1], Toros Tasgin[1], Patrick Schmidt[2], Richard P. Harbottle[1]

[1]German Cancer Research Centre (DKFZ), Heidelberg, Germany,[2]National Center for Tumor Diseases, Heidelberg, Germany

Achieving an optimal genetic modification of NK cells for enhanced cancer-fighting capabilities has posed significant challenges and relies mainly on retro- and lentiviral transduction in current clinical studies. NK cells play a crucial role in defending against viral infections. Accordingly, NK cells react strongly to viral vectors which leads to low transduction efficiencies. Additionally, the risk of insertional mutagenesis and constraints on transgene size limit the effectiveness of transduction methods. To address these challenges, we have created a DNA Vector platform which is devoid of viral components and comprises a minimal bacterial backbone. The vectors do not integrate into the target cell's genome but can replicate extrachromosomally in the nucleus of dividing cells using sequences derived from Scaffold/Matrix Attachment Regions (S/MAR). Therefore, they are promising candidates for long-term, stable modification of NK cells without compromising genomic integrity. We have developed electroporation protocols and modified our S/MAR vectors to determine optimal vector features to improve the genetic modification of NK cells as these cells are notoriously difficult to transfect. Using a feeder-based expansion protocol and electroporation we achieved transfection efficiencies of

up to 70 % in peripheral blood derived NK cells with reporter gene expressing S/MAR vectors and the transgene was detectable for three weeks. Furthermore, we studied our vectors in the NK-92 cell line which is used in preclinical and clinical studies to explore NK-cell based cancer immunotherapies and is suitable for off-the-shelf applications. We successfully generated an NK-92 cell line which stably expresses a chimeric antigen receptor (CAR) against the CEA antigen, a common antigen in solid tumours. The CAR expression was persistent for at least six months and was not influenced by cryogenic cell storage. The cell line shows enhanced and CAR specific killing against the CEA-expressing MCF7 breast cancer cell line while the molecular phenotype of the NK-92 line was unaltered. A key step to enable the modification of NK-92 cells with CAR-expressing S/MAR vectors was the treatment of NK-92 cells with small molecules inhibiting the TBK1/IKKε Kinase complex, a central node of cytosolic DNA sensing, before and after transfection which improved transfection efficiencies up to sevenfold for reporter gene vectors. These findings represent a significant stride toward the safer and stable modification of NK cells for clinical applications, laying a robust foundation to extend the utilization of our episomally maintained vectors to a diverse array of promising applications in the field of NK cell immunotherapy.

819. Outlast™ CAR-T Cells Exhibit Superior Effector Function Against Solid Tumors

Kevin Carbajal, Warren Anderson, Prasanna Ekambaram, Jessica Gorczynski, Matthew Esquivel, Adam Pecoraro, Max Richter, Matthias Schroff, Sumiti Jain

Inceptor Bio, Raleigh, NC

The success of CAR-T cell therapy in treating solid tumors has faced several limitations. Key factors limiting CAR-T efficacy in the hostile tumor microenvironment (TME) are lack of T cell persistence and poor durability due to the immunosuppressive and hypoxic milieu. To equip CAR-T cells with attributes that improve their function against solid tumors, we have developed a novel method to condition CAR-T cells during *ex vivo* expansion. Without the need for complex engineering, our conditioning regimen is a radically simple and effective way to epigenetically program CAR-T cells for long-term persistence and durable effector function, proven in *in vivo* models. Our proprietary conditioning regimen generates a unique brand of Outlast™ CAR-T cells (OTX), that exhibit superior effector function against solid tumors. Our first OTX CAR-T product is an autologous anti-CD70 CAR-T to treat clear cell renal cell carcinoma (ccRCC). When compared to conventional T cell (Tconv), we have shown that OTX CD70 CAR-T cells have 1) superior metabolic fitness, 2) superior activation state (by CD25 MFI) in the presence of target cells, 3) lower exhaustion state after repeated stimulation (by PD-1, LAG-3 and KLRG1 MFI), 4) superior resistance to TGFb suppression and 5) superior control of tumor cells *in vivo* in an aggressive repeat challenge model. Overall, we show that OTX CD70 CAR-T cells exhibit multiple attributes desired of CAR-T cells for effective and superior function in the solid tumor microenvironment, and that they 'outlast' conventional CAR-T cells leading to more durable control *in vivo*.

820. Constitutive IL-7 Signaling in Car-NK Cells is Associated with High AP-1 Activation and Effector Function Decline

Matthew Dysthe, Ishwar Navin, Dayenne van Leeuwen, Cliona M. Rooney, Robin Parihar

Baylor College of Medicine, Houston, TX

Background: The efficacy of CAR-NK cellular therapies is limited, in part, by insufficient survival and expansion within the tumor microenvironment (TME). To improve survival and anti-tumor function, CAR-NK cells can be augmented with cytokines or modified to express cytokine transgenes (e.g. IL-15/IL-15R-alpha) that converge on signal transducer and activator of transcription-5 (STAT5) activation. However, systemic administration or transgenic expression of cytokines is associated with toxicities, expansion of inhibitory T-regulatory (Treg) cell populations, and rejection of allogeneic CAR-NKs. Thus, novel cytokine approaches are needed to bypass the limitations of current strategies. IL-7 is a proto-typical NK-cell survival and expansion factor that does not activate Tregs or mediate allo-NK rejection, and thus is an attractive option for cytokine support. Here, we genetically modify CAR-NK cells to express a constitutively active IL-7 receptor complex, termed C7R (C7R.CAR-NK), that confers intrinsic, sustained STAT5 activity within CAR-NK cells. We hypothesized that C7R would provide a potent intrinsic activation signal that would promote NK cell survival and function within inhibitory TMEs typically devoid of such signals. **Results:** Activated and expanded primary human NK cells were co-transduced with retroviral constructs encoding C7R and a GD2-specific CAR. C7R.CAR-NK demonstrated a 3.4-fold increase in phosphorylated STAT5 ($p<0.01$) compared to CAR-NK without cytokine support [CAR-NK(-)]. In short-term co-cultures with GD2+ neuroblastoma, C7R.CAR-NK demonstrated superior intracellular IFN-gamma accumulation ($p<0.05$) compared to CAR-NK(-). We next used a novel *in vitro* TME that mimics a suppressive myeloid infiltrate. In this culture system, C7R.CAR-NK cells demonstrated superior cytotoxicity, survival, and IFN-gamma and TNF-alpha secretion ($p<0.05$) when compared to CAR-NK(-). Despite this promising *in vitro* activity, C7R.CAR-NK did not exhibit improvement in tumor control *in vivo* against neuroblastoma TME xenografts compared to non-treated mice and CAR-NK(-) treated mice, while CAR-NK augmented with systemic IL-15 administration (sIL-15+CAR-NK) demonstrated modest tumor control. *In vivo* bioluminescence imaging and intra-tumoral analysis by flow cytometry confirmed that C7R.CAR-NK cells were present in similar proportions to sIL-15+CAR-NK, both significantly increased over CAR-NK without cytokine support. To investigate the mechanisms behind the paradoxical lack of anti-tumor efficacy *in vivo* despite the C7R-mediated NK survival, we compared gene expression in C7R.CAR-NK and sIL-15+CAR-NK 14 days post cell generation in the absence of any antigen-mediated CAR signaling. C7R.CAR-NK exhibited significant increases in genes associated with AP-1 signaling, most notably *FOS*, *JUNB*, and *JUND*, as well as *NR4A1* and *DUSP1*, recently implicated in both NK- and T-cell dysfunction. This epigenetic phenotype was associated with significantly reduced cytotoxicity ($p<0.05$) compared to sIL-15+CAR-NK. **Conclusion:** While C7R enhanced short-term cytotoxicity and survival and expansion of CAR-NK cells both *in vitro* and *in vivo* TME models, these properties did not translate to enhanced *in vivo* anti-tumor efficacy. Long-term constitutive IL-7R signaling via C7R confers

a transcriptional signature associated with NK dysfunction. Our data inform consequences of continuous cytokine signals within CAR-NK cells and provide novel candidate genes related to NK dysfunction that represent targets for improving CAR-NK function with the solid TME.

821. Pooled Screening for CAR Signaling Optimizes Function in NK Cells

Khloe S. Gordon, Taeyoon Kyung, Aurelija Grignoyte, Siqi Zhao, Joshua Mace, Jai Raman, Michael Ledbetter, Narendra Maheshri, Shawdee Eshghi

Ginkgo Bioworks, Boston, MA

NK cells are an attractive alternative to T cell-based therapies because they are capable of producing similar levels of anti-tumor cytotoxicity and are a potentially universal source for "off-the-shelf" CAR therapies. However, exploration of activating signals used for CAR-NK cell architectures has been fairly limited, with the majority of inputs being derived from T cell or NK cell receptors. We hypothesized that a more systematic exploration of diversified CAR signaling in NK cells could enhance their antitumor function and expedite their utility beyond hematological malignancies. To address this, we evaluated 10,000 unique signaling domain combinations in CAR-NK cells. We expressed our previously reported library of anti-ROR1 2nd generation CARs with diversified signaling domains in human primary peripheral NK cells, which we then screened for cytotoxicity and cytokine release following endogenous NK cell receptor blockade and solid tumor challenge by sorting for degranulation markers and intracellular cytokines. We found hits that were enriched across multiple selection criteria, with most containing activating and costimulatory domains from various immune cell types. Notably, the membrane proximal position drove stronger enrichment of these signaling domains, while the membrane distal position showed overall lower domain preference with the exception of 5 costimulatory domains. Furthermore, screening for IFNy secretion was the most stringent selection criteria and produced the lowest levels of enrichment, while screening for CD107a was the least stringent. Polyfunctionally enriched hits were validated individually, where novel combinations that outperformed standard CARs in NK cell cytotoxicity and cytokine secretion were identified. Our platform is enabled by our expertise in molecular diversification and high-throughput screening, making it readily adaptable to antigen receptors designs, immune cell types, and disease contexts beyond CAR-T and NK cells for use as cancer therapies. For example, this approach could be applied to other structural elements such as the ligand binding or hinge domains or secreted payloads, other types of chimeric receptors like switch receptors, and emerging non-conventional immune cell types such as macrophages, γδ T, or NKT cells. Furthermore, it could be applied to optimize for a diverse range of functions, including immune suppression in the context of autoimmune disorders. Thus, our pooled screening approach is uniquely positioned to provide biological and preclinical insights in a broad range of therapeutic applications.

822. CAR T Cell Based Inducible Protein Delivery: Application and Analysis in Immunocompetent Mice

Sherri L. Newmyer[1], Harikrishnan Radhakrishnan[1], Harold S. Javitz[2], Parijat Bhatnagar[1]

[1]Biosciences Division, SRI International, Menlo Park, CA,[2]Education Division, SRI International, Menlo Park, CA

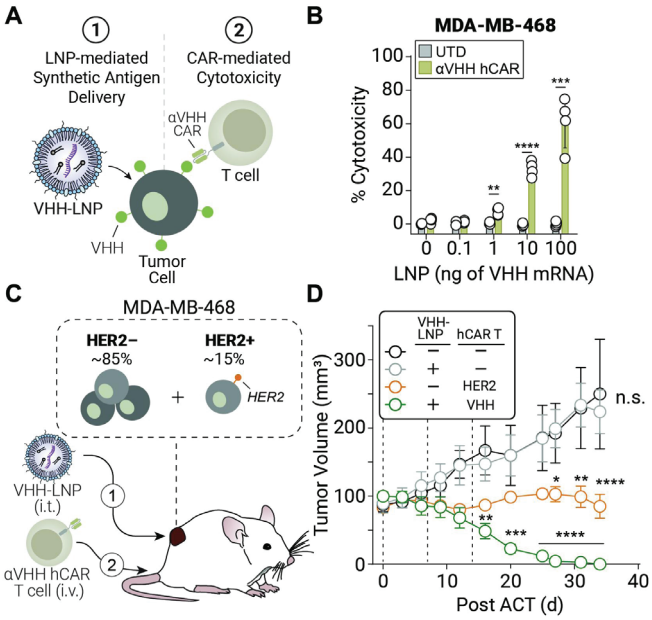
Recent advancements in CAR T cell therapy, primarily used to treat blood cancers, are now being explored for delivering therapeutic proteins. Such proteins could strategically counter the immunosuppressive tumor microenvironment associated with solid tumors that represents a barrier to immunotherapy. Preclinical CAR T cell therapy validation typically occurs in immunocompromised mice xenografted with human tumors, which inadequately assess potential toxicities, like cytokine release syndrome. Addressing this gap, our study introduces a novel CAR-triggered protein delivery system in murine T cells, enabling analysis in immunocompetent mice with intact immune systems. Lentivirus transduction efficiently generated engineered murine CD4 and CD8 T cell subsets, achieving 40% and 20% transduction efficiencies that expanded cells ~20- and 75-fold, respectively. The engineered cells' response to tumor antigen used a nanoluciferase (Nluc) reporter. In vitro, CD8 T cells demonstrated approximately double the Nluc expression of CD4 cells when exposed to MSLN-expressing A2780 tumor cells. Membrane-bound IL15 transgene was incorporated to enhance CAR-T cell persistence, comparing three anti-mesothelin (MSLN) CAR T cell variants: CAR alone, CAR with constitutive IL15 (cIL15), and CAR with inducible IL15 (inIL15). IL15 co-engineering did not significantly impact Nluc expression or cellular expansion upon coculture with MSLN expressing tumor cells. In vivo, anti-MSLN->Nluc CD4 and CD8 T cells were injected into C57BL/6 mice engrafted with pancreatic cancer model expressing MSLN. Here, membrane bound IL15 improved CAR T cell expansion within the tumor and was notably associated with Nluc activity measured in tumors treated with CAR + cIL15 with the CD8 T cell chassis. In contrast to inIL15, cIL15 increased CAR T cell expansion in peripheral tissues. These findings reveal that murine CD8 CAR T cells, in contrast to CD4 CAR T cells, demonstrate superior tumor-targeted reporter protein expression both in vitro and in vivo. The inclusion of IL15 enhances overall T cell persistence and targeted protein expression in vivo, improving cell therapy potency. Rendering IL15 expression inducible further drives tumor-specific activity, improving the precision of cell delivered therapy. This study highlights the potential of engineered CAR T cells for the delivery of therapeutic proteins in immunocompetent models, offering a more accurate assessment of therapeutic efficacy and safety.

823. Enhancing the Efficacy of Anti-HER2-JAK/STAT-CAR-T Cells through Shortening the Cell Production Period

Yasunori Amaishi, Ryosuke Nagata, Kumiko Uemura, Seina Inui, Yoko Kudo, Sachiko Okamoto

Takara Bio Inc., Kusatsu, Shiga, Japan

Human epidermal growth factor receptor 2 (HER2)-specific antibody or antibody-drug conjugate therapy is widely used for the treatment of HER2-positive tumors, including breast cancer and gastric cancer.



However, there is still a need for the development of alternative therapies due to the recurrence of tumors and the difficulty in achieving a cure for many patients. One promising solution is CAR-T therapy, which has demonstrated remarkable efficacy in targeting hematological tumors expressing antigens like CD19 and BCMA. However, its clinical effectiveness in solid tumors remains inadequate. Enhancing the persistence of CAR-T cells in the body is one of the challenges that needs to be addressed in CAR gene therapy. Our novel JAK/STAT CAR, a next-generation CAR, demonstrates antigen specific activation of the JAK/STAT signaling pathway through a truncated intracellular domain of the IL-2 receptor beta chain and a STAT3/5 binding motifs. Consequently, JAK/STAT CAR-T cells show lower expression of exhaustion markers compared to conventional CAR-T cells, exhibits antigen-specific high cell proliferation, and maintain long-term cytotoxic activity against continuous antigen stimulation. With these characteristics, JAK/STAT-CAR-T cells have sustained anti-tumor activity and are expected to be effective against solid tumors. In this study, we utilized three antibodies that recognize HER2 to construct anti-HER2-JAK/STAT-CAR expression vectors and Fc fusion proteins. The 4D5-8 and 2C4 clones were derived from antibodies already approved for clinical use, namely, Trastuzumab and Pertuzumab, respectively. The C6.5 clone is widely used in research targeting HER2. However, each clone exhibits different epitope recognition and affinity toward the HER2 molecule. We compared the reactivity of Fc fusion proteins and CAR-T cells against various HER2-positive tumor cell lines. The reactivity varied depending on the intensity of HER2 expression and scFv clone, but particularly strong correlation was observed between reactivity towards HER2-low-expressing PC-3 and Trastuzumab-resistant JIMT-1 cells and antibody affinity. CAR-T cells derived from the 4D5-8 and 2C4 antibodies demonstrated high antitumor activity in vivo, indicating their potential efficacy in clinical settings.Another challenge in CAR-T cell therapy is the cost of T cell manufacturing and the differentiation and exhaustion of T cells during the manufacturing process. Anti-HER2 (2C4)-JAK/STAT-CAR-T cells prepared using the Spo-T™(Short period operation for T-cell production) method showed higher cytotoxic activity and lower exhaustion than those using conventional methods. Furthermore, these cells demonstrated long-term survival and inhibited tumor engraftment in an in vivo experiment using a mouse model simulating tumor recurrence.Based on these results, anti-HER2-JAK/STAT-CAR-T cells prepared using the Spo-T™ method exhibited high antitumor activity, long-term survival, and the ability to suppress tumor recurrence. Therefore, anti-HER2-JAK/STAT-CAR-T cells have the potential to be a promising option for the treatment of HER2-positive tumors.

824. Sensitizing Solid Tumors to CAR-Mediated Immunity by Lipid Nanoparticle Delivery of Synthetic Antigens

Lena Gamboa[1], Ali Zamat[1], Chloé Thiveaud[1], Hee Jun Lee[1], Zizhen Zha[1], Elif Kulaksizoglu[1], Noah Campbell[1], Ching Shen Chan[1], Sydney Fábrega[1], Abbey Oliver[1], Fang-Yi Su[1], Hathaichanok Phuengkham[1], Daryll Vanover[1], Hannah Peck[1], Anirudh Sivakumar[1], Shreyas Dahotre[1], Adrian M. Harris[1], Philip Santangelo[2], Gabriel A. Kwong[1]

[1]Georgia Institute of Technology, Atlanta, GA,[2]Georgia Tech, Atlanta, GA

Despite the therapeutic efficacy of chimeric antigen receptor (CAR) T cells to treat certain hematological malignancies, their clinical success against solid tumors remains limited. Technical challenges associated with the identification of neoantigens characteristic of individual tumors - along with the need to engineer and validate CARs or TCRs against new targets - are significant bottlenecks to achieving therapeutic efficacy across tumor types. Additionally, identifying targetable tumor-associated antigens (TAA) remains challenging as heterogenous antigen expression, low antigen density, and antigen loss reduce CAR T cell efficacy and raise concerns with antigen escape. Expression of CAR antigens at low-levels in healthy tissue also pose safety concerns arising from on-target off-tumor toxicities. T cells targeting solid TAAs (e.g., HER2), for example, show cross-reactivity with healthy cells in vital organs that limit safe and effective clinical translation. Collectively, these limitations underscore the need to develop strategies that reduce the bottleneck of antigen selection and enable CAR T cell recognition of tumors otherwise lacking targetable antigens. Here, we developed synthetic antigens to sensitize solid tumors to CAR T cell mediated immunity agnostic to a tumor's endogenous antigen expression profile. We repurposed a xenogeneic protein, the antigen binding fragment of the heavy-chain-only camelid antibodies (VHH), as a synthetic antigen. We deliver VHH as an mRNA-encoded synthetic antigen using lipid nanoparticles (LNPs) and demonstrate stable expression on the surface of various tumor types - including breast, colon, lung, prostate, and brain cancer - which subsequently led to recognition and killing by αVHH CAR T cells (**Fig. 1A-B**). Moreover, we show that αVHH CARs are well tolerated based on the measurement of cytokine release in a coculture of human αVHH CARs T cells with PBMCs as well as serum chemistry analysis in naïve C57BL/6J mice up to 100 days following adoptive transfer of murine αVHH CARs T cells. Adoptive transfer of αVHH CAR T cells to mice bearing VHH-treated tumors reduced tumor burden in multiple syngeneic and xenograft models of cancer, improved survival, induced epitope spread, prevented tumor growth after rechallenge, and mitigated antigen escape in heterogenous tumors (**Fig. 1C-D**). Our data show that sensitizing tumors to CAR-mediated cytotoxicity using synthetic antigens can potentiate antitumor immunity and improve responses against solid tumors. **Caption**: **Fig. 1** | (**A**) Following LNP-mediated synthetic antigen delivery, tumor cells express VHH and become sensitized to killing by αVHH CAR T cells. (**B**) Cytotoxicity of MDA-MB-468 tumor cells following coincubation with untransduced (UTD) or αVHH CAR T cells at various VHH-LNP doses. 2-way ANOVA, mean ± s.e.m., n=4. (**C**) Mice bearing a heterogenous tumor mixture comprised of 85% HER2- and 15% HER2+ tumor cells were treated with i.t. with either saline or VHH-LNP followed by transfer of αVHH or αHER2 CAR T cells (**D**) Tumor growth curves of following i.t. treatment with with saline or VHH-LNP and systemically with indicated T cells. 2-way ANOVA, mean ± s.e.m. n= 4-5.

825. Manufacturing CAR T Cells with DNA Methylation Inhibitors Enhances Their Fitness in Immunocompetent Solid and Brain Tumor Models

Zhongzhen Yi[1], Elton VanNoy[1], Abigail Lee[2], Katherine Chiappinelli[2], Dalia Haydar[1]

[1]Center for Cancer and Immunology Research, Children's National Hospital, Washington, DC,[2]Department of Microbiology, Immunology, and Tropical Medicine, George Washington University, Washington, DC

Epigenetic reprogramming and T cell exhaustion emerge as critical factors significantly impacting the persistence and effectiveness of chimeric antigen receptor (CAR) T cell adoptive immunotherapies in solid and brain tumors. Several of these processes are regulated by DNA methylation, an epigenetic modification that is crucial for gene regulation and function. Therefore, this study investigates whether targeting the dysregulated DNA methylome in T cells can improve immune activation and anti-tumor efficacy of engineered adoptive immune cells. We optimized a transduction protocol that incorporates adding DNA methyltransferase inhibitors (DNMTi) early during the manufacturing process of murine CAR T cells targeting B7-H3. We then used standard *in vitro* assays and immunocompetent solid and brain tumor models to evaluate whether DNMTi treatment improved CAR T cell effector functions by regulating activation, memory differentiation, and cytokine responses in adoptive T cells. In repeated-stimulation assays, CAR T cells generated in the presence of DNMTi exhibited significantly higher levels of expansion and persistence compared to CAR T cells without DNMTi exposure. Notably, CAR T cells manufactured in the presence of DNMTi persisted up to 12 repeat stimulations, in contrast to a maximum of 7 stimulations for CAR T cells generated in the absence of DNMTi treatment. Moreover, DNMTi-treated CAR T cells expanded up to 55-fold higher than T cells generated without DNMTi treatment upon repeated stimulation with B7-H3-positive tumor cells. This was associated with remarkably enhanced secretion of immune-stimulatory cytokines that persisted across repetitive stimulations. Furthermore, DNMTi-treated CAR T cells exhibited greater cytotoxicity at lower effector-to-target ratios compared to untreated CAR-T cells, with sustained differential cytotoxicity even after the 4th stimulation. Preliminary *in vivo* data from ovarian and brain tumor immunocompetent models further support the potential of DNMTi pre-treatment, showing improved T cell persistence and reduced dose requirements. Mechanistic studies suggest that DNMT inhibition enhances B7-H3 CAR T cell anti-tumor activity by regulating activation and memory differentiation of CAR T cells early in the production phase. This study proposes that DNMTi pre-treatment may offer a promising approach for optimizing CAR-T cell manufacturing, improving product quality, and enhancing its performance. Our findings hold potential for addressing challenges related to CAR T cell exhaustion and improving the overall efficacy of adoptive cellular therapies in the treatment of solid and brain cancers, warranting further exploration.

826. *In Vivo* Pooled Screening Platform for the Discovery of Optimized Chimeric Antigen Receptor (CAR) Design in T cells

Taeyoon Kyung[1], Joshua Mace[1], Matthew Forsberg[2], Nina La Vonne Denne[3,4], Siqi Zhao[1], Khloe Gordon Wei[1], Jai Raman[1], Narendra Maheshri[1], Christian Capitini[2], Krishanu Saha[3,4], Shawdee Eshghi[1]

[1]Ginkgo Bioworks, Boston, MA,[2]University of Wisconsin School of Medicine and Public Health, Madison, WI,[3]Department of Biomedical Engineering, University of Wisconsin-Madison, Madison, WI,[4]Wisconsin Institute for Discovery, University of Wisconsin-Madison, Madison, WI

While Chimeric Antigen Receptor expressing T cells (CAR-T cells) have shown high response rates against hematological cancers in the clinic, they have shown limited efficacy against solid tumors due to lack of persistence and susceptibility to various immunosuppressive factors in the tumor microenvironment (TME). To address the suppressive TME, recent efforts to systemically discover novel intracellular signaling domains (ICDs) at scale have demonstrated success in engineering CAR designs with enhanced solid tumor efficacy. However, in vitro screens are inherently limited in mimicking the TME and other physiologically relevant aspects of adoptive cell therapy (ACT). Here, we developed an in vivo pooled screen approach to identify potent CAR-T designs in a CHLA-20 neuroblastoma xenograft model. We utilized a DNA-barcoded 10,000-member CAR ICD library that we previously used to identify novel ROR1 CAR ICDs with enhanced anti-tumor function. This library was cloned into a GD2 CAR-T backbone, GD2 CAR library-expressing primary T cells were injected into tumor-bearing mice at >100x coverage of our library size, and 2 weeks post-ACT, spleens and tumors were collected. Sequencing genomic DNA quantified the abundance of barcodes linked to each CAR ICD combination. Based on previous literature, we hypothesized that any remaining CAR-T cells at the tumor site and spleen would represent T cells with long-term persistence elicited by antigen-specific CAR ICD signaling. Novel ICD combinations were preferentially enriched across multiple replicate mice. We selected the top 100 shared hits and validated their anti-tumor function in an arrayed screen, assessing cytotoxicity, cytokine secretion profiles, proliferation, and memory and exhaustion phenotypes in a tumor rechallenge setting.

These functional datasets allowed us to dissect the effects of particular signaling components in T cells that endow long-term persistence and potentially resist immunosuppressive TME factors. In vivo pooled screen approach is readily applicable to identifying signaling modules driving favorable phenotypes of T cells against solid tumors. Further development of an in vivo screening platform in humanized mice could be a promising next step to discovering cell therapy products with strong translational potential.

827. Innovative This TCRT: Revolutionizing TCR-T Therapy for Solid Tumors without Gene Editing

Kaichun Liu, Yinhang Zhang, Shanshan Chen, Guanggui Xu, Jun Li

Fundamenta Therapeutics, Suzhou, China

Background: TCR-T therapy shows promise for treating solid tumors by targeting neoantigen peptides. However, its efficacy and individualized production are limiting factors. Our study introduces ThisTCRT, an innovative allogeneic TCR-T platform that bypasses gene editing. ThisTCRT employs a novel intracellular retention mechanism for endogenous TCRab, significantly enhancing efficacy against difficult targets like KRAS G12V/HLA-A*11:01. Methods: We developed ThisTCRT cells using a specialized vector encoding TCR chains and a KDEL-tagged anti-TCR scFv. Comprehensive in vitro and in vivo analyses assessed surface TCR expression, tumor cytotoxicity, and safety in a GvHD model. Results: ThisTCRT cells demonstrated a unique expression profile of exogenous TCRab with endogenous retention. They showed potent tumor-specific cytotoxicity, eradicating tumors in the Panc01 model without inducing GvHD, signifying a major advance in solid tumor therapy. Conclusions: ThisTCRT marks a breakthrough in TCR-T therapies, offering effective, off-the-shelf solutions for treating solid tumors. Its remarkable preclinical results warrant immediate clinical trials.

828. Antitumor Activities of Chimeric Antigen Receptor T cells Targeting Mucin-1 with Self-Secreting Anti PD-1 IgG Antibody

Nattarika Khuisangeam[1], Koramit Suppipat[2,3], Nattiya Hirankarn[2,4], Supanikar Tawinwung[2,5]

[1]Graduate Program in Medical Microbiology, Graduate School, Chulalongkorn University, Bangkok, Thailand,[2]Cancer Immunotherapy Excellence Center, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand,[3]Department of Research Affairs, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand,[4]Center of Excellence in Immunology and Immune-Mediated Diseases, Department of Microbiology, Chulalongkorn University, Bangkok, Thailand,[5]Department of Pharmacology and Physiology, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand

In various types of solid tumors, mucin-1 (MUC1) is overexpressed in hypoglysylated form which can be targeted using cellular immunotherapy. Chimeric antigen receptor (CAR) T cells targeting MUC1 have shown potential efficacy against multiple solid tumors. However, treatment using CAR T cells faces challenges in solid tumor due to the immunosuppressive microenvironment, particularly the overexpression of programmed death-ligand 1 (PD-L1) in solid tumors that can induce T cell exhaustion and dysfunction. To overcome immunosuppression and enhance the efficacy of MUC1 CAR T cells, we successfully generated MUC1 CAR T cells secreting anti PD-1 IgG antibody derived from nivolumab (MUC1.PD1) using retroviral system. The transduction level of MUC1.PD1 CAR was maintained at day 11 after transduction but was statistically lower than MUC1 CAR T cells (63.7% ± 3.96% and 82.8% ± 3.68%, n = 5). T cell expansion and cellular composition showed major subset was CD3+ T cell with a higher percentage of CD8+ than CD4+ T cells. To determine the cytolytic activities of the CAR Ts, the MUC1(-) 293T cells and two cholangiocarcinoma cell lines endogenously expressing MUC1 and PD-L1, HuCCT-1 and KKU-213, were used as targets. Both MUC1 and MUC1.PD1 CAR T cells showed anti-tumor activity against HuCCT-1 and KKU-213 in a dose-dependent manner but not 293T cell, indicating a specific antigenic response of the two CARs. However, the cytolytic activities of MUC1 and MUC1.PD1 CAR T cells were comparable. To explore the effects of the secreted anti PD-1 antibody, we used the repeated antigen stimulation assay, which determine the effector functions of T cells throughout multiple presentations of tumor cells. We found that MUC1.PD1 CAR T cells exhibited higher proliferation and lower expression of PD-1 compared with MUC1 CAR T cell after co-culture with MUC1+PD-L1+ tumor cells in vitro. Moreover, MUC1.PD1 CAR T cells decreased the tumor growth when compared with MUC1 CAR T cell in NOD-SCID mice bearing HuCCT-1 cholangiocarcinoma cell line. In conclusion, our work suggests that engineering CAR T cells to secrete anti PD-1 antibody tends to be more effective than second generation CAR T cells, partly owing to the enhanced T cell proliferation and the mitigated PD-1 expression after repeated antigen stimulation. Our study presents a strategy to improve the efficacy of CAR T cells.

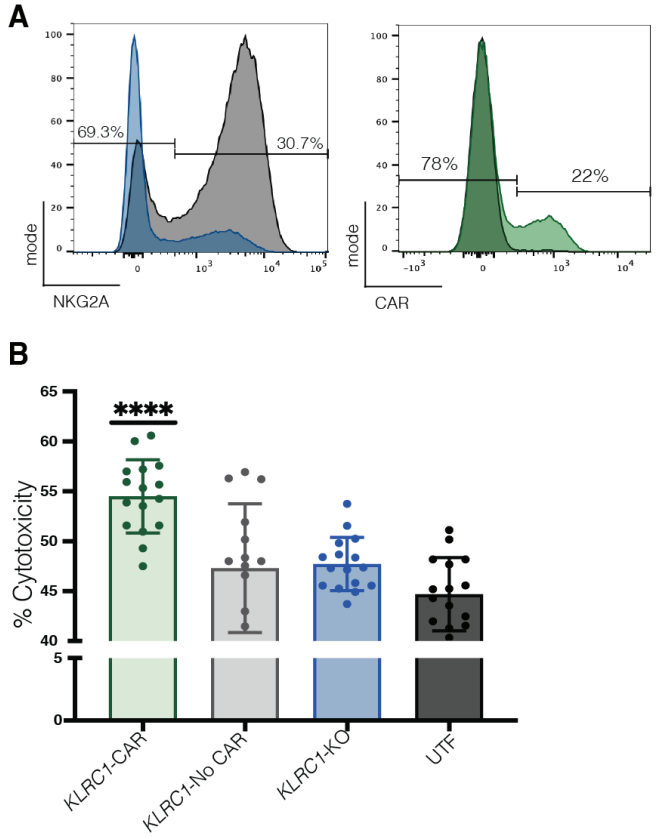
829. Virus-Free CRISPR Knock-In of a Chimeric Antigen Receptor into *KLRC1* Generates Potent Target-Specific Natural Killer Cells

Keerthana Shankar[1,2], Isabella Zingler-Hoslet[1], Lei Shi[3,4], Varun Katta[5], Brittany Russell[1], Shengdar Q. Tsai[5], Christian Capitini[3,4], Krishanu Saha[1,2,4]

[1]Department of Biomedical Engineering, University of Wisconsin-Madison, Madison, WI,[2]Wisconsin Institute for Discovery, University of Wisconsin-Madison, Madison, WI,[3]Department of Pediatrics, University of Wisconsin-Madison, Madison, WI,[4]Carbone Cancer Center, University of Wisconsin School of Medicine and Public Health, Madison, WI,[5]Department of Hematology, St. Jude Children's Research Hospital, Memphis, TN

Natural killer (NK) cells are strong candidates for "off-the-shelf" immunotherapy products due to their high cytotoxicity profile. However, their success against solid tumors remains suboptimal when compared to hematological malignancies due to the upregulation of NK-inhibitory ligands, such as HLA-E, within the tumor microenvironment. Moreover, the manufacturing of NK cell therapies largely relies on viral vectors, risking insertional mutagenesis. Here, we describe a robust gene editing platform utilizing CRISPR-Cas9 to disrupt the *KLRC1* gene, encoding for the HLA-E binding NKG2A inhibitory receptor, and virus-free insertion of large transgenes (>2.7

kb), including a GD2-targeting chimeric antigen receptor (CAR) within human primary NK cells. The use of Cas9 ribonucleoprotein (RNP) complexes yields high protein level knock-out of the *KLRC1* gene with 70% efficiency and specific insertion of the CAR transgene as high as 22% (*Figure A*). *KLRC1*-CAR NK cells display robust and specific cytotoxicity and cytokine release against GD2$^+$ human melanoma cells (*Figure B*). Moreover, deep sequencing analysis of the *KLRC1*-CAR NK cells shows minimal off-target activity, highlighting the specificity of our edit. Using a completely non-viral workflow, this work provides compelling evidence for the use of the CRISPR-Cas9 system to manufacture potent and effective allogeneic NK cell products from routine peripheral blood donation and collection.



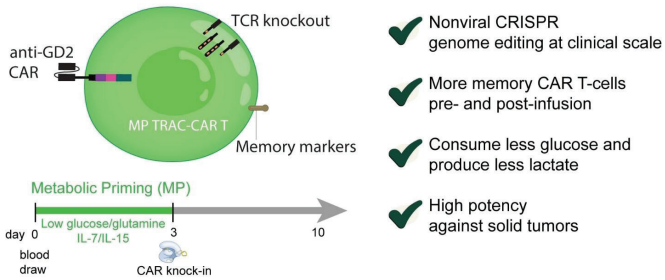


Figure. CRISPR-engineered anti-GD2 CAR NK cells show improved potency against melanoma target cells. **(A)** Representative histogram plots showing knockout of NKG2A and knock-in of CAR one week after nucleofection. X-axis describes protein expression levels. Y-axis describes frequency after normalization to the mode. UTF samples are shown as black histograms in both plots. The percent shown for each gate represents protein levels in the *KLRC1*-KO (left) and *KLRC1*-CAR (right) samples. **(B)** Following FACS, NK cells were co-cultured with M21 melanoma cells at a 5:1 E:T ratio for 24 hours, after which secreted LDH was measured with the CyQuant LDH Cytotoxicity Assay kit. Data is shown as the mean ± SD across three donors, with 5-6 replicates per donor (n = 3).

830. Metabolic Priming of GD2 *TRAC*-CAR T Cells During Manufacturing Promotes Memory Phenotypes While Enhancing Persistence

Dan Cappabianca[1], Dan L. Pham[1], Matthew H. Forsberg[1], Anna Tommasi[1], Tony Lauer[2], Jolanta Vidugiriene[2], Brooke Hrdlicka[1], Alexandria McHale[1], Quaovi Sodji[1], Melissa C. Skala[3], Christian M. Capitini[1], Krishanu Saha[1]

[1]University of Wisconsin-Madison, Madison, WI,[2]Promega Corporation, Fitchburg, WI,[3]Morgridge Institute for Research, Madison, WI

Manufacturing Chimeric Antigen Receptor (CAR) T-cell therapies is complex, with a limited understanding of how media composition impacts T cell phenotypes. CRISPR/Cas9 ribonucleoproteins can precisely insert a CAR sequence while disrupting the endogenous T cell receptor alpha constant (*TRAC*) gene, resulting in *TRAC*-CAR T cells with an enriched stem cell memory T-cell population, a process that could be further optimized through modifications to the media composition. In this study we generated anti-GD2 *TRAC*-CAR T cells using "metabolic priming" (MP), where the cells were activated in glucose/glutamine low media and then expanded in glucose/glutamine high media. T cell products were evaluated using spectral flow cytometry, metabolic assays, cytokine production, cytotoxicity assays *in vitro* and potency against human GD2+ xenograft neuroblastoma models *in vivo*. Compared to standard *TRAC*-CAR T cells, MP *TRAC*-CAR T cells showed less glycolysis, higher CCR7/CD62L expression, more bound NAD(P)H activity and reduced IFN-γ, IL-2, IP-10, IL-1β, IL-17, and TGFβ production at the end of manufacturing *ex vivo*, with increased central memory CAR T cells and better persistence observed *in vivo*. Metabolic priming with media during CAR T cell biomanufacturing can minimize glycolysis and enrich memory phenotypes *ex vivo*, which could lead to better responses against solid tumors *in vivo*.

831. Exploiting the Phosphocreatine Energy Pathway to Enhance CAR T Memory Differentiation and Cytolytic Activity

Zhiyang Gan, Alexander A. Shestov, Saba Ghassemi, Roddy S. O'Connor

Center for Cellular Immunotherapies, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

What fuels CAR T cell serial killing is unknown. T cells rely on their spare respiratory capacity (SRC), a finite energy reserve, to support persistence following adoptive transfer. The SRC depletes following antigen stimulation in vivo, rendering it obsolete. Given this inevitable decline, we explored alternate energy systems to support CAR T cell

growth and differentiation. Competition for nutrients provides a barrier to adoptive immunotherapies, a feature exacerbated in solid tumors. We developed a "crossover" model to exploit the most efficient fuel source that can be stored prior to adoptive transfer. As the phosphocreatine (PCr) energy system supports energy production independent of oxygen, we hypothesized that "loading" CAR T cells during their ex-vivo expansion will enhance their functional competence in hostile conditions. Using a gain-of-function approach, overexpression (OE) of key creatine kinases (CK), CKM and CKMT2, led to enhanced cytotoxicity, reduced terminal differentiation, and exhaustion-resistant phenotype following repeat antigen encounter. Using metabolic analysis and electron microscopy, we showed that CK-OE CAR T cells preserve intact mitochondrial structure and higher levels of citrate as well ATP, suggesting our model where the PCr/Creatine energy system can overcome energy deficits and sustain mitochondrial function in tumor environments. We are currently exploring the impact of creatine/CK on CAR T cell function in xenograft models of leukemia and neuroblastoma. Our findings reveal a novel conditioning strategy and genetic approach to overcome CAR T cell metabolic dysfunction in hostile tumor environments.

832. Engineering a Bispecific Claudin 18.2/TGF-β CAR to Target Claudin 18.2 Positive Tumors and Overcome the Tumor Microenvironment

Jessica Reyes, Ethan BenDavid, Orit Foord, Ximin Chen, Michael Weist, Giulia Parisi, Jiajia Cui, Melanie L. Munguia

Research, ImmPACT Bio, West Hills, CA

Gastric cancer (GC) is among the top three deadliest cancers and has the fifth-highest global cancer incidence (1). Claudin 18.2 (CLDN 18.2) is an isoform of the tight junction protein Claudin 18 and is emerging as a promising target for CAR T cell therapies against GC. Limited expression of CLDN 18.2 is observed in normal tissues but is increased during malignant transformation as seen in GC, making this molecule an attractive target. (2). Recently, a clinical trial used CLDN 18.2 CAR T cells to treat patients with GC and pancreatic cancer. For the GC population, the overall response rate and disease control rate was 57.1% and 75.0%, respectively (3). The median progression-free survival rate was 4.2 months and 39% of patients required repeat infusions of the CAR T product, which speaks to the potential need to enhance T cell persistence and function in solid tumors. Studies have shown that GC patients have elevated levels of transforming growth factor-β (TGF-β) in their gastric mucosa (4). This highly pleiotropic cytokine has profound immunosuppressive effects that limit T cell persistence while also promoting tumor survival, immune evasion, and tumor extravasation into the TME. Moreover, TGF-β induces the differentiation of CD4+ T cells into Treg cells that in turn attenuate immune activation and production of proinflammatory mediators (5). Therefore, we intend to convert the TGF-β anti-inflammatory signal into a pro-inflammatory signal to ameliorate its inhibitory effects by enhancing T-cell function, proliferation, and infiltration of CAR T cells in gastric tumors. We designed a bispecific CAR to target both CLDN 18.2 and TGF-β. The CLDN 18.2/TGF-β bispecific CAR T cells were co-cultured with either CLDN 18.2 positive gastric cancer cell lines or with different isoforms of TGF-β. When co-cultured with CLDN 18.2 cell lines, both the single input (CLDN 18.2 only) and bispecific CAR T cells, showed high cytotoxicity with similar levels of T cell activation, evaluated by IFN-ɣ secretion. In addition, the bispecific CAR T cells were challenged with a CLDN 18.2 positive cell line, that endogenously secretes TGF-β, in a repeat antigen challenge (RAC) assay. The bispecific CAR T cells demonstrated reduced exhaustion markers and fewer Treg cells compared to the single input CAR T cells and the benchmark CLDN 18.2 CAR. In summary, we show that the CLDN 18.2/TGF-β bispecific CAR converts the immunosuppressive TGF-β signal into an activation signal, thereby enhancing T cell fitness, reducing Treg cell conversion, and decreasing phenotypic exhaustion.

833. Transforming Tumor Research: Engineering MHCs as Versatile Reagents

Sherry Weems

KACTUS, Waltham, MA

When dealing with solid tumors lacking specific biomarkers, the effectiveness of adoptive T cell therapy using CAR-T treatments is limited. The absence of dependable, multifaceted MHC reagents has been a hindrance in the research and development of treatments for solid tumors. To tackle this challenge, we have engineered MHC molecules in several formats with diverse applications. Our chimeric MHC format can be used for MHC immunization, leading to the discovery of TCR-like monoclonal antibodies that target peptides derived from solid tumor antigens. Our peptide-ready MHC format enables researchers to load peptides conveniently and with ease, whereas the single-chain MHC format can be used for enhanced sensitivity. Our VLP MHC format can be a viable alternative to the conventional tetrameric MHC format, potentially with increased avidity. These improved MHC molecules have the potential to facilitate solid tumor research and development. Form 1: Mammalian-Expressed SCT (Single-Chain Trimer) MHC for High sensitivity. The SCT MHCs incorporate linkers strategically, maintaining MHC integrity and antigen presentation. The SCT design, on the other hand, has been facing scrutiny over worries that its linker might cause interference with TCR. Our structural investigations of over 200 TCR-peptide MHC complexes, however, reveal that SCT MHC's linkers are positioned apart from crucial TCR, peptide, and MHC interfaces (Figure 1). Furthermore, we use mammalian cells to express our SCT MHC rather than the common way of producing it from E. coli expression and then refolding it from the inclusion body. Thus, our SCT MHCs offer improved stability and sensitivity compared to conventional MHC complexes with separate chains, making the SCT design a promising advancement for immune research. Form 2: Chimeric MHCs for Reduced Off-Targets Humoral immune responses to MHC-I seldom induce T-cell receptor mimic (TCRm) antibodies. Furthermore, many antibodies are thought to detect the α3 domain of MHC-I and the β2 microglobulin (β2m), which are not directly involved in delivering the target peptide. Substituting the MHC-I α3 and β2m domains with their murine counterparts preserved the MHC's antigen specificity for T-cells and supplied an acceptable antigen for TCRm antibody recognition. Here, we engineered our own chimeric human-murine MHCs designed to be expressed in mammalian systems to retain their innate conformation and activity (Figure 2). This should increase the likelihood of generating peptide-specific antibodies while decreasing the frequency of non- specific antibodies and making screening less

labor-intensive. Form 3: prMHC (Peptide-Ready MHC) for Rapid Neoantigen Loading Jurkat cell Jurkat cell with 1G4 TCR Vendor M: PE-labeled MHC tetramer (HLA*01:01) pre-loaded with NY-ESO-1 peptide Human APC-equivalent prMHC tetramer (HLA- A*02:01), His Tag mixed with NY-ESO-1 peptide The Peptide-Ready MHCs (prMHC) offer unparalleled ease and convenience for scientists. By providing MHC molecules without pre-loaded peptides, scientists gain the flexibility to select and load any peptide of their choice, tailored precisely to their experimental needs. This ready-to-be-load peptide feature not only saves valuable time spent on peptide-MHC complex preparation (Figure 3), but also offers the highest level of flexibility and experimental control.

834. Nonclinical Development of T-Plex Component TSC-204-A0101: A Natural TCR-T Cell Therapy for the Treatment of MAGE-A1- and HLA-A*01:01-Positive Cancers

Shazad A. Khokhar, Shubhangi Kamalia, Daniel C. Pollacksmith, Jenny Tadros, Sveta Padmanabhan, Drashti Shah, Amanda Kordosky, Maytal Bowman, Tary Traore, Victor Ospina, Alok Das Mahapatra, Sanket Revadkar, Kimberly M. Cirelli, Vivin Karthik, Kenneth L. Jahan Jahan, Nicolas Gaspar, Livio Dukaj, Jin He, Ryan E. Kritzer, Alexander Cristafaro, Chandan K. Pavuluri, Elisaveta Todorova, Tyler M. Sinacola, Savannah G. Szemethy, Kyra N. Sur, Vandana Keskar, Carolyn Hardy, Hsin-Ho Huang, Zhonghua Zhu, Sarah C. Potter, Kenneth J. Olivier, Nancy Nabilsi, Antoine J. Boudot, Sonal Jangalwe, Ribhu Nayar

Tscan Therapeutics, Inc., Waltham, MA

Background: T-Plex is an autologous TCR-T cell therapy product for the potential treatment of solid tumors comprising customized combinations of two to three TCR-T cell components that recognize different tumor antigens presented on specific HLA class I molecules. T-Plex cell therapy products are engineered using a transposon-based vector encoding the therapeutic TCR, CD8α and CD8β co-receptors, a CD34 epitope tag, a dominant-negative TGFβRII (DN-TGFβRII), and a mutated form of dihydrofolate reductase (DHFRdm). TSC-204-A0101 is intended for the treatment of MAGE-A1- and HLA-A*01:01-positive cancers. The TCR-T cells recognize the cancer-testis antigen MAGE-A1, which is highly expressed in solid tumors but is virtually absent in healthy tissues except testis. **Methods:** The TSC-204-A0101 TCR is a naturally occurring TCR discovered using TScan's proprietary ReceptorScan platform. TSC-204-A0101 TCR-T cells engineered using a process representative workflow for the planned manufacturing process were used to investigate the *in vitro* pharmacology and toxicology of TSC-204-A0101. TSC-204-A0101 was evaluated for avidity and target-dependent cytotoxicity, proliferation, and cytokine secretion *in vitro* as well as for anti-tumor efficacy *in vivo*. The contribution of DN-TGFβRII was assessed by measuring resistance to TGFβ-mediated induction of pSMAD2 of TCR-T cells. Further, TSC-204-A0101 was assessed for risk of alloreactivity and off-target recognition using TScan's SafetyScan screen. Furthermore, to assess the risk of off-target/off-tumor activity, TSC-204-A0101 TCR-T cells were tested for their reactivity to an extensive panel of 53 healthy human primary cells, including those expressing high levels of the putative off-targets of TSC-204-A0101. Finally, to demonstrate the benefit of combining individual TCR-T cell components as part of the T-Plex product for treatment of heterogenous solid tumors, target cancer cell populations were produced to simulate target and/or HLA loss. **Results:** TSC-204-A0101 displayed high avidity for the cognate peptide and target-dependent secretion of proinflammatory cytokines, cytotoxicity, and proliferation of both engineered CD4+ and CD8+ T cells and successfully controlled the growth of HLA-A*01:01+ MAGE-A1+ tumors in mice. TGFβ-mediated pSMAD2 induction was strongly decreased in TSC-204-A0101 TCR-T cells demonstrating the resistance of TCR-T cells to immune-suppressive effects of TGFβ. Further, TSC-204-A0101 displayed no alloreactivity to the 110 most common class I HLAs in the US population. Although putative off-targets were identified in the SafetyScan screen, TSC-204-A0101 showed no reactivity to normal primary cells. Lastly, when facing a target cell population simulating heterogeneous target expression, TSC-204-A0101 combined with a second TCR-T cell component in a defined T-Plex product led to the efficient killing of both cell types. **Conclusions:** TSC-204-A0101 exhibits high specificity and potency against MAGE-A1- and HLA-A*01:01-positive tumor cells with no projected allo- or off-tumor reactivity. Based on these results, an IND for the clinical development of TSC-204-A0101 has been filed with plans in place to incorporate TSC-204-A0101 in TScan's ongoing T-Plex clinical trial master protocol.

835. Non-Clinical Development of T-Plex Component TSC-201-B0702: A TCR-T Cell Therapy Directed to a Novel HLA-B*07:02 Restricted MAGE-C2 Epitope for the Treatment of Solid Tumors

Hannah L. Bader, Amanda Kordosky, Sonal Jangalwe, Alok D. Mohapatra, Dalena Nguyen, Debanjan Goswamy, Maytal Bowman, Nivya Sharma, Victor Ospina, Shazad A. Khokhar, Shubhangi Kamalia, Sveta Padmanabhan, Drasthi Shah, Daniel Pollacksmith, Sanket Revadkar, Kimberly M. Cirelli, Kenneth Jahan, Livio Dukaj, Jin He, Ryan E. Kritzer, Alexander Cristofaro, Chandan Pavuluri, Zhonghua Zhu, Carolyn Hardy, Hsin-Ho Huang, Olivia Pryor, Elisaveta Todorova, Tyler M. Sinacola, Savannah G. Szemethy, Kyra N. Sur, Vandana Keskar, Andrew Ferretti, Ribhu Nayar, Antoine J. Boudot, Cagan Gurer

TScan Therapeutics, Waltham, MA

Introduction: T-Plex is an autologous TCR-T cell therapy product comprised of two to three TCR-T cell components for the potential treatment of solid tumors from TScan's ImmunoBank, a repository of therapeutic TCRs each recognizing a different antigen presented by an HLA class I molecule. By combining components from the ImmunoBank, a multiplexed product is customized to match the target and HLA expression pattern of a patient's tumor. Each component of T-Plex is engineered using a transposon-based vector encoding the therapeutic TCR, CD8α and CD8β co-receptors, a CD34 epitope tag, a dominant-negative TGFβRII (DN-TGFβRII), and a mutated form of dihydrofolate reductase (DHFRdm). TSC-

201-B0702 is a new component of the ImmunoBank designed to recognize an HLA-B*07:02 epitope derived from the cancer-testis antigen MAGE-C2, which is frequently overexpressed in solid tumors but is absent in healthy tissues except testis. **Methods:** A novel HLA-B*07:02-restricted T cell epitope of MAGE-C2 was discovered with TScan's proprietary TargetScan platform and TScan's ReceptorScan platform was used to identify a potent naturally occurring TCR recognizing this epitope. The MAGE-C2 specific TCR was then used to build TSC-201-B0702. TSC-201-B0702 TCR-T cells were engineered using a full-scale representative workflow for the planned clinical manufacturing process and were used to investigate the *in vitro* pharmacology and safety of TSC-201-B0702. The specificity of TSC-201-B0702 for the HLA-B*07:02 restricted MAGE-C2 epitope was tested, and target-dependent cytotoxicity, proliferation and cytokine secretion was evaluated *in vitro* and *in vivo*. Resistance to TGFβ—conferred by expression of DN-TGFβRII—was evaluated by assessing TGFβ-mediated induction of phospho-SMAD2, and resistance to suppression of IFN-γ secretion. Further, TScan's SafetyScan was used to investigate allo- and off-target reactivity. In addition, the reactivity of TSC-201-B0702 TCR-T cells to a panel of 54 healthy HLA-B*07:02-positive human primary and iPSC-derived cells isolated from tissues that are traditionally assessed in toxicology studies was evaluated. **Results:** TSC-201-B0702 TCR-T cells recognized their cognate MAGE-C2 peptide in a dose dependent manner and displayed potent target-dependent secretion of inflammatory cytokines, cytotoxicity, and proliferation of both engineered CD4+ and CD8+ T cells. Moreover, TSC-201-B0702 TCR-T cells displayed anti-tumor activity against A101D xenografts in mice. Target-dependent IFN-γ production was maintained in the presence of physiological levels of TGFβ, and TGFβ-mediated phospho-SMAD2 induction was strongly reduced. Further, TSC-201-B0702 displayed no alloreactivity to the 110 most common class I HLAs in the US population. Although two putative off-targets were identified in the SafetyScan screen, TSC-201-B0702 showed no off-tumor reactivity to normal primary or iPSC-derived cells. **Conclusions:** TSC-201-B0702 exhibits high specificity and potency against MAGE-C2-positive, HLA-B*07:02 tumor cells with no projected allo- or off-tumor reactivity. Based on these results, an IND for the clinical development of TSC-201-B0702 has been filed with the aim of incorporating TSC-201-B0702 in the ongoing T-Plex Phase 1 clinical trial master protocol.

836. THRIVE™ Non-Viral Targeted Transgene Knock-In Platform Generates Specific and Potent TCR T Cell Products for the Treatment of Solid Cancers

Santosh Narayan[1], Nathaniel Swanson[1], Allison Drain[1], Ken Gareau[1], Nicholas Rouillard[1], Jinsheng Liang[1], Hui-Wen Liu[1], Lauren Brown[1], Rebecca Lamothe[2], Philip D. Greenberg[3], Christopher A. Klebanoff[4], Ankit Gupta[1], Damien Hallet[1], Gary Shapiro[1], Kim Nguyen[1], Loic Vincent[1]

[1]Affini-T Therapeutics, Watertown, MA,[2]Metagenomi Inc., Emeryville, CA,[3]Program in Immunology and Translational Science and Therapeutics Division, Fred Hutchinson Cancer Research Center, Seattle, WA,[4]Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Selective and homogenous expression of oncogenic driver mutations such as $KRAS^{G12D}$ and $p53^{R175H}$ make them ideal targets for cancer therapies. Adoptive T cell therapies with engineered T cell receptors (TCRs) recognizing mutated driver proteins have led to durable responses in patients with solid tumors. Lentiviral vector (LVV)-based T cell manufacturing suffers from limited cargo size, heterogeneous transgene expression, high manufacturing cost and complexity, and the potential for oncogenesis due to random genomic insertions. To overcome these challenges, we have developed THRIVE™, a non-viral, gene-editing-based T cell manufacturing platform that achieves high rates of targeted transgene insertion and robust cell expansion, and yields potent TCR T cell therapies. Methods and Results: An efficient and specific novel type V CRISPR-Cas system was used for targeted transgene knock-in (KI) at the *TRAC* locus via homology directed repair (HDR) in primary human $CD4^+$ and $CD8^+$ T cells. The optimized HDR template and engineering process achieved efficient KI and expression of multi-cistronic constructs up to 7 kb in size that included: 1) a TCR specific for an oncogenic driver mutation, 2) a CD8αβ coreceptor allowing for effective $CD4^+$ T cell target recognition and stimulation, and 3) T cell function-enhancing synthetic fusion proteins. Unlike LVV-mediated random insertions, genotypic analysis of THRIVE-produced T cells showed targeted transgene insertion at the *TRAC* locus that also disrupted the endogenous TCRα chain, resulting in increased surface expression of the transgenic oncogene-specific TCR and enhanced antigen sensitivity. Thus, THRIVE gene-edited T cells demonstrated improved efficacy as compared to LVV-engineered T cells both *in vitro* during repeat tumor cell challenges and *in vivo* after single administration in mice harboring tumor xenografts. Gene-editing safety evaluation demonstrated specificity with no off-target activity in high sensitivity (~0.1%) NGS-based analyses or any gene-editing-related chromosomal rearrangements. When evaluated at expected clinical scale, the THRIVE platform yielded up to 50% transgene-positive T cells that showed a favorable T stem cell memory/ T central memory phenotype and >50-fold expansion achieving anticipated dose levels for clinical trials. Conclusion: The non-viral targeted knock-in platform, THRIVE, enables safe and cost-effective T cell engineering with high efficiency. THRIVE-engineered oncogene driver-specific TCR T cells demonstrated superior cytotoxicity against tumor cells relative to LVV-engineered cells both i*n vitro* and *in vivo*. These data support the clinical readiness and advancement of the THRIVE platform for engineering TCR T cell therapy for the treatment of advanced solid malignancies.

837. Generation of Allogeneic CAR T-Cells Using an Easy, Safe, and Effective Non-Gene Editing Technology

Matteo Rossi, Fanny Huberty, Jérôme Marijsse, Thuy Nguyen, Céline Jaques-Hespel, Eytan Breman

Celyad Oncology, Mont-Saint-Guibert, Belgium

Chimeric antigen receptor (CAR) T-cells have revolutionized the treatment of hematological malignancies. However, to date only approximately 10% of eligible patients can receive this treatment, due to the several drawbacks of autologous CAR T-cell production (difficulty to obtain high quality starting material from patients, limited manufacturing capacity, complex logistics, long vein-to-vein time, high costs). Allogeneic, "off-the-shelf" CAR T-cells could help

circumvent these issues, but their successful clinical application relies on the ability to manage graft-versus-host disease (GvHD) and host-versus-graft (HvG) reaction. To address these issues, a variety of gene-editing strategies have been attempted to ablate the expression of the molecules primarily involved in GvHD (T-cell receptor, TCR) and HvG (Human Leukocyte Antigen, HLA, class-I and class-II) on the CAR T-cell surface. However, these strategies are burdened by the technical complexity of effectively targeting multiple genes simultaneously and by the potential risk for introducing harmful genomic aberrations. As an alternative, we successfully applied our proprietary, clinically validated, non-gene editing technology to the generation of allogeneic CAR T-cells, by targeting genes essential in GvHD, HvG and T-cell apoptosis. Our approach is based on a microRNA (miRNA)-derived short hairpin RNA (shRNA) platform, which does not require the direct alteration of the genome, thus ensuring a high safety profile. Moreover, our small miRNA expression cassette, able to target up to four different genes simultaneously, can be deployed in a single construct with the other components required for CAR T-cell generation, easing the technical aspects of allogeneic CAR T-cell manufacturing. Most importantly, our technology allows for the fine-tuned modulation of gene expression. This is especially relevant for targets such as HLA class-I, whose complete ablation triggers recognition by NK cells, calling for further interventions (e.g., HLA-E overexpression). Thanks to the tunability of gene expression achievable with our platform, we obtained functionally relevant downregulation of HLA class-I to avoid recognition by the recipient's T-cells, ensuring at the same time sufficient expression to let CAR T-cells escape NK recognition. Allogeneic CAR T-cells generated through our miRNA-based shRNA technology displayed protection against GvHD, HvG and apoptosis in specifically designed *in vitro* assays, leading to significantly improved CAR T-cell survival while maintaining comparable efficiency to their non-engineered counterparts. Overall, we provide *in vitro* proof-of-concept that our miRNA-based shRNA technology can improve CAR T-cell viability by allowing evasion from GvHD and HvG and target-cell induced apoptosis. This in turn demonstrates the feasibility of the generation of allogeneic CAR T-cells via a non-gene editing approach, making our technology stand out as an easy, safe, and effective strategy for the generation of allogeneic CAR T-cells.

838. Two Distinct Activation Methods Yield Clinical-Scale Expansion of Peripheral Blood Derived γδT Cells

Chengkang Zhang, Amy Burkall, Elizabeth Kagan, Karen Roderick, Erin Brooks, Kenneth Low, Alexis Bossie

Lonza Walkersville Inc, Rockville, MD

Gamma delta (γδ) T cells have the inherent ability to infiltrate solid tumors and can directly recognize and kill transformed cells independently of HLA-antigen presentation. Moreover, γδ T cells do not cause graft-versus-host disease (GVHD) and hence, provide a promising platform for the development of cell therapies targeting solid tumors. However, due to the low prevalence of γδ T cells in peripheral blood, it remains a challenge to generate sufficient numbers of γδ T cells *ex vivo* to produce a clinical dose. In this study, we demonstrate that billions of γδ T cells can be generated from peripheral blood in the 2L rocking motion platform with two distinct activation methods, by using TheraPEAK® T-VIVO® Medium - a chemically defined, non-animal origin, serum-free medium. In the first method which uses 6μM zoledronic acid as the activating agent, more than 1e9 Vδ2 T cells are produced within 14 days starting from 500e6 peripheral blood mononuclear cells (PBMCs). Furthermore, using a process that specifically depletes αβ T cells from PBMCs prior to anti-CD3 and anti-CD28 co-stimulation, billions of γδ T cells - including both Vδ1 and Vδ2 T cell subsets - are produced from the same PBMCs source. The γδ T cells expanded using either activation method exhibit innate cytotoxicity towards the K562 cell line and produce cytokines including IFN-γ and TNF-α *in vitro*. Both activation methods and expansion protocols may be utilized to generate sufficient numbers of γδ T cells to support clinical applications.

839. Single-Cell, Pooled CRISPR Screening Reveals T Cell Intrinsic Regulators of Exhaustion in the Context of Chronic Antigen Stimulation

Glenn G. Wozniak[1], Sahil Joshi[1], Kristina Vucci[1], Angela Boroughs[1], Andrew Cardozo[1], Ashley Cass[1], Bob Chen[2], Julie Chow[1], David DeTomaso[1], Celine Eidenschenk[2], Jake Freimer[2], Brendan Galvin[1], Katie Geiger-Schuller[2], Levi Gray-Rupp[1], Jan-Christian Huetter[2], Jacob Levine[2], Allyson Merrell[1], Catherine Oh[1], Soyoung Oh[2], Sascha Rutz[2], Jill Schartner[2], Mandi Simon[1], Pratiksha Thakore[2], Li Wang[1], Emily Wheeler[2], Grace Zheng[1], Orit Rozenblatt-Rosen[2], W. Nicholas Haining[1], Ira Mellman[2]

[1]Arsenal Biosciences Inc., South San Francisco, CA,[2]Genentech Inc., South San Francisco, CA

T cell therapies for solid tumors are limited by T cell exhaustion resulting from chronic antigen stimulation, and by an immunosuppressive tumor microenvironment. Engineering chimeric antigen receptor (CAR) T cells that are able to resist exhaustion represents a promising strategy in the development of potent immunotherapies. To this end, we sought to identify T cell intrinsic genetic perturbations that can prevent exhaustion, a state not only characterized by altered cell function but also by distinct transcriptional and epigenetic alterations. In order to screen many perturbations at once for their effect on exhaustion, we established a pooled, in vitro, CRISPR/Cas9-based screening approach paired with multimodal, single cell readouts in the context of chronic antigen stimulation. To achieve this we developed a lentiviral delivery method to generate pools of genetically engineered CAR T cells, wherein each cell carries a CRISPRko, CRISPRi or CRISPRa perturbation to achieve up- or downregulation of a single target gene. Subjecting these T cell pools to chronic antigen stimulation using a cell-based repetitive stimulation assay (RSA) recapitulated key hallmarks of T cell exhaustion, including loss of proliferation and effector function. Multimodal, single cell characterization of engineered T cells throughout the assay revealed not only acquisition of transcriptional and epigenetic signatures of exhaustion, but also a diverse landscape of perturbation-dependent T cell states. Moreover, we observed clustering of perturbed genes with similar biological functions based on similar gene expression changes allowing for prioritization of genetic perturbations to be tested in next-generation CAR T cells.

These results demonstrate the utility of pooled CRISPR screening to measure complex phenotypes and to direct the development of advanced CAR T cell therapies.

840. Sugar-Conjugated Poly(Beta-Amino Ester) Nanoparticles for Targeted mRNA Delivery to Immune Cells *In Vivo*

Tiarra R. Warren, Stephany Yi Tzeng, Jordan J. Green
Johns Hopkins University, Baltimore, MD

Introduction. Intracellular mRNA delivery systems have been remarkable in the context of vaccination, spurring the exploration and development of a wide array of carriers. There is an opportunity for these carriers to be designed to exhibit unique tropisms tailored for various therapeutic targets. Poly(beta-amino ester)s (PBAE) are cationic, hydrolytically degradable polymers that can deliver various nucleic acid cargos and reach several organs and tissues. However, there is a need for further enhancement of delivery efficiency and specificity following systemic injection. This study investigates the utilization of sugar-targeting ligands to enhance the precision of mRNA/PBAE nanoparticles towards immune cells. *Methods*. PBAEs were synthesized using Michael addition reactions, with the structure optimized for mRNA delivery. Nanoparticles (NPs) were formed by mixing polymer, mRNA, and sugar conjugates in buffer and allowing self-assembly to occur. For *in vivo* transfection studies, Cre mRNA NPs were injected into Ai9 mice intravenously (loxP-flanked STOP cassette removal led to tdTomato expression), sacrificed 3 days post-injection and organs were collected. For uptake studies, Cy3-labeled mRNA NPs were injected into C57BL/6 mice intravenously and sacrificed 2 hours post-injection. The tissues were processed into single cell suspensions and prepared for flow cytometry. Staining included markers for neutrophils, dendritic cells, Kupffer cells, M1 monocytes and macrophages. Fluorescence of Cy3 indicated particle uptake and expression of tdTomato indicated successful particle transfection via flow cytometry. *Results*. Within liver samples, NPs without sugar targeting displayed high cellular internalization into M1 monocytes and macrophages (20%) and Kupffer cells (40%), a liver-specific macrophage population (Fig. 1A). These populations also had positive transfection of ~10% and ~5%, respectively. Sugar-targeted nanoparticles (Fig. 1B), dramatically reduced total NP uptake in the liver, including especially by Kupffer cells to a measured value of Cy3 uptake of ~2%. Positive transfection of neutrophils, Kupffer cells, monocytes and macrophages was observed in the range of 3-7%. Interestingly, the results indicate that the efficiency of uptake leading to successful transfection (instead of NP degradation) improved with the sugar-mediated uptake. The results also indicate that immune cells that only internalized a small amount of Cy3-labeled NPs (such that the fluorescence signal did not shift significantly by FACS), nonetheless were able to lead to successful Cre-mediated recombination (which has a stronger fluorescence signal). Cellular uptake and transfection of other organs with these particles (and analogs) is also currently being investigated and will be further discussed. *Conclusion*. The inclusion of sugar-conjugated to PBAE/mRNA nanoparticles reduces uptake by Kupffer cells in the liver and increases the efficiency of transfection in immune cells post cellular uptake, including in monocyte and macrophage populations in the liver. These sugar-conjugated PBAE/mRNA particles hold promise as a targeted platform for effective gene delivery, specifically designed to target monocytes and macrophages.

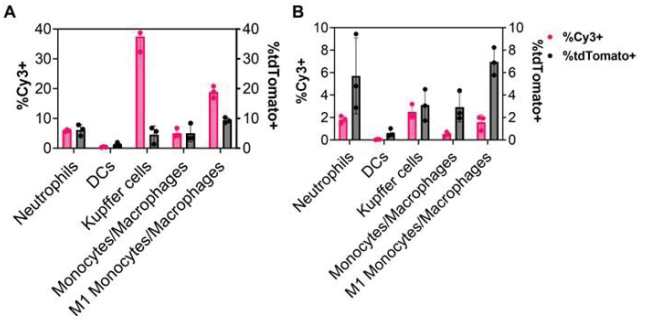

Figure. 1 *In vivo* biodistribution and transfection in the liver by PBAE mRNA nanoparticles following intravenous administration. (A) NPs without sugar conjugation. (B) NPs with sugar conjugation.

Wednesday Posters: Other Cellular and Regenerative Therapies

841. The Role of ZEB1 in Neural Stem Cells; Powerful Strategy for Stem Cell Therapy in Multiple Sclerosis

Elham Poonaki[1,2], Ulf Dietrich Kahlert[3], Ali Gorji[2], Sven G. Meuth[1]
[1]Department of Neurology, Heinrich Heine University, Düsseldorf, Germany,[2]Department of Neurosurgery, University of Münster, Münster, Germany,[3]Molecular and Experimental Surgery, Faculty of Medicine, Magdeburg, Germany

Stem cell therapy is one of the main remedies for curing some chronic neurological disorders such as multiple sclerosis (MS). However, how to overcome the failure of neural cell transplantation following treatment remains controversial. The key role of Zinc Finger E-Box Binding Homeobox 1 (ZEB1) has a well-established role in both inflammatory signaling and epithelial-to-mesenchymal transition (EMT) regulation. Since neuroinflammation is one of the main hypotheses for the failure of stem cell transplantation in MS, this work studied the inflammatory response of neural stem cells (NSCs) by down-regulating the ZEB1 gene. First, we looked at ZEB1 expression in neural stem cells (NSCs) isolated from the subventricular zone (SVZ) of rat brains and differentiated into mature myelinating oligodendrocytes (OLs) using our standard methodology. The ZEB1 gene was then downregulated in neuronal stem cells, and its effect on migration and neuroinflammatory cytokines like IL6, IL1β, TNFα, and IL17 was studied using immunocytochemistry (ICC), qPCR, wound healing, ROS, and colony formation in a simulated inflammatory condition with LPS soup derived from brain microglia. The results demonstrated that silencing the *ZEB1* gene significantly affected the expression of neuroinflammatory cytokines, colony formation, and migration in neuronal stem cells. In conclusion, more research is needed to fully understand the role of ZEB1, even though targeting it may be useful for localizing neuronal stem cells.

842. Preclinical Characterization and Emerging Clinical Trial Results for NRTX-1001 - A Human Pluripotent Stem Cell-Derived Inhibitory Interneuron Cell Therapy for Drug-Resistant Chronic Focal Epilepsy

Marina Bershteyn, Yves Maury, Luis Fuenteabla, Robin Zhou, Steven Havlicek Havlicek, Sonja Kriks, Seonok Lee, Geetha Subramanyam, Meliz Sezan, Mansi Parekh, Eric Sevilla, Alexandra Vogel, Philip Hampel, Brianna Feld, Rose Larios, Ji-Hye Jung, Tia Kowal, Shrei Madrid, Alessandro Bulfone, John Hixson, Gautam Banik, Catherine Priest, David Blum, Cory R. Nicholas

Neurona Therapeutics, South San Francisco, CA

Epilepsy is one of the most common central nervous system disorders, characterized by hyperactive neuronal networks that precipitate and propagate seizures. Pallial inhibitory GABAergic interneurons regulate excitatory neural activity and, when lost or dysfunctional, can lead to epilepsy. Anti-seizure drugs (ASDs) largely dampen overexcitation and decrease seizures, but can cause adverse effects due to systemic administration. Moreover, one-third of individuals with epilepsy have drug-resistant seizures that are not ameliorated with ASDs. For some people with focal epilepsy, surgical resection or laser ablation of a seizure focus can be an effective option; however, these procedures are tissue-destructive, risk permanent cognitive deficits, and are not indicated for all. Cell therapy represents an alternative therapeutic strategy to administer inhibitory interneurons that secrete GABA to the seizure focus to potentially suppress chronic seizures. NRTX-1001 is an investigational cellular therapeutic candidate comprising GABAergic, post-mitotic interneurons of a specific pallial lineage derived from human pluripotent stem cells. Clinically compliant processes were developed to reliably manufacture and cryopreserve NRTX1001, with an assessment of cell identity, composition, neuronal migration, GABA secretion, sterility, and viability. Following transplantation into the rodent brain, human graft composition and neuronal subtype fate were investigated for up to 18 months using single nuclei RNA sequencing, demonstrating long-term persistence and stable composition of GABAergic pallial interneuron subtypes. A single intrahippocampal administration of NRTX-1001 into mice with chronic drug-resistant temporal lobe epilepsy (TLE) resulted in pronounced and dose-dependent suppression of focal seizures and reduction of hippocampal pathology. Approximately two-thirds of epileptic mice were stably seizure-free after receiving NRTX-1001. A phase I/II clinical trial (NCT05135091) is underway to evaluate NRTX-1001 safety and efficacy in people with drug-resistant TLE. The initial stage of the trial includes an open-label dose escalation in up to 10 subjects, and we will discuss the preliminary clinical data. The first two subjects are now past one year after receiving NRTX-1001, and have reported >95% seizure reduction from baseline, improved performance on select visuospatial neurocognitive memory tests, and an absence of any serious or severe adverse events to date. In summary, these preclinical and clinical data highlight the promise of human inhibitory interneuron cell therapy for the potential future treatment of chronic focal epilepsy.

843. The Preclinical and First-in-Human Study of iPSC-Derived Human Forebrain Neural Progenitor Cell Injection-hNPC01 in Treating Chronic Ischemic Stroke

Jing Fan[1,2], Anxin Wang[1,2], Fang Ren[1,2], Yinggang Yan[2], Shuning Zhang[1,2], Jasmine Wang[1]

[1]Hopstem Biotechnology, Houston, TX,[2]Hopstem Bioengineering Ltd. Co., Hangzhou, China

The hNPC01 injection, is an injection containing Human Forebrain Neural Progenitor Cells (hFNPCs) derived from induced Pluripotent Stem Cell (iPSC) and manufactured under GMP condition. This allogenic cell therapy product contains more than 95% hFNPCs and its progeny cells, and was able to differentiate further into functional cortical neurons and glia cells both *in vitro* and *in vivo*. In previous mechanism and preclinical studies, hNPC01 showed potential in promoting functional recovery of ischemic stroke rat and cynomolgus monkey models and forming neural circuitry *in vivo*. The preclinical safety study programs including tumorigenicity study in NOG mice up to 52 weeks indicated a good safety profile of hNPC01. A phase I open-lable dose-escalation clinical study of hNPC01 injection treating chronic ischemic stroke by intracerebral injection is approved by NMPA and currently undergoing. The current observation of first dose cohorts showed good safety and tolerance of hNPC01, as well as sign of motor function improvement in volunteer subjects with ischemic stroke onset 17 to 40 months prior to the enrollment. It is expected that the 12 month safety observation and exploration of evaluation tools will provide more valuable information for the future development of iPSC cell therapy for stroke or traumatic brain injury caused brain injury patients with chronic symptoms.

844. Transplantation of Gene-Edited Hematopoietic Stem Cells Rescues Neuronal and Cardiac Complications in a Mouse Model of Friedreich's Ataxia

Anusha Sivakumar[1], Alexis N. Corl[1], Angelyn B. Solis[1], Lilas Rony El-Hachem[1], Rishika Murthy[1], Rafael Andres Badell-Grau[2], Rita Wan[1], Eric Thai[1], Veenita Khare[3], Stephanie Cherqui[4]

[1]Department of Pediatrics, Division of Genetics, University of California, San Diego, La Jolla, CA,[2]UCSD, La Jolla, CA,[3]UCSD, San Diego, CA,[4]University of California, San Diego, La Jolla, CA

Friedreich's ataxia (FRDA) is a multi-systemic, autosomal recessive, neurodegenerative disorder caused by homozygous GAA repeat expansion mutation in intron 1 of frataxin gene (*FXN*). FRDA is characterized by ataxia, areflexia, sensory loss, muscle weakness, and cardiomyopathy. Symptoms typically begin between 5 to 15 years of age and patients will be in wheelchair within 10-15 years of onset. This intronic expansion reduces FXN expression, a mitochondrial protein required for its homeostasis. Currently, there is no effective treatment for FRDA. We previously showed complete rescue of the neurologic, muscular, and cardiac complications in the YG8R mouse model of FRDA with a single, systemic infusion of wild-type hematopoietic stem and progenitor cells (HSPCs). We showed that the rescue was mediated by FXN transfer from the engrafted HSPC-derived microglia/

macrophages to neurons/myocytes. We next developed an ex *vivo* CRISPR/Cas9 gene editing approach that excises GAA expansion in FRDA patients' $CD34^+$ HSPCs as a potential autologous transplantation therapy. We are now investigating the *in vivo* safety and efficacy of our CRISPR/Cas9 gene editing approach in YG8s$(GAA)_{>800}$ mice (YG8JR) carrying the human *FXN* (h*FXN*) with >800 GAA repeats. Two-month-old myeloablated YG8J mice were transplanted with either *ex vivo* gene edited $Sca1^+$ HSPCs (GAAed) or mock-edited HSPCs (Mock) and analyzed 6-7 months later. Despite limited gene editing efficiency in the cell product (mean 15.7%), we observed substantial amounts of gene edited HSPC-derived cells in the hematopoietic tissues: ~ 5.25% in bone marrow cells, ~ 8.3% editing in blood, 19% in spleen and 16.51% in thymus, and in the primary organs affected in FRDA such as heart (2.4%), spinal cord (1.1%), cerebellum (0.69%), and skeletal muscle (4.4%). Significantly increased FXN expression was observed in the affected organs that led to significant tissue preservation. In the brain, the density of cerebellar granular cell layer neurons, essential for motor coordination, were comparable to wildtype mice whereas the non-treated and mock transplanted YG8JR exhibited significant neuronal loss. Furthermore, non-treated and mock YG8JR mice exhibited significant cardiac defects such as hypertrophic cardiomyocytes, infiltration and proliferation of non-myocytic cells, ultrastructural myofibrillar and mitochondrial abnormalities. In contrast, these defects were mostly absent in the YG8JR mice treated with GAAed HSPCs. Taken together, these promising findings demonstrate that single infusion of *FXN* gene corrected HSPCs engraft in the bone marrow niche to become a reservoir of healthy cells that can engraft into all injured organs for their long-term preservation. This work will support the clinical translation of this approach for FRDA.

845. Hematopoietic Stem Cell Gene Therapy for Mucopolysaccharidosis Type IIIC

Rafael A. Badell-Grau, Kasra Pakravesh, Rola Chen, Eric Thai, Frankie Son, Kalvin Duong, Pauline Losay, Rushil Pithia, Anusha Sivakumar, Veenita Khare, Alexis N. Corl, Christine Tran, Jefferey Esko, Stephanie Cherqui

UCSD, La Jolla, CA

Mucopolysaccharidosis type IIIC (MPSIIIC) or Sanfilippo Syndrome type C is a severe neurodegenerative lysosomal storage disease (LSD) caused by loss-of-function of the lysosomal transmembrane protein Heparan-α-glucosamine N-acetyltransferase (HGSNAT). MPSIIIC has no available treatment and is characterised by accumulation of glycosaminoglycans (GAGs). This disease presents with developmental delay and neuronal cell loss leading to death from severe neurodegeneration. Our group has shown that transplantation of wildtype hematopoietic stem cells (HSPCs) rescue cystinosis, another LSD due to mutations in a transmembrane lysosomal protein. One of the mechanisms of rescue involved lysosomal cross-correction from HSPC-derived macrophages to the disease cells via tunnelling nanotubes. We believe that the same principles could be used to treat MPSIIIC.We generated a novel MPSIIIC mouse model by knocking-out exon 2 in *Hgsnat* and confirmed disease phenotypes such as GAG accumulation, enlarged liver, lysosomal expansion, neurological defects, increased inflammation, and presence of disease specific non-reducing end carbohydrates. We transplanted MPSIIIC mice with HSPCs isolated from WT GFP-transgenic mice or $Hgsnat^{-/-}$ mice as controls. WT-HSPC transplant improved neurological and gait defects, hepatomegaly, urine retention, as well as decreased inflammatory markers in the treated MPSIIIC mice. Nonetheless, whilst we see engraftment of HSPC-derived cells, tissue expression of *Hgsnat* was low and no significant reduction of total GAG storage was observed. These data suggest that endogenous *Hgsnat* is not well expressed in macrophages/microglia explaining the limited impact on GAG accumulation.Limited efficacy of WT-HPSCs has also been reported in MPSIIIA, which was overcome by using gene-modified HSPCs to overexpress *SGSH*. Therefore, we are developing an autologous transplantation of ex-vivo gene modified HSPCs. We have generated self-inactivated (SIN)-lentivirus vector containing human *HGSNAT* cDNA (NM_152419) and performed *in-vitro* testing. Following transduction of mice and patient cells lines, we observed increased *HGSNAT* expression, lysosomal localization, recovery of HGSNAT enzyme activity, decreased GAG storage, and decreased lysosomal accumulation. We also transplanted gene-modified HSPCs in MPSIIIC mice, and have confirmed engraftment of our treated mice at 2 months post-transplantation. This study represent the first step towards the clinical translation of an ex vivo gene therapy approach for MPSIIIC.

846. Intrauterine Cellular Therapy Using a Non-Human Primate (NHP) Model

Julie Yeo[1], Nuryanti Johana[1], Yi Wan Tan[1], Yiping Fan[1], Citra N. Mattar[2,3], Fritz Lai[4], Qingfeng Chen[4], Arijit Biswas[2,3], Mahesh Choolani[2,3], Simon Waddington[5], William Peranteau[6], Alan W. Flake[7], Els Verhoeyen[8], Jerry Chan[9]

[1]KKH Women's and Children's Hospital, Singapore, Singapore,[2]National University of Singapore, Singapore, Singapore,[3]National University Health System, Singapore, Singapore,[4]Institute of Molecular and Cell Biology, Singapore, Singapore,[5]University College London, London, United Kingdom,[6]The Children's Hospital of Philadelphia, Philadelphia, PA,[7]Childrens Hospital of Philadelphia, Philadelphia, PA,[8]INSERM/CIRI/EVIR, Lyon, France,[9]KK Women's and Children's Hospital / Duke NUS Medical School, Singapore, Singapore

In utero haematopoietic stem cell transplantation (IUHSCT) for the treatment of congenital hematological disorders has been proposed to be an ideal form of therapy. This is due to the immature immune system of the early gestation fetus that allows the development of donor-specific tolerance. Hopefully within the fetal environment, the haematopoietic stem cells (HSC) would be able to survive and proliferate. In this work, we have used a macaque model to transplant GFP-labelled maternal cells into the fetus in order to study the rate of engraftment and fate of the maternal cells. Maternal HSC were harvested from bone marrow aspirates, magnetically enriched for CD34+ cells, and labeled with eGFP using a simian immnodeficiency virus (20-70% GFP+). Transduced CD34+ cells were CD26 inhibited prior to intravenous injections at ~ $1x\ 10^8$ cells/ estimated fetal weight (kg) with a final 1-3% CD3+ in the inoculum into 0.4-0.5 gestation fetal macaques. Following transplant, fetal subjects (n=6) were delivered via cesarean section and hand-reared. Fetal tissue harvested at 12 weeks post-IUHSCT showed chimerism levels ranged from 0.05% to 3.31%. Whereas cord blood collected at birth was evaluated for presence of GFP cells by both qPCR and FACs, demonstrating levels to be very low

if not absent (<0.05%). Mixed lymphocyte reaction between treated offspring and same-donor (maternal) CD45 cells showed evidence of tolerance towards maternal cells. Postnatal same donor boosting of offspring with GFP labelled cells was performed after busulfan treatment. Chimerism in the blood and bone marrow was still low (<1%) after 20weeks post boost. NSG (Nod-Scid Gamma) mouse model was used to evaluate how long the GFP labelled cells were able to proliferate and continue to express GFP *in vivo.* GFP-labelled HSC were injected into irradiated newly born mice. Engraftment was assessed through regular blood sampling and labeling of NHP and mice blood cells by FACs analysis. Results show that NHP chimerism in the NSG blood was low <1% even after 14 weeks. Cells expressing GFP in blood circulation decreased at 14 weeks in some animals. NHP chimerism levels were higher in the bone marrow and spleen than peripheral blood at 14 weeks, although less than 1%. These tissues also have GFP expressing NHP cells in the tissues indicating that the GFP can still be expressed at 14 weeks post injection. Prenatal maternal donor IUHSCT with postnatal boosting has been shown to be efficacious in murine and canine models. However, we were unable to demonstrate that maternal donor cells were able to engraft in a fetal macaque model.

847. Rational Inclusion of Antimetabolites to ADC-Based Non-Genotoxic Conditioning Strategies for the Transplantation of Engineered Hematopoietic Stem Cells

Jennifer Okalova, Jordan S. Alexander, Gianna M. Branella, W. Hunter Baldwin, Chengyu Prince, Seema R. Patel, Andrew Fedanov, Shanmuganathan Chandrakasan, Christopher B. Doering, H. Trent Spencer

Department of Pediatrics, Aflac Cancer and Blood Disorders Center, Emory University, Atlanta, GA

Hematopoietic stem cell (HSC)-directed lentiviral (LV) gene therapy is a promising curative strategy for monogenic diseases. However, therapeutic application of genetically engineered HSCs is limited by potential infertility and genotoxicity associated with pre-transplant non-targeted conditioning, such as total body irradiation (TBI) or alkylating chemotherapies. Since conditioning is needed to create space in the bone marrow (BM) niche for transplanted HSCs, the development of non-genotoxic conditioning regimens is a high priority translational objective. Indeed, we pioneered the use of LV-engineered HSCs for the treatment of hemophilia A (HA) by incorporating a bioengineered high expression fVIII variant, termed ET3, which is currently under clinical investigation [ClinicalTrials.gov identifiers: NCT04418414 and NCT05265767]. To achieve targeted HSC killing, we and others tested an antibody-drug-conjugate (ADC) using anti-CD117 (c-kit) and saporin (SAP), which selectively depletes CD117-expressing HSCs and progenitor cells by ribosome inactivation. Even though ADC-based conditioning shows preclinical promise, robust engraftment of genetically engineered HSCs continues to be a clinical limitation. This study investigates the hypothesis that current non-genotoxic conditioning regimens with ADCs like CD117-SAP are not effective as single agents due to a lack of deep HSC/progenitor cell depletion. Herein, we found administration of CD117-SAP in HA mice induces residual HSC exit from a quiescence state and entry into a proliferative state, as determined by flow cytometric analysis of isolated murine HSCs using defined HSC markers coupled with Ki-67 and DAPI staining. Thus, to achieve sufficient HSC/progenitor clearance, we tested intermittent IV injections of the antimetabolites 5-fluorouracil (5-FU) and fludarabine (Flu) post-ADC treatment and confirmed augmented clearance by flow cytometry and colony-forming unit assays of BM harvested from conditioned HA mice. Although 200 mg/kg of either antimetabolite alone is well tolerated, addition of CD117-SAP did not affect the maximum tolerated dose (MTD) of Flu but lowered the MTD of 5-FU to 50 mg/kg. This suggests antimetabolites can display different degrees of synergy with CD117-SAP and, in turn, distinct toxicity profiles. Subsequent HSCTs with unmodified Sca-1+ HSCs isolated from either GFP or CD45.1 donor mice resulted in >80% engraftment in HA (CD45.2+) recipient mice pre-conditioned with both CD117-SAP and the antimetabolite. However, in the context of 5-FU, deeper depletion must be coupled with additional T-cell immunosuppression, e.g. anti-thymocyte globulin (ATG), to permit unmodified Sca-1+ HSC engraftment. Inconsistent outcomes with mouse-specific ATG reagents in the setting of our murine HSCTs with CD117-SAP led us to incorporate the immunoglobulin G-degrading enzyme of *Streptococcus pyogenes* (IdeS) to ensure cleavage of residual circulating ATG antibodies at the time of transplantation, which resulted in robust engraftment (>80%). Together, these studies show CD117-SAP and antimetabolites display synergistic clearance of proliferating progenitors, resulting in long-term engraftment of transplanted HSCs comparable to TBI. Ongoing studies explore transgene tolerance, durability, and immunogenicity of engrafted ET3-modified cells after HSC-directed LV gene therapy for HA. Therefore, antimetabolites such as 5-FU and Flu provide proof of concept for the repurposing of existing small molecule drugs in non-genotoxic conditioning platforms for HSCTs.

848. Human Donor Islets and iPSCs, Encapsulated in Immuno-Privileged Next-Generation Hydrogels, Are Viable and Functional *In Vitro* and *In Vivo*

Harald Stover

Allarta Life Science, Dundas, ON, Canada

Introduction & Objective: Encapsulation carries the promise to physically immuno-protect cell clusters, to provide a safer and more durable vehicle for cell therapies. This expands the potential for patients to access these cell therapies without the use of immunosuppressive regimens. Our proprietary synthetic hydrogels can support different cell types and cell densities, and here, we report the assessment of *in vitro* and *in vivo* functionality. **Methods:** Next-Gen hydrogels were implanted in mice, rats and pigs to assess tissue response. Human donor islets and human iPSCs were encapsulated in next generation shape-agnostic hydrogels at different cell densities and in vitro viability and function was assessed, then they were implanted in healthy or streptozotocin (STZ)-induced diabetic immunocompetent rodents and pigs to assess their *in vivo* functionality. **Results:** Our hydrogels successfully supported cell function *in vitro* and had no-to-minimal tissue response with strong robustness in the various animal species. Encapsulated human iPSCs have good *in vitro* viability and proliferation and maintain good viability signals 3 months post-explant. Human donor islets, encapsulated at different cell densities, had good

in vitro function in response to glucose stimulation, and showed dose-dependent *in vivo* response in rodents. The cells also demonstrate good function in pigs with reduced blood glucose and increased C-peptide levels. **Conclusion:** Our proprietary hydrogels enable delivery of both primary islets and iPSCs, and demostrated robustness without eliciting particularly strong host reponses in a variety of animal models. Encapsulated cells remain viable and functional *in vitro* and *in vivo,* without any immunosuppression. We are currently scaling to therapeutic doses in large animals, in pursuit of a curative therapy based on an optimal balance of cell protection and functionality.

849. Immune-Stealthy Hepatocytes Engraft and Expand in the Allogeneic Mouse Liver

Anne Vonada, Leslie Wakefield, Markus Grompe, Amita Tiyaboonchai

Oregon Health and Science University, Portland, OR

Hepatocyte transplantation is a cell therapy approach with applicability to a variety of liver disorders, including both inherited and acquired conditions. Unlike gene therapy, for which the genetic cargo must be customized for each condition, hepatocyte transplantation allows wild type hepatocytes to be used as a therapeutic for a wide variety of disease indications. Many attempts at hepatocyte transplantation in humans have achieved partial efficacy, but the benefits are consistently lost in long-term follow up due to rejection of transplanted cells. Standard immunosuppression regimens, similar to those given after whole organ transplantation, are insufficient to prevent allorejection. The beneficial effects of hepatocyte transplant are typically lost by 1 year post-transplant. Ex vivo engineering of the patients' own cells to correct the disease-causing mutation (i.e., use of an autologous cell source) is a possible solution to this problem, although this approach is invasive and low-throughput. An optimized approach would involve creation of immune-stealthy hepatocytes to allow production of an off-the-shelf cell therapy product. Approaches to engineering "universal donor" cells have been reported for T-cells and induced pluripotent stem cells (iPSCs) by genetic manipulation of major histocompatibility complex (MHC) presentation. These modifications include knockout of the beta-2-microglobulin (*B2m*) gene to prevent MHC class I presentation, class II major histocompatibility complex transactivator (*Ciita*) knockout to prevent MHC class II presentation, and transgenic expression of immune-inhibitory ligands to prevent NK cell responses. Similar methods are expected to be applicable to hepatocytes, but these have never been tested in vivo. To assess whether a similar approach is applicable to hepatocyte transplantation, primary hepatocytes from a transgenic tdTomato reporter mouse on the C57BL/6 background were triple edited in vitro. This included knocking out *B2m* and *Ciita* with CRISPR ribonucleoprotein (RNP) complexes, along with lentiviral overexpression of Cd47. An additional single-edited cell group included only RNP-mediated knockout of B2m. Edited donor cells were transplanted into recipient mice on an allo-mismatched 129S4 background as well as congenic C57BL/6 controls. All recipient mice were deficient in fumarylacetoacetate hydrolase (Fah), which leads to a strong selective effect for wild type hepatocytes. Transplantation of triple-edited donor cells produced stable engraftment in 6 out of 9 recipients for at least 2 months. Interestingly, transplantation of allogeneic donor cells deficient in only B2m also led to engraftment and clonal expansion in 8 out of 13 transplanted animals. Control animals transplanted with B2m-proficient hepatocytes in the same allotransplantation paradigm never showed any engraftment (0/8) and congenic controls always displayed engraftment. In some recipients, transplantation of B2m-deficient allogeneic hepatocytes resulted in complete liver repopulation, subsequent weight stabilization and long-term survival of the recipient animals. These data indicate that knockout of *B2M* may be the only genetic modification needed for creation of immune-stealthy donor hepatocytes. B2M-deficient donor hepatocytes may represent an off-the-shelf cell therapy product enabling hepatocyte transplantation without immunosuppression.

850. Engineered T Cells as a Platform to Treat Enzymopathies

Evan W. Kleinbohl[1], Kanut Laoharawee[1], Jacob D. Jensen[1], Joseph J. Peterson[1], Nicholas J. Slipek[2], Bryce J. Wick[1], Matthew J. Johnson[2], Beau R. Webber[2], Branden S. Moriarity[2]

[1]University of Minnesota - Moriarity Lab, Minneapolis, MN,[2]University of Minnesota, Minneapolis, MN

Inherited metabolic disorders account for nearly seventy percent of lysosomal storage diseases. While treatments with enzyme replacement therapy (ERT) regiment are possible for several of these diseases, enzyme replacement halflife/turnover is too short to be a lifelong solution for patients with most diseases. To build a longer-term therapeutic modality, we aimed to harness T cells to deliver therapeutically relevant levels of replacement proteins for lysosomal storage diseases, specifically mucopolysaccharidosis type I (MPS I). T cells are capable of migrating throughout all of the body's tissues, can persist for many years, and have highly validated gene engineering protocols, making them one of the most attractive platforms for cell-based systemic enzyme replacement therapy. This study shows IDUA delivery via engineered T cells can sustainably correct enzyme deficiencies systemically. Within a preclinical immunodeficient MPS I mouse model, a single dose of engineered memory CD4+ T cells resulted in detectable IDUA activity levels surpassing heterozygous levels in the blood and organ tissues, leading to reduced glycosaminoglycans (GAGs) waste product accumulation and alleviation of MPS I indications. Furthermore, 10 weeks post T cell delivery, no significant difference in organ GAG accumulation was observed in MPS I treated and IDUA heterozygous mice. This therapeutic effect was observed through the course of our 22 week study. Immunohistochemistry of liver and brain samples showed a >2 fold decrease in lysosomal associated membrane protein 1 (LAMP1), a hallmark of lysosomal storage disease manifestations, further indicating alleviation of MPS I. This therapeutic strategy is being further improved with newly developed methods for in vivo cell activation and enhancing the ability of IDUA to cross the blood brain barrier using protein fusions. These promising findings underscore the potential of our cell-based therapy platform for enzyme replacement, not only in MPS I, but also in addressing a spectrum of enzymopathies and protein deficiencies.

851. Optimization of Lysosome Extraction for Future Downstream Applications in Cell Therapy

Ilana Chefetz Menaker
Biomedical Sciences, Mercer University, Macon, GA

The lysosomes are a membrane-enclosed recycling bin/suicidal bag organelles that digest a variety of biomolecules such as proteins, carbohydrates, lipids, and nucleic acids. The digestion process is performed by lysosomal enzymes that require an acidic pH for optimal activity. Dysfunction of lysosomal proteins causes Lysosomal Storage Diseases and currently enzyme replacement therapy or gene therapy are being clinically developed. Interestingly, recent studies confirmed the lysosome transfer between cells, suggesting use of healthy lysosomes as cell therapy. After lysosome substrates are broken down, their components can be recycled and reused. Besides their role in feeding cells from the inside, lysosomes have a central role in metabolic growth signaling. Thus, targeting lysosomes, could be a logical approach in metabolically deranged conditions such as cancer. Additionally, lysosomes are detrimental for completion of autophagy, a process that is often reduces efficiency of cancer therapeutics, triggering pro-survival of cancer cells. Thus, it is important to be able to isolate lysosomes without other organelle contamination using a validated protocol that will ensure purity and intactness for downstream applications and reproducibility. While several methods have been developed, including immunoprecipitation of the exogeneous lysosomal gene TMEM192-3-HA following its overexpression using magnetic beads, we decided to asses a commercially available the lysosome extraction kit (Thermo Fisher) that utilizes gradient and ultracentrifugation that results in appearance of three phases with the upper phases containing lysosomes. Following series of optimizations of sonication frequency, we were able to confirm enriched expression of the lysosome protein LAMP1 in the upper phase that also contained a significant contamination of mitochondrial proteins as assessed by COXIV expression. We further optimized this procedure, by modifying the gradient conditions of Opti Prep cell separation media and subdividing the upper phase into 4 different phases. Based on the purity of fractions (Lamp1/COXIV) we choose 2 gradient conditions and collected two upper phases (out of 4) with highest LAMP1 expression to validate our optimization in comparison to the intermediate phase that includes mitochondria. The fraction purity was further confirmed by the ratio of the lysosome protein LAMP2 and the mitochondria protein SDHA. All collected fractions were sent to proteomic analysis to establish optimal conditions for the lysosome enrichment signature. For label free quantification LC-MS/MS, peptides would be reconstituted in 5% Acetonitrile (ACN) and 5% formic acid (FA) and analyzed using a nano-UHPLC-Dionex Ultimate 3000 system connected to an Orbitrap Fusion Lumos mass spectrometer. In summary, we developed a method that allows extraction of intact pure lysosome fractions to allow downstream cell therapy applications and analyzed proteomic content to compare purity and enrichment across different experimental conditions.

852. Genetically Engineered Macrophage Cell Therapy Reverses Liver and Lung Fibrosis in Preclinical Models

David Christopher Sloas, Yumi Ohtani, Angela Mosebarger, Ben Johnson, Nancy Carson, Julia Smith, MacKenzie Villano, Joanna Schmidt, Sascha Abramson, Thomas Condamine, Michael Klichinsky, Bradley Zinker
Carisma Therapeutics Inc., Philadelphia, PA

Introduction: Fibrosis of the liver and lung can lead to organ failure and the need for transplantation. Currently available therapies are unable to reverse established fibrosis. The development of fibrosis is an interplay of inflammatory and pro-fibrotic pathways leading to collagen deposition and disease progression. Macrophages play a central role in the development and resolution of fibrosis, and pre-clinical/Phase I studies have previously shown the feasibility, safety, and potential efficacy of non-genetically modified macrophage cell therapy in liver cirrhosis. We genetically engineered macrophages targeting relaxin, IL-10 or TGFbR2 signaling pathways and assessed the efficacy of engineered macrophage cell therapy in preclinical models of liver and lung fibrosis. **Methods:** Primary macrophages were efficiently transduced to express anti-inflammatory or anti-fibrotic payloads, such as IL-10, relaxin, and dominant negative (DN) TGFbR2. Engineered primary murine and human macrophages were highly viable and durably expressed functional payloads. Liver fibrosis efficacy was investigated in vivo in the hallmark CCl_4 mouse model of established fibrosis. Mice were challenged with CCl_4 2X/week for 6 weeks. At week 4, mice were intravenously dosed once with vehicle control, untransduced macrophages (UTD-M), or engineered macrophages then sacrificed 2 weeks later (n=9/group). A non-CCl_4 group was included as a non-disease control and efficacy was examined histologically. Separately, we investigated lung fibrosis efficacy utilizing the hallmark bleomycin mouse model of pulmonary fibrosis. Following bleomycin exposure, all mice were dosed once with either vehicle control, UTD-M, or engineered macrophages (n=10-15/group). A non-bleomycin group (non-disease control) was included and efficacy was determined via hydroxyproline biochemical analysis. **Results:** Genetically engineered macrophages were able to traffic to fibrotic tissues in two independent models and durably expressed their payloads. Picrosirius red and Masson's trichrome staining, independent collagen biomarkers, were significantly elevated in livers following CCl_4 exposure and significantly reduced upon UTD-M (55% reduction relative to control) and relaxin-IL10 (116% reduction relative to control) macrophage treatment. Furthermore, relaxin-IL10 macrophage treatment significantly reduced fibrosis compared to UTD-M, demonstrating an enhanced benefit with genetic macrophage modification. In the lung fibrosis model, a significant reduction in lung hydroxyproline levels in the relaxin-IL-10 and TGFbR2 DN (90% reduction relative to control) engineered macrophage treated groups vs bleomycin control was observed. Macrophage cell therapy was well tolerated in both fibrosis models with no weight loss observed. **Conclusion:** Macrophages engineered to co-express relaxin and IL10 reversed established liver fibrosis, and macrophages engineered to express DN TGFbR2 ameliorated pulmonary fibrosis. These results demonstrate the pre-clinical feasibility, safety, and efficacy of genetically modified macrophage cell therapy for the treatment of fibrosis.

853. Impact of Origin and Delivery Route on Efficacy of Mesenchymal Stromal Cell-Based Therapy in Acute Lung Injury

Jayita Barua[1], Loredana Asarian[1], Keara L. McElroy-Yaggy[2], Daniel Weiss[1]

[1]Dept. of Medicine, Larner College of Medicine, University of Vermont, Burlington, VT,[2]Dept. of Medicine, Stem Cell Core, University of Vermont, Burlington, VT

In-vivo models of acute lung injuries (ALI) have been widely used to evaluate efficacy of mesenchymal stromal cell-based (MSCs) therapies and investigating the underlying mechanisms. LPS, a gram-negative bacterial endotoxin delivered intra-tracheally has been used in mouse models to mimic the hallmarks of acute respiratory distress syndrome (ARDS), a form of ALI. However, the methodologies to treat LPS-treated mice with MSCs lack consensus. This makes it difficult to compare the studies for their outcomes to determine efficacy. Unsurprisingly, contrasting outcomes from non-COVID ARDS clinical trials also reflect similar issues. This led us to examine experimental variables in our mouse model, such as species matching between donor and recipient, different routes to deliver MSCs in LPS-treated mice. 2.5 ug of O55:B5 LPS (or vehicle) is administered intra-tracheally to C57BL/6J (B6) mice (8-12 weeks old, male) to induce lung injury. 4 hours post-LPS, human bone marrow derived MSCs (hBM-MSCs) or mouse BM-MSCs are delivered either intratracheally or subcutaneously. Mice are harvested at day 3(D3) and disease outcomes, such as total protein content of bronchoalveolar lavage fluid (BALF) and percentage of infiltrated neutrophils in alveoli are measured as indicators of breach of alveolar-capillary barrier and inflammation respectively. Lungs are gravity-fixed with 4% formalin, sectioned and stained with Eosin-Hematoxylin (H&E) to determine cellular infiltration, thickening of the alveolar septa and presence of protein rich edema fluid. Intra-tracheally delivered $1x10^6$ mouse MSCs were shown to lower the neutrophil infiltration significantly (**;p=0.0097, n=3),but failed to lower the protein concentration in BALF of LPS-treated mice. H&E-stained lung sections also corroborated that data. In the following pilot experiment, we tested the efficacy with subcutaneous delivery of mMSCs dose-dependently. At a higher dose ($1x10^7$) mMSCs, delivered subcutaneously were shown to lower the neutrophil infiltration significantly (*;p=0.04, n=4 in LPS, n=2 in LPS-MSC groups). However, protein concentration in BALF was not lowered at D3. Currently, we are in the process of repeating the experiments with higher sample number and a later timepoint for harvest to measure the outcomes. In conclusion, our studies showed that syngeneic, but not xenogeneic MSCs partly mitigate LPS-induced lung injury. In addition, subcutaneous delivery of mMSCs may prove to have better therapeutic potential in our disease model than intra-tracheal delivery. The presence of proteins in alveoli can be attributed to the early examination (D3) of BALF and remain to be tested at day 7. It can also be evaluated for the presence of other proteins such as cytokines (TNF-α, IL-10, IL-6, IFN-γ etc.), chemokines (CXCL1/2 , SDF-1α, CXCL5 etc.) that could add to the BALF protein repertoire. Once established, our model can provide the platform to investigate the pertinent questions about the underlying mechanisms of MSC-therapy, not only in lung disease, but also in other acute inflammatory diseases.

854. *In Vitro* Production of Somite-Derived Muscle Stem Cells from Human Pluripotent Stem Cells for Cell Replacement Therapy in Duchenne Muscular Dystrophy

Yannis Djeffal[1,2,3], Lu Yan[1,2,4], Yuchuan Miao[1,2], Alejandra Rodriguez-de-la-Rosa[1,2], Yori Endo[5], Indranil Sinha[5], Frédéric Relaix[3], Emanuela Gussoni[6], Allon Klein[4,7], Olivier Pourquié[1,2,4]

[1]Department of Pathology, Brigham and Women's Hospital, Boston, MA,[2]Department of Genetics/Harvard Stem Cell Institute, Harvard Medical School, Boston, MA,[3]Univ Paris Est Créteil, INSERM, IMRB, Créteil, France,[4]Somite Therapeutics, Boston, MA,[5]Division of Plastic Surgery, Brigham and Women's Hospital, Boston, MA,[6]Harvard Medical School/ Children's Hospital, Boston, MA,[7]Department of Systems Biology, Blavatnik Institute, Harvard Medical School, Boston, MA

Cell replacement therapy is an innovative approach to treat Duchenne muscular dystrophy by transplanting functional muscle stem cells directly to muscle. We have developed a differentiation process that can yield somite cells from human pluripotent stem cells (PSCs). Somites are transient structures in developing embryos which give rise to diverse cell types including skeletal muscle, dermis, bone, cartilage, tendons, and brown adipose. We have developed a stepwise myogenic induction protocol that recapitulates the developmental trajectories of skeletal muscle, resulting in the efficient production of myofibers and satellite cells (muscle stem cells) in vitro. To meet the requirements for the cell therapy applications, we optimized the protocol using a newly developed bioinformatics pipeline. Compared to our original protocol, this optimization allowed us to double the proportion of satellite cells in human iPS-derived myogenic cultures. Additionally, adjusting the differentiation duration led to the identification of a satellite cell population with enhanced maturity and increased cell fusion ability. In proof-of-concept experiments, these in vitro-generated cells were transplanted into mice to assess their in vivo functionality. When transplanted in irradiated pre-injured immunocompromised mice in which leg muscles are atrophied, in vitro-produced human muscle stem cells could generate up to 80% of the grafted Tibialis Anterior muscle cells, demonstrating a restoration of force production. This preclinical success underscores the potential of in vitro-produced somite-derived cells as a promising source for cell replacement therapy in muscle-related diseases and injuries. The regenerative capacity of these cells, characterized by self-renewal and differentiation into mature functional muscle fibers, positions them as top-tier cell sources for long-term patient benefits. In conclusion, our established protocols serve as a significant advancement in the production of somite-derived muscle cells, providing a proof of concept for their promising use in cell replacement therapy. This successful strategy also lays the groundwork for exploring other somite-derived cell lineages.

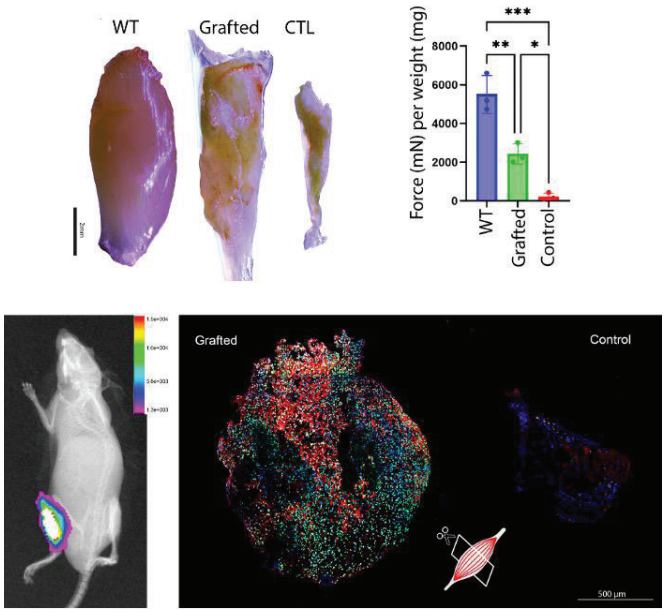

Figure: Top. (Left). Comparison between wild type (WT), grafted, and control (CTL) dissected Tibialis Anterior muscles one month after irradiation and cardiotoxin injection with (grafted) and without (CTL) injection of human iPSC-derived satellite cells. (right), restoration of force production in grafted muscles. Bottom. (Left) detection of the luciferase signal in the grafted human satellite cells after one month. (Right) comparison between sections of grafted and control TA muscles after one month showing the expression of human dystrophin (red) and human laminB2 (nuclei, green).

855. Cell-Based Treatment of Skeletal Muscle Atrophy Induced by Amyotrophic Lateral Sclerosis

Raphael Severino Bonadio[1], Silvia Scalabrin[1], Mattia Polato[1], Alessandro Bertoli[2], Maria Lina Massimino[3], Stefano Cagnin[1]

[1]Department of Biology, University of Padova, Padova, Italy,[2]Department of Biomedical Science, University of Padova, Padova, Italy,[3]CNR, Padova, Italy

Introduction. Amyotrophic Lateral Sclerosis (ALS) is the most common adult motor neuron (MN) disease whose causes remain largely unknown and whose treatment options are ineffective in the long term. The hallmark of ALS is selective and progressive degeneration of lower and upper MNs, leading to spasticity, weakness, and muscle atrophy. Several studies suggest that non-coding RNAs are central to the onset and progression of ALS. Most ALS studies are neurocentric and assume that MN dysfunction is the main origin of the disease and that muscle changes are the consequence. Growing evidence, however, suggests that molecular alterations in muscle fibers in the presymptomatic phase may trigger ALS pathology. Methods. We analyzed noncoding and coding genes differentially expressed in skeletal muscle of SOD1*G93A mice, an established model for studying ALS. We identified as altered a signature involved in the maintenance of muscle mass. We produced cells stably expressing miRNAs that modulate this signature and tested their ability to affect non-engineered cells in a paracrine manner. Conclusions. We have shown that cells overexpressing a specific miRNA sequence (patenting process) produce thicker myotubes and secrete the same miRNA to affect other non-engineered muscle cells. Furthermore, the thickness of myotubes from ALS mice was improved not only by transfecting them with the DNA construct we developed, but also just by using the RNA secreted by the transfected cells. This is a promising approach to delineate or rescue muscle atrophy that occurs in various pathological conditions not only of skeletal muscle but also of the nervous system.

856. Development of Novel Immunological-Directed Synthetic Biology-Based Microbiome Therapeutics

Christian Furlan Freguia[1], Govindaraj Anumanthan[2], Ananta Prasad Arukha[2], Bikash Sahay[2], Gary Fanger[1]

[1]Rise Therapeutics, Rockville, MD,[2]University of Florida, Gainsville, FL

As cell therapies offer a promising prospect for the treatment of several diseases, engineered probiotics represent the new frontier of non-viral cell-based drug-delivery platforms, produced by leveraging synthetic biology to modify natural probiotics through gene editing. Using probiotics as non-viral chassis to deliver therapeutics offers many advantages over other viral-based gene delivery approaches, such as reduced pathogenicity, low cost, and ease of manufacturing. In addition, oral engineered probiotics can directly interact with the gut microbiome, which has emerged as a vital regulator of the host immunity by the induction, functional modulation, or suppression of local and systemic immune responses. Therefore, a promising novel strategy to manage human diseases is to leverage the body's own natural microbiome-associated immune regulatory mechanisms with oral engineered probiotic therapy. Rise Therapeutics' oral platform consists of GRAS probiotics, engineered to express novel microbial-derived immunomodulatory proteins. Our lead clinical program, R-3750, consists of the food-grade *Lactococcus lactis* engineered to delivered Surface layer protein A (SlpA) from a genome integrated operon. R-3750 has been tested in several murine models of colitis. In the T cell-induced colitis model, oral administration of R-3750 at dose of 1E8 CFU was sufficient to significantly diminish intestinal pro-inflammatory cytokines (IL-1β, TNF-α, IL-6, and IL-17), and modulate the immune response by reducing inflammatory T cells ($CD3^+CD4^+IL\text{-}17^+$ and $CD3^+CD4^+Ror\gamma T^+$) and by upregulating regulatory T cells ($CD3^+CD4^+IL\text{-}10^+$ and $CD3^+CD4^+FoxP3^+$). Oral administration of R-3750 also restored gut epithelium barrier integrity as shown by upregulation of tight junction protein genes (*tight junction protein 2* and *3*) and mucin production genes (*mucine 2* and *mucine 3*). When the gut microbiome was analyzed, mice that received R-3750 showed higher relative abundance of species. Notably, R-3750 mechanism of action was corroborated using *in vitro* models where co-incubation of R-3750 with human or murine-derived dendritic cells similarly resulted in expression of IL-10. Single and repeat dose murine toxicology studies were performed with R-3750. In those studies, oral administration of R-3750 at doses 100-fold higher than the clinical dose, showed no toxicity as measured by hematology and clinical chemistry testing, and histopathology. Importantly, there was no R-3750 exposure detected in the blood of any animals using a validated qPCR assay, while fecal levels of R-3750 were detected in the treated animals, demonstrating that R-3750 remains confined in the

gut. R-3750 is currently in a Phase 1 clinical study (NCT05666960) in patients with mild to moderate ulcerative colitis. This study consists of a dose escalation stage, in which three doses of R-3750 are tested; and an expansion stage, where additional patients are enrolled at the highest tolerated dose. The study is currently enrolling. Overall, non-viral engineered probiotic-based therapies, like R-3750, represent a new strategy to tackle hard-to-treat diseases by allowing to treat patients sooner, improve compliance, and, for a drug like R-3750 which remains localized to the oral-gut cavity and is not systemically delivered, minimizes potential adverse reactions.

857. Building Synthetic Biosensors Using Red Blood Cell Proteins

Taylor F. Gunnels[1], Taylor B. Dolberg[2], Te Ling[3], Kelly A. Sarnese[2], John D. Crispino[3], Joshua N. Leonard[2]

[1]Department of Biomedical Engineering, Northwestern University, Evanston, IL,[2]Department of Chemical and Biological Engineering, Northwestern University, Evanston, IL,[3]Department of Hematology, St. Jude Children's Research Hospital, Memphis, TN

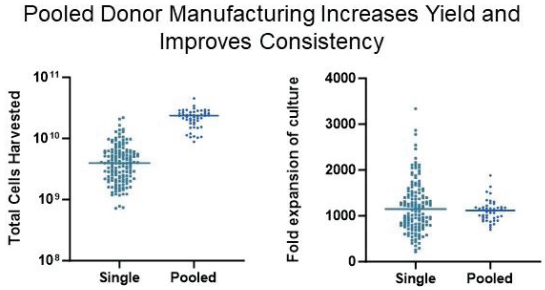
The success of engineered immune cell therapies for cancer treatment has opened the door for building cell-based devices for other applications and using alternative cell types. An exciting such direction is developing engineered red blood cells (RBCs) as *in situ* biosensors for long-term physiological monitoring and diagnostics. In this context, RBCs are an attractive platform because of their exposure to important biomarkers in blood and their long circulation time. A key biological hurdle to generating RBC biosensors is that red blood cells undergo dramatic cellular changes during their maturation process, including expelling their nucleus and changing the protein composition of the plasma membrane. As a result, traditional genetic engineering approaches are of limited use directly, and we largely lack tools to convert RBCs into cell-based biosensors. We set out to address this need towards the goal of building RBC biosensors for physiological monitoring. In this study, we demonstrate proof-of-concept for a technology that may ultimately enable the engineering of RBCs for *in situ* diagnostic purposes. Specifically, we built protein-based biosensors that respond to an extracellular cue via reconstitution of a split fluorescent protein or luminescent enzyme. We chose to use membrane proteins found natively in mature RBCs as biosensor scaffolds to overcome traditional limitations associated with erythropoiesis such as protein turnover and membrane remodeling. Prototyping designs via transient transfection of biosensor-encoding plasmids in a model cell line generated useful insights into how design considerations such as scaffold choice, linker length, and output protein modulate the ligand-induced signaling of this biosensor platform. Promising designs were stably implemented genetically into an erythroid precursor cell line and more deeply characterized for *in vitro* biosensor performance and kinetics. Finally, erythroid precursor cells containing the biosensor were injected into mice and successfully detected and reported on the presence of a model ligand. We anticipate this technology will be of interest in the cell therapy and diagnostic fields towards the goal of *in situ*, real-time physiological monitoring.

858. Enhanced Human CD34+ Cell Engraftment and Differentiation Depend on Pre-Conditioning Regimen in NSG and NBSGW Mouse Models

Bala Sai Sundarasetty, Maj-Kristin Holz, Fabian Musch, Johanna Mueller, Celeste Rizzello, Jens Dorna, Eileen Rauch, Claudia Pertab, Anke Beutel, Timo Kraushaar, Joachim Roeder, Maximilian Bielohuby

CSL Behring Innovation GmbH, Marburg, Germany

Immunodeficient mice are invaluable tools to study modeling of the human hemato-lymphoid system post hematopoietic stem cell (HSC) transplantation and has paved way in understanding of hematopoiesis and safety of the novel cellular therapeutics, in particular gene modified HSCs. One important consideration here, is to make the hematopoietic niche available to the transplanted HSCs by reducing the cellularity in mouse bone marrow, either by sublethal irradiation (X-ray or ^{137}Cs) or by the myeloablative drug busulfan. Here we compared the effects of irradiation vs busulfan pre-conditioning in two different, frequently used immunodeficient mouse strains: NOD.SCID.IL2rγ$^{-/-}$ (NSG) and NOD.Cg-Kit^{W-41J} Tyr^{+} Prkdc^{scid} Il2rg^{tm1Wjl}/ThomJ (NBSGW) mice and assessed the HSC engraftment and the HSC ability to give rise to various immune cell lineages post transplantation. NSG mice were pre-conditioned with irradiation (X-ray; 270cGy) or Busulfan (clinical grade; 25 mg/Kg or 35 mg/Kg) whereas NBSGW mice were either not pre-conditioned or pre-conditioned with a low dose of Busulfan dose (12.5 mg/Kg). All mice received CD34^{+} cells (mobilized peripheral blood derived CD34^{+} cells; 2x10^{6} cells/mouse) after pre-conditioning and the human cell engraftment was assessed by flow cytometry up to 16 weeks post transplantation. NBSGW mice without preconditioning supported the engraftment of human HSCs (week 10: 25% hCD45^{+} and 20% at termination). In comparison, mild pre-conditioning of NBSGW mice with Busulfan has improved the human cell engraftment (week 10: 53%) and the engraftment levels were sustained till the end of the study. At week 10 post transplantation, NSG mice pre-conditioned with a high dose of busulfan supported the engraftment of human cells at a higher rate compared to the low dose of busulfan (51% and 30% hCD45^{+} for 35 and 25 mg/kg, respectively). Notably, NSG mice conditioned with 35 mg/kg showed a constant increase of human cells in the periphery compared to the lower dose of busulfan (at termination: 70% vs 21% respectively). However, the high dose of busulfan conditioning led to higher mortality (50% survival) compared to low dose busulfan conditioning (90% survival). NSG mice irradiated did support the human cell engraftment albeit with a lot of variability (cohort 1: >40% vs cohort 2: <20%). Moreover, irradiation led to other side effects, such as tooth loss and reduced food intake. In conclusion, busulfan conditioning showed a better and less variable pre-conditioning in NSG mice compared to irradiation. Mild pre-conditioning in NBSGW mice improved the human cell engraftment compared to the non-conditioned NBSGW mice but appears to increase anemia. Overall, different options to improve the engraftment rate of HSCs in mice exist, however, the higher engraftment rate may be connected to higher dropouts in mice and therefore needs to be carefully considered, depending on the specific study requirements.



Wednesday Posters: Cell Therapy Product Engineering, Development, and Manufacturing

859. Overcoming Current Challenges in Allogeneic Cell Therapy Manufacturing by Using Pooled Donor Cord Blood CD34+ Cells as Starting Material

Joe Blake, Carrie Stoltzman, Håkan P. Svensson, Colleen Delaney

Deverra Therapeutics, Seattle, WA

Background & Aim: Allogeneic cellular immunotherapies hold the promise of improved clinical access as compared to autologous approaches, but many biological and regulatory challenges remain including optimal starting material, donor variability, scalability, cost of goods, in vivo persistence, and ability to cryopreserve formulated product. Most allogeneic cell therapies start with single-donor source material (e.g. cord blood, peripheral blood) with resulting high lot-to-lot variability, limited scalability, and high costs. To overcome these common challenges, we developed a manufacturing process to expand enriched CD34+ cells from pooled cord blood units (CBU) and then differentiate them to immune effector cells. This allows scalability and improves lot-to-lot consistency. Pooled donor products from this platform are used without HLA-matching and have now been used in four clinical trials to date, two with an expanded stem/progenitor cell product and two with an unmodified NK cell therapy derived from CB CD34+ cells. **Methods & Results:** For our expanded stem/progenitor cell product, CBU from FDA-licensed banks were thawed, pooled, and CD34-enriched. CD34+ cells were plated in vessels coated with a proprietary Notch ligand and cultured for 14-16 days before harvesting. Final products were cryopreserved in fixed doses, tested and released for clinical use. Using the same process to generate our expanded stem/progenitor cell product, data were collected for 55 pooled-donor (8 CBU: n=53, 6 CBU: n=2) and 155 single-donor manufacturing runs. Pooling CBU increased the consistency and output of the CD34+ enrichment process. Total cell fold expansion after culture was comparable with less variation observed in the pooled donor runs, while total cell output was increased by pooling CBU (Figure 1). Total number of CD34+ cells generated after culture was also increased, and purity of CD34+ was higher at harvest. Single and pooled donor products were cryopreserved and used in clinical trials as off-the-shelf universal donor products, including 184 infusions of pooled donor product; to date there have been no product-related SAEs.

Discussion: Pooling CBUs streamlined manufacturing and led to a large increase in cell product output and consistency without compromising growth or quality. Generating large batches of product reduces manufacturing cost and increases lot-to-lot consistency versus multiple small single donor manufacturing runs. Further, without requirement for HLA matching, our clinical products are manufactured, cryopreserved and released ahead of patient need and are available on-demand. Data described here reflect manufacturing using pools of 6-8 CBU, but the process is scalable to pool larger numbers of CBU. We now leverage this pooled donor expansion platform for generation of large numbers of progenitor cells which are then differentiated into immune effector cells, including myeloid cells (in preclinical development) and NK cells that have been safely used in 2 trials to date.

860. Optimising Lentiviral Transduction Using Microfluidics

Lindsey A. Clarke, Nicholas Akosa, Maria Kalli, Antonio de Grazia, James Kusena, Césaré M. Cejas, Antoine Espinet

MicrofluidX, Stevenage, United Kingdom

Background & Aim: Transduction via lentiviral methods in conventional bioreactors are susceptible to efficiency limitations, particularly often requiring high multiplicity of infection (MOI) to achieve acceptable efficiency levels. High MOIs typically translate to high experimental costs and sometimes even risk, with some studies reporting toxicity. In this study, we demonstrate that even at lower MOIs, we optimise the contact probability of the virus reaching the cell by leveraging the advantages of microfluidics. Methods: We fabricated a bespoke microfluidics-based bioreactor that takes advantage of high surface-to-volume ratios. This results in a reduced fluid height and elongated form factor. Using an exemplar CAR-T transduction process with Primary T-cells with CD19 lentiviral vector, we compare transduction efficiency in these bioreactors with conventional transduction methods. Results: Using a design of experiment methodology, we find that these novel microfluidics-based bioreactors benefit from high cell densities, and seeding by cell density (cells/cm2) similar to adherent cell culture, as opposed to cell concentration (cells/mL). This approach increases contact with the vector; thereby fostering a conducive environment that maintains paracrine signalling. We also show that despite the low fluid height environments, we still maintain high cell viability under optimal seeding conditions. Overall, we achieved a three-fold increase in transduction efficiency in these microfluidics-based bioreactors compared to conventional methodology. Conclusion: Here we demonstrate that even at low MOIs, a higher transduction efficiency can be achieved in comparison to conventional methodology. Ongoing work explores the impact of this low volume environment on transduction enhancers as well as the effect of agitation to further increase probability of contact between lentiviral particles and target cells. We continue to investigate new methods & protocols to collectively improve the transduction efficiency while reducing viral vector usage, ultimately contributing to reducing overall costs of CAR-T processes.

861. Non-Viral Cell Engineering of Peripheral Blood Natural Killer Cells Using a GMP-Compliant, Scalable Electroporation Platform

Lauren E. Unsworth, Ashley B. Strickland, Cornell Allen, James Brady
MaxCyte, Inc., Rockville, MD

Natural killer (NK) cells are an integral part of the innate immune system as they recognize an abundance of surface receptors on target cells without the need for antigen specificity and recruit and activate other immune cells by secreting a myriad of cytokines. The hallmark of NK cells is their cytotoxic function which enables them to recognize and attack tumor or infected cells by releasing granules that induce apoptosis of target cells. Electroporation (EP) is a non-viral method for cellular engineering that has been used with virtually all cell types and has been specifically shown to be an effective cell engineering method for peripheral blood NK cells. Advantages of electroporation include highly efficient transfection with a variety of molecules (e.g., DNA, RNA, and ribonucleoprotein (RNP) complexes), regulatory acceptance, and cGMP compatibility. In this study, we optimized conditions for electroporating primary NK cells with the GMP-compliant MaxCyte® ExPERT GTx™ electroporation platform, with specific focus on maximizing cell viability, cell recovery, transfection efficiency, cell expansion and functionality. Previous studies showed that expansion of NK cells before electroporation was necessary for effective transfection, and therefore larger scale platforms were required, leading to the use of more costly reagents. Here, we showed that the MaxCyte ExPERT GTx could genetically modify naïve or expanded primary NK cells using mRNA, RNP complexes or plasmid DNA at both a small ($1x10^6$ cells in 25µl) and larger scale ($1x10^8$ cells in 5ml). We observed over 90% gene expression and viability following mRNA electroporation and over 60% expression and viability after minicircle DNA (mcDNA) loading at both small and larger scales. We also evaluated the effect of commercially available DNA sensing pathway inhibitors to determine if transfection efficiency and cell viability could be increased when loading small and large plasmid DNA. Furthermore, we knocked-out the NKG2A inhibitory receptor at different timepoints during expansion by loading a sgRNA-Cas9 RNP complex and looked at post-electroporation effects. With our optimized transfection conditions specific for NK cells, we determined that electroporation had minimal impact on cell viability, cell expansion, surface marker expression, and killing capacity.

862. Potency Assurance Testing of a CAR-T Cell Therapy Product: Evaluating T Cell Function Using Multiple Quantitative Bioassays

Katrina Adlerz, Ellie Jafari, Morgan Trapp, Jon Pileggi, Chantale Bernatchez, Priya Balasubramanian
CTMC (Cell Therapy Manufacturing Center), Houston, TX

Background & Aim: Cell therapy is a promising treatment for cancer patients, with six CAR-T therapies approved by the FDA. One of the challenges on the path to approval, however, is establishing a strategy to ensure product potency. In fact, the newly issued FDA draft guidance "Potency Assurance for Cellular and Gene Therapy Products" acknowledges the specific challenges that product developers of complex cell therapies face. This draft guidance outlines recommendations for a Potency Assurance Strategy including a potency assay or assays that measure at least one potency-related Critical Quality Attribute (CQA) related to the product's bioactivity while avoiding redundant assays measuring various biological activities that occur in a stepwise chain. Here, we describe results of measuring the T cell Function of a CAR-T Product across multiple bioassays. We also compare critical aspects of the assays including precision, specificity, range, and robustness towards selection of a potency assay for evaluating T cell function of an early-stage investigational new drug. **Methods, Results, & Conclusion:** Autologous CAR-T cell product was manufactured from CD4/CD8-selected T Cells from three healthy donor apheresis. The T cells were activated, transduced with a CAR lentiviral vector, expanded, and cryopreserved. The cryopreserved final drug product was then tested for T Cell function in four different assays: 1) IFNγ secretion after TCR-activation 2) IFNγ secretion after antigen-specific stimulation, and two cytotoxicity assays with readouts by 3) bioluminescence and 4) cell impedance using the Agilent xCELLigence Analyzer. A concordance in trends was observed between the different assays with donor-to-donor biological variability a significant driver of T Cell function. Assays were also evaluated for suitability for use as product release in accordance with the FDA draft guidance and ICH recommendations, including precision, specificity, range and select robustness parameters. All assays showed high specificity with low IFNγ secretion or killing in non-stimulated or non-transduced samples. Precision varied among the assays with ELISA-based readouts having better precision with lower coefficient of variation and a broader range. Finally, CAR-T cells from the same apheresis but manufactured with two different processes were assessed. Significant differences were observed between the manufacturing processes. The results described here are impactful in understanding how to assess CAR T Cell function and towards defining the Potency Assurance Strategy for an early-stage investigational new drug.

863. Expansion of Stem-Like T Cells by Protein Nanoscaffold-Based NanoSpark™ STEM-T Activator

Zachary I. Imam, Donna Marsh, Luke Haines, Curtis D. Hodge
Nanotein Technologies, Berkeley, CA

Cellular therapies are the cancer treatment of the future. CAR-T cells are the most clinically and commercially advanced of anti-cancer cellular therapies. Despite their effectiveness, CAR-T cell therapy has encountered some obstacles including manufacturing failures, long manufacturing times, and short-lived or poor treatment outcomes. One solution to these problems is optimizing the activation and expansion step of the manufacturing process. Here, we used a novel protein-based T cell activation technology called NanoSpark STEM-T, a soluble reagent that promotes the growth of stem-like, less differentiated T cells with a bias towards clinically relevant CD8+ stem-like central memory T cells (Tscm) during 7 to 10-day expansions of donor T cells. We used NanoSpark to expand T cells from multiple donors, using several cell culture medias, different cytokine concentrations and combinations, and comparing expansion in conventional 6-well plates and G-Rex6M bioreactors over the course of a 10-day manufacturing process. NanoSpark STEM-T formulation achieved great expansion of total live T cells, CD8+ cells, and CD8+ Tscm cells during the 10-day

expansions. We quantified the fold-change of total live cells from day 0, quantifying Tnaive, Tscm, Tcm, Tem, and Temra cell phenotypes, and created the stemness score metric to quantitatively determine the stemness of the expanded T cell population on day 10 of expansion. Our results indicated that NanoSpark STEM-T readily expanded CD8+ T cells and preserved their stemness. These results were conserved across donors, different cell culture media, cytokine combinations and concentrations, and in different cell growth vessels.

864. Decentralized Manufacturing of Cell and Gene Therapies: A Novel Approach

Emily Heffernan[1], Forrest Brown[2]

[1]Arcadis, Cary, NC,[2]Germfree, Ormond Beach, FL

Since the approval of the first cell and gene therapies in 2017, demand and approvals for ATMPs continues to accelerate. While these therapies are life altering for the patients they serve, they have also been associated with such concerns as high price tags and critical supply chain shortages. This has raised concerns with the ability to provide access to patients with serious indications– particularly in developing nations. Historically, centralized manufacturing has for many entities led to economies of scale and thus the lowest cost model for manufacturing. However, due to the personalized nature of cell and gene therapies (CGT), the advantages to the economies of scale that favor centralized manufacturing are less prominent. Global regulators are concerned with issues arising from CGT cold-chain logistics. For example, the EU guideline on *Good Clinical Practice specific to Advanced Therapy Medicinal Products* notes: "Storage, transport and handling conditions have the potential to negatively impact the quality of ATMPs." For such reasons, decentralized manufacturing should be considered as an alternative to enable greater patient access. We will review specific benefits and disadvantages, as well as alternative contemporary models, of decentralized CGT manufacturing. Pharma 4.0 initiatives including process automation support manufacturing consistency in decentralized manufacturing approaches. A case study exploring the use of stand-alone cleanroom modules for decentralized manufacturing will also be reviewed and discussed.

865. Rapid and Precise Process Monitoring with Label-Free Laser Force Cytology™ Driving Improvements in CGT Manufacturing Quality and Consistency

Sean J. Hart

LumaCyte, Charlottesville, VA

The development and production of life saving advanced therapies can be challenging and time-consuming due to the complex nature of the cellular starting materials, manufacturing processes, and challenges around final product yields. Many current analytical tools face challenges in terms of speed, precision, reproducibility, and the high resource requirements needed to operate them. LumaCyte will present applications of Laser Force Cytology as a rapid process analytical technology (PAT) for biologics production monitoring which enables rapid characterization of cellular starting materials, the ability to precisely monitor and quantify biological processes affording developers and manufacturers a deeper understanding of cellular behavior across important bioprocess and production steps. Laser Force Cytology delivers novel label-free quantitative data in minutes to support rapid process optimization and scale up. The ability to minimize variability and batch failures during the manufacturing process with a real-time PAT can enable significant improvements in production quality and consistency. Process development and manufacturing efforts will benefit from a powerful yet simple to use analytics platform, enabling ease of deployment across multiple sites and the entire manufacturing process helping to minimize challenges around comparability.

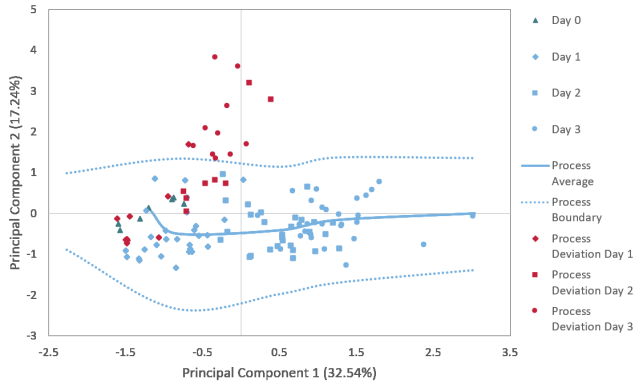


Figure: T Cell activation multivariate process road map showing successful process data for three patients (blue), and a process deviation of cells treated with doxorubicin (red). Data collected across five independent experiments using Radiance Laser Force Cytology instrument.

866. A Multiplexed and Scalable Continuous-Flow Electroporation Paltform for Efficient Cell Transfection

Harold Craighead, Jacob VanderBurgh, Stephen Levy, Grant Corso

CyteQuest, Ithaca, NY

Electroporation has emerged as an alternative to viral vectors for cellular reprogramming for CAR-T cell therapies. However, widespread adoption requires addressing difficulties with traditional electroporation such as process variability, arduous empirical process optimization, and limited throughput for cellular manufacturing. We addressed these issues with an electroporation platform that provides flexible, 8-channel multiplexed and efficient optimization capabilities, combined with ease of scaling from low-volume research/optimization to high-volume cell manufacturing. Flexibility and ease of scaling are enabled by a continuous-flow, planar microfluidic flow chip (Fig. 1A-B). The flow chip ensures cells experience reproducible electric fields and provides seamless scalability of experimental throughput by scaling the channel width. Up to 8 of these flow chips are incorporated into a continuous-flow microfluidic system that uses automated liquid handling to simultaneously test up to 8 chemical conditions combined with a range of flexible electrical conditions for rapid optimization of transfection. As a demonstration of the optimization capabilities of the system we transfected Jurkat cells with plasmid DNA encoding GFP within the multiplexed optimization system. We measured GFP expression and viability 24 hours post-transfection using flow cytometry, and a unifying metric, efficiency was calculated as the

product of GFP expression and viability. We simultaneously screened 8 different plasmid concentrations and 9 different electrical waveforms, depositing electroporated cells into a 96-well plate. We found that in this case, the optimal plasmid concentration was 37.5 μg/mL (Fig. 1C). Next, using this plasmid concentration, we rapidly screened hundreds of different voltage waveforms of varying shapes, durations, and amplitudes using varied parameters using ~20 μL of cells per condition. As a demonstration of the scaling capabilities of the system, we used the parameters optimized in the low-volume flow chip with 2 mm channel width to perform electroporation in a higher throughput flow chip with a 10 mm channel width. By keeping the channel height constant and proportionally increasing the flow channel width (from 2 mm to 10 mm) with the volumetric flow rate, cells experience identical mechanical, electrical, and chemical environments resulting in essentially identical transfection performance without re-optimization. Notably, we found that GFP expression and viability values were less than 5% different from Jurkat cells transfected in the 2 mm and 10 mm channel widths, demonstrating the ability to seamlessly scale processed cell volumes. (Fig. 1D). These results demonstrate the possibilities with a flexible electroporation platform for rapid, multiplexed optimization that is easily scaled to high-volume cell manufacturing without re-optimization. These capabilities bypass limitations of traditional electroporation equipment, creating a promising platform for non-viral cellular reprogramming for cell therapies.

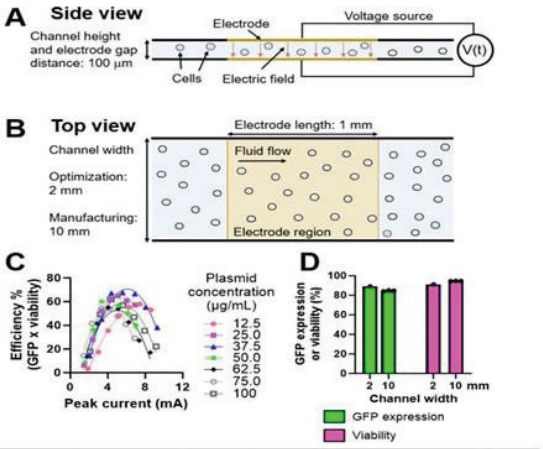

Figure 1: (A) Side and (B) Top view schematics of microfluidic flow chip. (C) Efficiency (GFP expression x viability) plotted as a function of plasmid concentration or peak current experienced by the cells. (D) GFP expression and viability data from Jurkat cells transfected with plasmid DNA encoding GFP in a flow chip with either a 2- or 10-mm channel width.

867. Closed Automation Enables Quick Fill-Finish of Large-Scale T Cell Therapy While Maintaining Consistency and Quality of the Final Product

Minsung Park[1], Meredith Safford[1], Jade Scheers[2], Lora Hammill[2], Despina Pleitez[1], Sarah Campion[2], Gibb L. Stuart[3], Mindy M. Miller[3], Smith Trevor[3], Alex Sargent[1]

[1]Process Development, Charles River Laboratory, Hanover, MD,[2]Analytical Development, Charles River Laboratory, Hanover, MD,[3]Terumo Blood and Cell Technologies, Lakewood, CO

Scaling up the manufacture of cell therapies can be complex and challenging. Maintaining critical quality attributes of the cell product during its final formulation and fill-finish into greater quantities of containers can be difficult and laborious. Here, we tested the automated FINIA platform to efficiently scale up the formulation and fill-finish of a T-cell product, and then assessed cell quality and product consistency across different sub-lots filled during this expanded process. We found that this automated system could be effectively scaled to four times its singular capacity in a two-hour time interval, and reduced operator hands-on time by 60%. The variation in cell product volume across all containers was less than 5%. Analysis of the different sub-lots of the final product revealed high cell viability and consistent T-cell phenotype, with a high proportion of effector and central memory T-cells and low expression of T-cell senescence or exhaustion markers. The functionality of the T-cell product was compared by measuring cytokine response after restimulation, with secreted levels of effector cytokines like IFN-γ and TNF-α being similar across the different sub-lots. Collectively, these results show that automation with the FINIA platform can scale up the formulation and fill-finish of a cell manufacturing process while maintaining the phenotype and functionality of the cell product. Demonstrating this automated, scalable approach to fill-finish that can maintain product uniformity and quality is important for the future development of cell therapies.

868. Efficient T-cell Activation and Expansion for CAR-T Therapy is Dependent on a Complex Interplay of the Starting Donor Population, Activation Antibodies and Expansion Platform

Matt Heidtman, Brandon Wagner, Christine Goetz, Nidhi Nath

Antibody Development, Bio-Techne, Minneapolis, MN

Chimeric antigen receptor (CAR) modified T cell therapies have revolutionized the area of cancer treatment, showing long term remission and minimal toxicity in many refractory and relapsed patients that have few available alternative treatments. Even with these promising results, the field continues to make improvements in targeting new cancer types, engineering new and more potent CAR-T cells, and improving manufacturability to reduce cost and time to therapy. Critical early steps in CAR-T manufacturing are isolation and enrichment of T cells from PBMCs followed by T cell activation and expansion using CD3 and CD28 antibodies. Commonly used activation methods involve anti-CD3/anti-CD28 coated culture dishes or bags, antibody coated-magnetic beads, direct antibody addition as soluble factors, and conjugated-polymeric matrices, among others. In

this study we explore two interconnected factors that may impact the T cell activation profile and phenotype. In the first study, we analyzed the effect of 3 different antibody-based activation methods (soluble, plate-bound, and bead-bound) on T cell activation/expansion by using chimeric (human and mouse) CD3 and CD28 antibodies. We observed similar levels of T cell expansion over 14 days across the different activation methods, using cells obtained from 4 donors. Interestingly, we found that bead-based expansion of T cells resulted in a lower percentage of cells expressing a subset of activation markers (CD25 and CD38) and a higher proportion CD45RO+ memory T cells relative to plate-bound and soluble antibody platforms. Furthermore, T cells expanded by stimulation via bead-bound antibodies displayed higher levels of the exhaustion marker, PD-1, but lower levels of TIM-3 and LAG-3 compared to stimulation via soluble and plate-based antibodies. These phenotypic differences may have important consequences for efficacy in a clinical setting. In a subsequent study we tested whether altering the ratios of CD3/CD28 antibodies resulted in differences in T cell phenotype after expansion. Surprisingly, we found that increasing the amount of the CD28 antibody relative to constant CD3 antibody did not impact T cell expansion or phenotype over a 14-day process. These results suggest that addition of other agonist antibodies (e.g., anti-CD2, anti-CD137) or altering the amount of CD28 more extensively, may be necessary to generate a desired phenotypic outcome. Taken together, our results highlight the importance of CD3/CD28 antibody presentation when used to stimulate T cell proliferation, particularly when developing expansion protocols for routine, reproducible manufacture of cell therapies. Among various modes of cell activation, we further noted significant differences in the resulting activated T-cell population, underscoring the importance of monitoring cell phenotype during the production of CAR-T therapies. This work further confirms the need for larger studies to analyze the T cell expansion and phenotypic profiles from a wide cohort of individuals of different sex and ages. This will build a knowledge base to meet the need for truly personalized T cell activation profiles to deliver highly effective T cell therapies.

869. Aptamer-Based, Traceless Selection of CD62L$^+$ CD8$^+$ T Cells for Improved Adoptive T Cell Manufacturing

Abe Y. Wu[1], Emmeline L. Cheng[1], Nataly Kacherovsky[1], Stephen J. Salipante[2], Michael C. Jensen[3], Suzie H. Pun[1]

[1]Department of Bioengineering, University of Washington, Seattle, WA,[2]Department of Laboratory Medicine, University of Washington, Seattle, WA,[3]Seattle Children's Research Institute, Seattle, WA

INTRODUCTION: CAR T cells manufactured from more defined, less differentiated T cell subsets have shown greater persistence and potency than those derived from more differentiated effector cells. However, current selection relies on antibody-based magnetic activated cell sorting (MACS) technology, which is costly and largely precludes multiple positive selections in series due to the surface retention of magnetic beads. Consequently, selection of T cell subsets requires a combination of positive and negative selection strategies that can result in low product purity and yield, presenting a significant challenge for clinical translation. Previously, we discovered a CD8 aptamer (CD8Apt) and developed an aptamer-based method to tracelessly isolate CD8$^+$ cells for CAR T cell therapy[1]. In this work, we discovered a high-affinity CD62L aptamer (CD62LApt) and applied CD62LApt and CD8Apt to tracelessly and sequentially select less differentiated CD62L$^+$CD8$^+$ T cells with high yield and purity. **RESULTS:** We conducted cell-SELEX for 8 rounds to identify T cell-binding aptamers and discovered an aptamer that binds to CD62L (CD62LApt). CD62LApt binds to primary human T cells with K_D=0.31nM and to soluble CD62L with K_D=5.30nM. Using CD62LApt and our previously discovered CD8Apt, we designed a method to tracelessly and sequentially select CD62L$^+$CD8$^+$ T cells from human PBMCs. In each selection step, we show >95% capture of all CD8$^+$ and CD62L$^+$ cells (Fig. 1A). After selection, we show that CD3$^+$CD8$^+$CD62L$^+$ T cells are highly enriched from 5.18 ± 2.16% in the PBMCs to 69.7 ± 8.16% in the post-selection product (antidote elution), comparable to antibody-selected cells (Fig. 1B and C). However, the aptamer-based, serial positive selection approach delivers an overall CD8$^+$CD62L$^+$ yield of 59.14 ± 2.55% that is significantly higher than that from antibody-based selection (Fig. 1D). **CONCLUSIONS**: These results suggest that the aptamer-based approach enables the precise selection of T cell subsets with high yield for manufacturing CAR T cells from less differentiated cell subsets in a mostly synthetic system. We are currently evaluating the performance of CAR T cells manufactured from our aptamer-selected cells in in vivo tumor models.

870. Impact of Media Exchange Strategy on T-Cell Expansion

Lindsey A. Clarke, Noman Naeem, Richard Baxter, Nicholas Akosa, Maria Kalli, James Kusena, Césaré Cejas, Antoine Espinet

MFX, Stevenage, United Kingdom

Background & Aim: Media supplementation (replacement/addition/perfusion) of Primary T-cell culture plays a crucial part in maintaining robust expansion ex vivo in a variety of systems and is key to achieving high cell densities. Scaled-down bioreactors are advantageous for understanding the impact that media exchange strategies can have as smaller environments help users to better comprehend the underlying cell biology by allowing rapid generation of data in a cost effective manner. Existing automated systems for manufacturing and process development have high price-points that curtail accessibility.

Therefore, users rely on current research tools and systems - largely labour-intensive - where manual feeds limit the opportunity to closely monitor the expansion process and control cell growth densities. Methods:We designed a machine platform that automates media replacement via continuous perfusion. This system uses a bespoke scaled-down microfluidics-based bioreactor, designed specifically for automation integration while still offering optimal conditions for cell growth. Using Primary T-cells from different donors (both fresh & frozen) as well as a cell line (Jurkats), we demonstrate the performance of this machine platform in delivering consistent media continuously by investigating its impact on cell expansion numbers, viability, phenotype and morphology. We also compare results from automation with that of a manual batch-fed media exchange strategy on the same bioreactor. In addition, we contrast the performance of our bioreactor vs. conventional industry standard tools. Results:We demonstrate via automation that controlled frequent media replenishment regularly help minimise lactate build-up and maintains more conducive microenvironments for cell growth than more standard manually-operated protocols. Through automation, we can push cell densities even higher and by multiplexing multiple bioreactors can perform parallel multivariant experiments, thereby permitting more efficient process optimisation at scaled-down level. Some of the challenges of automated continuous perfusion strategy are cell loss and cell shear. However, with this bespoke microfluidics-based bioreactor, we demonstrate that we are able to maintain high cell retention efficiencies with low shear and consistent viable growth.. Conclusion:Our study highlights the benefits of automation to improve T-cell expansion for more efficient process development using a lower-cost machine platform with custom-designed microfluidics-based bioreactors. Future works aims to explore the feasibility of bringing other unit operations such as transduction and washing into the same microfluidics bioreactor.

871. Considerations in Raw Materials when Manufacturing Cell Therapies and Other Biologics

Rebecca Warfield[1], Spencer Chiang[2], Yanke Liu[2], Jane Liu[2]

[1]ACROBiosystems, Newark, DE,[2]ACROBiosystems, Beijing, China

Growth factors are a cornerstone in the intricate landscape of cell therapy manufacturing, playing multifaceted roles essential to produce biologics and other advanced therapeutic medicines. These biomolecules are intricately utilized throughout various manufacturing phases. As growth factors, they stimulate cell reproduction for desired therapeutic compounds as well as differentiate stem cells into cells of interest. After the initial adoption of several cell therapies, focus has become on ensuring manufacturing consistency, quality, and reliability in biopharmaceutical manufacturing. As such, quality control of cell therapies requires a multi-faceted approach for QC of not only the final therapeutic, but also raw materials that go into manufacturing cell therapies. Herein, we explore the different key methods and new assay validation procedures behind GMP product development to ensure a safe raw material for use in therapeutic manufacturing. We also highlight key facets of growth factor 'grades' that are associated with different stages of cell therapy manufacturing. As the biopharmaceutical industry continues to evolve and innovate, cell therapy manufacturers need to further emphasize the need for suppliers to ensure these tools are high-quality and provided at the required structure to continue to provide the foundational elements in pursuing improved global healthcare outcomes.

872. Closed Modular Clinical-Scale Manufacturing of CAR T Cells for Cancer Immunotherapy Using Activated and Non-Activated T Cells

Akshaya Chandrasekaran[1], Ranganatha Somasagara[1], Monique LaCourse[1], Anna Liu[1], Arseny Smirnov[1], Gregory Bonello[1], Namritha Ravinder[2]

[1]Thermo Fisher Scientific, Carlsbad, CA,[2]ThermoFisher Scientific, Carlsbad, CA

Introduction: Rapid developments in the field of chimeric antigen receptor (CAR) T-based immunotherapies and the need for generating efficient and cost-effective cell therapies have increased the demand for manufacturing workflow improvements to improve patient access while maintaining quality control and performance. Conventional CAR T cell manufacturing workflows involve T cell activation, followed by payload delivery, and *ex vivo* expansion. However, the activation and expansion of CAR T cells leads to their progressive differentiation, T cell exhaustion, and ultimately results in resistance to CAR T therapies. Accumulating evidence in mice and humans suggests that T cell differentiation negatively correlates with long-term anti-tumor activity, with early memory T cells allowing for greater and persistent anti-tumor effects. More recently, it has been established that a modified cell manufacturing process implementing activation after Cas9 delivery minimizes occurrence and impact of chromosome loss in the manufactured product. Non-activated cells are also desirable as a starting material to achieve shorter workflow times critical to point-of-care and decentralized therapy manufacturing and reduced costs. Here we demonstrate a closed and modular system for the generation of CAR T cell products starting from non-activated/resting and activated T cell populations. Methods: We use an automated counterflow centrifugation method where PBMCs are isolated from fresh leukopaks using the Rotea™ system and then downstream T cell enrichment is performed. Electroporation (EP) reactions for payload delivery are set up and optimized at small scale using Neon™ NxT™ platform and then scaled up using CTS™ Xenon™ Electroporation System. Transfection efficiency and cell viability are measured by flow cytometry and resting T cell phenotype is monitored pre- and post-EP to monitor maintenance of stemness in comparison to the starting population. Electroporations are performed using the CTS™ Xenon™ Lower Conductivity Buffer that enables higher energy setting on the Xenon system for hard-to-transfect cell types thereby providing a wider design space for process development and commercial manufacturing. Cells are activated post-electroporation and expanded for downstream functional assays. For the activated T cell protocol, PBMCs are isolated from frozen leukopaks using the Rotea™ system and activated using CD3/CD28 CTS™ Dynabeads™. The activated T cells are then resuspended in CTS™ Xenon™ Genome Editing Buffer and electroporated to deliver the Cas9 RNP complex and donor DNA expressing anti-CD19 CAR. Post-expansion, cells are washed and concentrated using Rotea™ and analyzed for transgene expression and

cryopreserved for downstream functional studies. Targeted Amplicon-seq validation assay (TAV-seq) confirmed no detectable off-targets in CAR T cells and functional cancer cell cytotoxic assays against CD19 presenting-Nalm-6 cells showed effective killing by anti CD19 CAR-T cells. Conclusions: In summary, we established a closed modular workflow for CAR T cell generation using automated instrumentation for cell processing and gene delivery thereby minimizing human intervention in the cell therapy manufacturing process. The transfection reagents and gene editing payloads in combination with the closed automated workflows described here will help reduce labor-intensive open system hurdles and improve the engineering of hard-to-transfect primary cells used for the development of efficient adoptive immunotherapies.

Wednesday Posters: Pharmacology/Toxicology Studies and Analytics/Assay Development

873. Validation of AntiAdeno Associated Virus Serotype rh10 (AAVrh.10) Total and Neutralizing Antibody Immunogenicity Assays

Elizabeth Butala-Flores, Thien Nguyen, Luke Armstrong, Amanda Hays
BioAgilytix, Durham, NC

Purpose/Background: Immunogenicity assessments used for inclusion/exclusion for safety and efficacy are critical for the development of Adeno-Associated Virus (AAV)-based gene therapies. There are different assay formats that can be used and that are being used for this context and yet it is not clear which of the assays should be implemented at what stage of drug development. AAVrh.10 has gained interest for use in gene therapies given its superior transduction efficiency, however there is limited information in the literature on anti-AAVrh.10 antibodies and their clinical impact. Herein, we highlight the validation of a total antibody assay (TAb) and a neutralizing antibody (NAb) assay for detection of anti-AAVrh.10 antibodies to be used in enrollment of patients into an AAVrh.10 gene therapy clinical study. Both assays were compared in terms of sensitivity, drug tolerance, and precision, along with a concordance analysis to determine if both assays produce similar results if used in enrollment. Methods/Materials: For the TAb assay, a sequential bridging ECLIA assay was developed. Briefly, MSD standard binding plates were coated with unlabeled AAVrh.10 for capture, followed by blocking then incubation with human serum and detection with a ruthenium labeled AAVrh.10-Luc and MSD Read Buffer T. A signal within the well correlates with the presence of TAb in the sample. For the NAb assay, an AAVrh.10 vector containing firefly luciferase reporter gene was applied to a transduction permissive cell line, 2V6.11. Cells were seeded in 96-well Poly-D-Lysine coated plates and incubated overnight at 37°C/5% CO_2. The next day, AAVrh.10-Luc vector was mixed with human serum samples, added to the cell plate and placed in an incubator for 24 hours. One-Glo reagent was added to the plate before reading luminescence on a Biotek Cytation 3. The presence of NAb in human serum samples inhibits the luminescence-generating activity of the virus, thereby reducing signal in the assay. Both assays were validated including determination of screening cut-points in accordance with the 2019 FDA immunogenicity guidance. Results: Both assay formats (TAb and NAb) were validated to determine sensitivity, cut-point determinations, precision, drug tolerance, and selectivity. Both assays were compared in terms of sensitivity and other performance parameters. In addition, a concordance analysis was performed to understand the agreement in response between samples that were evaluated in both the TAb and NAb assays. Of the 140 screened samples, 34% (48 samples) screened negative in both the TAb and NAb assays (TAb-/NAb-), whereas 55% (77 samples) screened positive in both assays (TAb+/NAb+). Five samples (3.6%) that screened positive in the TAb assay did not demonstrate positivity for neutralizing antibodies to AAVrh.10 (TAb+/NAb-) and 10 samples screened negative in the TAb and positive in the NAb (TAb-/NAb+). Further evaluations were performed to understand the antibody titer response for samples that screened positive in one assay and negative in the other. Conclusions: The information we present herein suggests a concordance between TAb and NAb assays that demonstrates the suitability of either to be used as a screening assay for patient enrollment into AAVrh.10 gene therapy clinical studies. This information contributes to the acceleration of drug development and provides the industry with information on assays that can be used for patient enrollment and as a potential companion diagnostic for AAVrh.10 gene therapies.

Correlation of TAb and NAb assay			
		Anti-AAVrh.10 NAb	Anti-AAVrh.10 NAb
		Negative	Positive
Anti-AAVrh.10 TAb	Positive	5	77
Anti-AAVrh.10 TAb	Negative	48	10

874. Qualification of a Universal IFN-gamma ELISpot Assay That Can Monitor Cellular Immune Responses in Gene Therapy, Cell Therapy, and Vaccine Development

Lu Zhang, George Zhu, Hongrong Hu, Tongyuan Li, Dongbei Li, Xiao-Yan Cai
Accurant Biotech Inc., Cranbury, NJ

Gene therapy, cell therapy, and clinical vaccine development all require cellular immunity testing performed in a regulated environment to ensure that they are safe and effective. Enzyme-Linked Immunospot (ELISpot) assays are currently the most commonly used cellular immunoassays that can measure cytokine-secreting cells at the single cell level in a semi-quantitative manner. In our current study, we developed and qualified a universal and sensitive interferon-gamma (IFN-γ)-based ELISpot method that can monitor T-cell immune responses during pre- and post-dose periods in clinical trials. This method explored the following parameters: Lower limit of quantification (LLOQ), upper limit of quantification (ULOQ), precision tested at two different levels of CEF (Cytomegalovirus, Epstein-Barr virus, and Influenza virus epitopes)-stimulated spots, linearity, robustness ranges, and plate and sample storage stability. We

tested this method using PBMCs collected and isolated in different ways, and designed each of these platform parameters so that they could be utilized by a wide variety of future assays. For each individual therapy development, the confirmatory cut point (CCP) of test article-specific antigens, limit of detection (LOD), and minimum immune response (MIR) have been established at the 95th percentile, using 28 PBMC lots to achieve reasonable statistical power. This qualified IFN-γ ELISpot platform has been utilized in several gene therapy clinical studies (AAV2, AAV9 etc.), demonstrating the value of this universal ELISpot methodology to reliably measure cellular immune responses against AAV gene therapy.

875. Comparison of a Microfluidic Generic Total Antibody (TAb) Assay with Independent Neutralizing Antibody (NAb) and TAb Assays for the Detection of Pre-Existing Antibodies Against AAV Vectors

Eric Feeley[1], Frida Löthberg[2], Kira Hedström[2], Jordi Rodo[3], Lone Frier Bovin[3], Selvi Celik[3], Cecilia Klint[3], Maria Gianneli[2]

[1]Gyros Protein Technologies, Warren, NJ,[2]Gyros Protein Technologies, Uppsala, Sweden,[3]Svar Life Science AB, Malmo, Sweden

PURPOSE: In clinical trials with adeno-associated virus (AAV) vectors, screening for participants lacking pre-existing neutralizing antibodies is crucial for effective gene therapies. Various methods, such as Neutralizing (NAb) assays and Total Antibody (TAb) assays, are used to screen for anti-AAV antibodies. NAb assays assess how NAbs and other non-antibody factors hinder AAV transduction as measured by the expression of a reporter gene mediated by the AAV therapy. TAb assays, with their simpler design and operational ease, typically require serotype-specific assays or AAV capsid labeling (when bridging format is used), introducing time and variability. We developed a generic anti-AAV TAb immunoassay on the automated Gyrolab platform that enables the detection of anti-AAV antibodies in human samples, eliminating the need for serotype-specific assays or AAV capsid labeling. The assay's robustness was confirmed through comparison with independent NAb and TAb assays. METHODS: Anti-AAV TAb analysis in an automated, CD-based format was performed on the Gyrolab microfluidic platform with commercially available Gyrolab Generic Anti-AAV kit reagents on human serum samples. NAb assays were completed using SVAR Life Science iLite® AAV Neutralizing Platform for 2 different serotypes (AAV2 and AAV8), whereas SVAR Life Science ELISA TAb assay was performed for serotype AAV2. RESULTS: The NAb results for 12 human samples are given in % neutralization (transduction inhibition). For this comparison, a cut point was set at 35% for AAV2, with samples reading above qualifying as positive and samples reading below qualifying as negative. For AAV2, 8/12 NAb-samples correlated well with the Gyrolab microfluidic assay. Samples S58, S72 and S74 came in as negative in the NAb assay and positive in the Gyrolab assay while S69 qualified as positive in the NAb and negative in the Gyrolab assay. For AAV8, with a cut point of 38%, the NAb and Gyrolab assays correlated completely. In the comparison of the AAV2 ELISA TAb assay to the Gyrolab assay, samples quantifying above 1 ug/mL in a 1/30 dilution in the TAb are considered positive. There is a clear correlation between samples qualifying as positive in both assays. The TAb data for samples S58, S69, S72 and S74 is consistent with the Gyrolab assay. This speaks to the conclusion that the differences in qualification for these samples are due to the assay formats (NAb vs TAb) rather than an inaccurate read. CONCLUSIONS: We have developed a Gyrolab generic assay that allows for the qualitative assessment/screening of binding antibodies against AVV vectors for different serotypes. The results correlate strongly with independent NAb and TAb assays despite a small sample size. This highlights the potential of our Gyrolab assay as a stand-alone or complementary tool for the assessment and screening of pre-existing anti-AAV antibodies in patients.

876. The Role of Thermal Stability in AAV Titration of Engineered Variants

Emilia Araujo Zin[1], Melissa Desrosiers[1], Guillaume Labernede[1], Camille Robert[1], Deniz Dalkara[2]

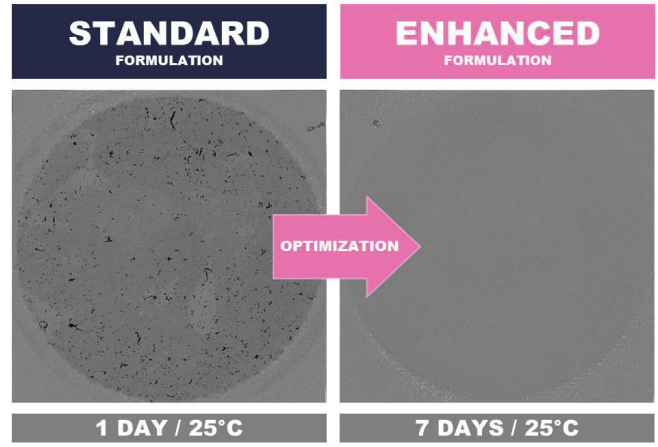
[1]Institut de la Vision, Paris, France,[2]Institut de La Vision / Sorbonne Universites, Paris, France

Determining accurate and reproducible titers for recombinant adeno-associated virus (rAAV) productions is essential to their development and downstream therapeutic applications. However, reproducible and reliable titering is a bottleneck in the field of AAV-mediated gene therapy. Moreover, the fast growing number of engineered AAV capsids further complicates the generalization of titering schemes, sometimes resulting in low and unreliable viral titers, questioning their adequacy for clinical development and use. Traditionally, AAV titers are expressed as genome copies or viral genomes per milliliter. Before amplifying viral genomes through qPCR or ddPCR, the free-floating DNA requires enzymatic digestion. In this study we propose for the first time that the DNase inactivation step, at 65°C or above, is a critical bottleneck for variants who have a melting temperature within the DNase inactivation temperature range. Here we measure melting temperatures for engineered AAV variants and demonstrate a correlation between lower thermal stability and titer variability emphasizing the need for titering methods that do not require heating of the sample. This finding is especially important for work involving engineered AAV variants with lower thermostability.

877. Evaluating Transduction Efficiencies of AAV Vectors in Human iPSC-Derived Cell Types

Ravi Vaidyanathan[1], Rebecca Fiene[1], Morten Seirup[2], Trish Hoang[2], Jeff Nelson[2], Brett Johnson[3], Belen Torres[3], Sreenath Palle[3], Emigdio Reyes[3], Margrethe Boyd[4], Ana Wang[4], Anthony Essex[4], Simon Hilcove[1], Coby Carlson[1]

[1]FUJIFILM Cellular Dynamics Inc. - Madison WI, Madison, WI,[2]Promega Corporation, Fitchburg, WI,[3]FUJIFILM Diosynth Biotechnologies, College Station, TX,[4]PhenoVista Biosciences, San Diego, CA



INTRODUCTION: The differentiation of induced pluripotent stem cells (iPSC) into specialized cell types of the human body represents a major advancement for the development of biologically relevant in vitro models. These cellular systems enable "disease-in-a-dish" studies and are compatible with various gene targeting approaches, including

adeno-associated viral (AAV) vectors, to directly correct the genetic mutation. However, the permissibility of AAV transduction across different iPSC-derived cell types needs to be defined. This requires the implementation of a sensitive and versatile technology to monitor transduction efficiencies and quantify the impact of various factors, including viral vector serotype, multiplicity of infection (MOI), choice of promoter, transduction media, and/or timing of transduction. **METHODS:** Commercially available cryopreserved human iPSC-derived "iCell" products from FUJIFILM Cellular Dynamics, Inc. (FCDI) were used according to manufacturer's recommendations. Viral vectors were engineered with the AAV NanoLuc®-HaloTag® Dual Reporter System and viruses were generated by Promega. A subset of parallel experiments utilized AAV reagents from commercial vendors driving the expression of green fluorescent protein (GFP), comparing CAG and CMV promoters were also used in this study. These panels of AAV reagents was used to transduce several different iCell® products at MOI ranging from 10 to 10^6. Transduction efficiency was monitored either kinetically for 48 hours or via endpoint assay measuring luminescence on a plate reader or fluorescence by flow cytometry or imaging. **RESULTS:** iCell products (including astrocytes, cardiomyocytes, hepatocytes, neurons, and retinal pigmented epithelial (RPE) cells) were transduced with different serotypes (including AAV1, 2, 4, 5, 6, 8, and 9) containing various promoters (CAG, CMV, or Synapsin) in serum-free media. Broadly speaking, AAV6 showed the highest transduction efficiency across iPSC-derived cell types. Moreover, Synapsin drove higher expression in neuronal cells, whereas CMV was better in other cells. CAG was also very effective in cardiomyocytes. Neuronal cell types required longer transduction times (i.e., 96 h exposure to AAV) than did cardiomyocytes (24 h to peak signal, for example). In general, transductions were more efficient at earlier timepoints in culture (i.e., Day 7 vs. Day 10 for cardiomyocytes and Day 14 vs. Day 21 for RPE) with some exceptions. Importantly, the fluorescent aspect of the reporter enabled imaging of the cells to verify no impact to cell health or morphology post-transduction, in addition to efficient expression of the transgene.**CONCLUSION:** iCell products make a great model to evaluate transduction efficiency of different AAV serotypes preclinically. The systematic exploration of the numerous variables that impact the efficiency of AAV transduction for any given cell type is required. Cryopreserved cells from commercial sources that are manufactured reproducibly at scale are an ideal reagent for use in these studies because of their "thaw-and-go" consistency. Proper handling and storage of AAV material is critically important as it can affect transduction efficiency. Finally, the combination of iPSC-derived cells and AAV technology to modulate in vitro cellular disease models for pre-clinical studies and potentially even potency release assays is a powerful system that is now available as part of a drug manufacturing process for material release.

878. Combination of BMI, DLS and Visual Inspection to Resolve Particle Formation Issues in Formulations Commonly Used in Gene Therapy

Astrid Stockinger, Philipp Beck, Sonya Schermann
Ascend, Planegg, Germany

The development of gene therapies necessitates a rigorous approach to ensure product safety and efficacy. Historically, consideration of subvisible particles as a parameter in formulation development was deferred to later stages due to resource-intensive methods like light obscuration (LO) and micro flow imaging (MFI). The **scarcity of material** in **early-stage gene therapy** requires the exploration of **low-volume, high-throughput methods** for early detection of both **subvisible** and **visible particles**. This study highlights the effectiveness of **backgrounded membrane imaging (BMI)** as a low-volume method to identify optimal buffer conditions that mitigate subvisible and visible particle formation **early in formulation development**. Starting from a standard PBS AAV formulation, we **screened a range of excipient conditions at room temperature over the course of 7 days** to discover the optimal formulation for prevention of particle formation. The low volume requirement of BMI enabled us to perform this study with only **150 µL of sample per condition**. Complemented by dynamic light scattering (DLS) and visual inspection (VI), our findings showcase the successful resolution of particle aggregation by introducing a common surfactant to the formulation buffer and determining the optimal concentration. The use of BMI allows particles in both the **subvisible & visible range (2 µm - 5 mm)** to be characterized at low volumes and **complements DLS data**, which captures smaller aggregates (less than 1 µm) and **visual inspection**, which primarily identifies larger particles (> 150 µm). Nonetheless, a potential blind spot exists for particles between 1 µm and 2 µm, posing a challenge to achieving thorough characterization of the entire particle size range. However, the **combination of all three methods represents a comprehensive and synergistic approach** to mitigate the challenges associated with particle formation in formulation development for gene therapies.

879. *In Vitro* Assessment for Innate Immune Activation by AAV

Hideyoshi Kawasaki[1], Daisuke Sasaki[1], Shogo Matsumura[1], Geoffrey de Couto[2], Takeshi Sato[2], Ko Omura[2], Katsuyuki Kazusa[1]
[1]Exploratory Pathophysiology, Non-Clinical Biomedical Science, Applied Research & Operations, Astellas Pharma Inc., Tsukuba, Japan,[2]Safety Assessment, Integrative Biology, Astellas Gene Therapies, South San Francisco, CA

Adeno-associated virus (AAV) vectors are widely used in gene therapy, but immune response against AAV is known as one of the concerns. It

was reported that unmethylated CpG dinucleotides contained in the AAV genomes can induce activation of innate immune response via Toll-like receptor 9 (TLR9). It has also been reported that the production of type I interferon via TLR9 activation in plasmacytoid dendritic cells (pDCs) contributes to the activation of CD8+ T cell responses to AAV capsid. Because these activated CD8+ T cells have been reported to lower transgene expression via cytotoxicity to transduced cells, it is considered that to minimize the innate immune activation by AAV is valuable from the perspective of maintaining transgene expression and reduction of safety risks. Moreover, because it is known that there are species differences in immune responses, estimating the potential risk in humans at the non-clinical stage will lead to lower safety risks in the clinical setting and increase the probability of development success. Therefore, the purpose of this study is to establish an *in vitro* assay using human-derived samples to predict the innate immune response to AAV in humans. In this study, healthy volunteer-derived whole blood or frozen primary pDCs were used as human-derived samples. We analyzed secreted type I interferon levels in response to AAV as an indicator of innate immune activation. In contrast to AAV alone, addition of anti-AAV antibody led to robust type I interferon secretion. We analyzed the variability between donor lots, reactivity of multiple AAV serotypes, and the impact of TLR9 inhibition. To assess the implementation of this assay with higher throughput, we investigated innate immune signal response to AAV using THP-1 reporter cells. The results of these experiments will be shared in this presentation. In this study, it was concluded that innate immune response against AAV can be evaluated with *in vitro* assay using human-derived samples. This assay may improve gene therapy product development by selecting AAV genomic sequences with lower innate immune activation, lower safety risks, and greater pharmacological efficacy. Funding Statement: This research was funded by Astellas.

880. IdeS *In Vitro* Specificity Testing and GLP-Compliant Toxicology Study Yielded No Off-Target Substrate Cleavage or Test Article Related Toxicity

Scott N. Ashley, Sarah T. C. Elliott, Kelvin See, Saghana Muraleetharan, Rhyan Paul, Stephanie Kutza, Sayali Saykhedkar, Andria Culbert, Timothy S. Luongo, Jeffrey M. Alexander, Christopher R. Riling

Spark Therapeutics, Philadelphia, PA

AAV-based gene therapy has demonstrated promise in its ability to treat genetic disease. Pre-existing humoral immunity to the AAV vector may present a barrier to access for AAV-based gene therapy because a significant proportion of the population has naturally occurring antibodies that neutralize AAV vectors and inhibit transduction when delivered systemically. Overcoming this obstacle is critical for broad access to AAV-based gene therapy as a therapeutic. IgG-degrading enzyme (IdeS) is a cysteine endopeptidase derived from *Streptococcus pyogenes* that progressively cleaves the lower hinge region of IgG, generating F(ab')2 and Fc fragments and reducing IgG-mediated neutralization. Utilizing IdeS as a pre-treatment to eliminate anti-AAV IgG may enable treatment of seropositive patients with preexisting immunity to AAV. To evaluate the potential safety risks of using IdeS as a pre-treatment for AAV-based gene therapy, we investigated the specificity of IdeS through an *in vitro* characterization of potential substrates and evaluated the *in vivo* tolerability of IdeS in the rabbit model. To determine the specificity of IdeS, we digested a panel of human proteins selected on a variety of characteristics including predicted binding to IdeS and prevalence in human serum. IdeS demonstrated singular specificity as cleavage was only observed in the immunoglobulin IgG isotype. To investigate the safety of IdeS, we conducted a GLP-compliant toxicology study in New Zealand white rabbits, an animal model in which IdeS has been shown to be pharmacologically active. Both female and male rabbits were randomly assigned to one of four dosing groups given a single intravenous dose of IdeS at 0 mg/kg, 2.5 mg/kg, 7.75 mg/kg, or 20 mg/kg with half of each group taken down on study day 3 and remaining half taken down on study day 29, resulting in no significant pathology or mortality when monitored over 3 or 29 days. IdeS treatment demonstrated a range of 99.2% to 99.7% mean IgG cleavage despite a relatively short range of mean serum IdeS half-life, 4.63-8.15 hours. There were no test article findings in clinical observations, macro and microscopic histopathology, hematology, clinical chemistry, and coagulation. These findings provide evidence for specificity and tolerability of IdeS.

881. Optimal Prescreening Number of Non-Human Primates (NHPs) for Adeno-Associated Virus (AAV) Neutralizing Antibodies (NAb) in Gene Therapy Studies

Rajeev K. Dhawan, Connor John Balzer, Sarah Bernard, Lachelle Campbell, Brittany Egan, Donald Nicholson

Charles River Laboratories, Wilmington, MA

Adeno-associated virus (AAV) is the preferred vector for gene therapy studies. However, presence of neutralizing antibodies (NAb), from prior exposure to the virus, can limit its use in patients or research animals. Prior to studies, it's a common practice to prescreen the animals to detect the preexisting NAb using cell based assays. This may need screening of 3X to as high as 10X the number of NHPs enrolled in studies to find enough seronegative animals for the AAV vector serotype being utilized. Given today's NHP supply shortages, it's becoming difficult to find enough animals to accommodate testing of large numbers leading to increased costs and delays in studies. Using the data collected by our lab over the past 2 years, we sought to identify variables that can better predict the likelihood of AAV seropositivity in NHPs to minimize the number of animals required for prescreening to achieve the desired total of seronegative NHPs. To this end, data for four different AAV serotypes including AAV2, AAV8, AAV9 and AAVrh74 from nearly 2500 cynomolgus macaque sera was collated and analyzed. Results showed that seroprevalence ranged between 50% and 80% for all serotypes with AAV2 being the most prevalent and AAV9 the least. Both sex and age (2-3 years old) did not influence the percentage of AAV NAb positive NHPs for any of the tested serotypes. Small variations in seroprevalence were found in NHPs from different countries of origin and even different colonies from the same country. For example, between two Asian countries, one showed ~15% higher prevalence of AAV9 NAbs but ~10% lower prevalence of AAV2 NAbs. Variations in AAV seroprevalence was observed between different serotypes for NHPs sourced from different countries and vendors. However, no big change was seen between males vs. females. Additionally, in some cases, seroconversion was observed between

prescreening and the study start date, so it is advisable to screen NHPs as close to the start of a study as possible. To summarize, when screening NHPs to select subjects for study, it's important to consult the NHP supplier for suggestions about optimal screening timing and numbers based on specific seroprevalence observed in their colonies.

882. Comprehensive Immunogenicity Analysis of AAV Therapies: Correlating Anti-AAV Antibodies (NAbs/TAbs) with Complement Activation Dynamics

Jordi Rodo[1], Klaudia Kulak[2], Viktoria Kozma[2], Cecilia Klint[2], Michael Tovey[3], Michael Schwenkert[2], Lone Frier Bovin[2], Therese Segerstein[2]

[1]Svar Life Science, Cambridge, MA,[2]Svar Life Science, Malmö, Sweden,[3]Svar Life Science, Paris, Sweden

The extensive study of adeno-associated virus (AAV) vectors as carriers in gene therapy has progressed the field from a promising concept to a tangible medical reality. Despite these advancements, significant bottlenecks persist in the development of gene therapy products, particularly in meeting stringent regulatory requirements. A key challenge is the influence of antibodies against AAV on the efficacy of in vivo AAV-mediated gene therapy. This includes issues like capsid neutralization and triggering of immune reactions, notably the activation of the complement system. Currently, it is recommended by different industry leaders to analyze both the presence of total binding antibodies (TAbs) as well as neutralizing antibodies (NAbs). Additionally, assessing patient sensitivity to complement activation due to AAV adds a critical dimension to immunogenicity evaluation. Here we present the evaluation on 100+ samples of Svar's AAV immunogenicity solutions, which includes the assessment of anti-AAV antibodies (both NAbs and TAbs) and each sample's sensitivity to AAV-mediated complement activation. Our approach first employs a novel cell-based iLite® AAV platform for accurate NAb assessment to detect NAb-mediated reduction of AAV transduction. Secondly, TAbs are assessed with a standardized immunoassay with a high sensitivity, allowing the evaluation of the presence of anti-AAV antibodies Finally, the potential for AAV-mediated complement activation is evaluated in each sample, a crucial step in identifying susceptibilities that may lead to adverse effects. This evaluation is adaptable for both pre- and post-AAV administration scenarios. These three assays combine the advantages of both immuno- and cell-based assays. By offering reliable and customizable solutions for assessment and differentiation of humoral antibody responses against AAV vectors we respond to the expert demand for such assays. Svar's AAV immunogenicity solutions represent a unique toolbox designed to accelerate and support the clinical development of todays and tomorrow's AAV-mediated gene therapies.

883. Anti-Drug Antibody Assay for an Antisense Oligonucleotide

Mary Wojcinski, Leslie Kuiper, Jessica St. Charles

Charles River Laboratories, Mattawan, MI

Antisense oligonucleotide (ASO) drugs have been emerging as a gene therapy for protein misfunction as opposed to protein replacement. ASOs bind RNA to produce non-disease state proteins or inhibit the production of disease-causing proteins. To evaluate safety, the anti-drug antibody (ADA) response needs to be recorded. Due to the small size of an ASO, the development of an ADA assay was challenging; however, the resulting assay was similar to an ADA assay for an antibody. We developed a regulated ADA assay to an ASO to support a nonclinical cynomolgus monkey study. The assay had a 5'-Biotion-ASO as capture. The positive control was produced by immunizing rabbits with the ASO and isolating the ADA from the serum using affinity chromatography. ADA presence was detected by commercially available anti-ADA conjugated antibodies. Because the PC was produced in rabbits and the samples were being collected in monkeys, two detection antibodies were used to detect both PC and samples simultaneously. Development began with testing feasibility using the MSD. Detection concentrations were determined by coating the PC directly to the plate and testing different concentrations of anti-species-sulfotag. The concentration at which both detections overlapped was the optimal detection condition. The challenging aspect of MSD was sensitivity. These curves did not have workable S:N values. Therefore, different MRDs and buffers were tested. As no option improved S:N, the assay was switched to absorbance-based on the spectrophotometer using anti-species-HRP as detection. The detection assessment was performed again to determine the most optimal concentrations. Once determined, matrix testing was performed, and a theoretical screening cut point factor and sensitivity were calculated. The sensitivity curve had better S:N values when compared to MSD. There was also decent variability between the lots with a theoretical S:N value of 1.412. During this assessment, the plate was inadvertently shaken at the coating step. This run had higher than previously seen %CVs. Therefore, it was determined that the assay plate should not be shaken at any step. Drug tolerance was assessed next to determine the amount of drug tolerated by the assay as well as the concentration at which to test confirmatory sensitivity. Drug tolerance was sufficient based on PK data available. Confirmatory sensitivity performed well and a concentration of the ASO to do confirmatory at was determined. The assay was validated with a workable screening cut point factor (1.48) and confirmatory cut point (26.8%) that resulted in a highly sensitive assay (85.2 ng/mL). Even with the unique properties of an ASO, we saw values that are optimal for an ADA to an antibody-based drug. The assay also tolerated drug beyond the Cmax seen with the PK. Sample analysis is currently on-going. Of the 200 samples, 35 screened positive and 12 confirmed positive.

884. Can AI Improve Compliance, Consistency, and Efficiency for CGTP Data Analysis?

Stephanie Pasas-Farmer[1], Carrie Vyhlidal[2]

[1]BioData Solutions, LLC, Lawrence, KS,[2]KCAS Bioanalytical & Biomarker Services, Olathe, KS

Introduction: With the promise of treating cancer, Parkinson's, and other rare diseases, cell and gene therapy products (CGTPs) are gaining traction in the biopharma industry. As of 2023, the FDA has approved 34 CGTPs and over 1500 clinical trials are currently ongoing globally. Despite the increasing number of CGTP drug candidates, the bioanalysis supporting these programs is still fraught with many hurdles. These challenges include limited or no well-defined guidance; lack of harmonization of validation approaches and acceptance criteria; and limited software tools to facilitate the management of the high

volume of bioanalytical data being generated. Artificial intelligence (AI) offers a unique opportunity to alleviate these data analysis and throughput challenges by automating key processes that reduce time and increase efficiencies while maintaining data security, integrity, and compliance, such as 21 CFR part 11. More importantly, AI-enabled auditing data tools can facilitate consistency in scientific approaches and standardization of acceptance criteria. Challenges: While molecular assays are not new to the world of drug development, their application in CGTPs is more recent. Consequently, the regulations are either not specific or have yet to be established. Validation approaches and acceptance criteria lack harmonization. This results in inconsistencies in data analysis across and within studies. Additionally, a lack of tools for tabulating the high volumes of raw data used for FDA submissions often leads to transcription errors, data analysis errors, and overburdened quality control staff. Hypothesis and Solution Workflow: To overcome data analysis challenges facing molecular assays in highly regulated environments, an AI-enabled automation prototype was developed for evaluation. The tool would replace the common manual, repetitive, error-prone tasks and increase the efficiency of the laboratory scientists while improving the quality and compliance of the results and requiring minimal training. Firstly, a scientist would upload text/csv data file(s) to a validated and secure system with some minimal input fields. Due to the lack of harmonization around acceptance criteria, the system would permit study-specific customizable acceptance criteria to accommodate discovery data. Next, automated data analysis would substitute human processes of flagging of data outside of acceptance criteria are performed per regulatory guidance and industry best practices; tabulating raw data to reportable tables; and interim quality control (QC) and quality assurance (QA) checks for data transcription. Finally, data output would be generated. Results: The process of performing data calculation, creating reportable excel tables, and performing interim checks was completed in less than 1 minute. To make it more robust, R code simultaneously validates all calculations for additional validity and data integrity. It eliminated the need for interim QC and QA checks for transcription errors and data calculations as the data from the instrument is uploaded directly to the tool and converted to reportable output. Based on data gathered from end users, the automation tool prototype yielded time savings of 96.4%, going from 5.8 FTE to 0.2 FTE (46.4 work hours to 1.6 work hours) for a project with 15 plates. The reported times include extracting reports from instruments, uploading files, performing calculations, completing interim QC and QA checks, and populating the tables. Additionally, cost savings from the time saved were 97.3% and despite customization costs, an ROI of 600% was observed. Some unmeasurable benefits of automated data analysis and tabulation include the time given back to the scientists to focus on more important tasks that require human discretion and decision-making capabilities.

Wednesday Posters: Molecular and Cellular Methods

885. Ex-Vivo Platforms for Assessing Cell and Gene Therapy Agents in the Human Cornea and Retina

Khoa D. Tran, Megan M. W. Straiko, Katie Breitinger, Mark S. Ellison

VisionGift, Portland, OR

Gene therapy holds great promise for treating ocular disorders, particularly those affecting the corneal endothelium and the retina. To facilitate the preclinical assessment of gene therapy agents targeting these tissues, we established two tissue culture platforms for evaluating the efficacy of therapeutic interventions using human cornea and retina tissues from post-mortem donors. The first platform utilizes whole corneas, providing a native and intact tissue where the corneal endothelium can be treated with AAV, LNPs, small molecules, and other agents designed for genetic or cellular modifications. After treating the endothelium (for up to 4 hours), the cornea is cultured in organ culture media for up to one month at 31°C. Following the culture period, the cornea can be processed using methods compatible with different techniques for downstream analysis. These methods may include fixation for histological analysis, placement in preservation solutions, and flash freezing with LN_2. The endothelium can also be isolated by removing Descemet's membrane and corneal endothelial cells from the whole corneal structure, enabling cell dissociation, sorting, and molecular analysis of an enriched cell population of corneal endothelium. AAV-mediated transduction of GFP reporter genes resulted in detectable expression of GFP in corneal endothelial cells at 2 weeks post-transduction and was maintained for up to 1 month. The second platform employs retina explant cultures (retina only, as well as chorioretinal tissues). Explants are cultured on polycarbonate membranes in transwell culture plates at 37°C with 5% CO_2. Explants can be treated with test articles as described above, and the explants can be cultured for up to 1 month. Tissue preservation at experimental endpoints is similar to the methods described above. Previous success includes AAV-mediated gene editing and promoter-driven reporter gene expression at 2 weeks and 1-month post-transduction. Our results indicate that both platforms successfully replicate key aspects of the human cornea and retina, allowing for the assessment of gene therapy agents in a more native environment. The platforms can be used to examine vector transduction efficiency and biological responses, making them ideal for pre-clinical studies to support the optimization of treatment strategies for corneal and retinal disorders in a more clinically relevant context.

886. Broadly Expressed Synthetic NRF1-Array Mini-Promoters for Application to Gene Therapy and Disease Modeling Vectors

Robert D. Nicholls[1], Ting Zhang[2], Wan Zhu[3], Emma J. Hundertmark[4], Jia Qi Cheng Zhang[1], Marie A. Johnson[1], Haley L. Crable[1], Erik A. Koppes[1], Dwi U. Kemaladewi[1], George K. Gittes[2]

[1]Pediatrics, UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA,[2]Surgery, UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA,[3]Human Genetics, University of Pittsburgh School of Public Health, Pittsburgh, PA,[4]Bioengineering, University of Pittsburgh, Pittsburgh, PA

Introduction: Adeno-associated virus (AAV) has strict size limitations for packing into a viral particle, which previously limited the size of encoded therapeutic proteins or genome editing applications. To overcome this size limitation of AAV vectors and to provide a modular component for gene regulation in any vector type, rather than the commonly used CMV promoter-enhancer (613-nt) or many cell-type specific promoters for gene expression, we rationally designed mini-promoters of length 34-nt to 210-nt. **Results:** These mini-promoters are tandem arrays of 2-10 units in length of motifs (consensus is 5′-YGCGCANGCGCR-3′) for a transcription factor, NRF1, with 10-11 nucleotides spacing equal to one-turn of the DNA α-helix between binding sites to allow each NRF1-dimer to interact for potential cooperative binding. An additional set of NRF1-array mini-promoters includes a TATA-box motif. Indeed, use of NRF1-arrays of 1, 2, 4, 6, 8 and 10 units displayed cooperative increases in luciferase expression within transfected SK-N-SH neuroblastoma cells. Subsequent characterization has focused on the 4xNRF1 and 10xNRF1 promoters, with high levels of mNeonGreen or luc-EGFP expression detected from mammalian expression plasmids in rat INS-1 and mouse MIN6 insulin-secreting β-cells, mouse αTC1-6 glucagon-secreting α-cells, mouse C2C12 myoblasts, mouse mHippoE-2 hippocampal neurons, as well as human HEI-193 schwannoma (peripheral nerve) and HEK293T (adrenal) cell lines. Next, robust expression was also demonstrated by fluorescence microscopy and luciferase assays using each of these two promoters in an AAV6-luc-EGFP vector following viral transduction of rodent β- and α-cell lines, primary human α-cells, and by tail vein or pancreatic duct infusion of each virus in wildtype mice with *in vivo* imaging of bioluminescence, clear expression was observed in the liver and pancreas, respectively, and confirmed by tissue dissection. Critically, the 4xNRF1 mini-promoter was also utilized in a miniaturized CRISPR-activation (CRISPRa) AAV9 vector for therapeutic *Lama1* gene upregulation in a *Lama2*-deficient muscular dystrophy mouse model, resulting in reduced hindlimb paralysis, improved mobility, body weight, and survival. **Conclusions:** Previously generated synthetic promoters have typically been based on random DNA motifs or utilized endogenous promoter fragments, but few have the broad expression profile or minimal size as for our panel of NRF1-array mini-promoters. Miniaturization of promoter and encoded functions will aid *in vitro* and *in vivo* disease modeling and gene therapy applications, not only for AAV but also for non-viral approaches such as lipid nanoparticle (LNP)-mediated nucleic acids delivery.

887. A Novel Next-Gen Sequencing Library Preparation Method to Sequence Small, Long, and Low-Quality (Fragmented/ Degraded) with Low (*Pico*-Grams) Quantity of DNA/RNA Templates for Better Diagnostics, Biomarker Discovery, and Research

Praveensingh B. Hajeri[1], Masato Yamamoto[2], Adam Herman[1], Nuri Alpey Temiz[2]

[1]Department of Surgery, University of Minnesota, Minneapolis, MN,[2]University of Minnesota, Minneapolis, MN

Background and limitations of current technologies: Next-generation sequencing (NGS) of RNA and DNA is a method of high-throughput sequencing of biological samples. There are several well-established methods in published literature and also commercially available in the form of products/kits dedicated to sequencing total RNA, DNA, exome, small RNAs, and selected panels of gene/ loci to address specific issues. However, it has been a great challenge to sequence highly fragmented and degraded DNA/RNA due to the limitations of library preparation methods. This affects the sequencing of clinical samples, biological research materials, liquid biopsy, FFPE tissue, exosomes, forensics, cell-free RNA/DNA, and archeology, among several other types of materials. A large fraction of archived and even fresh samples do not generate high-quality data, which cripples basic research, biomarker discovery, and diagnostics. Currently, it is also impossible to sequence small RNAs alone or small and long RNAs together with pico-gram quantities of total RNA template. ***Methods and results:*** We have addressed these limitations by developing a novel method to prepare NGS libraries from pico-gram quantities of total RNA templates. Our methods could efficiently capture RNA of all sizes (20bp and above, including small and long RNAs) simultaneously and detect 2-10 times more unique transcripts at a similar sequencing depth than the current state-of-the-art methods. We could capture 20,000 to 100,000 more transcripts than an established method in a proof-of-concept study. We could capture small (as small as 20 bases and above) and long RNAs in the same library using very low (pico-grams) quantities of total RNA. ***Applications and broader impacts:*** Our method is applicable to highly fragmented and degraded samples like biological samples, clinical samples, FFPE tissue, cell-free RNA/DNA, liquid biopsies, archeological samples, and also normal samples. The variations and errors observed in NGS data due to differential degradation between samples are negligible in our method. This helps generate consistent and high-quality sequencing data. We could generate 2-10 times more high-quality data with as little as 500pg of total RNA, which is close to the total RNA obtained by a single cell and hence applies to single-cell sequencing. The method is compatible with automation as well. Due to its high efficiency and sensitivity, we think our method will enable better diagnostics, biomarker discovery, and research.

888. Harnessing the Power of Multiomics from Fresh and Fixed Patient Sample Characterization

Andrea O'Hara, Yang Han, Yongjun Fan, David Corney, Chris Mozdzierz, Haythem Latif, Ginger Zhou
Azenta Life Sciences, Burlington, MA

The omics era has greatly expanded the repertoire of approaches available for researchers and clinicians to unravel the complexity underpinning human health: Next Generation Sequencing (NGS) approaches can characterize genomes, epigenomes, transcriptomes and proteomes. The analyses are critical to assess in individuals both pre- and post-treatment during therapeutic development and early-stage clinical trials. Peripheral blood mononuclear cells (PBMCs) offer a non-invasive approach that, when combined with omics tools, can provide a near holistic view of immune processes across patient cohorts. Meanwhile, Formalin Fixed Paraffin Embedded (FFPE) tissues are a staple in clinical diagnostics and an ideal means to store archival tissue but can be difficult to work with in traditional NGS assays. Here we detail workflows using both fresh and fixed patient samples to rapidly produce a diverse set of multiomics results including genomics, epigenomics, transcriptomics and proteomics. For fresh blood draws, this starts with automated sample handling and processing to ensure high viability and yield of PBMCs, along with simultaneous plasma separation and collection. Samples are then aliquoted and simultaneously processed for whole exome sequencing, single cell RNA sequencing, epigenetic characterization and Olink biomarker analysis. For fixed tissues, FFPE blocks were serially sliced into various FFPE slides, with a single slide H&E stained. Individual slides were then utilized for genome, epigenome, single cell RNA-seq, and digital spatial profiling. Genome information was captured using hybrid capture based approaches followed by deep NGS on an Illumina platform and analyzed for a variety of variants and tumor mutational burden. DNA methylation was detailed using target capture probes targeting DNA methylation sites. Single cell approaches were applied to explore the transcriptome using 10X Genomics scRNAseq kit, and Digital Spatial Profiling (DSP) was done using the NanoString GeoMx Whole Transcriptome Atlas and immunostaining. With these robust workflows, all these datatypes can be produced within days of fresh or fixed sample receipt using minimal sample amounts. High throughput integrative omics workflows, as described here, drive greater insights in human health, allowing for a rapid combined approach to address the biological questions at hand.

889. Validated Solution for High Throughput Analyses with Flexible Mods for Custom Assay Design

Hubert F. Arokium[1], Howard Rosoff[2], Francis Kim[2], Sean Hsu[2], Rebekkah Hesson[1], Patrick Trainor[3], Victoria M. Velazquez[1], Karim Khoury[1], Sam Pan[2], Sapna Varia[1]
[1]AmplifyBio, West Jefferson, OH,[2]AmplifyBio, South San Francisco, CA,[3]BioinfoScientist, Louisville, KY

Introduction: Fast expanding parameters and criteria for determining safety, efficacy, and biodistribution analyses of Cell and Gene Therapies require sizeable datasets looking at complex overlapping variables. Interpretation requires high throughput biostatistical analyses for achieving the desired results in individual preclinical studies. Performing intricate data analysis requires considerable effort and precise execution, which can lead to a depletion of resources, risk data integrity, and a turnaround time that is often months when relying solely on rudimentary IT tools like spreadsheets. The goal of this study was to design, develop, and validate a more efficient tailor-made solution using modern data automation practices and ETL (extract, transform, load) techniques to reduce the time it takes to perform repetitive analyses and use the best analysis strategy for critical preclinical safety and biodistribution data sets. *Approach:* Using a well-qualified Digital PCR (dPCR and RT-dPCR) biodistribution method as a test case, the data pipeline was designed to use single and multi-plex dPCR and RT-dPCR output results from a QIAGEN QIAcuity dPCR system. We defined the system's capabilities to include statistical analyses, reportable values, statistical results with output files, the ability to generate various summary plots and not alter any raw data points. *Results:* The use of the validated data pipeline system successfully demonstrated the technical performance of dPCR and RT-dPCR data through the application of method validation precision standards and established pass/fail benchmarks. The Data pipeline performed as designed and met all the validation requirements for i) data handling/ user defined access ii) performing technical quality control of the dPCR runs by flagging the results that fall outside of the acceptance criteria and distinguishing valid data from flagged data and iii) exporting data to a centralized data for pickup by biostatistical analysis modules. It featured user-friendly components, such as an exported Excel file with a "valid results" tab, showcasing data meeting the set criteria, and a "review" tab. This "review" tab displayed all relevant precision calculations (like %CV, mean, standard deviation), along with any technical indicators, for straightforward examination by a subject matter expert. Pipeline operation included separate Development and Production environments, the use of source code from an industry standard library, access and functionality controls, and a strict requirement that the pipeline itself did not affect the raw data. The data pipeline was able to accurately facilitate the comparative analysis of target gene copies or gene expression as defined by method validation precision standards and plate pass/fail criteria. In summary, the use of the validated data pipeline in a GxP setting ensures adherence to high standards of technical quality, data integrity, and traceability. Significantly, the ability to analyze samples within minutes or hours, as opposed to days or weeks, opens up possibilities for study sponsors to conduct extra analyses, thereby enhancing the depth of understanding derived from multi-faceted interpretation of study outcomes.

890. A Comprehensive ddPCR Portfolio for In-Depth DNA Impurity Profiling

Sonya M. Schermann, Sabine Geiger, Renée Kober, Felicia Thoennissen, Marina Magerl, Sophie Beer, Markus Hoerer
Ascend, Planegg, Germany

DNA impurities present in recombinant adeno-associated virus (rAAV) products pose a potential risk to patients and therefore need to be thoroughly understood. Methods are required for quality control (QC) of final product and also for extended product characterization. Here we discuss some of the ways in which multiplex digital droplet polymerase chain reaction (ddPCR) can be used in these two

applications. For QC release, multiplexing can be used to monitor multiple DNA impurities in a single assay, reducing the number of assays required for release of product and thereby minimizing the time and cost of batch release. Here we present a duplex method for monitoring residual DNA impurities of different origin and discuss aspects of method development and qualification/validation of such assays. For extended product characterization, we show how multiplexing can be used in a variety of applications, for example in understanding the length profile of encapsidated plasmid or host cell DNA, which is an important attribute when considering potential risk to patients of such encapsidated sequences. Long read NGS sequencing established in-house is used as an orthogonal method to validate the results obtained. We also demonstrate applications in which multiplex ddPCR can be used to interrogate whether two different sequences are present in the same capsid, for example residual rep and cap DNA, an application which can be used to predict the potential for rAAV batches to contain replication competent AAV (rcAAV). Taken together, such multiplex ddPCR methods represent powerful tools to determine not only the presence, but the amount, size and identity of encapsidated residual DNA and as such can be used both in QC and in extended characterization of rAAV products.

891. Development and Qualification of a Quality Control Panel for the Characterization of Recombinant Adeno Associated Viral Vectors

Francesca Rossetti[1], Veronica Meraviglia[2], Anna Longatti[2], Giulia Maria Nava[2], Matteo Paolillo[2], Marco Rausa[2], Chiara Portugalli[2], Chiara Boroni[2], Grazia Frizzale[2], Claudia Piovan[2], Margherita Neri[3], Giuliana Vallanti[2]

[1]AGC Biologics - Milan, Bresso (Milano), Italy,[2]AGC Biologics, Milano, Italy,[3]AGC Biologics, Milan, Italy

AGC Biologics is a leading global Contract Development and Manufacturing Organization (CDMO), providing world-class development and manufacture of mammalian and microbial-based therapeutic proteins, plasmid DNA, viral vectors and genetically engineered cells. Recombinant Adeno Associated Viral Vectors (rAAVs) produced with transient transfection in HEK293 are extensively used for genetic modification in gene therapy treatments. Companies that decide to go down the road of AAV production face two major challenges. The first challenge is the availability of an efficient and scalable off-the-shelf vector production processes. AGC Biologics is developing different systems for AAV production at large scale, in adhesion and suspension, flexible to be adapted to different GOI and serotypes. The second challenge is to develop a solid analytical panel for vector characterization. A full quality control plan has been designed for the release of clinical lots, in accordance with GMP rules, EU and US Guidelines, CBER Points and ICH. The panel designed foresees all the assays to assess the identity, potency, safety and purity of the vector. The tests to determine vector particles, vector genome and infectious particles (potency test) were developed and qualified. Both assays for vector genome and infectious titer have been designed in order to be quickly applied to all different serotypes and GOIs and to be easily switched to product specific assays, according to the different applications. Assays for the determination of full/empty ratio, vector aggregation and determination of AAV viral capsid proteins have settled scouting different technologies. Even if the gold standard for F/E is Analytical Ultracentrifugation (AUC), other techniques are now acquiring visibility, due to their easier set up, time-saving and lower cost. Anion-Exchange Chromatography (AEX) performed by UHPLC instrument has been chosen as good strategy for the separation of full and empty capsids. Data obtained have been compared with the ratio calculated from viral genome titer and vector particles titer, and with orthogonal procedure AUC in outsourcing for AAV6 and AAV8 samples. Percentage difference among the different procedures is ≤ 36%. Introduction of Dynamic Light Scattering instrument for the determination of vector aggregation helps to nicely verify aggregates removal throughout the purification process, with percentage of aggregates that span from 10% to 40% in the post affinity sample to below 1% in the final purified vector analysing six different serotypes. AGC biologics is then putting a lot of effort for the assays for residuals characterization to have from one site more sensible assays to meet guidelines request for in vivo applications and form the other to have precise, accurate and high throughput assays, that can be coupled with automatic station. Assay for the determination of DNA size, total DNA, E1A DNA, HCP, benzonase are some of the assays ready to use for vector release. In the context of a comprehensive CDMO offer, a higher value is added considering that more than 90% of the assays is performed in house, optimizing volume and number of samples dedicated to QC analysis.

892. Short- and Long-Read Sequencing for Integration Site Analysis (ISA) of Viral Vectors for Gene Therapy

Ben Niu, Andrea O'Hara, Candy Mao, Brian Sereni, Brad Scherer, Haythem Latif, Ginger Zhou

Azenta Life Sciences, Burlington, MA

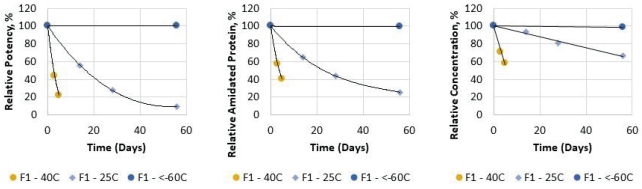
While lentivirus has historically been the viral vector of choice for gene therapy, recombinant adeno-associated viral (rAAV) vectors have seen widespread application as a gene therapy delivery platform in preclinical and clinical studies. Unlike lentiviral vectors, which are fundamentally integrated into the host genome, recombinant AAV largely remains episomal after transduction into the nucleus of the host cells; however, data has shown AAV may integrate into the host genome in a random, non-homologous manner. The frequency of AAV integration has been estimated at 0.1% to 10% in hepatocytes. In consideration of the theoretical risk of tumorigenesis associated with lentiviral and AAV integration in humans, assessment of viral vector integration in *in vitro* studies, animal models, and patient samples are recommended by FDA for preclinical and clinical studies and long-term follow-up studies (LTFU). AAV integration analysis presents several challenges, including the random nature of AAV integration sites and low expected integration frequency. To address this, Next Generation Sequencing (NGS) for viral vector integration analysis has been adopted as a highly sensitive assay. Traditional approaches utilize targeted enrichment sequencing with hybrid-capture or linear amplification PCR in combination with short-read sequencing technology. The addition of long-read sequencing offers the advantage of being able to identify chimeric reads with clear sequence structure

as genome-insert-genome. Here we describe multiple mixed ISA approaches in lentiviral and AAV studies, with improved sensitivity and specificity for ideal detection of viral vector integration.

893. Investigating Tropism of AAV5 and AAV3b Using Multi-Organ Human Tissue Equivalents

Ritu M. Ramamurthy[1], Aya El-Taibany[1], Janmejay Hingu[1], Jonathan H. Diaz[1], Yu Zhou[1], Sarah E. Wachtman[1], John C. Armstrong[1], Daniel Porada[1], Douglas E. Shankle[1], Meimei Wan[1], Colin E. Bishop[1], Michael Seeds[1], Christopher B. Doering[2], H. Trent Spencer[2], Hooman Sadri-Ardekani[1], Sean V. Murphy[1], Anthony Atala[1], Christopher D. Porada[1], M Graça D. Almeida-Porada[1]

[1]Fetal Research and Therapy Program, Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC,[2]Department of Pediatrics, Aflac Cancer and Blood Disorders Center, Emory University, Atlanta, GA



There is no definitive data concerning human tropism/cell-specificity of adeno-associated viral (AAV) vector serotypes in clinical use due to the inability to justify multiple organ biopsies in patients receiving the therapy. Thus, most clinical approaches have relied upon tissue-specific promoters to restrict transgene expression to the desired cell type *in vivo*. However, tissue-specific promoter does not limit transduction itself to a particular cell type and such an approach continues to be inherently problematic, as off-target effects are possible and binding/uptake of the vector by cells that will not contribute to transgene expression reduce the effective vector dose reaching the desired cells. Here, we used human multi-organ tissue equivalents (OTEs), which are 3D culture systems comprised of major cell types present in respective tissues and that can mimic function and histology of actual human organs to define human tropism of AAV. Two clinically-relevant AAV serotypes, AAV5 and AAV3b, encoding a GFP reporter to enable tracing of transduction were used. Transduction was performed at a dose of 2.6E10 vg/mL, predicted to be the dose circulating after administration of a total dose of 1.72E14 vg in an adult weighing 86 kg. Transduction efficiency was determined using digital PCR to quantify GFP mRNA and ELISA (n=3) to quantify protein concentration in samples collected 1 wk post transduction. Incucyte live imaging for GFP fluorescence was also performed throughout the study period. Transduction was repeated three times with biological (liver and testicular OTE) and technical (BBB and lung OTE) replicates, and a minimum of 96 OTEs were used per group for every transduction. Statistical analysis was performed using ANOVA and *post hoc* Tukey test. Live/dead imaging and maintained ATP levels 1 wk post transduction confirmed OTE viability in all groups. The presence of GFP mRNA verified transduction in all OTEs, however only BBB, testicular, and liver OTEs exhibited detectable levels of GFP protein. In the AAV5-transduced group, BBB OTEs produced the highest levels of GFP protein (27.7 ± 4.4 pg/100 µg total protein) followed by testicular (15.42 ± 3.1 pg) and liver OTEs (< 3 pg) ($p<0.05$). Similarly, in the AAV3b group, BBB OTEs produced the most GFP protein (12.28 ± 2.67 pg/100 µg total protein; $p<0.05$) followed by testicular (5.09 ± 0.8 pg) and liver OTEs (< 3 pg). Of the two serotypes, AAV5 exhibited significantly higher transduction efficiency ($p<0.05$) compared to AAV3b in BBB and testicular OTEs, while the efficiencies were comparable in liver OTEs. Transduction of testicular OTEs is of note and warrants further investigation. Studies are currently underway to investigate underlying mechanisms for the observed differences in tropism, but data thus far demonstrate the potential of human-derived OTEs to serve as a tool to determine the human tropism of AAV, accelerating preclinical studies for AAV gene therapy.

894. Deamidation Drives AAV9 Potency Loss

Austin E. Smith, Michael Murphy, Stephen Ollosi

Analytical Development and QC, Advanced Medicine Partners, Durham, NC

Recombinant adeno-associated viruses (AAV) are promising single-stranded DNA delivery vectors for treating genetic diseases. The viral capsid is formed by three proteins whose sequence and structure determine tissue specificity and vector potency: the ability to infect cells, deliver payload and induce protein expression. Successful development and storage requires understanding how the physical state of the viral proteins and resulting capsid affect potency. Here, we demonstrate that protein deamidation is a primary factor determining potency by examining three wild-type AAV9 vectors, each containing a different DNA payload. The vectors were produced in HEK293 cells, purified using ion-exchange chromatography and density-gradient ultracentrifugation and formulated in a single buffer. AAVs were stored at different temperatures and tested at various times for concentration, aggregation, protein purity, deamidation and cell-based potency focusing on function in the target cell. For all three vectors, a time- and temperature-dependent potency decrease occurred concomitant with increased deamidation. Two of the three vectors also decreased in concentration. Results from one of the model vectors, AAV9 encoding eGFP, are shown below.

These results highlight the need for manufacturing process controls that limit deamidated species and routine quality control analytical methods to quantify deamidation. These results also suggest that engineering capsids that are less prone to temperature-induced deamidation will combat loss of potency during AVV9 manufacturing and storage.

895. Peeling the Onion: A Stratified Approach to rAAV DNA Purity and Integrity Characterization

Melissa Carver, Stephen Ollosi, Austin E. Smith, Michael Murphy

Advanced Medicine Partners, Durham, NC

The previous decade has shown rapid advancement of recombinant adeno-associated viral vectors (rAAV) for the treatment of a broad range of genetic diseases. As production of rAAV products advances, so must the analytics used to assess quality attributes. There is a need in the field for robust assessment of methods characterizing DNA purity in rAAV products. One well characterized purification strategy includes a

CsCl ultracentrifugation (UC) process for the separation of functional rAAV capsids from partially filled and empty capsids. During the UC process, capsids of different densities form bands which can be extracted individually and represent differing percentages of empty, partial and full capsids. Here we describe a robust characterization of samples taken from across a CsCl density gradient. We distinguish between methods which can assess DNA content of intact capsids, extracted DNA length, and extracted DNA sequence composition. This stratified approach allows for the complete characterization of DNA purity and integrity in rAAV preparations. Methods assessing intact capsids include Analytical Ultracentrifugation (AUC), Mass Photometry and Charge Detection Mass Spectroscopy (CDMS). These methods share the benefit of limited sample preparation and the ability to assess empty capsids but cannot directly assess genome length or sequence composition. Methods directly assessing genome length include Agarose Gel Electrophoresis (AGE), Capillary Electrophoresis (CE) and Reverse Phase HPLC (RP-HPLC), however these methods cannot assess empty capsids or sequence composition. Methods assessing sequence composition include Short Read Sequencing by Illumina and Oxford Nanopore platforms. These methods provide a direct assessment of sequence composition but cannot assess empty capsids or genome length. Long Read Sequencing by PacBio is unique as it provides information on both genome length and sequence composition. The scope of this evaluation includes extracted bands within a CsCl density gradient, however the methods described here are applicable to the characterization of any rAAV purification strategy. Each method described provides a unique but incomplete view on the question of DNA purity and integrity. We assert that to fully characterize DNA purity and integrity of an rAAV product, the appropriate subset of methods described here should be performed.

896. Development of a Universal Genomic DNA Digital PCR Assay Targeting the ZEB2 Gene for the Measurement of AAV Biodistribution

Trang P. D. Nguyen, Bezawit F. Ejigu, Sungyeon Cho, Ye Liu, Olivier F. Danos, Samantha A. Yost

REGENXBIO, Inc., Rockville, MD

Biodistribution is an important measurement in gene therapy studies to determine the transduction efficiency of adeno-associated viral (AAV) vectors in target tissues. AAV biodistribution is often represented with a unit of vector genome copy (VGC) per host diploid genome (DG) or VGC per nucleus. In the literature, VGC/nucleus has been calculated in two ways: VGC per microgram template DNA divided by a theoretical correction factor based on the genome size of a species (e.g., $1.548x10^5$ DG/μg DNA for humans), or VGC divided by the host DG measured by a separate PCR assay with primer/probe targeting a host genomic DNA sequence. The former method does not account for experimental variation regarding nucleic acid extraction efficiency or resulting DNA quality. A host DG assay can mitigate these problems, leading to a more accurate calculation of VGC/nucleus and providing additional assay robustness against experimental variations. As gene therapy development moves from rodents to monkeys and finally to humans, an ideal host DG assay would be applicable across species, decreasing the cost and developmental timeline. Previously published universal primers/probes that target ribosomal genes (28S rRNA, 18S rRNA), histone genes (HIST2H4), or mitochondrial DNA (mtDNA; cytochrome b) are highly conserved but have limitations: their copy numbers are not consistent between species and tissue types, and often have many pseudogenes, impeding the accurate measurement of the diploid genome. We present a cross-species digital PCR assay targeting a highly conserved gene, Zinc finger E-box-binding homeobox 2 (ZEB2), which presents at two copies per nucleus in all mammals. A stretch of DNA in exon 2 of the ZEB2 gene was used to design a PCR primer/probe assay with no off-target binding sites predicted via Primer-BLAST for several relevant species to gene therapy research [human (*Homo sapiens*), non-human primate (NHP; *Macaca fascicularis*), pig (*Sus scrofa*), rat (*Rattus norvegicus*), mouse (*Mus musculus*), cat (*Felis catus*), and ferret (*Mustela putorius furo*)]. ZEB2 digital PCR assay was evaluated across 109 genomic DNA samples from various tissues (e.g., liver, muscle, eye) of 5 species (human, pig, NHP, rat, and mouse) and compared to in-house historical data using species-specific digital PCR assay targeting the glucagon gene. The average ratio between ZEB2 and glucagon copy number per microgram input DNA is 1.01 with a standard deviation of 0.13, confirming the accurate measurement of 2 copies of ZEB2 per nucleus in all tested tissues and species. Adopting a universal cross-species ZEB2 digital PCR assay to measure host DG has the potential to streamline the biodistribution assay transfer from research to clinical development, reduce cost, and improve assay accuracy.

897. A Process for Identifying AAV and Transgene Integrations in Mouse and Human Genomes Using Long Read Oxford Nanopore Sequencing

Terrence Turner, Jose Rojas, Yajun Tang, Charleen Hunt, Michael Glasser, Ciro Bonetti, Gregg Warshaw, Daisuke Kajimura, Susannah Brydges, Jeffrey D. Lee, Jeremy Rabinowitz, Chia-Jen Siao, Eric Chiao, Brian Zambrowicz

Velocigene, Regeneron Pharmaceuticals, Tarrytown, NY

Adeno-associated virus (AAV) vectors and transgenesis are pivotal tools in gene therapy and genetic engineering. However, identifying precise integration sites of these genetic segments within the host genome remains challenging. This study presents a process for identifying AAV and transgene integrations in mouse and human genomes using long read Oxford Nanopore Technology (ONT) sequencing. Our method uses long read sequencing generating sequencing libraries, enriched for the regions of interest. After alignment to the reference genome, the long read capability of ONT spans entire transgene and vector sequences, providing a comprehensive view of the integration sites. Subsequent read alignment and breakpoint identification are performed using a custom bioinformatics pipeline designed to handle the unique challenges posed by long read sequencing data, such as sequencing error rates and how to interpret complex transgene rearrangements. Our results demonstrate the effectiveness of this process in accurately identifying AAV and transgene integration sites. We have also characterized tandem/inverted integrations and off target integrations of AAVs in the host genome. This method allows

for the precise and more comprehensive understanding of vector and transgene integration, an important consideration given the recent advances in AAV based gene therapies.

898. DNA Leakage of rAAV Under Freeze/Thaw Stress and Analytical Method Development for Free DNA Characterization

Shuai Li, Xiaoyan Wang, Kuan-Yu (Nick) Lai, Jonathan Wert, Li Zhi, Mohammed Shameem, Dingjiang Liu
Formulation Development, Regeneron Pharmaceuticals, Tarrytown, NY

Recombinant adeno-associated virus (rAAV) vectors are widely used to deliver therapeutic transgenes due to their superior safety, relatively low immunogenicity, and ability to target diverse tissues. Recent studies have shown that DNA leakage could be induced by freeze/thaw stress, which is concerning since rAAV gene therapy products are typically stored below -65°C and subjected to multiple freeze/thaw cycles during manufacturing and administration. DNA leakage from rAAV capsids could potentially impact rAAV product stability, induce immune responses, and compromise product efficacy, therefore it is important to characterize DNA leakage during rAAV product development. However, currently reported analytical methods used to characterize free DNA often lack the desired sensitivity and reproducibility required for reliable detection and quantitation of free DNA. In this work, we have developed a size exclusion chromatography (SEC)-based free DNA quantitation method. This method demonstrated satisfactory assay performance in specificity, accuracy, reproducibility, and linearity for quantitative analysis of free DNA. It has been applied into our current formulation development and characterization work. Thus, this SEC-based free DNA method can be used to reliably characterize the DNA leakage during rAAV formulation, product, and process development to ensure the quality and stability of rAAV gene therapy products.

899. Identification of Degradation Pathways of rAAV8 to Aid Stable Drug Product Formulation Development

Ariel Chen, Shuai Li, Marilia Barros, Xiaoyan Wang, Jonathan Wert, Kuan-Yu Lai, Li Zhi, Mohammed Shameem, Dingjiang Liu
Formulation Development, Regeneron Pharmaceuticals, Tarrytown, NY

Recombinant adeno-associated viruses (rAAVs) have emerged as promising gene therapy vectors for delivering therapeutic genes to target tissues. However, our understanding of the critical quality attributes (CQAs) of rAAVs and degradation pathways is limited. To increase our understanding, we performed a forced degradation study on rAAV8 under various stress conditions relevant to AAV drug product manufacturing and clinical use. A panel of analytical methods was applied to characterize the stressed samples. The results revealed multiple degradation pathways for rAAV8, including aggregation, release of AAV genome DNA, and post-translational modifications (PTM). After identifying the degradation pathways, a formulation optimization study was conducted, leading to a rAAV8 formulation with significantly improved stability under thermal and freeze-thaw stress conditions. This work enhanced our understanding of degradation pathways and critical quality attributes of rAAV8; the knowledge gained here can be applied to other AAV serotypes for developing stable AAV drug product formulation, robust analytical control strategy and systematic process development, potentially reducing development time and cost for gene therapy products.

900. Long-Read Sequencing of Single Stranded AAV Isolated from Crude Lysate for Qualitative Analysis, Improving Characterization, and Informing Vector Design

Russell Buchanan[1], Asher Baltzell[1], Michael Walker[1], Jennifer Israel[2]
[1]Kriya Therapeutics, Durham, NC,[2]Kriya Therapeutics, Redwood City, CA

Understanding the purity, identity, and capsid packaging of recombinant AAV (rAAV) is critical to inform future vector design and production decisions for manufacturing a safer, more effective therapy. Sequencing is the best available method to understand vector genome quality, however characterizing single-stranded AAV (ssAAV) has been hindered by challenging innate features of the viral genome along with limitations of sequencing technology. The source of rAAV being characterized can present further hurdles, such as isolating from preparations containing host genome and other DNA impurities. To address these challenges and qualitatively assess ssAAV, we developed a long-read sequencing workflow which enables the evaluation of key attributes early in development. For our process, we utilized viral particles prepared by a freeze-thaw of pelleted HEK293 cells and resuspended in lysis buffer, performed a Salt Active Nuclease (SAN) treatment, affinity purification of rAAV capsids from the lysate utilizing AAVX Magnetic Beads, and then ssDNA extraction using the viral spin columns. DNA polymerase was added to the isolated material to perform a second strand synthesis, converting ssDNA viral genome to double-stranded DNA (dsDNA) with a hairpin at the 3' ITR end. Libraries were prepared via Oxford Nanopore's Ligation Sequencing Kit V14 and sequenced using a minION Mk1b. A bioinformatic workflow for analyzing the data that separates packaged DNA reads from background impurities, separates synthesized double-stranded DNA/hybridized ssDNA reads, and re-constructs packaged DNA sequences is provided. This method produces >80% of total reads that map to the packaged vector genome, including both synthesized dsDNA and hybridized ssDNA, with the majority of remaining reads mapping to unpackaged lysate material. We conclude that this method yields enough packaged DNA data to reconstruct full ITR-ITR length sequences and shorter sequences which enables us to investigate potential sources of impurities and incomplete capsid packaging.

901. Ensuring Genome Integrity of Recombinant AAV Vectors Using Digital PCR

Domenica Martorana[1], Kevin Matthäi[1], Jonathan Thorn[1], Mario Quinto[1], Julius Albers[1], Anne Schieren[1], Anida Mesihovic[2], Andreas Hecker[2], Francesca Di Pasquale[1]
[1]R&D, QIAGEN GmbH, Hilden, Germany,[2]Product Management, QIAGEN GmbH, Hilden, Germany

Development of safe and effective cell and gene therapies is key to potentially treat a wide spectrum of diseases. Viral vectors have become powerful delivery vehicles for gene therapies. Adeno-associated virus (AAV) vectors have turned into primary modalities for efficient gene therapy applications due to their lack of pathogenicity and persistent transgene expression. Besides the requirement to accurately and reproducibly quantify viral vector genome titers, it is essential to determine the intactness of the viral vector genomes for a safe, stable and effective therapy. Errors made during the replication and packaging process of recombinant AAVs can lead to heterogenous viral vector populations with direct impact on their efficacy and safety. Current purification workflows can efficiently separate empty capsids from full capsids. However, removal of capsids carrying partial or truncated genomes as well as capsids packaged with host cell or plasmid DNA, are difficult to separate and can be present in the viral vector product after purification. Traditionally, genome integrity has been determined via agarose gel electrophoresis and southern blot. Next generation sequencing approaches have been used to characterize the capsid content as well. Nevertheless, high resolution and accuracy needed for integrity determination as well as repeatability and high-throughput capabilities remain unmet needs. Lately, multiplex digital PCR has been adopted for genome integrity analyses. Digital PCR enables absolute quantification with unprecedented precision and a higher tolerance towards inhibitors without the need for any standards. Here we layout a rapid dPCR approach for characterizing genome integrity of in-process and purified AAV samples using the same primers and probes that have been optimized for vector genome titration. The underlying Poisson distribution of dPCR enables the assessment of genome integrity over a broad dynamic range by differentiating between physically linked and unlinked targets. As the calculation estimates the concentration for all present groups of template molecules within a sample individually, it could also be used for other applications such as determination of integrity and stability of DNA and plasmids after e.g., certain processing procedures or storage. We show that up to five targets can be analyzed simultaneously once increasing precision and reproducibility of the analyses.

902. Quantification of Plasmid Copy Number of *Escherichia coli* (*E. coli)* Master Cell Bank by Digital PCR

Syam Pillai[1], Honggeun Park[2], Fernanda Vasconcelos[1], Maryam Rahimian[1], Chun-Ti Chen[1] Tatiana Nanda[1]

[1]Analytical Development, SK Pharmteco, King of Prussia, PA,[2]Testing Operations: Molecular; SK pharmteco - US, King of Prussia, PA

Accurate measurement of plasmid copy number (PCN) is highly desirable for *E. coli* master cell bank to understand the distribution of plasmids in daughter cells, and thus is crucial for the plasmid DNA (pDNA) production by upstream process. Here, we developed a fast and effortless method utilizing dual channel QIAcuity dPCR to monitor the activity of designed promotors in DH5α cells. To prevent any bias toward genomic DNA and plasmid DNA generated by DNA isolation, no extra step of DNA purification was applied in this assay. Simply boiling the bacterial cultures after a serial dilution, samples are span down to separate the supernatant (that contains entire genomic information), and cell debris. Primer-probe sets designed to target *Kanamycin* Resistance and *cysG* genes represent the plasmid DNA and the chromosomal DNA, respectively. A step of restriction digestion is included prior to dPCR analysis to facilitate the partition of template DNA which thus leads to precise quantification. Our results showed that fragmentation of the template DNA increased the plasmid/chromosome ratio at least 5 times compared to reactions without enzyme treatment, thus accurately detecting the PCN. In conclusion, we present a simple and efficient method optimized for the accurate quantification of PCN by dPCR in E. *coli* master cell bank.

903. Optimization of Sonication Linker Mediated (SLiM)-PCR for Vector Integration Sites Retrieval and Quantification

Fabrizio Benedicenti, Sergio Arevalo, Maria Luisa Dalessandro, Giulio Spinozzi, Giulia Pais, Andrea Calabria, Daniela Cesana, Alessandro Aiuti, Eugenio Montini

San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), IRCCS San Raffaele Scientific Institute, Milan, Italy

In gene therapy (GT) applications based on integrative vectors, the retrieval and mapping of vector integration sites (IS) in the genome of transduced cells and their progeny using specialized PCR-based techniques combined with next-generation sequencing (NGS) and bioinformatics analyses allows to obtain safety and efficacy readouts of the treatment. We developed Sonication Linker mediated- PCR (SLiM-PCR), a method for IS retrieval based on specific PCR amplification of vector/genome junctions from sheared genomic DNA and NGS. SLiM-PCR identification and quantification of IS and the downstream analyses are performed by dedicated software VISPA2 and ISAnalytics. The abundance of each IS is then obtained by counting the number of amplified DNA fragments of different lengths (depending on the shear site position) containing the same IS, which is proportional to the number of cells contributing to a specific clone, avoiding the biases introduced by PCR amplification. SLiM-PCR showed to be highly efficient in IS retrieval and allowed accurate quantification of a single lentiviral (LV) or γ-retroviral (γ-RV) IS down to 0.1% of relative abundance, when applied to an experimental framework in which DNA standards were composed of monoclonal samples carrying a defined number of IS in known positions of the genome mixed to a polyclonal sample harboring a random IS distribution. Given its accuracy and efficiency, we adopted SLiM-PCR as reference assay for IS analysis. SLiM-PCR is currently being applied on thousands of samples derived from more than 30 preclinical studies and 7 different GT clinical trials exploiting different vector types, like γ-RV, LV, Sleeping Beauty Transposons and Adeno-Associated Vectors. SLiM-PCR has been fully automated with liquid handlers able to process hundreds of DNA samples per week in 96/384-well plates. We are currently working on the miniaturization of the reactions exploiting the Acoustic Droplet Ejection technology of the Beckman Labcyte 525, an instrument capable of moving nanoliters of liquids by acoustic waves. So far, we could reduce reaction volumes by 10 times, down to 5 microliters, achieving cost reduction, higher sample throughput, and higher overall assay speed and reproducibility. We tested the miniaturized SLiM-PCR on DNA standards, using different amounts of genomic material and vector copy number (VCN), PCR amplification conditions and reagents, to understand the best balance between miniaturization and performance. Miniaturized SLiM-PCR can obtain comparable or even

better results to those obtained with standard volumes in terms of IS number retrieved from the same amount of genomic DNA, maintaining the precision in IS abundance estimation and detection limit. To reduce the number of false positives and sequence-sample misassignments caused by index hopping, we are currently comparing the emerging MGI DNBseq to the Illumina NGS technology and investigating if the lower error rate potentially provided by the rolling circle amplification instead of the conventional exponential amplification during sequencing may have a beneficial impact. Overall, our results showed that SLiM-PCR is a reproducible, accurate and versatile method that allows to perform high-throughput IS analyses, which may be further improved by the ongoing optimization process.

904. Optimizing Transgene and Integration Site Analysis with Minimal Cell Input

Maya Wright, Joost Swennenhuis, Nicole Hendriks, Georgios Georgiou, Erik Splinter, Ellen Stelloo
Cergentis, Utrecht, Netherlands

Introduction TLA, a technology invented by Cergentis, is an unmatched NGS-based technology for transgene and integration site analysis. The unique proximity ligation reaction in combination with a PCR-based target enrichment step allows for complete analysis of integrations and the surrounding sequences. While the present technology is robust and highly specific, there are certain aspects that warrant further enhancement. The minimum input required for optimal complexity is currently minimal 3 million cells. It is preferable to reduce the minimum cell input, which would also enable automation options. Additionally, there is need to address the sequence ambiguity of the at the exact restriction sites of the restriction enzyme used to generate TLA template and mitigate bias arising due to PCR efficiency of fragments of variable size and composition. To enable these improvements, a hybrid-capture TLA-based approach has been developed starting from 100,000 cells (Targeted Locus Capture, TLC). Hybrid-capture target enrichment, using capture probes e.g. specific for either the transgene or vector sequence, is done on randomly fragmented, proximity ligated DNA. The random fragmentation ensures equal distribution of the reads without restriction enzyme bias. Through proximity ligation, co-capture will occur of DNA which was spatially close to the targeted sequences in-vivo. Supported by the many reads with the vector-genome breakpoint sequence and reads on the proximal genomic regions, the improvements maintained the robust transgene and integration site analysis. **Method** As an illustrative project, we conducted a comparative analysis of both technologies on a CHO cell line (CHO DP-12 clone#1933 [CHO DP-12, clone#1933 aIL8.92 NB 28605/12] (ATCC CRL-12444)) which has been transfected with a vector designed to co-express variable light and heavy chain regions of a monoclonal antibody, anti- IL-8. The conventional TLA technology utilizing 5 million cells as input material and two primer sets targeting the vector was compared to the new TLC technology using 100.000 cells and capture probes designed from the entire vector sequence. **Results** The comparative analysis between TLA and TLC revealed a general alignment in the overall conclusions. Both technologies identified vector integration sites on chromosome 4, 5, 7 and 8. The integrations were all accompanied by genomic rearrangements. Despite identical conclusions, small variations were seen which can be ascribed to the use of the specific technology. TLC exhibits a more uniform distribution of coverage across the vector and the integration site locus due to the absence of restriction enzyme bias. Therefore, TLC was more complete in capturing sequence and structural variants, whereas TLA encountered challenges related to local coverage or restriction enzyme bias. **Conclusion** We present a robust and automatable new technology on a limited amount of input material, yielding complete and detailed data of integrated sequences. TLC has significant advances: random fragmentation eliminates the restriction enzyme bias and using capture-based target enrichment overcomes PCR bias ensuring uniform and high coverage across complete transgenes.

Wednesday Posters: Chemistry, Manufacturing, and Controls

905. Regulatory Agility: Value of CDMOs Utilizing Platform Technology

Angela Coy, Christopher J. Shilling
Forge Biologics, Grove City, OH

Bespoke gene therapies are often developed in a siloed manner, which can require a significant investment of time and resources - a challenging strategy for developing treatments for patients in nearly 10,000 rare diseases. The provisions introduced in the Consolidated Appropriations Act of 2023 aim to address this issue by defining platform technologies and authorizing FDA to expedite the development and review of a product that uses a designated platform technology. As part of the premarket notification (510k) clearance pathway for medical devices, new medical devices of a certain class can gain regulatory approval based on the 'substantial equivalence' to a previously approved device, or predicate device, thereby minimizing the amount of regulatory burden on developers of substantially equivalent devices. The legislation introduced in the 2023 Appropriations Act presents a great opportunity to allow regulators the ability to consider 'predicate' information from previously approved drug products in the review of new drug products manufactured using 'equivalent' processes. Forge participated in a Scientific Exchange with other stakeholders from industry, academia, and FDA recently to identify platform technologies in CGT that can serve as reusable predicate tools, defined as "building blocks," across development programs. Some of the proposed building blocks include starting materials (cell banks, plasmids) and entire unit operations (cell culture, sterile filtration). While many details and logistics of the building blocks concept have yet to be worked out, we propose that contract development and manufacturing organizations (CDMO) like Forge are poised to be leaders in this space. CDMOs are experienced in developing and validating a platform process, which includes reusing building blocks from one development program to another. We present here examples of how Forge Biologics is leveraging predicate information from its own building blocks to accelerate regulatory activities for developers. Forge Biologics is also experienced in documenting and sharing details of its building blocks with regulators through the use of master files. We will provide a review on the success of our master files and how they have aided in developers' regulatory agility. The principles introduced in the

Consolidated Appropriations Act are already being explored through initiatives like the Bespoke Gene Therapy Consortium, which Forge Biologics is an industry sponsor and participant. Our review suggests that the information and experiences from platform CDMOs offers a leading perspective and deep insight into the possibilities of building predicate data, which can be leveraged by future programs to address a substantial need in the CGT industry.

906. A Change is Gonna Come - Managing Process Changes Through the Product Lifecycle for ATMPs

Darius Pillsbury
Valsource Inc, New Paltz, NY

The only constant in life is change! This adage certainly applies to the development and manufacture of the many new modalities including cell and gene therapies and how an organization manages and embraces change is paramount to the ultimate success of the commercialization of these novel products for those patients in need. In this presentation we will explore how to navigate various types of changes to cell and gene therapy manufacturing processes using key enablers like knowledge management and risk management in order to ensure success. The recent draft guidance by the FDA "Manufacturing Changes and Comparability for Human Cellular and Gene Therapy Products" will be reviewed. Process changes at all stages of the product lifecycle from the manufacture and testing of initial clinical trial materials to the commercialization and long-term management of the manufacturing process based on optimization of the Process Control Strategy (referred to by the FDA as the "Cookbook") will be presented. A case study will be provided with an example of a significant process change made to an autologous gene-modified cellular therapy. The case study will encompass the initial identification of the need for a change, the supporting activities to implement the change, and the design and execution of an analytical product comparability study, based on best industry practices including the use of risk assessment and compliance with the expectations of global regulatory agencies. The challenges will be highlighted with solutions provided to overcome any barriers and challenges to implementation, as well as the follow up activities also important post-change.

907. Failure to Plan is Planning to Fail: Risk Assessment for an Early-Stage Autologous Product to Identify and Mitigate Process Hazards

Beth Fulton
ValSource, Inc., Downington, PA

Cell therapy products inherently have unique manufacturing challenges. Processes for autologous products may be limited by patient condition (e.g. low volume or titer available as a starting point). Both autologous and allogenic products may be limited by the capabilities of early stage processes (e.g. failure rate of laboratory assays, failures of equipment that may not be purpose-designed) or by logistical failures (related to tight timelines for shipment of product and materials, given the short shelf life of product/materials). These problems are not insurmountable; careful risk-based planning can allow for agile response and recovery. In this talk, a case-study is presented in which the manufacturer of an autologous product conducts a risk assessment to identify foreseeable process hazards. Examples of identified mitigations for these failures are provided.

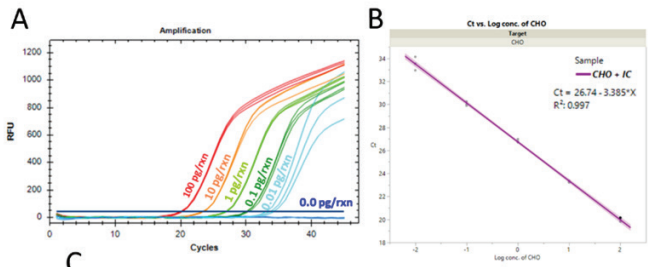
908. The Impact of Joint Auditing with Cell & Gene Therapy

James Fries
Rx-360, Philadelphia, PA

De-risking of supply chain through effective utilization of joint audit program model. To protect patient safety by ensuring the quality of the materials within the supply chain in a scalable sustainable way, biopharma manufacturers and critical material suppliers leverage a joint audit program or model as a best practice. Utilization of the model has resulted in increased standardization of approach delivering quality oversight complimented by significant efficiencies in the process, estimated at approaching $10M in 2023 with continued growth expected as industry broadens utilization of the model. This case study jointly presented by representatives from a critical material supplier and biomanufacturer explains how the value is being recognized based on actual data.

909. HAA-Based Ion Pair Reversed Phase HPLC Method for More Accurate gRNA Purity Test

Toshifumi Kano, Masataka Shibata, Daisuke Furukawa, Yoshimi Fujii, Hideki Ihara
Sumitomo Chemical Co., Ltd., Osaka, Japan



CRISPR-based gene therapy has a potential to treat unmet genetic diseases. Since gRNA is a component to specifically bind the target site, the success of CRISPR-mediated gene editing is highly dependent on the quality of the gRNA. Therefore, high-purity gRNA is critical for clinical applications, and optimization of the gRNA manufacturing process has been studied intensively in recent years. Meanwhile, there are few reports on analytical methods to determine the gRNA purity. We evaluated various analytical methods such as capillary electrophoresis and IP-RP-HPLC methods, and finally found that Hexylammonium Acetate (HAA)-based IP-RP-HPLC method showed better separation than ever. This method enabled us to achieve peak-top separation of 96-103nt single-stranded RNAs mixture. Then, we performed a comparative analysis of a commercially available gRNA between a general HPLC method and our newly developed HPLC method. The purity was about 80% by the general HPLC method, on the other hand, our new method revealed that the purity was 38%. This method will be helpful in precisely understanding the safety of gRNAs for clinical applications.

910. A Realtime PCR Assay for CHO Host Cell DNA Detection for Bioprocess QC

Nidhi Nandu, Yanhong Tong, Zhi-xiang Lu
Revvity, Waltham, MA

Therapeutic recombinant proteins and monoclonal antibodies have become pivotal and expanding categories of biologic products employed in the treatment and management of various diseases. The

presence of residual DNA derived from host cells such as CHO cell lines at elevated levels during the production of biologic products raises significant concerns due to its potential oncogenic or immunogenic risks. This highlights the essential need for analytical solutions to measure CHO residual DNA in biologic products. Here, we developed real-time PCR assay using hydrolysis probe-based method to quantify CHO residual DNA. The quantification range is wide, from 0.01 pg to 100 pg CHO genomic DNA per reaction (***Figure 1***), which meets the United States Pharmacopeial Convention (USP) General Chapter <509> "Residual DNA Testing" criteria. By using Revvity proprietary PCR formulation, the residual DNA quantification workflow allows industrial experts to simultaneously test 96 or 384 samples (including controls and standard materials) in less than 2 hours (~15minute hands-on time) from sample PCR amplification to data report.

911. Digital PCR Applications for Cell and Gene Therapy - High-Quality Detection of Mycoplasma Contamination

Janina Bracker[1], Julius Albers[1], Anida Mesihovic[2], Andreas Hecker[2], Francesca Di Pasquale[1]

[1]R&D, QIAGEN GmbH, Hilden, Germany,[2]Product Management, QIAGEN GmbH, Hilden, Germany

Cell and gene therapies seek to target previously untreatable diseases at their source using individualized treatments. Developing safe and effective cell and gene therapies requires strict quality controls at all stages of the development and manufacturing process. The determination of potential impurities is crucial. Manufacturers of biologics use different approaches to test for Mycoplasma contaminant throughout the production process and for final substance release. The sensitivity of mycoplasma detection is crucial for ensuring safe and high-quality ATMPs. The detection of mycoplasma contamination using Nucleic Acid Techniques (NATs) is well established and described by different Pharmacopeias worldwide. Some compendia like the European Pharmacopeia have already announced a revision of the detection method that will make it more stringent particularly for the validation step. Indeed, the qualification of the standards and the GC:CFU ratio will be probably better defined. We would like to show the advantage of using RNA instead of mere DNA to detect mycoplasma contamination in a variety of samples. Indeed, the use of RNA enables to detect a transcript with a higher copy number enhancing the sensitivity down to 5 CFU/ml. Moreover, the robust RNA detection also enables ability to process samples at different stages of manufacturing that may be more complex in terms of composition, like containing high salts or high amounts of producer cells.

912. Advancing Quality Control for CRISPR-Cas9 Systems: Separation of CRISPR Components Using Ion Exchange Chromatography

Kyle Scheel[1], Matthew Lauber[2], Rachel C. Ginther[1]

[1]MRIGlobal, Kansas City, MO,[2]Waters Corporation, Milford, MA

Recently, the first CRISPR/Cas9 edited cell therapy was approved for treatment of sickle cell anemia, with other CRISPR-based therapies in the pipeline. However, despite the growing market for CRISPR-based therapeutics, technologies for all-in-one quality control analysis of CRISPR components and ribonucleoprotein (RNP) complexes are not well-established. In order to ensure safe and effective CRISPR drug substances, thorough quality control assessment of CRISPR reagents and characterization of RNP complex formation is needed. Current methods for characterization of CRISPR/Cas components are limited and do not typically allow for simultaneous characterization of apo-Cas, apo-sgRNA, and RNP species. Here, we exploit the differing charges of apo-Cas, apo-sgRNA, and RNP in order to achieve separation of CRISPR components by ion exchange (IEX) high-performance liquid chromatography (HPLC) with ultraviolet (UV) detection. In this work, we have applied a corrosion resistant UHPLC instrument equipped with UV detection and low adsorption flow path components. Anion exchange and cation exchange columns were coupled, allowing for simultaneous retention of Cas9 on the cation exchange column and sgRNA on the anion exchange column. A number of practical considerations for the analysis of CRISPR components by IEX chromatography were determined during method development. Considerations include UV detector flow cell/analyte compatibility, sample diluent, system suitability, choice of mobile phase buffer and ionic strength, and the impact of sgRNA sample heterogeneity. Adequately addressing these considerations will remain of critical importance as more CRISPR drug substances enter the drug development pipeline.

913. A Novel Network of Cell Processing and Cryopreservation Hubs Addressing Critical Gaps in Clinical Sample Processing Capabilities for Pharmaceutical Companies and Clinical Trial Sponsors

Sarah Alter, Andrew Larson, Priya R. Baraniak

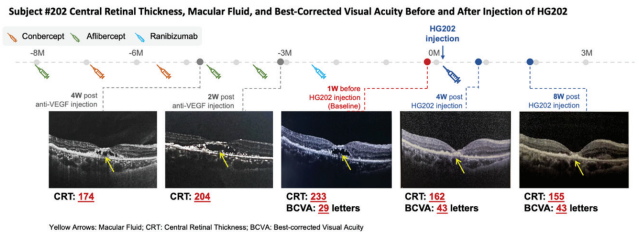
OrganaBio, South Miami, FL

Following the global COVID-19 pandemic and due to recent advancements of mRNA vaccines for a host of diseases, the need for organizations with capabilities to support clinical trials has been increasing and is expected to continue to increase in coming

years. Clinical Research Organizations (CROs), clinical sites, and translational centers/hospitals often have the capabilities to administer drug doses to participants, perform autologous leukapheresis, and draw blood samples over a period of time. However, many of these organizations lack the laboratory infrastructure and staff to support sample processing, such as peripheral blood mononuclear cells (PBMCs) isolation and cryopreservation and cryopreservation of patient apheresis materials, a critical intermediate manufacturing step for many cell-based therapies. Samples often need to be shipped to a central lab, which adds risk for sample loss and prolongs transit time, leading to unintended functional and phenotypic changes in cells, compromising quality and data analyses. To address this issue, OrganaBio's Cell Processing and Cryopreservation Services (CPC Services) business unit has partnered with several large multinational, multibillion dollar pharmaceuticals companies (Sponsors) to support clinical studies enrolling participants in the greater Miami, FL and Irvine, CA metro regions. OrganaBio team members were trained and qualified by Sponsors within 4 weeks of initial contract execution, and a dedicated Project Manager works alongside clinical sites to effectively manage timing of sample deliveries and to ensure that the OrganaBio team is prepared to receive and process samples 5 days a week. In the first 18 months, over 1,200 samples were received and processed with >99% success. Given the team's expertise in sample and document management, it now takes merely 30 minutes on average to initiate processing of blood samples from time of sample receipt, which is critical to accurate data analysis and data integrity for the trials. In addition to cell isolation, OrganaBio cryopreserves and stores study participants' PBMC samples and retains, allowing for batch shipping to Sponsors, simplifying cold chain management, mitigating risk of loss, and keeping Sponsors' shipping costs down. In addition, add on business for new trials is experiencing contract turnaround times of less than one week, driving efficiencies on the business side as well. OrganaBio's unique Hub Processing model has proven vital to the success of Sponsors' clinical trial collection and processing functions and performs more efficiently and faster than the required four- to six-hour sample processing window, ensuring consistency and validity of sample data. CPC Services has successfully scaled processing and cryopreservation capacities to fulfill initial and ongoing requirements to cover the lifespan of the trials. OrganaBio's client-centric and data-driven approach enables seamless operation and timely processing and delivery of crucial clinical trial participant samples. This purpose-built solution has been specifically developed to provide decentralized clinical trial support, including timely sample processing and data capture that are essential to accurately gauge the outcomes of clinical trials.

Wednesday Posters: Gene Therapy Trials - In Vivo Modification

914. CRISPR/Cas13 RNA-Targeting Therapy to Treat Patients with Neovascular Age-Related Macular Degeneration



Dongjun Xin[1], Boshi Liu[1], Weiwei Liu[2], Shuaishuai Zhang[2], Yuhan Jiang[2], Xuan Yao[2], Linyu Shi[2], Hui Yang[2], Alvin Luk[3], Yiqun Yuan[2], Xiaorong Li[1]

[1]Tianjin Medical University Eye Hosptial, Tianjin, China,[2]Huidagene Therapeutics Co., Ltd, Shanghai, China,[3]Huidagene Therapeutics Inc, Clinton, NJ

Purpose: Neovascular age-related macular degeneration (nAMD) is a leading cause of blindness in the aging population, with vascular endothelial growth factor (VEGF) playing a key role. Frequent intravitreal injection of anti-VEGF therapy is the front-line treatment of nAMD; however, it is only effective for 1-2 months at a time and requires frequent re-administration. Despite favorable clinical outcomes, persistent fluid or recurrent exudation returns in numerous patients after repeated administrations which lead to serious complications and reduce patient adherence to treatment, resulting in vision loss over time. Therefore, we developed HG202, a CRISPR/Cas13-based RNA targeting therapy, to partially knock down the mRNA expression of VEGFA in the retina with a single dose, reducing the frequency of treatment and potentially improving clinical outcomes. Here, we initiated the **SIGHT-I** clinical study (NCT06031727) investigating HG202 in patients with nAMD. **Methods: SIGHT-I** is an open-label, multi-center, and dose-escalation study investigating the safety, tolerability, and preliminary efficacy of HG202, a single adeno-associated viral (AAV) vector packaging novel high-fidelity CRISPR/Cas13 RNA targeting technology, to reduce the expression of VEGFA and thus inhibit choroidal neovascularization (CNV) formation. A total of 9 nAMD patients who are either non-responsive and resistant to anti-VEGF therapies or responsive to anti-VEGF therapies but require frequent injections with Early Treatment Diabetic Retinopathy Study (ETDRS) best-corrected visual acuity (BCVA) between 73 and 23 in the study eye at Screening will be randomized to one of the three doses of HG202. The primary objectives are the safety and tolerability of HG202 at different doses. Secondary objectives include mean change in BCVA, central retinal thickness (CRT), and other efficacy endpoints. **Results:** As of Jan-2024, 5 subjects have signed the ICF and 3 subjects have been enrolled in the low-dose cohort. Subject #202, a non-responsive and resistant to anti-VEGF therapies patient, had a history of 6 anti-VEGF injections within 8 months with persistent macular fluid before the injection. Subject #202 baseline included CRT of 233 μm and BCVA of 29 letters. Retinal fluid was significantly eliminated post-injection, and CRT was recovered to 162 and 155 μm at 4- and 8-week post-injection, respectively. The BCVA improvement of nearly 15 letters was observed starting at 4 weeks and sustained at 8 weeks post-injection visit (**Figure 1**). No drug-related serious adverse event has been observed in all three treated subjects. **Conclusions:** Three subjects with nAMD had an acceptable local and systemic adverse-event profile after the delivery of HG202. Subject #202 had significant improvement in BCVA, CRT, and elimination of persistent fluid within

8 weeks after the injection of HG202. Although only a low-dose cohort completed the enrollment, this study provides the basis for CRISPR/Cas13 RNA therapy is relatively safe in humans.

915. Preliminary Safety and Efficacy of HG004 Gene Therapy Trial for Leber's Congenital Amaurosis Associated with Mutations in *RPE65* Gene

Ping Fei[1], Yuan Yang[1], Jie Peng[1], Xiang Zhang[1], Yanfei Wang[2], Shuaishuai Zhang[2], Xuan Yao[2], Alvin Luk[3], Yiqun Yuan[2], Peiquan Zhao[1]

[1]Xinhua Hospital affiliated to Shanghai Jiao Tong University, Shanghai, China,[2]Huidagene Therapeutics Co., Ltd, Shanghai, China,[3]Huidagene Therapeutics Inc, Clinton, NJ

Purpose: Leber's Congenital Amaurosis (LCA) is a group of inherited retinal diseases involving retinal degeneration with abnormal eye movements (nystagmus) and severe vision loss in early infancy and childhood. One of the forms of the disease, type 2 LCA (LCA2), is associated with mutations in the retinal pigment epithelium-specific 65-kDa protein gene (*RPE65*). The safety and efficacy of adeno-associated virus (AAV) gene therapy for LCA2 have been validated in humans using AAV serotype 2 (AAV2). However, transduction of retinal pigment epithelial (RPE) cells with AAV2 has partially corrected LCA2 in animals while AAV serotype 9 (AAV9) is an ideal AAV vector to restore cone-photoreceptor function than AAV2. We, therefore, initiated the **LIGHT** (**L**eber congenital amaurosis **I**nherited blindness of **G**ene t**H**erapy **T**rial) clinical study (NCT06088992) to evaluate a single injection of HG004 (AAV9-*RPE65*) in children and adults with LCA2. **Methods: LIGHT** is an open-label and dose-escalation study investigating the safety, tolerability, and preliminary efficacy of a single subretinal injection of HG004 (AAV9-*hRPE65*). We assessed the retinal and visual function in subjects with LCA2 given 200 µL of HG004 in the worst eye at low ($6.0x10^9$ vector genomes, vg), middle ($1.0x10^{10}$ vg), and high ($2.0x10^{10}$ vg) doses. After completing the informed consent process and confirming the eligibility criteria, the eye with the worst visual function was selected for subretinal injection of one of the three doses of HG004. Subjects were evaluated before and after surgery at designated follow-up visits up to 5 years by complete ophthalmic examination. Efficacy for each treated patient was monitored with best-corrected visual acuity (BCVA), full-field stimulus threshold (FST), and kinetic visual field (KVF) assessments. **Results:** Nine adults or children (aged 8-38 years) with *RPE65*-associated LCA have enrolled in the low, middle, and high-dose cohorts. The average BCVA, FST-white light, and KVF improvements are +11 letters, -2.268 log cd.s/m^2, and +554.25 deg^2 (III4e), respectively, at 6-month post-injection in the low dose cohort, +7.5 letters, -1.413 log cd.s/m^2, and +958.30 deg^2 (III4e), respectively, at 3-month post-injection in the middle dose cohort, and +12.7 letters, -3.038 log cd.s/m^2, and +1142.77 deg^2 (III4e), respectively, at 1-month post-injection in the high dose cohort. No serious adverse event or dose-limiting toxicity has been observed. The majority of subjects after injection had at least a 2-log unit increase in pupillary light responses. Most adverse events were mild and transient which have resolved without any intervention. No signs of inflammation or acute retinal toxicity after the injection of HG004. **Conclusions:** Most of the treated subjects had at least a 2-log unit increase in pupillary light responses with durable effects during follow-up. There is no retinal detachment or drug-related serious adverse events, suggesting subretinal gene therapy at lower total volume (200 µL) is safe. These three doses (25-,15-, and 7.5-fold lower than the approved AAV2-*hRPE65* gene therapy in the Phase 3 trial) in this **LIGHT** trial showed comparable results, suggesting that HG004 may be a safer and more efficacious alternative treatment option for LCA2. Currently, HG004 is being evaluated in a multi-regional clinical trial (NCT05906953) with both Orphan Drug Designation and Rare Pediatric Disease Designation granted by the U.S. FDA.

916. PRODYGY: A First-in-Human Trial of Rod-Derived Cone Viability Factor (RdCVF) Gene Therapy in Subjects with Rod-Cone Dystrophy

James A. Gow[1], Joseph Martel[2], Laure Blouin[3], Anne-Sophie Gautron[3], Alice Le Meur[1], Nelle Messeca[3], Anne Celle[3], Daniel C. Chung[1], Isabelle Audo[4,5]

[1]SparingVision, Inc., Philadelphia, PA,[2]Department of Ophthalmology, University of Pittsburgh Medical Center, Pittsburgh, PA,[3]SparingVision, Inc., Paris, France,[4]Centre Hospitalier National d'Ophtalmologie des Quinze-Vingts, Centre de Référence Maladies Rares REFERET, INSERM-DHOS CIC 1423, Paris, France,[5]Sorbonne Université, INSERM, CNRS, Institut de la Vision, Paris, France

Purpose Rod-cone dystrophy (RCD) is a rare inherited retinal disorder leading to significant vision loss, and for which no treatment is currently available to most patients. SPVN06 is a gene-independent investigational gene therapy expressing the neurotrophic rod-derived cone viability factor (RdCVF) and the thioredoxin RdCVF-Long (RdCVFL), that aims at slowing down the progression of central vision loss in patients with RCD, regardless of the underlying pathogenic variant(s). **Methods** PRODYGY (NCT05748873) is a first-in-human Phase I//II trial enrolling subjects with advanced RCD due to a mutation in the *RHO*, *PDE6A*, or *PDE6B* gene. The study will assess the safety and tolerability of a unilateral subretinal injection of SPVN06, one year after treatment administration. Its two-step design includes an open-label dose-escalation phase (Step 1) followed by a controlled, double-masked, randomized, extension phase (Step 2). Step 1 will test 3 increasing doses of SPVN06 in subjects with severe advanced RCD, and two doses will be selected for assessment in Step 2. Step 2 will include 3 cohorts of subjects with intermediate advanced RCD. A total of 33 subjects is planned to be enrolled, of whom 27 will receive a single injection of SPVN06 in their worse-seeing eye. **Results** Six months after SPVN06 administration in the first cohort treated at the lowest dose, 7 adverse events (AEs) were reported in the treated eyes, including mild subconjunctival hemorrhage that resolved spontaneously, transient mild intraocular pressure elevation, and mild macular edema. One month after SPVN06 administration

in the last subject of the second cohort treated at the medium dose, 15 AEs were reported in the treated eyes, which included but were not limited to mild-to-moderate subconjunctival hemorrhage that resolved spontaneously; macular hole during subretinal injection that resolved without sequelae; and mild-to-moderate intraocular pressure elevation that resolved with standard treatment. Mild cells in the vitreous and anterior chamber were observed in 4 subjects (3 at the medium dose), vitreous haze was reported in 3 subjects, and anterior chamber flare in 1 subject. All findings were of Grade 1 or less and resolved spontaneously within 4 weeks after injection. A transient increase in anti-capsid antibodies, peaking at Week 2, was observed in 2 subjects who had pre-existing antibodies before injection of SPVN06. To date, no dose-limiting toxicities have been observed. An independent Data Safety Monitoring Board provided a positive recommendation to continue the trial without modifications, and to proceed with treatment administration at the highest dose in the third cohort. **Conclusions** First administration of SPVN06 to patients showed a favorable safety profile at low and medium doses, with no significant immune response.

917. Longitudinal Analysis of BCVA and Near-Field Object Recognition in Low- or High-Dose MCO-010 Mutation Agnostic Optogenetic Therapy for Retinitis Pigmentosa: 12-Month Results from a Phase 2b/3 Randomized, Sham-Controlled, Patient- and Assessor-Masked Clinical Trial (RESTORE)

Samuel Barone

Nanoscope Therapeutics, Dallas, TX

Purpose MCO-010 is a gene mutation agnostic optogenetic therapy being evaluated in an ongoing Phase 2b/3 RESTORE clinical trial in individuals with advanced retinitis pigmentosa (RP). We performed an analysis of 52-week longitudinal data to evaluate the safety and efficacy of a single administration of 2 different doses of MCO-010 therapy vs sham. MCO-010 is an AAV2-delivered multi-characteristic opsin (MCO) transgene administered by intravitreal injection. MCO-010 transduces bipolar cells to express a photosensitive opsin protein, restoring light sensitivity to the retina in patients with RP. **Methods** Subjects had an advanced RP clinical diagnosis and baseline visual acuity worse than 1.9 logMAR (CF, 20/1600 equivalent) in the study eye and no better than 1.6 logMAR in the fellow eye. Subjects (n = 27) were randomized 1:1:1 to receive a single dose of 0.9E11 gc/eye (low-dose), 1.2E11 gc/eye (high-dose) MCO-010, or sham IVT in the study eye at day 0. Visual function was assessed systematically through week 52 by best-corrected visual acuity (BCVA) using Freiburg visual acuity and a multi-luminance shape discrimination test (MLSDT). BCVA data were analyzed comparing the low- or high-dose MCO-010-treated individuals vs sham using a mixed-effects model for repeated measures with treatment, visit, and treatment-by-visit interaction as factors in the model, using the baseline score as a covariate. MLSDT data were analyzed by comparing the baseline scores of the low-dose, high-dose or sham vs Week 52 scores using a paired samples t-test. **Results** MCO-010 patients had mean baseline BCVA scores of 2.207 ± 0.105 and 2.250 ± 0.00 logMAR (low- and high-dose, respectively), and the sham patients had a mean baseline BCVA of 2.172 ± 0.1342 logMAR. The following BCVA results are reported from weeks 16, 24, 36, and 52. Compared to sham, low-dose MCO-010 patients had a mean improvement of 0.160, 0.192, 0.431, and 0.336 logMAR (P = 0.2780, 0.1958, 0.0060 and 0.0300 respectively). High-dose MCO-010 patients had a mean improvement of 0.022, 0.197, 0.214, and 0.287 logMAR (vs sham; P = 0.8392, 0.0765, 0.0544 and 0.0103, respectively). MCO-010 patients had mean baseline MLSDT scores of 1.44 ± 0.67 and 0.22 ± 0.15 (low- and high-dose, respectively), and the sham patients had a mean baseline MLSDT score of 1.67 ± 0.62. The following MLSDT results are reported as the mean change from baseline for weeks 16, 24, 36 and 52. The low-dose MCO-010 patients had mean scores of 0.22, 0.00, 1.22, and 1.33 (P = 0.8337, 1.000, 0.2489, and 0.2721, respectively). High-dose MCO-010 patients had mean scores of 1.57, 0.78, 1.00, and 1.89 (P = 0.0914, 0.2594, 0.1599, 0.0265, respectively). Sham patients had mean scores of -0.25, 0.33, -0.11, and 0.22 (P = 0.7486, 0.6666, 0.5943, and 0.8032, respectively). MCO-010 was well tolerated with no serious adverse effects observed through week 52. **Conclusion** BCVA assessed with Freiburg visual acuity can objectively quantify visual acuity for low-vision patients on a logMAR scale and has been recommended for clinical trials in individuals with low vision, including optogenetics, by the International HOVER Taskforce (Harmonization of Outcomes and Vision Endpoints in Vision Restoration Trials). The RESTORE data further support the validity of using Freiburg visual acuity for low-vision patients as an efficacy endpoint. RESTORE data demonstrate MCO-010-treated patients improved in BCVA in both dose groups, compared to sham-treated patients, where statistically significant improvements in visual acuity were observed at week 36 and was maintained through the 52-week study. Furthermore, a dose-dependent improvement in near-field object recognition was observed in the MCO-010-treated patients; the high-dose patients statistically improved in MLSDT at week 52 compared to baseline.

918. Preliminary Safety and Efficacy Results from an Open-Label, Dose-Escalation Pilot Gene Therapy Study of FT-002 in Subjects with RPGR Gene Mutation Associated X-Linked Retinitis Pigmentosa (XLRP)

Jihong Wu[1], Ruifang Sui[2]

[1]Eye and ENT Hospital of Fudan University, Shanghai, China,[2]Peking Union Medical College Hospital, Beijing, China

Background: X-linked retinitis pigmentosa (XLRP) is a severe form of retinitis pigmentosa (RP) with impaired night vision and constriction of the peripheral visual field, which leads to visual impairment or even functional blindness. The mutation of the RPGR gene accounts for a majority of XLRP cases. Although there is still no effective treatment for XLRP due to defects in the RPGR gene, gene therapy has the potential to prevent and halt the progression of the disease, or even revert the pathological phenotype, constituting a long-lasting cure. FT-002, a novel AAV5 gene therapy vector introducing the codon-optimized $hRPGR^{ORF15}$ gene into retinal photoreceptor cells by subretinal injection to express active RPGR protein which participates in photoreceptor ciliary transport function, rescues photoreceptor cell loss due to RPGR gene mutation and improves visual function or delays the progression of visual impairment of XLRP patients. **Methods and Results:** A pilot clinical study was launched to investigate the safety, tolerability, and

preliminary efficacy of FT-002 via subretinal administration in male patients with RPGR mutation-associated XLRP (NCT05874310). In this first-in-human dose escalation study, dose levels of 5 x 10^{10} vg/eye, 10 x 10^{10} vg/eye, and 20 x 10^{10} vg/eye were evaluated, with 6 subjects enrolled in each dose group from two investigational sites in China. All 18 subjects received one-time FT-002 in the study eye via subretinal injection, with the safety, efficacy, immunogenicity, and virus shedding being evaluated up to 1 year, with a total follow-up of 5 years. FT-002 is well tolerated in all 18 subjects, with no DLT or FT-002 related SAE observed. Most AEs are related to the surgical procedure, and signs of FT-002 related ocular inflammation were observed in some subjects but controllable via the topical use of steroids. Improved retinal sensitivity and visual function were seen in the medium and high dose groups assessed by microperimetry, full-field stimulus threshold (FST), or mobility test. Notably, 4 subjects were with 28 loci, 24 loci, 21 loci, and 28 loci ≥5 dB improvement, and with 6 loci, 15 loci, 4 loci, and 22 loci ≥7 dB improvement, respectively, among the 68 loci of the whole grid in microperimetry evaluated up to the most recent visit (Day 56-168). **Conclusion:** XLRP due to defects in the RPGR gene is a rare disease that causes patients to go blind. Effective treatments remain a critical unmet need. The novel AAV-based gene therapy drug FT-002 shows favorable therapeutic effects with a good safety profile in XLRP male patients; although more clinical data are yet to be collected from the longer follow-up visit, FT-002 targeting RPGR is a potentially effective cure for XLRP due to defects in the RPGR gene.

920. Clinical Periodic Study Report on Safety and Efficacy of NGGT001 for Treating Bietti's Crystalline Dystrophy

Xiuju Chen[1], Xiao Liu[2,3,4], Shihe Cui[5], Gang Wang[5], Yiting Liu[6], Guang Qu[5,6], Lixin Jiang[5,6], Yong Liu[2,3,4], Xiaoxin Li[1]

[1]Xiamen Eye Center of Xiamen University, Xiamen, Fujian, China,[2]Ophthalmology, Southwest Hospital, Army Medical University, Chongqing, China,[3]Key Lab of Visual Damage and Regeneration & Restoration of Chongqing, Chongqing, China,[4]Jinfeng Laboratory, Chongqing, China,[5]NGGT (Suzhou) Biotechnology Co., Ltd., Suzhou, Jiangsu, China,[6]NGGT, Inc, Walnut Creek, CA

Introduction: Bietti's crystalline corneoretinal dystrophy (BCD) is caused by mutations in the cytochrome P450 (CYP) family 4 subfamily V member 2 gene (*CYP4V2*) encoding a polyunsaturated fatty acid hydroxylase which is dominantly expressed in RPE cells in retina. There has not been any treatment available for BCD. NGGT Biotechnology has developed NGGT001, an rAAV2-based vector expressing codon optimized human CYP4V2 for treating BCD. A two-site investigator-initiated trial (IIT) study is conducted to assess the safety and the efficacy of NGGT001 in adult patients with BCD. **Methods:** Twelve adults, aged 30 to 60 years old with BCD received a unilateral subretinal injection of NGGT001 in the poorer-seeing eye, at 2 dose levels of 1.5X10^{11} or 3X10^{11} vg/eye with 6 subjects in each cohort. As of data cutoff, patients have been followed up for 6 to 9 months after treatment. The primary safety measures were ocular and non-ocular adverse events (AEs). Exploratory efficacy included changes in best-corrected visual acuity (BCVA) assessed by ETDRS charts and patient daily life quality self-report. **Results:** All patients tolerated subretinal injections of NGGT001 and there were no treatment-related serious adverse events (sAEs). A total of 6 transit AEs were reported in 5 participants, such as calcaneal stress fracture and eye conjunctival or eyelid edema, which were associated with the surgical procedures and mostly recovered without any medications. In 11 patients completed the 6-month follow-up, 55% of them had a ≥10-letter and 36% had a ≥15-letter improvement in ETDRS letter counts, respectively. At 6 months, the improvement was 12.36 ± 3.47 (Mean ± SEM, n=11) letters from baseline in the treated eyes and remained stable in patients who completed 9-month follow-ups (n=5). The treatment effect of NGGT001 reached statistical significance when compared to baseline (p=0.0019). In untreated eyes, an increase of 6.64 ± 1.75 (Mean ± SEM, n=11) letters was also observed at the 6-month follow-up. 11 out of total 12 patients reported improvements in visual functions and daily life activities. **Conclusions:** These results of the IIT study demonstrated the safety of NGGT001 and highlighted that NGGT001 achieved preliminary efficacy in adult BCD patients.

921. Efficacy and Safety of Intravitreal rAAV2-*ND4* Therapy for Leber's Hereditary Optic Neuropathy

Wenbin Wei[1], Libin Jiang[1], Sitong Guo[2]

[1]Beijing Tongren Hospital, CMU, Beijing, China,[2]Beijing Friendship Hospital, CMU, Beijing, China

Objective: To evaluate the safety and efficacy of a recombinant adeno-associated virus serotype 2 (rAAV2) carrying normal *ND4* (rAAV2-*ND4*) (NR082) in participants with visual loss from Leber hereditary optic neuropathy (LHON) carrying the m.11778G>A mutation, and explore a safe dose of NR082 intravitreal injection. Methods: 12 participants with the m.11778G>A mitochondrial DNA mutation and vision loss more than 6 months from onset in both eyes were included in this prospective open-label trial. They were treated with intravitreally injection unilaterally, the first 6 participantswere treated at the initial dose of vector (1.5*109 vg, 0.05mL) (Group I), and the other 6 participants weretreated at the high dose (4.5*109 vg, 0.05mL) (Group II).Treated participants were followed for 52 weeks and underwent ocular and systemic safety assessments along with visual structure and function examinations.Results: A total of 12 participants were included in this study, 5 male subjects and 1 female in Group I with a mean age of 19.0 ± 1.55 years and 21.8 ± 5.27 years in Group II. The baseline BCVA in the injected eyes in Group I was 1.89 ± 0.36 logMAR, which improved to 1.59 ± 0.10 logMAR at week 52nd after intravitreal rAAV2-ND4. In Group II, the baseline BCVA in the injected eyes was 2.20 ± 0.15 logMAR, and BCVA at week 52nd after treatment was 1.92 ± 0.32 logMAR.There were three and four injected eyes improved significantly after 52-week's follow-up in Group I and Group II respectively. There was no serious ocular or systemic adverse events or dose-limiting toxicity in all participants. The adverse events possibly related to thetreatment included uveitis,vitreous opacity and keratic precipitates.Conclusion: No serious safety problems were observed in the 12 participants enrolled in this phase 1/2 trial of virus-based gene transfer in this mitochondrial disorder. Additional study follow-up of these and additional participants is needed to confirm these preliminary observations. Key Words: safety, efficacy, gene therapy, rAAV2-*ND4*, leber's hereditary optic neuropathy

922. Honoring the Generizeables

Rafael D. Escandon

Rafael Escandon, Bainbridge IS, WA

To date, since ASGCT's 26th Annual Meeting in May of 2023, six gene replacement and gene editing therapies in inherited, monogenic conditions have been approved in the USA. Many of these programs employed dose-escalation designs in attempts to rapidly translate a preclinical dose into a safe and efficacious dose in humans. Unlike with drugs and biologics, risks of gene therapies are not limited to unknown and untoward effects, it is also the permanence of a limited or a lack of efficacy due to underdosing that distinguishes early clinical gene therapy development from that of traditional drugs and biologics. Gene therapies cannot currently be turned up, turned down, or turned off. To conduct research ethically, participants and guardians are informed that one of the exchanges for a research participant's possible lack of direct benefit is the possibility of providing generalizable knowledge that may be useful to future participants in research, and/or future patients with the genetic condition. As safe and effective doses are sought, most gene therapy programs, whether approved or in development, have created and continue to create groups of research participants who were under-dosed, or dosed outside of an optimal window of opportunity to halt or reverse progression of disability. Since re-dosing of vector-based gene therapies is not feasible for myriad reasons, and participation of prior gene therapy recipients is often excluded from clinical trials of other interventions, options for these patients are limited. While creation of such a population was unintended, it continues to grow. It is, therefore, reasonable to ask whether the scientific community is appropriately honoring such altruism, and if not, how and in what ways it may do so in the future.

923. AAV Therapeutic Windows by Route of Administration: A Meta-Analysis Covering 20 Years of Clinical Dosing Data from 154 AAV Trials

Gregg Wagner, Chris A. Learn

Cell & Gene Therapy Center of Excellence, Parexel, Durham, NC

Introduction: Summary data guiding clinical dose selection for adeno-associated virus (AAV) gene therapy investigational products have largely been underreported. The high homology of AAV product classes suggest that their pharmacologic properties, including therapeutic window, may be comparable by route of administration (RoA) irrespective of capsid serotype, expression construct, and target indication. Here, we collected and analyzed dosing information from 154 AAV clinical trials to estimate the therapeutic window of AAV products by RoA to demonstrate the potential importance of mining public databases for 1) clinical trial design and 2) to illustrate safety considerations on dose to further inform clinical practice. *Methods:* We collected dosing information and other reported metadata (e.g., RoA, indication, etc.) from 154 AAV clinical trials over 20 years on ClinicalTrials.gov. The dataset contains 50 phase 1 trials, 76 phase 1/2 trials, 12 phase 2 trials, 5 phase 2/3 trials, and 11 phase 3 trials. Of the trials surveyed, 53% (82/154) reported dose information. This data was subsequently stratified by RoA and, for trials reporting multiple doses, the highest dose was selected for analysis. Using this strategy, we determined the clinical dosing range for six RoAs: intravenous (IV), intracoronary, intramuscular, intra-articular, intravitreal (IVT), and subretinal. AAV trials using an IV RoA were further stratified into hepatic and non-hepatic indications to consider the effect of AAV hepatotropism on dose selection. Considering the data were collected from clinical studies in which the optimal dosing risk: benefit profile had yet to be determined, we accept that a subset of lower doses reported may lack efficacy and a subset of higher doses may show dose-limiting toxicity. Accordingly, we excluded the first and fourth quartile of the clinical dosing range and define the interquartile range (IQR; middle 50%) as the estimated therapeutic window for each RoA. In addition, we performed exploratory analyses of AAV doses and stratified with trial metadata to uncover novel trends. *Results:* The estimated therapeutic window as defined by the interquartile range for each RoA is as follows: IV-hepatic indication, 6E12-2E13 gc/kg; IV-non-hepatic indication, 9.75E13-1.85E14 gc/kg ; intracoronary, 1E13 - 1.9E14 gc; intramuscular, 3.5E12 - 3.5E13 gc/kg; intra-articular, 1.1E13 - 6E13 gc/joint; subretinal, 4.6E10 - 2.25E11 gc/eye; IVT, 1.8E11 - 4.1E11 gc/eye. Exploratory analyses indicate a higher IV dose range in pediatric and infant patient populations relative to adult populations. In addition, the results show an increase, on average, in AAV doses over time for IV, intracoronary, and intra-articular RoAs while subretinal and IVT RoAs exhibit a decrease over time. We acknowledge that other factors may influence dose (e.g., full/empty ratios) but these data have either not been collected or reported. *Conclusions:* These findings support the notion that the therapeutic windows of AAV products administered via the same RoA are comparable despite different target indications, capsid serotypes, and expression constructs. In doing so, the data provide preliminary guidance to sponsors regarding safe and efficacious clinical dosing windows for AAV products by RoA. Differences in AAV doses over time and across ages may signify an evolving understanding of the risks and benefits of AAV gene therapy products, considering RoA, target population, and disease severity. This work collectively provides early proof-of-concept for estimating therapeutic windows using publicly available data - a strategy to guide clinical dose selection in AAV trials. Broadly, this effort highlights the potential of focused mining of public databases to inform trial design, with potential implications for the clinical testing of adjacent advanced therapy product classes, such as lentiviral and CAR-T cell therapy.

924. Recommendations for rhe Safe Handling of Gene Therapy within Institutions

Estela Rodriguez Garcia[1], Kevin Zinchuk[2], Jon Silverman[2], John Ryan Stackhouse[2]

[1]University of Navarra, Pamplona, Spain,[2]Brigham and Women´s Hospital, Boston, MA

With an increasing volume of viral vector-based gene therapies on the horizon, ensuring the safety and protection of healthcare workers handling these agents of primary importance. Staff who prepare and administer these agents, as well as those caring for patients should be considered in the developing safe handling policy and procedures along with institutional occupational health, quality and safety administrators. Establishing and operationalizing standardized gene therapy handling practices presents a challenge. As these agents have specific handling requirements based on safety designations not typically used in clinical care settings. However, regulations governing their handling in a consistent manner in these settings are not available for reference.

Although the last edition of the Biosafety in Microbiological and Biomedical Laboratories ("BMBL") and the National Institutes of Health Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules ("NIH Guidelines") outline best practices for handling biohazardous agents and recombinant DNA product in a laboratory research setting, laboratory guidance is not easily translatable to the handling considerations that healthcare workers take when caring for patients. Specific guidelines need to be established to assist institution based healthcare workers in assessing designated risk groups, biological safety level and other various product characteristics. In addition, standardized requirements for storage and handling of viral vector-based therapies, like those outlined in USP <800>, must be designated. Only after an objective and clearly defined process is developed and implemented will institutions be able to control and mitigate the occupational risks associated with providing gene therapy agents to an institution's patient population. In the absence of recent national or international guidance, each clinical facility or institution must develop its own standard operating procedures based on historical guidance with careful considerations of current legislation and regulations in their country, state and local municipality. Appropriate policies and procedures, guidelines and best practice recommendations should be developed and implemented in advance of these products being needed at clinical sites. Existing Biosafety guidance and oversight bodies, usually in the form of an Institutional Biosafety Committee ("IBC"), need to evaluate and adjust their committee membership to ensure that clinical staff are appropriately represented. Institutions should also consider establishing a "Clinical Biosafety Committee" to fulfill the duties of an IBC but for marketed products. With continuing advances in the field of gene therapy, the institutional oversight structure needs to evolve to address the necessary changes in order to deliver safe practice guidance for healthcare workers, researchers and patient caregivers. Once clinical environments are able to standardize guidance for working with viral vector-based gene therapy products, a comprehensive risk assessment framework is needed to ensure that each new agent is reviewed and identified such that caregivers know what safeguards to apply. These safeguards alert institutional staff to the specific requirements for each product's storage, handling, administration, and disposal. The guidelines described here will help direct healthcare institutions in the operational management of vector-based gene therapies, define risk levels, identify necessary infrastructure, and develop suitable policies and protocols, to protect workers and caregivers handling and administering these therapies.

925. Delivering on the Ethics of Gene Therapy Trials

Carolyn R. Chapman

Multi-Regional Clinical Trials Center of Brigham and Women's Hospital and Harvard, Boston, MA

The tremendous excitement about the vast potential for gene therapies, including genetically modified cell therapies, is justified. As of January 2024, the FDA has already granted marketing authorization to 17 such therapies and hundreds more are in various stages of research and development. This new class of therapeutics targets a wide variety of diseases and disorders, including those with significant unmet medical needs, creating expectations but also raising the stakes. This presentation will provide an overview of the complex and unique ethical issues arising in the specific context of gene therapy research and development. The discussion will be grounded on ethical principles that undergird all clinical research. We will discuss the ethical implications of study design choices, such as whether and which controls are included, how and what doses are chosen as starting points, which endpoints/outcomes are studied, which participants are included and excluded, what supports are provided, and how long participants are followed. We will consider how the analysis and resolution of ethical challenges depend on facts that are specific to each disease context at a given point in time. Finally, we will illustrate how different stakeholders in the clinical trial ecosystem, such as patients, caregivers and families, investigators, companies, and regulators, have both convergent and divergent interests that must be balanced to support the ethical conduct of gene therapy research. Ways to respect and engage affected communities, as well as prospective and enrolled research participants, will be discussed.

926. AAV Mediated Gene Therapy Restores Hearing in Patients with DNFB9 Deafness

Shanzhong Zhang, Jieyu Qi, Fangzhi Tan

Suzhou Otovia Therapeutics Co., Ltd., Shanghai, China

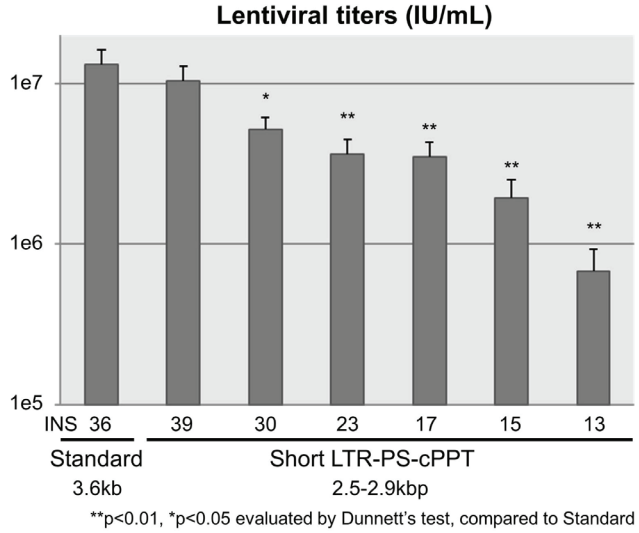
Mutations in *OTOF* lead to the autosomal recessive auditory neuropathy DFNB9. The efficacy of adeno-associated virus (AAV)-mediated *OTOF* gene replacement therapy has been extensively validated in *Otof*-deficient mice. However, the clinical safety and efficacy of AAV-*OTOF* have not been reported. Here, we generated AAV-*OTOF*, using good manufacturing practice and validated its efficacy and safety in mouse models and non-human primates in order to determine the optimal injection dose, volume, and administration route for clinical trials. Subsequently, AAV-*OTOF* was delivered into one cochlea of 5-years-old and into bilateral cochleae of 8-years-old deaf patients with *OTOF* mutations. Obvious hearing ability improvement was detected by the click and pure-tone auditory brainstem response (ABR) and the pure-tone audiometry tests (PTA) in these two patients. Hearing in the injected ear of the 5-years-old patient could be restored to the normal range at 1 month after AAV-*OTOF* injection. And the 8-years-old patient reached maybe 50%-70% of normal hearing. Most importantly, the 5-years-old patient could hear and recognize speech only through the AAV-*OTOF*-injected ear. Our study is firstly to demonstrate the safety and efficacy of AAV-*OTOF* in patients and expands and optimizes current *OTOF*-related gene therapy, which provides valuable information for further application of gene therapies for deafness.

Thursday Posters: Viral Vectors

927. Addressing the *Ex Vivo* Lentivirus Black Box Warning: Reducing Risk through Engineering

Matt P. Ercolino[1], Jade Bose[1], Jonathan Morgan[1], Shangzhen Zhou[2], Lucia Fernandez[1]

[1]Process Development and Manufacturing, VintaBio, Philadelphia, PA,[2]Research Vector Core, VintaBio, Philadelphia, PA



Lentivirus (LV) vectors are commonly used in cell therapy applications as a reagent used to produce the final drug product. Recently, LV has seen an uptick in use for *in vivo* transduction. LV production has been performed using transient transfection methods in HEK293T cells to produce high titer viral stocks. HEK293T cells were generated by transforming HEK293 cells with a temperature stable form of SV40 large T-antigen (Tag, a known risk factor) enabling cells to express viral proteins at high levels. Given the secondary cancer concerns with CAR-T therapies (FDA just required all 6 CAR-T therapy products to add a black box warning) the removal of Tag in the production process could help to reduce risk and safely expand LV vectors' usability for *in vivo* gene therapies. There is known productivity per cell gap between the titers achieved with HEK293T vs HEK293 cells. Through process engineering this gap can be significantly reduced if not effectively closed. This enhanced process can be achieved through improved transfection methods and effective scaling into fixed-bed bioreactors with high surface areas. LV production has broadly moved from adherent to suspension-based processes. The shift was prompted by concern over the lack of scalability of adherent processes. However, the suspension processes face challenges such as low productivity per cell, and increased pressure on downstream purification process. Our goal in this work is to compare the production of LV in proprietary HEK293 cells and an HEK293T cell line through the following aims: • Aim 1: Examine the production gap between HEK293 and HEK293T with improved transfection methods and our proprietary HEK293 cells vs prevailing methods in HEK293T. • Aim 2: Assess LV production in the HEK293 adherent system vs a commercially available HEK293T suspension system as well as production system impact on process characteristics including impurity profiles • Aim 3: Investigate the transduction efficiency of the virus produced with different modalities. In our experiments HEK293T cells indeed produce higher titer LV stocks than HEK293 cells operated under the same conditions. High titer LV production is possible with HEK293 cells when used with improved transfection methods and our proprietary transfection reagent, narrowing the production gap to less than a 1-log decrease versus HEK293T cells. HEK293 adherent cultures demonstrate similar productivity to second-generation HEK293T suspension processes while using less nutrient medium per cell. The HEK293 cell in general exhibit more consistent and predictable growth profiles in their native state of adherence. This native state results in a more reliable cell behavior allowing for more control in the industrial setting. Adherent processes offer the ability to manipulate cell attachment surfaces allows for fine tuning of the cellular process. LV produced in both adherent and suspension modalities display similar transduction efficiencies. Adherent systems also offer advantages in terms of downstream processing. Harvesting and purification of viral vectors from adherent systems are often less challenging due to the reduced presence of cellular debris and impurities indicated by the reduced presence of host cell protein (HCP) and host cell DNA (hcDNA). Harvest streams with less process impurities contribute to higher vector purity and facilitates higher recoveries across subsequent purification steps. Although HEK293T still retain higher productivity at per cell level, one can achieve commercially viable scale production using HEK293 cells; hence improve the safety profile for the final drug product with the removal of the SV40 Tag.

928. The Inclusion of HIV-1 Inhibitory Sequences Improves the Minimal Size of Lentiviral Vectors for Hemoglobinopathies

Naoya Uchida[1], Anh Le[1], Avery Bradley[1], Julia Ball[1], Selami Demirci[1], Xiong Liu[1], Matthew M. Hsieh[1], Takashi Okada[2], John F. Tisdale[1]

Hematopoietic stem cell (HSC) gene therapy is curative for various genetic diseases, including sickle cell disease, and HIV-1-based lentiviral vectors are utilized for therapeutic β^{T87Q}-globin gene delivery to HSCs. However, the lentiviral gene-packaging capacity (~10kb) limits this application, and thus, size reduction of the lentiviral backbone remains crucial. Previous attempts for size reduction resulted in decreased titers and transduction efficiency; therefore, in this study, we sought to generate small-size lentiviral vectors while retaining their titer and transduction. We designed a range of smaller sizes of MSCV promoter-driven *EGFP*-expressing lentiviral vectors by using only the core sequence of essential fragments, including long terminal repeats (LTR), packaging signal (PS), rev response element (RRE), and central polypurine tract (cPPT). We evaluated lentiviral titers and transduction efficiency in human CD34+ cells at a multiplicity of infection 50. Switching to the core of each essential fragment gradually decreased vector sizes and lentiviral titers (short LTR-cPPT, or further deletions, $p<0.05$). Transduction efficiency in CD34+ cells was reduced by the use of core fragments as well as the splicing donor mutation (Short LTR-PS-cPPT, or further deletions, $p<0.01$), likely due to less efficient lentiviral integration. These data suggest that some key sequences for transduction are included in various locations in the lentiviral vector backbone. HIV-1 nuclear export is restricted by their inhibitory sequences (INS) and allowed by rev-RRE interaction; therefore, we hypothesized that the inclusion of HIV-1 INS is important for lentiviral integration and thereby, required for small-size lentiviral vectors with high titers and efficient transduction. We designed ~1kb-shorter LTR-PS-cPPT vectors including escalating amounts of INS motifs (13-39 INS), compared to the full-size standard vector (36 INS). As expected, lentiviral titers decreased in response to reducing INS numbers in the small-size vectors ($p<0.05$) except for that including maximal 39 INS (Figure). We then designed a small-size β^{T87Q}-globin vector using our forward-oriented construct with β-globin promoter/enhancers (Nat Commun. 2019) and the ~1kb-shorter lentiviral backbone with additional INS. When using *EGFP* instead of the β^{T87Q}-globin, the small-size vector with additional INS (50 INS) allowed for 1.7-fold higher titer and 1.2-fold more efficient transduction in CD34+ cell-derived erythroid cells ($p<0.01$), compared to a small-size vector without additional INS (32 INS), at similar levels to a full-size backbone vector (50 INS). The small-size β^{T87Q}-globin-encoding vector with additional INS (61 INS) resulted in a similar titer, 1.2-fold more efficient transduction, and 1.4-fold higher β^{T87Q}-globin production at the protein level, compared to that without additional INS (47 INS), which are comparable to a full-size backbone vector (58 INS). In summary, we demonstrated that the inclusion of HIV-1 INS motifs is important to maintain lentiviral titers when reducing the vector size. The additional INS allowed for more efficient transduction in CD34+ cells with small-size vectors. These findings would allow for further development of gene therapy applications.

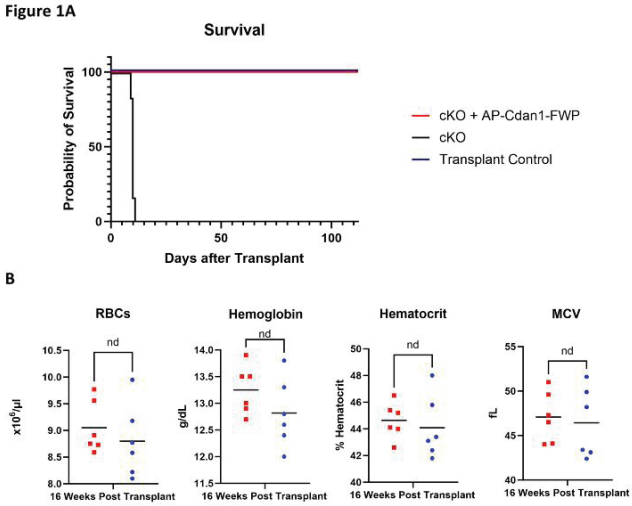
929. Post-Natal Maturation of Myocardium Likely Causes a Post-Entry Block of Transduction by Lentiviral Vectors

Ruud N. Visser[1], Vincent Portero[2], Niels Harlaar[2], Jianan Wang[1], Timo Jonker[1], Max Medina-Ramirez[1], Harsha Devalla[1], Mischa Klerk[1], Arnie R. Boender[1], Klaus Neef[3], Hanno L. Tan[1], Antoine A. F. de Vries[2], Vincent M. Christoffels[1], Gerard J. J. Boink[1]

[1]Amsterdam UMC, Amsterdam, Netherlands,[2]Leiden University Medical Center, Leiden, Netherlands,[3]University Medical Center Utrecht, Utrecht, Netherlands

Introduction In cardiac gene therapy, two viral vectors are typically used for long-term transgene expression, i.e. lentivirus (LV) and adeno-associated virus (AAV) vectors. Compared to AAV vectors, LV vectors have a larger insert capacity and potentially confer permanent transgene expression integrating the vector genome in that of the host cell. However, standard VSV G protein-pseudotyped LV vectors (VSVg-LV) have shown suboptimal transduction of cardiomyocytes *in vivo*. In this study, we aimed to improve LV-mediated transduction of cardiomyocytes by evaluating LV vectors carrying various different envelope proteins and compared the most potent variants with AAV vectors. **Methods** We made a panel of 76 LV vectors pseudotyped with envelope proteins from various viruses carrying an expression cassette for enhanced green fluorescent protein (eGFP). Transduction efficiencies in neonatal rat ventricular myocytes (NRVMs), human induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) and cardiomyocyte progenitor cells (CMPCs) were determined by fluorescence-activated cell sorting as fraction of eGFP-positive cells. 7-weeks old male Wistar rats were injected directly into the left ventricle with 200,000 IU of vector. One control rat followed the same procedure but instead of LV, it was injected with 5.8 x 10^{11} genomic copies (gc) of AAV9.45 capsid pseudotyped AAV2 (AAV9.45). VSVg-, Cocal virus (CoCV)- and Foamy virus (Foamy)-LV vectors were produced carrying an expression cassette to allow co-expression of ReaChR, a light-gated ion channel used in optopacing, and GFP. An AAV9.45 vector was produced with a corresponding transene cassette. LVs were functionally titrated in NRMVs. Four weeks after the surgery, optopacing responses were evaluated *in vivo* and *ex vivo*. Transduction efficiency was evaluated by immunohistochemistry on GFP. Human neonatal and adult heart slices were cultured and transduced with VSVg-LV and AAV DJ capsid-pseudotyped AAV2 (AAV-DJ) vectors as a control. Vectors carryied an expression cassette for eGFP under a cardiomyocyte promoter. Immunohistochemistry was performed to visualize GFP. **Results** Of the pseudotyped LVs, none outperformed VSVg-LV vectors, which reached transduction efficiencies *in vitro* of 58% in NRVMs to 96% in hiPSC-CMs and 100% in CMPCs. In addition to VSVg-LV, the second (CoCV-LV) and third (Foamy-LV) best performers were included for *in vivo* testing. While the heart transduced with AAV9.45 showed consistent left ventricular optical pacing, none of the three tested LV pseudotypes caused enough ReaChR expression to sustain optical pacing. These results were confirmed via immunohistochemistry, where only the AAV9.45 injected tissue was positive for GFP. To investigate the impact of tissue maturity on transduction, we proceeded testing with the transduction of human neonatal and adult cardiac slices. These experiments indicated absence of substantial transduction by VSVg-LV in human adult cardiac tissue slices, which was in contrast to the potent transduction realized by AAV-DJ in neonatal and adult tissue. **Conclusion** *In vitro* screening of a panel of pseudotyped LV vectors showed standard VSVg-LV vectors we most effective. Despite encouraging *in vitro* results and previously reported findings, LV vectors did not provide robust *in vivo* transduction. The observation that VSVg-LV was able to transduce NRVMs but not adult human cardiac tissue slices suggest the emergence of a post-entry block could be a critical limiting factor in the transduction of adult tissue, both *in vitro* as well as *in vivo*.

930. Lentiviral Gene Therapy Rescues a Novel Inducible Codanin-1 KO Mouse Model of Bone Marrow Failure



Perry Demsko[1], Laura Breda[1], Carlo Castruccio Castracani[1], Ariel Rivera[1], Tyler Papp[2], Yink Tam[3], Barbara Mui[3], Megan Fedorky[1], Hamideh Parhiz[4], Stefano Rivella[1]

[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, Philadelphia, PA,[3]Acuitas Therapeutics, Vancouver, BC, Canada,[4]University of Pennsylvania, Philadelphia, PA

Congenital Dyserythropoietic Anemia 1 (CDA1) is an inherited blood disorder caused by biallelic mutations in Codanin-1 (Cdan1), a protein of uncertain function. CDA1 is characterized by macrocytic anemia, multinucleated erythroid precursors, and characteristic 'spongy' chromatin morphology under electron microscopy inspection. CDA1 manifests with moderate to severe anemia, skeletal deformities, and reduced stature. Complications from CDA1 are primarily derived from deficient erythropoiesis and include splenomegaly, hemochromatosis, and hyperbilirubinemia, which are further exacerbated by chronic transfusion dependence. Currently, no cure is available, and the lack of a viable CDA1 mouse model has prevented attempts to develop treatments. No homozygous-null mutant patients have been documented, and *Cdan1*-KO mice abort early in embryogenesis, generally by E7. Murine embryos with erythroid-specific KO of Cdan1 are viable until E14.5 when they succumb from pronounced anemia,

informing the need for an inducible KO system to generate an adult model of CDA1. We have developed two CDA1 models wherein a floxed Cdan1 allele is excised either by Mx-Cre after induction with a dsRNA analog (Cdan1$^{Mx\text{-}cre}$-KO) or via Cre mRNA containing lipid nanoparticles targeted to hematopoietic stem cells (Cdan1^{LNP}-KO). We found that biallelic loss of *Cdan1* is incompatible with life as both models are fatal upon induction (**Figure 1A**). The fatal phenotype can be reversed by rescuing the model by delivering the human CDAN1 gene via lentiviral gene transfer (AP-CDAN1-FWP). All surviving KO animals show normal erythropoiesis and complete blood counts (**Figure 1B**). Additional studies are underway to analyze lineage-specific hematopoiesis in the bone marrow and as colony assays. Without any known dominant negative effect for Cdan1 mutations, this directly demonstrates the applicability of a gene addition-based strategy for treating CDA1. Since hematopoietic stem cells lacking *Cdan1* are not viable, we generated mice KO with transgenic *Cdan1* using vectors expressing known hypomorphic human CDAN1 mutations. The goal is to explore the function and pathophysiology of mice expressing mutant CDAN1 alleles. In early studies, and similarly to human CDA1 patients, the mice transduced with mutated CDAN1 alleles exhibit variable decreases in hemoglobin and red blood cell count. In particular, the anemic state is more prominent up to 4 weeks following transplant or a challenge bleed, with CDAN1 mutant mice exhibiting a protracted recovery compared to WT controls. Additional experiments are underway to characterize erythropoiesis and iron metabolism in these animals.In summary, these data indicate that our novel vector has the potential to cure CDA1 and further characterize this disease.

Figure 1A

931. Envelope Protein Specific B Cell Receptors Direct Lentiviral Vector Tropism *In Vivo*

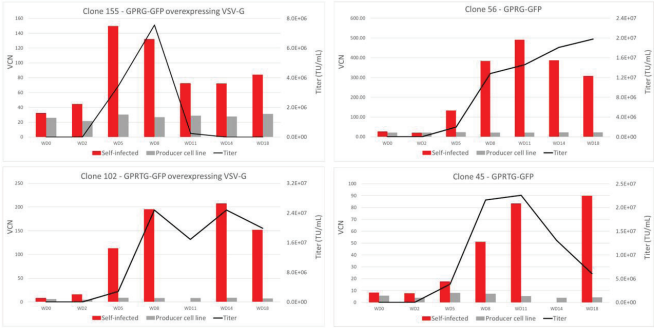
[1]UCLA, Los Angeles, CA,[2]University of Alabama at Birmingham, Hoover, AL

While studying transgene expression after systemic administration of lentiviral vectors, we found that splenic B cells are robustly transduced, regardless of the types of pseudotyped envelope proteins. However, the administration of two different pseudotypes resulted in transduction of two distinct B cell populations, suggesting that each pseudotype uses unique and specific receptors for their attachment and entry into splenic B cells. Single-cell RNA sequencing analysis of the transduced cells demonstrated that different pseudotypes transduce distinct B cell subpopulations characterized by specific B cell receptor (BCR) genotypes. Functional analysis of the BCRs of the transduced cells demonstrated that BCRs specific to the pseudotyping envelope proteins mediate viral entry, enabling the vectors to selectively transduce the B cell populations that are capable of producing antibodies specific to their envelope proteins. Lentiviral vector entry via the BCR activated the transduced B cells and induced proliferation and differentiation into mature effectors such as memory B and plasma cells. BCR-mediated viral entry into clonally specific B cell subpopulations raises new concepts for understanding the biodistribution of transgene expression after systemic administration of lentiviral vectors and offers new opportunities for BCR-targeted gene delivery by pseudotyped lentiviral vectors.



932. Challenges in Upstream Lentiviral Vector Manufacturing: Assessing VSV-G Mediated Self-Infection of Stable Suspension Producer Cells

Christin Obert[1], Parameswari Govindarajan[1], Holger Laux[1], Silke Wissing[1], Andreas Gille[2], Monica Terrao[1]

[1]CSL Behring Innovation GmbH, Marburg, Germany,[2]CSL, Pasadena, CA

Introduction Lentiviral vectors (LVVs) are a frequently used resource for gene transfer in the field of cell & gene therapy, and their high demand raises the need for highly concentrated vector material that can be produced robustly, efficiently, and on a larger scale. The manufacturing process faces different challenges in this regard, which include the possibility of the produced LVV to transduce the producer cell lines ("self-infection"). Due to the binding affinity of the lentiviral envelope protein VSV-G to the LDL receptor on the surface of the producer cells, lentiviral particles might enter the producer cells shortly after their assembly and before harvesting. A high "self-infection" of the producer cells in turn might lead to an increased cytotoxicity, cellular detachment, and a reduced virus yield, affecting the process and titer of the manufactured material. The assessment

of the degree of "self-infection" under different conditions and its putative correlation to cell toxicity and impact on the LVV yield is therefore of high interest. **Methods** To assess the correlation between the VSV-G levels in the surface of lentiviral vectors and the degree of "self-infection" during the LVV production, two suspension-adapted stable producer cell lines based on the GPRG and GPRTG packing cells were transfected to overexpress the VSV-G protein. After selection and single-cell cloning, one clone for each packing cell line together with its progenitor was used to produce lentivirus in bioreactors in a process extended up to 18 days. GPRTG clone 45 and GPRG clone 56 with normal levels of VSV-G expression, and GPRTG clone 102 and GPRG clone 155 overexpressing VSV-G. A portion of the producer cells was removed from each bioreactor and its genomic DNA was purified and digested. Primers and probes specific to regions outside and inside of the lentivirus genome were designed to differentiate the amplicons originating from the lentivirus or the producer cell lines. The amount of "self-infection" was quantified using an assay based on ddPCR during the LVV production process on days 0, 2, 5, 8, 14 and 18 post bioreactor inoculation and displayed in virus copy number (VCN)/cell. The LVV functional titer was determined by transducing HEK293T cells with a subsequent flow cytometry readout. **Results and Conclusion** A high "self-infection" level was observed in all clones with a maximum of 469 VCN/cell in GPRG clone 56 on working day 11, which poses a 20-fold increase compared to the pre-inoculation condition. The levels of "self-infection" increased in all tested clones during the vector production reaching a plateau mostly around day 8. Within these four clones, two clones showed a decreased titer at later harvest stages, which correlates with a decreased viability seen in the bioreactors at later time points. The viability might have been influenced by the high levels of "self-infection" as well as a side-effect of the bleeding process of the bioreactor. Overall, there was no distinct correlation between the functional titer and the measured self-infection for the present clones. A preliminary calculation based on the assumption of titer loss due to the high VCN/cell caused by "self-infection" suggested a total loss of roughly 95 % at the peak time point. To conclude the assessment, the analysis showed that indeed "self-infection" is a relevant topic in the production of lentiviral particles and should be further investigated with the impact on the manufacturing process in mind.

933. Enhancing CAR-Expressing Lentiviral Vector Yield Using the V-Pac System

Jiali Yang, Liping Zhang, Jia Xu, Hua Gao, Jing Bi, Houliang Wei, Guodong Jia, Weiran Shen, Xinglin Yang
OBiO Technology (Shanghai) Corp., Ltd., Shanghai, China

Lentiviral vector transduction is the preferred approach for delivering Chimeric Antigen Receptor (CAR) products. However, challenges in packaging arise due to the unique characteristics of the CAR sequence and its expression. Ubiquitous promoters such as CMV, CAG, and EF1a commonly used for CAR expression face resistance during vector packaging. To overcome this challenge, we implemented the V-Pac system for lentiviral (LV) production associated with CAR sequences. The V-Pac system integrates a concise CuO regulatory element positioned upstream of the CAR coding region and involves the expression of the CymR protein in the packaging cell line. CymR binds to CuO, thereby inhibiting CAR expression. The LV vector efficiently expresses CAR upon cell transduction in the absence of CymR. In this study, we systematically examined multiple CAR sequences, including plasmid construction, vector manufacturing, and gene expression. A comprehensive side-by-side comparison demonstrated that the V-Pac system significantly enhanced vector yield by 3~18 times, with no adverse impact on CAR expression levels. Consequently, the V-Pac system emerges as an excellent choice for efficiently packaging challenging viral CAR genes.

934. Development of the Asimov LV Edge Packaging Cell Line and Upstream Process

Omar El-Ghouch, Michelle M. Chang, Jeremy J. Gam, Paulena L. Lieske, Micheal R. Leahy, Jeffrey McMahan, Dan Weaver, Martín Cárcamo, Kevin D. Smith
Asimov, Boston, MA

Success of chimeric antigen receptor T-cell (CAR-T) therapies requires improved lentiviral vector manufacturing to meet demand and overcome the challenges of traditional production methods. Fully transient transfection systems encounter scalability and batch reproducibility limitations, and require large-scale GMP grade DNA for multiple plasmids. The Asimov LV Edge Packaging System has been engineered to overcome these challenges and achieves >1E8 TU/mL titers at harvest. Our clonal suspension HEK293T-based cell line has the necessary lentiviral packaging elements stably integrated into the genome, only requiring transfection of the transfer plasmid and induction of the packaging elements for lentiviral vector production. Further, by focusing on three distinct phases during the production run, we have generated a robust and scalable upstream process that can be transferred as part of the LV Edge packaging system. Our optimization approach encompasses three distinct phases. In the initial phase, growth characterization, the packaging cell line's growth trends and viability were assessed to establish optimal conditions. Bioreactor parameters, seed densities, and production media were evaluated and optimized, laying the foundation for the subsequent two phases. In the second phase, production characterization, the focus shifted to refining the transfer plasmid transfection process. This involved optimization of the transfection mix, timing of transfection, and incorporation of enhancers. The final phase, production optimization, focused entirely on the production phase of the process where bioreactor parameters

and process duration adjustments were explored to maximize overall productivity. Leveraging the ambr250 bioreactor system with integrated metabolite analysis and data-driven models enabled systematic, rapid data generation and iterative optimization throughout all phases of development. Put together, Asimov's LV Edge packaging platform achieves >1E8 TU/mL titers at harvest with a 4-day bioreactor process for multiple CAR transgenes. The platform exhibits high infectivity (TU/pg p24) and similar productivity levels compared to established transient systems, presenting a reliable, scalable, and robust alternative for lentiviral vector production.

935. Env-Y, a Novel Recombinant Protein to Improve Lentiviral Yield and Quality in Production and Purification

Ellen A. Otte[1], Alex Petzke[1], Yan Wei[1], Anup Gopinathan Nair[1], Ryszard Braczkowski[1], Jo Leen Lim[1], Melina Braeuer[2], Holger Laux[2], Parameswari Govindarajan[2], Tobias Brandt[2], Jessica Vogel[2], Louis Fabris[3], Andreas Gille[4]

[1]CSL, Melbourne, Australia,[2]CSL Behring Innovation GmbH, Marburg, Germany,[3]Seqirus, Holly Springs, NC,[4]CSL, Pasadena, CA

Lentiviral vectors (LVVs) play a crucial role in cell and gene therapies, exhibiting the capability to insert relatively large genes into the chromosomal DNA of various cell types with high efficiency. However, despite their numerous benefits, the clinical deployment of LVVs is hindered by substantial challenges, particularly in the upstream and downstream aspects of their production process. LVVs pseudotyped with vesicular stomatitis virus glycoprotein G (VSV-G) target the low-density lipoprotein receptor (LDLR) for cellular binding and uptake. The broad expression of this receptor significantly enhances the versatility of these vectors. However, it also poses a challenge when LVVs are expressed in cells that express LDLR, leading to (self-) infection of these cells. This situation results in diminished productivity, impaired viability of the cell culture, and consequently, lower yields of LVVs. Downstream, the fragile nature of LVVs, coupled with the stringent purification conditions, poses further challenges resulting in diminished recovery and quality. These challenges overall contribute to suboptimal and variable quality and the high cost of LVV. We have developed a recombinant envelope-binding protein to address both issues, which we have dubbed Env-Y. Env-Y is a fusion protein of Fc with the VSV-G binding domain of LDLR, which can bind and neutralize lentiviral VSV-G, thereby preventing transduction and enabling selective purification via protein A. The binding is reversible at pH <6.2, at which VSV-G changes reversibly from its pre- to a post-fusion conformation, or, by removal of calcium, allowing for gentle recovery of functional LVV particles. Here we present the molecular design and characterization of this protein. Binding of Env-Y to VSV-G was assessed by surface plasmon resonance (SPR), which determined an apparent binding affinity of $K_D \approx 1$ nM with small differences for different versions of the molecule. Dissociation at pH 6.0 was also observed by SPR, and no binding of VSV-G to the Env-Y proteins was observed in the absence of calcium ions. Binding of Env-Y to VSV-G expressing cells was assessed using an anti-Fc fluorescent antibody detected by flow cytometry. These experiments documented binding of Env-Y to VSV-G expressed on cell membranes, as well as dissociation on exposure to pH 6 and 10 mM EDTA. Importantly, subsequent re-exposure of these cells to Env-Y at pH 7.4 showed binding at >95% of the level observed prior to dissociation, demonstrating that the VSV-G returned to pre-fusion conformation. Env-Y was able to neutralize LVV in an infectivity assay, reducing transduction of HEK293T cells in a concentration-dependent manner up to 85%. Lentiviral purification of Env-Y-bound LVV using protein A capture and mildly acidic elution condition (pH6) and EDTA was shown in principle and requires further optimization. These data show promise for the concept of the application of Env-Y in in upstream and downstream LVV production process, to increase yield and quality of LVV and reducing cost of LVV manufacturing.

936. Introducing the CAZL Element: A Minimal 3' UTR Sequence That Imparts Enhanced Expression to Transgenes in Target Cells

Cristina Nogueira[1], Jordan Wright[1], Bozhena Caratti[1], Lorena Martinez Quiles[1], Ben M. Alberts[1], Alissa S. Bray[1], Kyriacos A. Mitrophanous[1], Nicholas G. Clarkson[2], Dan C. Farley[1]

[1]Innovation Group, Oxford Biomedica, Oxford, United Kingdom,[2]Process Development, Oxford Biomedica, Oxford, United Kingdom

Expression cassettes within gene therapy vectors are usually engineered to produce optimal expression in target cells. These expression cassettes have some common features including an enhancer-promoter to drive mRNA synthesis in a constitutive or tissue-specific manner, the use of 5' introns to increase mRNA abundance/stability, sequence-optimisation of the open-reading frame (ORF), and 3' UTR enhancer sequences to improve polyadenylation efficiency or polyA tail length and/or composition. There is an inverse correlation between 5'/3' UTR length and gene expression; higher expression is associated with 5' and 3' UTRs of <200 and <800 nucleotides respectively, likely due to the absence of secondary structures and microRNA target sites. For viral vectors, another pressure exists to keep these sequences short: vector genome packaging limit. For ssDNA-based AAV vectors, this limit is a 'hard' one, with packaging efficiency of intact genomes reducing substantially as the length increases above ~5kb. For lentiviral vectors, the efficiency of vector genomic RNA (vRNA) packaging (and ultimately titre) is related to vRNA steady-state abundance, which is also inversely correlated to RNA length, and tends to reduce in a semi-linear fashion over the 'softer' ~10kb limit. The decision to include *cis*-elements employed within UTRs of the transgene cassette is therefore one of 'cost-benefit', related to output titre versus transgene protein per target cell. Given the stricter packaging limit for AAV, this often means that 3' UTR enhancers are not utilised, perhaps lowering product potency. Viral post-transcriptional regulatory elements (PREs), such as from the Woodchuck Hepatitis Virus (wPRE; ~600 nucleotides), are widely used in LVs to increase expression, although this can be dependent on the promoter employed. The wPRE has been shown to promote mixed polyA tailing of mRNAs by recruitment of a TENT4-ZCCHC14 complex via a minimal stem loop. Others have identified a mammalian consensus cytoplasmic accumulation region element (CAR-E; sequence CCAGATCCTG) derived from intronless cellular transcripts that improve export of heterologous mRNAs when tandemised in the 5' UTR. Here we generate a novel composite 3' UTR enhancer element called 'CAZL', wherein a tandemised CAR-E consensus is fused to a minimal TENT4-ZCCHC14 stem loop. The

magnitude of increase in gene expression can be fine-tuned by altering the number of CAR-E consensus repeats, giving a range of sizes from just 60-to-200 nucleotides. We show that CAZLs can replace the wPRE and can be used in the context of different promoters with or without 5' introns. Being small, CAZLs are ideal tools for AAV-based products and for LVs with larger payloads.

937. Orthogonal Characterization of Lentivirus for Size, Charge, Titer, and Stability Using Multiple Malvern Panalytical Technologies (DLS, MADLS, ELS, NTA)

Jonathan Mehtala

Malvern Panalytical, Westborough, MA

Compared to smaller viral vectors, such as the Adeno Associated Virus (AAV), Lentiviral vectors are larger and more complex. Whereas AAVs are 25 nm and consist of primarily two components: a protein capsid shell and a transgene cargo, Lentivirus is 120 nm and consists of at least 7 components: an outer envelope membrane, membrane-embedded proteins, matrix proteins, protein capsid, nucleocapsid, transgene cargo, and other free proteins and enzymes. As a result of the complex Lentiviral structure, it is essential to have robust analytics that can measure Lentiviral properties that predict efficacy and stability. In this study, we characterized Lentivirus samples using four Malvern Panalytical technologies: Nanoparticle Tracking Analysis (NTA), Dynamic Light Scattering (DLS), Multi Angle Dynamic Light Scattering (MADLS), and Electrophoretic Light Scattering (ELS). High resolution Lentivirus size was performed using NTA. Size and aggregation measurements were performed using NTA, DLS, and MADLS. Charge measurements were performed using ELS. Thermal aggregation temperature was measured using DLS and NTA over the course of a thermal ramp. Lentiviral titer and titer linearity were measured using MADLS and NTA. Long term stability experiments were performed over 7 days for Lentivirus samples stored at -80, 4, and RT. Additionally, Lentivirus stability in a high salt buffer was also investigated.

938. Overview of CAR-T Cell Generation Using Optimized Plasmid Design and Lentiviral Vector Production

Gene modified cell therapy such as CAR-T is one of the most promising advanced therapy medicinal products (ATMP) to fight against cancer. These therapies typically use lentiviral vectors to transfer a gene of interest and modify patient's cells. All the raw material used during the lentiviral vector manufacturing must be carefully selected based on different parameters such as quality, performance, supplier, etc. In this project, we generated CAR-T cells based different plasmid construct expressing a fusion protein CAR to track transduction efficiency. We first built different plasmid constructs using the plasmid engineering service from Polyplus, then encapsulate this gene of interest using a lentiviral vector produced with FectoVIR®-LV, transduce CD4+ CD8+ T cells from peripheral blood with this lentiviral vector, expand them for 14 days and finally test the efficiency of the transduced CAR-T cells using a killing assay.

939. Investigating the Relation Between Lentiviral Particle Functionality and the Design of UbC and EF1α Promoter Variants

Cordula Pertl[1], Bianca Volkmann[2], Viola Haeusler[3], Sebastian Fladerer[1], Jana Bauer[3], Irene Ferreira[2], Georg Huber[1], Carl Christel[4]

[1]Vector Development Department, Revvity Gene Delivery (SIRION Biotech Legacy), Munich, Germany,[2]Platform Innovation & Management Department, Revvity Gene Delivery (SIRION Biotech Legacy), Munich, Germany,[3]Quality Control Department, Revvity Gene Delivery (SIRION Biotech Legacy), Munich, Germany,[4]US Site Sales Department, Revvity Gene Delivery (SIRION Biotech Legacy), Munich, Germany

In the last decades, lentiviral vectors of the 3rd generation plasmid system demonstrated an excellent safety record and allowed to shift the attention to the detailed vector design to optimize the manufacturability of LV particles and to improve LV vector titers. With the fast evolution of the cell- therapy field, new demands emerged to intensively characterize the impact of the vector design on LV particle functionality. In this study, we investigate two constitutive promoters, elongation factor 1α (EF1α) and Ubiquitin C (UbC), that are commonly used for lentiviral gene transfer. Our analysis was driven by the hypothesis, that the promoter design alters the activation of splice sites and can lead to truncated LV genomes during production und subsequently to low functional titers. Therefore, we characterized LV particles generated from intron-containing promoters UbC and EF1α and their respective intron-free variants with two separate metrics: particle functionality, defined as total number of infectious LV mRNAs successfully expressed in the test cell by quantifying viral mRNA transcripts , and promoter activity, defined by the mRNA expression level for a specific transgene. We were able to prevent the splicing of the UbC-intron out of an intron-containing UbC promoter-driven GFP construct by a reverse cassette design. However, the particle functionality decreased by 10-fold. This can be caused by the formation of dsRNA initiating degradation by the endogenous defense mechanism against viral pathogens. Excluding the intron completely from the UbC promoter sequence rescued particle functionality and increased the mRNA expression level of GFP by 2-fold compared to the original UbC promoter design. In a second study investigating the impact of an intron-containing EF1α promoter, regulating the expression of a therapeutic Cas9 construct, the same strategy of excluding the intron lead to an 28-fold increase in particle functionality and a 1,3-fold increase in Cas9 mRNA expression level. This increase might be linked to a decrease in size in possible combination with an impact on the activity of splice sites and thus vector genome integrity. In summary our analyses support the hypothesis that, apart from the overall vector size, particle functionality is influenced by the promoter design as it is connected to the splice site landscape of a LV vector. However additional mechanisms have to be considered. As a next step, the composition and integrity of the vector genomes need further qualification, to investigate the impact of promoter-choice on the RNA sequence packed into LV particles.

Moreover, a deeper characterization of vector genomes is the basis to investigate the safety risk that arises from products of these truncated LV RNAs and their potential toxic or harmful clinical effects.

940. Lentiviral Vector Cargo Gene Silencing During Manufacturing

Sherin Parokkaran Johny[1], Maria Ababi[1], Harry Jenkins[1], Weimin Valenti[1,2], David Chang[1,2], Keith Meaney[1], Qian Liu[1], Maria Patrício[1], Matthew Tridgett[1]
[1]OXGENE, Oxford, United Kingdom,[2]WuXi Advanced Therapies, Philadelphia, PA

Lentiviral vectors (LVV) are commonly used for cargo gene delivery in cell and gene therapy. However, although constitutive cargo gene expression in the target cells is typically desired, constitutive cargo gene expression during LVV production is often problematic for two reasons: 1) Production titre can be impacted by cargo gene expression either through the additional metabolic burden placed upon the production cells or by direct inhibition of essential viral processes; 2) Membrane-displayed gene products, e.g. chimeric antigen receptors, can be presented on the LVV surface since its envelope is derived from the production cell membrane. This could have implications for downstream processing, transduction efficiency, and immunogenicity. An ideal LVV production system would silence cargo gene expression without negatively impacting titres. Crucially, to ensure optimal vector production, the packaged viral RNA must not be damaged or have its generation by transcription inhibited. However, since the viral RNA contains the entire sequence of the cargo gene mRNA, typical gene silencing approaches would disrupt vector production, thus limiting titres. To address this issue, we have engineered a distinction between the LVV viral RNA and the cargo gene mRNA, enabling selective silencing of the cargo gene while leaving titres and cargo gene expression in target cells unaffected. This system will enable the use of consistent upstream and downstream processes with different cargo genes, thus expediting, simplifying, and reducing the cost of therapeutic development. Furthermore, since gene product display on the LVV surface is reduced, the LVV safety profile will be improved.

941. Single-Chain Variable Fragment-Based Cell Surface Marker-Targeting by Sindbis-Pseudotyped Retrovectors

Makoto Sato[1], Alexander Cunha[1], Noriyuki Kasahara[2], Cecilia Roh[1], Robert G. Johnson[1]
[1]GenVivo Inc, San Marino, CA,[2]University of California, San Francisco, San Francisco, CA

Advances in genetic engineering and cGMP manufacturing have enabled high-dose intravenous delivery of murine leukemia virus (MLV)-based retrovectors for prodrug activator gene therapy and immunotherapy in cancer patients in recent clinical trials (GenVivo IND# 29718). More efficient delivery to cancer cells and tumor tissues could be achieved by altering biodistribution through physical re-targeting of intravenously administered retrovectors, but this remains a challenge. Here, we have developed a modular platform for generating retrovectors pseudotyped with engineered Sindbis Virus envelopes (SVE) for selective binding to therapeutically relevant receptors. First-generation SVE-pseudotyped retrovectors were produced by engineering the 'universal' immunoglobulin (IgG)-binding domain from Staphylococcal Protein A into the SVE gene. These vectors were tested on PiT2-KO A375 human melanoma cells, which lack the phosphate transporter (PiT2) that serves as the natural receptor for amphotropic MLV envelope. As expected, parental amphotropic MLV vectors were unable to transduce these cells. However, an optimized version of this first-generation vector conjugated with anti-HLA IgG antibody showed successful transduction of PiT2-KO A375 cells. Furthermore, in HCT-15 cells (which lack HLA expression), the anti-HLA IgG-conjugated vector showed minimal transduction, while a vector conjugated with anti-EGFR IgG showed robust transduction. Next, second-generation SVE-pseudotyped retrovectors were developed by direct incorporation of single-chain antibody (scFv) sequences into the structure of the envelope itself. This was accomplished by first restoring a furin cleavage site between the E3 and E2 domains of SVE, which enhanced the transduction efficiency of SVE-pseudotyped MLV by up to 20-fold without loss of specificity, followed by incorporation of scFvs into the modified E2 region. While there have been previous reports of similar constructs, no prior publication has studied the relationship between the targeting motifs' structures and transduction efficiencies of pseudotyped vectors. Fourteen linker variants were created of SVEs bearing an anti-CD47 scFv. These variants were comprised of three sections: two "base" linkers that link E2 and scFv domains; and, one "mid" linker between VH and VL. We selected four "base" and two "mid" linkers to construct seven such variants and tested the VL in both relative orientations. As expected, constructs with "reverse" VL were not functional; the other seven showed transduction at different levels. Based on the results, we selected AAGHVG as "base" linkers and a longer 18-amino acid "mid" linker for further SVE-scFv constructs.We then constructed and tested SVE-scFv targeting HER2, CD47, EGFR, or Nectin-4. These targeting vectors exhibited excellent cell-specificity and transduction efficiency. For instance, the Nectin-4-targeting scFv vector efficiently transduced MDA-MB-468 cells, which show high levels of Nectin-4 (95.5%), but significantly reduced transduction of PC-3 cells, which show much lower levels of the target (13.8%). The SB-scFv vector targeting EGFR transduced most cancer cell lines. Two types of HER2-targeting vectors were also developed: scFv and diabody (DB) vectors, which exhibited excellent HER2 expression-dependent transduction. Transduction efficiency of these vectors was high in HER2-overexpressing cells such as SKBR3 and SKOV3 but minimal in HER2-null cells such as MDA-MB-468.In summary, the stepwise evolution of our SVE-based targeting vectors, from Ab-conjugated SVE to scFv- or DB-engineered SVE-pseudotyped retrovectors, has culminated in the development of a reliable and modular targeting system that may contribute to improved gene therapy for cancer and other indications.

942. Scalable Manufacturing and Qualified Assays to Generate High Quality Lentivirus for Consistent Generation of CAR-T Cells

Wesley Williams, Jennifer Kandell, Kyle Sylakowski, Md Nasimuzzaman, Venkatesh Sivanadam, Henry Rupp, Sergio Salazar, Anthony Kupchek, Sergio Ita, Olivia Welch, Allison Kifer, Ilena Zavala, Uma Lakshmipathy
Thermo Fisher Scientific, San Diego, CA

As advanced therapies continue to be a promising field for therapeutics, viral vectors have proven to be a critical component, notably in the generation of lenti-modified CAR-T cells for treatment for various types of immune oncology targets. The complex biological manufacturing systems for viral vector production have the inherent challenge of establishing and maintaining product consistency throughout development while allowing for flexibility required at an early stage. Here, we utilize a scalable manufacturing process and have established robust assays to generate lentivirus at a target titer that is critical to achieve consistent CAR-T production from different donor cells. Using a suspension culture system, virus was consistently produced in 1 - 10 L scale in both shake flash and stir tank bioreactors. Additional, downstream purification was scaled based on the starting volume without compromising yield or functionality. A qualified universal infectious titer assays with ddPCR and orthogonal flow cytometry was established. These systems together were used to generate 4 batches of CD19 CAR lentivirus with titers at or above the target of 1E7 infectious units per milli liter. The resulting lentivirus was tested with 4 different donors and, split collection of one of the donors leukopaks compared as frozen versus fresh. Results indicate that inherently donor variability results in different lenti transduction efficiency ranging from 10-30%, albeit highly dependent on the quality of lentivirus. However, no significant difference was observed between transduction efficiency of T cells from fresh or frozen leukopak from a single donor with the same lentivirus lot. Our approach to implementing controlled methods for the generation and characterization of lentivirus minimizes variability introduced during viral modification of cells from different donors. This capability offers an improved understanding of variable factors that can be tightly controlled early on during the development of manufacturing process.

943. Lentiviral Vector Production in Adherent and Suspension Platforms

Olga Makovich, Kavita Sapru, Saya Vijily, Janna Q. Wisniewski, Elena Prikhodko

Upstream Process Development, Catalent Cell & Gene Therapy, Baltimore, MD

Lentiviral vector (LVV) characteristics were compared between scale down production in three types of bioreactors. iCELLis™ Nano, 2.46 m^2 fixed-bed (PALL Corp.), Scale-X Hydro™, 2.40 m^2 fixed-bed (Univercells SA), and UniVessel™ SU stirred-tank reactor (STR), 2.0 L vessel (Sartorius AG) were inoculated with HEK293 T-cells and used for LVV expression and packaging. Cells were transiently transfected with four plasmids encoding components of the LVV using PEIpro™ transfection reagent, and cell-free conditioned medium was harvested on day 3 post-transfection. Vector titers were measured by p24 ELISA. In addition, the titers of virions with capsids, virions without capsid, virion aggregates, encapsidated p24, and soluble p24 were analyzed by the Leprechaun system (Unchained Labs). Residual host cell protein concentration was evaluated by HEK293 Host Cell Protein assay (ELISA). Under the conditions tested, the highest LVV yields were obtained in the Scale-X Hydro and UniVessel SU bioreactors, both measuring ~2.1-fold greater than the iCELLis Nano yield based on p24-specific ELISA. The concentration of host cell protein was the lowest in the conditioned medium from the iCELLis Nano, less than half the levels measured in the UniVessel SU. Characterization of the LVV structure by Leprechaun in the conditioned media obtained in all bioreactors demonstrated that only a fraction of virions was "full" and contained an enveloped capsid. Data highlighted potential differences in levels of virions with capsids between each platform under the conditions tested. Soluble p24 protein concentration was lower in the samples with high titers of LVV with capsids and higher in the samples with low titers of "full" LVV. High linear liquid speed in both fixed-bed bioreactors and high impeller speed of the stirred-tank reactor may have caused altered capsid and virion assembly. Data suggests that bioreactor type, agitation, and linear speed conditions impact quality attributes during LVV production.

Thursday Posters: AAV Vectors - Virology and Vectorology

944. Influence of Species Differences of the AAVR Receptor Sequence on AAV Transduction Efficiency Among Mice, Pigs, Nonhuman Primates and Humans

Slawomir Andrzejewski, Jenifer Vasquez, Neil R. Hackett, Ronald G. Crystal

Genetic Medicine, Weill Cornell Medical College, New York, NY

Adeno-associated virus (AAV) gene therapy vectors are routinely evaluated in experimental animals to assess the level of gene expression in target organs. However, the level of gene expression differs among different species, despite use of the same AAV vector administered by the same route and same dose (adjusted by size of the experimental animal). Based on the knowledge that cell surface receptors used by AAV play a critical role in the ability of vector to genetically modify a target organ, and that AAVR, the product of the KIAA0319L gene, is the primary receptor for most AAVs, we hypothesized that the differences in transduction mediated by the same AAV vector in different experimental animals could be due, in part, to differences in the AAVR sequence among different experimental animals. Compared to the amino acid sequence of human AAVR, rhesus macaque AAVR has 98.6% identify, pigs have 90.3% and mice 84.0%. To test whether these differences affect the efficiency of transduction by AAV vectors, *in vitro* studies were carried out to assess the level of luciferase reporter gene expression resulting from AAVrh.10Luc-mediated gene transfer in HeLa AAVR knockout ($AAVR^{-/-}$) cells that had been transfected with human, rhesus macaque, pig or mouse AAVR. Transfection efficiency was based on transgene expression with human AAVR set as 100%. The same dose of AAVrh.10Luc mediated 76.4 ±5.3% with AAVR from NHP ($p<0.005$ compared to human), 30.3 ± 7.4% with AAVR from pig ($p<0.0001$ compared to human) and 45.3±2.4% with AAVR from mouse ($p<0.0001$ compared to human). This pattern mediated by AAVR species differences was dose and transgene independent. To assess whether these differences in species-specific AAVR-mediated gene transfer were unique to AAVrh.10 (clade E), the same assay was carried out with other naturally occurring AAVs including AAV9 (clade F) and AAV32.33 (unique clade, AAVR independent) and multiple novel variants of AAVrh.10 with peptide insertions in loop IV and substitutions in loop VIII including AB3 (loop IV GVSLKQG);

NY2 (loop IV DGNNTRK); 36.10 (loop IV IDGAATK; loop VIII ENHTKND) and 9D (loop VIII TTRGDRP). With AAV9, AB3, NY2 and 9D, the same species variation was observed as with wildtype rh.10 with reporter gene expression from human AAVR>rhesus>mouse>pig. In all cases pig AAVR mediated <15% expression of that derived from human AAVR. But interestingly, for 32.33 and 36.10, two AAVR independent capsids, the species origin of AAVR had no effect on AAV-mediated transduction with pig AAVR providing >90% of expression level compared to human AAVR. We conclude that, for many serotypes, cross-species comparisons are complicated by variations in the interactions between AAV with the AAVR primary receptor. These observations of AAVR species variation have implications for making decisions regarding the AAV capsid choice and using experimental animals to predict human AAV vector biodistribution.

945. Plasmid Engineering to Improve AAV Productivity and Packaging Efficiency

Chien-Ting Li[1], Brian Carpenter[2], Peng Wang[1], Lisa Prendergast[3], Dan Cohen[2], Divakar Rajeswaran[2], Paul Morin[2], Glen B. Banks[2], Bingnan Gu[1]

[1]R&D, Lonza Cell and Gene, Houston, TX,[2]BMS, Princeton, NJ,[3]Licensing, Lonza Cell and Gene, Houston, TX

The genome packaging efficiency (full to total capsid ratio, or F/T ratio) for Adeno-Associated Virus (AAV) is a critical quality attribute for the manufacturing and commercialization of AAV-based gene therapies. A higher F/T ratio has the potential for reducing dosage and eventually the cost of goods (COGS). In this study, we present design improvements in pHelper and pRepCap plasmids that can support increased AAV titers, whilst improving F/T ratio in upstream crude harvest using a triple-plasmid transfection process. Performance was measured both at Lonza and at BMS R&D labs independently. Both scenarios show significant increments in full ratio. A tentative plan to further improve productivity will also be shared. In summary, this study demonstrates that we can significantly increase the AAV productivity and packaging efficiency for various AAV serotypes and client-specific Gene of Interest (GOIs) at the upstream production stage through plasmid engineering approaches.

946. A Versatile Cell Line for Establishing Potency of Cell Type-Specific AAV Transgenes

Refugio A. Martinez, John K. Mich, Yemeserach M. Bishaw, Meagan A. Quinlan, Ed S. Lein, Boaz P. Levi

Allen Institute for Brain Science, Seattle, WA

Potency assays are essential for AAV therapeutic development allowing simple and quantitative assessments of therapeutic activity, target engagement, vector stability, and activity per batch. Ideally, potency assays are conducted in a simplified system with homogeneous culture cells as substrates. However, robust cell culture-based potency assays have been hampered by two limitations: 1) Commonly used cell lines have low AAV transduction efficiency due to their lack of appropriate surface receptors; and 2) Cell type-specific AAV transgenes are often not expressed in cell lines because their regulatory elements (enhancers, promoters, etc.) may not be active in the cell lines. A more receptive cell line to common AAVs, and one that would express any transgene regardless of enhancer or promoter, would be a major advantage to developing potency assays for future cell-type selective therapeutic AAVs. In this work, we overcome both hurdles by creating a homogeneous cell line that expresses an AAV receptor to increase transduction efficiency, as well as a transactivator to drive ectopic expression of AAV-delivered transgenes, regardless of enhancer or promoter used. We used the PinPoint-FC platform to deliver a transgene expression cassette containing a guide RNA targeting the AAV genome, a strong dSpCas9-VPR transactivator, and the AAVR cell surface receptor, to a single insulated genomic site. The result is an engineered HEK293T-derived cell line CRAAVR (CRISPRa-AAV-Receptor) that maintains expression and AAV transducibility over several passages. We show that CRAAVR cells exhibit significantly improved AAV transduction efficiency compared to the parental cell line. Moreover, high transduction rates in CRAAVR cells are achieved using orders of magnitudes fewer virus particles than in parental cells. Using enhancer-AAVs with different neural cell-type specificities targeting oligodendrocytes or astrocytes, and not predicted to be active in HEK293 cells, we demonstrate the ability of the dSpCas9-VPR transactivator to drive ectopic expression of AAV-delivered cargos. Last, we demonstrate the utility of CRAAVR cells as a tool for use in quantitative potency assays by transducing them with an AAV-delivered SLC6A11 transgene encoding the GABA transporter, GAT-3, and measuring their ability to transport GABA. We show an AAV dose-dependent relationship to GABA transport specific to the transgenic GAT-3, as GABA transport was abolished when the GAT-3-specific inhibitor SNAP5114 was applied to the cells. Together, these data highlight the superior transduction efficiency, and regulatory element-agnostic expression achieved by CRAAVR cells. Furthermore, we demonstrate the utility of CRAAVR cells as an AAV-transgene potency assay tool that could help streamline the development and validation of AAV-based therapeutics.

947. A Comprehensive Study of Truncated Inverted Terminal Repeats (ITRs) on the Productivity, Genome Packaging, and Potency of AAV Vectors

Yinxing Chen, Shiliang Hu, Lee William, Noel Walsh, Kayla Iozza, Neil Huang, Gregory Preston, Lauren Drouin, Nannan Jia, June Deng, Matthias Hebben, Jing Liao

Alexion Genomic Medicine, AstraZeneca Rare Disease, Lexington, MA

One of the challenges associated with working with Adeno-associated virus (AAV) lies in the inherent instability of its inverted terminal repeats (ITRs), which play a crucial role in AAV replication, encapsidation, and genome integration. The ITRs exhibit a high GC content and possess a palindromic structure, occasionally resulting in truncations and mutations during plasmid amplification in bacterial cells. Despite the pivotal role of ITRs, there exists a notable gap in comprehensive studies exploring how alterations in ITRs impact the essential characteristics of the final AAV vector. To address this knowledge gap, our study focused on designing ITRs with common variations, including single deletions in the B, C, or D regions at one end and dual deletions at both ends of the vector genome. These engineered ITR-carrying plasmids were employed to generate AAV vectors in HEK293 cells. Crude and purified AAV samples were collected for

the analysis of yield, capsid DNA-filled percentage, potency, and ITR integrity. The results of our investigation indicate that a single deletion had a negligible impact on AAV productivity, packaging efficiency, and potency. However, deletions at both ends, excluding the A region, exhibited notable negative effects on these characteristics. This valuable insight into the distinct roles of ITR regions—A, B, C, and D—sheds light on their significance in AAV production and DNA replication. Our work also proposes a novel strategy for quality control in both ITR-bearing plasmids and the ultimate AAV products, with the aim of ensuring the consistent production of high-quality AAV vectors.

948. A Multiplex Screening Strategy for Resolving Cell-Type Enhancer-AAV Expression Patterns in the Brain

Avery C. Hunker, John K. Mich, Naz Taskin, Amy Torkelson, Trangthanh Pham, Jeff Goldy, Christine Rimorin, Michael Tieu, Kimberly Smith, Ed S. Lein, Boaz P. Levi, Jonathan T. Ting

Allen Institute for Brain Science, Seattle, WA

Cis-acting regulatory enhancer elements are valuable tools for gaining cell-type specific genetic access. First identified as isolated peaks in chromatin accessibility datasets, putative enhancer sequences can be cloned and packaged into AAVs to drive custom gene expression in the mammalian brain. While recent advancements in peak detection have enabled large scale enhancer discovery, a significant bottleneck in enhancer-AAV tool generation is caused by the necessity for detailed expression pattern validation *in vivo*. Here we present a barcoded multiplex strategy for screening pools of enhancer-AAVs at cell-type resolution using a single cell isolation protocol optimized for the detection of AAV-derived transcripts. We executed a proof-of-concept study involving twenty enhancer-AAVs expressing in a variety of neuronal and non-neuronal cell types across the mouse brain and were able to successfully recapitulate previously reported enhancer specificities. We found this streamlined screening method rivals the granularity achieved by individual testing while only requiring a fraction of the time, mice, and resources essential for enhancer-AAV characterizations.

949. ITR Instability Challenge Solved: From Basic *E. coli* Genetics to Implications for rAAV Quantity and Quality

Marco T. Radukic[1], Dinh To Le[1,2], Timo Krassuski[1], Daniel Falk[1], Kristian M. Müller[1]

[1]Faculty of Technology, Cellular and Molecular Biotechnology, Bielefeld University, Bielefeld, Germany,[2]III. Department of Medicine, University Medical Center Hamburg- Eppendorf, Hamburg, Germany

Plasmids used for recombinant adeno-associated virus (rAAV) manufacturing typically encode truncated inverted terminal repeats (ITRs) of 130 bp or less, compared to the 143 - 145 bp wild-type ITRs. The small change may make a big difference to rAAV quantity and quality, but its effects remain understudied because of challenges in ITR sequencing and ITR genetic instability in *E. coli* that led to the utilization of truncated but stable ITRs in the first place. We developed a direct sequencing workflow to assess tens of thousands of ITRs on a single molecule level which allowed us to quantify ITR degradation in different E. coli strains and culture conditions. We found that wild-type ITRs were stabilized when consistently propagated at 42 °C compared to standard propagation at 37 °C or 30 °C. The effect was not due to typical heat stress responses, overexpression of single-strand binding protein, or induction of chaperone expression, while inhibition of the E. coli DNA gyrase exacerbated ITR degradation. We, thus, hypothesized that positive supercoiling preceding the plasmid replication fork leads to ITR extrusion from the double strand and subsequent cleavage and ITR loss by the 'structural maintenance of chromosome' proteins SbcCD. Indeed, only moderately significant levels of ITR degradation were observed in a single knockout ΔSbcC strain, JW0387-KC, cultivated at 37 °C, and no ITR degradation was detected in this strain at 42 °C, even after three days of continuous plasmid propagation. Importantly, producing rAAV in HEK293 cells with such wild-type ITR plasmids increased the genomic titer up to 7-fold, depending on the plasmid system used, while reducing reverse packaged backbone DNA. In conclusion, our work enables careful monitoring and maintaining "healthy" wild-type ITRs, which may be vital for manufacturing the highest quality rAAV products.

950. Short-Hairpin Sequences as Stoppers to Limit Replication-Competent AAV Formation and Propagation During Vector Packaging

Jisun Lee, Phillip WL Tai, Guangping Gao, Jun Xie

UMass Chan Medical School, Worcester, MA

Recombinant adeno-associated viruses (rAAVs) have emerged as one of the most advanced gene transfer systems for human gene therapy. Despite their great promise for treating a range of genetic diseases, rAAV manufacturing faces some challenges such as generating replication-competent (rc)AAV contaminants during vector packaging. It has been speculated that rcAAVs arise from non-homologous and random recombination between packaging plasmid DNAs and vector genomes during the replication and packaging of AAV vectors, producing pseudo-wild type genomes with intact *rep*/*cap* ORFs flanked by functional ITRs. However, attempts to reduce rcAAV by reducing recombination and, therefore rcAAV formation during AAV production by the 293 cell-triple transfection platform have not been effective. Thus, one potential strategy to diminish rcAAV formation and propagation is to compromise the replication of recombined rcAAV genomes. Our previous study revealed that nucleotide sequences that form short hairpins hinder normal replication of rAAV genomes by changing directionality of polymerase activity during rAAV manufacturing. We, therefore, hypothesized that flanking rep/cap ORFs with short-hairpin DNA sequences (shDNAs) as "stoppers" or inserting them into the intronic region of rep could reduce rcAAV by suppressing the rcAAV genome formation, replication, and propagation. We incorporated one shDNA with three different designs into the chimeric packaging plasmid expressing rep from AAV2 and cap from AAV1 (pRep2/Cap1): 1). flanking rep, 2). flanking cap, or 3). in the intron of rep. Furthermore, combination of two or three shDNAs at different positions was also introduced to pRep2/Cap1 plasmid. We then packaged the ssAAV vectors with these modified rep2/cap1 plasmids followed by CsCl gradient ultracentrifugation for purification and multiplex dd-PCR and silver stained SDS-Page analyses for rAAV and rcAAV genomes and rAAV virions respectively. Compared to the

original rep2/cap1 plasmid, all the rAAV1 preps produced by using modified rep2/cap1 plasmids showed 2- to 10-fold less rcAAV and no difference in VP1-3 ratio with rAAV1. Interestingly, modified rep2/cap1 plasmids harboring shDNA in the intronic region of rep were able to achieve vector yield comparable to that using original rep2/cap1 plasmid. In addition, such modifications on pRep2/Cap1 had no impact on the plasmid production. In summary, the incorporation of shDNAs in the rep/cap plasmid can reduce the frequency of rcAAV without compromising the vector yield and VP ratio. G.G. and J.X are co-corresponding authors.

951. AAV Full to Empty Ratio Study, Comparison of Analytical Techniques

Owen Leeser[1], Darren W. Begley[2], Dave Foster[1], Daniel Haq[1]

[1]Analytical Development, Resilience, Waltham, MA,[2]Resilience, Inc., Waltham, MA

After the production of Adeno Associated Virus (AAV) the final material is a mixture of full capsids (containing the gene of interest), empty capsids (without the transgene) and partial capsids (containing parts of the transgene). With the goal of limiting the number of empty and partial capsids. The effects of the empty and partial capsids are not well known and therefore can cause complications for the patients. It is important to determine the ratio of full to empty capsids but, there should be a greater emphasis on the full to total ratio as it factors in the partial capsids. Analytic Ultra Centrifugation is used as "the gold standard" to determine the ratio of full to empty capsids. Although there are other analytical methods that may be more feasible and have higher throughput. This study is a comparison between analytical techniques to determine full to empty ratio and the full to total ratio.

952. Evaluation of a Novel Strand-Specific Approach for AAV Genome Titer and Genome Integrity Quantification Using DNA Hybridization Biolayer Interferometry

David Dobnik[1], Nejc Košir[2], Rebecca Vollmeier Kovačić[2], Nejc Jakoš[2]

[1]National Institute of Biology, Ljubljana, Slovenia,[2]Niba Labs, Ljubljana, Slovenia

High specificity AAV genome titer is one of the most important assays, traditionally done using qPCR and digital PCR. Although both approaches have specific advantages and limitations, the availability of other target specific quantitative assays, which could fill some gaps, is limited. One of the promising developments in this field is a novel method using DNA hybridization biolayer interferometry (Figure 1) that shows promise of high accuracy, fast run time and high repeatability and precision. Additionally, the assay provides a strand specific quantitative information that could not be obtained by any other technique. The 30-minute assay involves single tube AAV capsid lysis plus a single hybridization step with DNA probes, followed by interferometry detection. We have evaluated the applicability of the assay for genome titer quantification of various AAV serotypes and have demonstrated appropriate repeatability, dynamic range, and robustness. Moreover, as evaluation of vector genome integrity is becoming more and more important, we have adapted the assay in a way to provide the strand specific results on quantity of full-length and fragmented genomes. To the best of our knowledge, this is the fastest approach to quantitatively evaluate vector genome integrity.

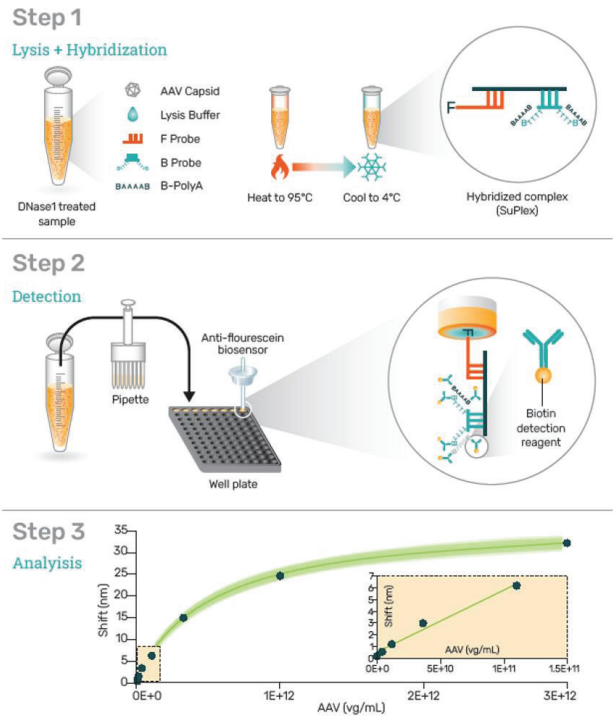

Figure 1: Schematic representation of Gator Bio BLI approach to vector genome titer quantification. First step includes single tube lysis plus hybridization of the two oligos, one labelled with fluorescein and other with biotin. In second step detection of hybridized targets is performed by Gator BLI system (in our case Gator Plus). After detection, analysis is performed in third step, where the wavelength shift can be analysed, and standard curve can later be used for unknown sample quantification.

953. Massively Parallel Screening of Barcoded AAV Capsid Variants for Neutralizing Antibody Reactivity

Kleopatra Rapti, Chiara Krämer, Ning Meng, Dirk Grimm

Department of Infectious Diseases/Virology, Section Viral Vector Technologies, Heidelberg University Hospital, Heidelberg, Germany

Recombinant adeno-associated viruses (rAAVs) stand out as highly promising vectors for delivering therapeutic genes to address genetic diseases. Their potential is evidenced by the approval of seven gene therapies over the past decade, as well as the approval of hundreds of clinical trials spanning various diseases. However, the presence of pre-existing neutralizing antibodies (NAbs), resulting from natural exposure to wild-type AAVs usually early in a patient's life, can impede the efficient transduction of target tissues by rAAVs. The conventional approach involves routine screening for NAbs, primarily in large animal models and human subjects, serving as an exclusion criterion. NAb assays fall into two primary categories: (1) cell-based assays gauging NAb inhibition of rAAV cell transduction, and (2) total anti-capsid antibody assays measuring total antibodies, irrespective of neutralizing activity. While cell-based assays, typically using luciferase as a reporter gene, are formally approved and utilized

for determining clinical enrollment cutoffs, they may not always be practical for pre-clinical studies due to time or sample constraints. To address this gap, we have devised a technology that allows swift and comprehensive screening of multiple serotypes against various samples by combining two methods: traditional cell-based NAb assays and next-generation high-throughput screening of barcoded AAV libraries. In a proof-of-concept approach, similar to cell-based assays, a library of barcoded natural AAV capsid variants carrying luciferase were mixed with samples and subsequently used to transduce cells. Transduction inhibition was evaluated at both DNA and RNA levels through next-generation sequencing (NGS) and bioinformatics analysis, outlining a serological profile for the library. In parallel, the same rAAVs were used individually to perform the classical cell-based NAb assay, enabling a head-to-head comparison of our high-throughput NAb NGS assay with the traditional NAb luciferase assay. We have expanded on this work by optimizing transduction efficiency and establishing the limit of detection. We have also performed the same assay using scAAVs and another transgene, enhanced green fluorescent protein, in order to determine the correlation of neutralization titers between the classical NAb assay and different types of libraries. In summary, our assay facilitates the simultaneous assessment of NAbs against AAVs on a large scale and offers an efficient and cost-effective alternative to conventional methods.

954. The Sixth Element: Identification and Evaluation of the Adenovirus L4 22/33K Region as a Requirement for Adeno-Associated Virus Production

Angela Adsero, Brendan Chestnut, Sara Shahnejat-Bushehri, Lalita Sasnoor, Travis McMurphy, Michael J. Swenor, Ryan Pasquino, Arun Pradhan, Victor Hernandez, Linas Padegimas, David J. Dismuke

Forge Biologics, Grove City, OH

Viral vectors based on adeno-associated virus (AAV) continue to be a leading modality in gene therapy. The most common method used for generating recombinant AAV (rAAV) vectors is by transient triple plasmid transfection of HEK293 cells. In this method the AAV replication (rep) and capsid (cap) genes are supplied via a RepCap plasmid, the ITR-flanked recombinant genome is supplied via the transgene plasmid, and the requisite Adenoviral (Ad) helper genes are supplied via an Ad helper plasmid. To improve rAAV manufacturability and safety we reasoned that excessive Adenovirus sequences could be removed or functionally replaced to make the Ad helper plasmid smaller and safer. The prevailing knowledge in the field has been that five Ad elements are necessary and sufficient to provide the Ad helper functions for rAAV production in HEK293 cells: E1a, E1b, E2a, E4ORF6, and VA RNA. Our data demonstrates that a sixth Ad element, known as the 22K protein within the L4 region is also required for rAAV production in the HEK293 transient transfection platform. Additionally, the L4 region 33K protein appears to synergistically boost titer and may possibly increase production titer in a dosage dependent manner. The L4 region, which contains the 22K and 33K coding sequences, resides in a region upstream of the E2a open reading frame (ORF). This upstream region also contains the E2a promoter. Thorough analysis of the E2a promoter region and substitution with alternative promoters showed that the upstream region is needed not only due to its E2a promoter activity, but because it also contains the L4 region expressing 33K and 22K proteins. E2a promoter activity was decoupled from the L4 region by testing multiple experimental and design changes, including providing the L4 region on a separate plasmid, reducing sequence homology to the natural E2a promoters, and relocating the L4 region within the helper plasmid to prevent *in cis* E2a regulation. We have utilized this knowledge of L4 22K/33K and the minimal promoter requirements for E2a to design smaller pEMBR™ Ad helper plasmids. These new Ad helper plasmids were tested in the production of a number of reporter and therapeutic vectors. The minimized pEMBR versions of the Ad helper plasmid led to substantial increases AAV yield, despite their smaller size. Commonly used Ad helper plasmids were developed as research tools and often contain up to 3500 bp upstream of the E2a ORF, with much of this sequence being dispensable. Our findings support that Ad helper plasmids can be optimized for high yields of rAAV production in HEK293 cells through the reduction and modification of the supplied Ad helper elements. This work also highlights the potential for improving the manufacturability of plasmids and AAV through better understanding and systematic design of the molecular elements needed for rAAV production.

955. Bridging the Gap in AAV Production Between Transient Transfection and Engineered Packaging Cell Lines Using Synthetic Biology and Advanced Analytics

Brandon Razooky[1], Michael Gapinske[1], Ed Aguilar[1], Andy Tran[1], Kailey Myers[1], Min Zong[1], Alexandra Cole[1], Kenny Shimada[1], Raquel Vega[1], Christos Galanis[1], Gilad Doron[2], Bryan St. Germain[2], Jason Carte[1], John F. Kerwin[2]

[1]National Resilience, Inc., San Diego, CA,[2]National Resilience, Inc., Waltham, MA

Adeno-associated virus (AAV) gene therapy has emerged as a groundbreaking approach for a wide range of genetic disorders. However, current manufacturing processes are costly due to the widespread use of transient transfection systems, which necessitate substantial amounts of high-quality DNA. To overcome this challenge, extensive efforts have been directed towards establishing packaging and producer AAV cell lines, eliminating the need for DNA synthesis. However, to date, many commercial and academic packaging cell lines do not produce the quality or quantity of AAV produced by transient systems, highlighting a gap in knowledge between transient settings and engineered cell lines. Here, we utilize a combination of high-throughput plasmid screening, advanced single-cell analytics, and synthetic biology to pinpoint bottlenecks in producer cell lines compared to transient transfection systems. Strikingly, we identify a novel set of previously undefined Adenoviral helper components essential for high titer AAV production. We then build on these findings to inform synthetic biology strategies to overcome challenges in establishing engineered packaging cell lines, including expressing AAV components at levels and ratios matching those observed in transient transfection settings, thus yielding producer cell lines with high titer AAV production. In summary, our research significantly advances AAV gene therapy by

identifying a pivotal helper protein, unraveling single-cell dynamics, and implementing synthetic biology principles for improved and cheaper vector manufacturing.

956. In-Trans Activation of the p40 Promoter by AAV Inverted Terminal Repeats

Anusha Sairavi[1], Pratheppa Rajagopal[1], Hiroyuki Nakai[1,2]

[1]Molecular and Medical Genetics, Oregon Health and Science University, Portland, OR,[2]Molecular Microbiology and Immunology, Oregon Health and Science University, Portland, OR

Meeting the high vector yields while keeping the desired properties of AAV vectors represents a major rate-limiting step in current AAV gene therapy approaches. Understanding AAV biology would help us better harness AAV's natural design, allowing us to create novel constructs that can enhance vector yields. Previous studies on AAV biology have shown that the AAV inverted terminal repeats (ITRs) activate the p40 promoter and indirectly drive AAV capsid protein expression through p5 promoter activation. They have also shown that the Rep binding sites (RBSs), the functional elements present in both ITRs and the p5 promoter, and their upstream placement are essential for the ITR and p5-mediated p40 activation. These prior observations have underscored the crucial roles of the in-cis placement of ITRs and p5 within the AAV viral genome as p40 activators and highlighted the importance of the positional relationship, whether positioned upstream or downstream, relative to the p40 promoter. Here, we show that AAV-ITR contained in recombinant AAV vector plasmids functions as an in-trans p40 promoter activator when AAV vectors are produced in HEK293 cells using a Rep-Cap and pHelper (i.e., an adenoviral helper) plasmids. In this study, we used a Rep2-AAV9Cap construct with the p5 promoter positioned downstream of the Cap ORF. A prominent feature of this construct is the presence of the 3' terminal potion of the p5 promoter (i.e., p5 remnant) upstream of the Rep ORF. As in-trans test constructs, we used an AAV vector plasmid containing a pair of AAV2-ITRs (ITR+ plasmid) and a respective control plasmid devoid of the ITRs (ITR- plasmid). Using these constructs and HEK293-based transient plasmid transfection, we investigated how the presence or absence of AAV-ITRs in trans might influence the level of AAV9 capsid protein expression from the Rep2-AAV9Cap plasmid, which is driven by the p40 promoter upstream of the AAV9Cap ORF. Consequently, we found that ITR+ plasmid significantly increased capsid protein expression from Rep2-AAV9Cap compared to ITR- plasmid in the presence of pHelper. Interestingly, when the p5 remnant was removed from Rep2-AAV9Cap, there was no increase in capsid protein expression with ITR+ plasmid, indicating a requirement of the p5 remnant for ITR-mediated in-trans activation of the p40 promoter. When ITRs are placed at both ends of Rep2-AAV9Cap, making ITR-Rep2-AAV9Cap-ITR plasmid providing ITRs in cis relative to the p40 promoter, capsid protein expression was comparable in the presence or absence of the p5 remnant. Comparison of capsid protein expression between ITRs in trans to that of ITRs in cis showed a significant difference, with the former yielding a higher expression. Based on these observations together with the insights obtained from prior studies, we propose a model for how ITRs activate the p40 promoter. In this model, when ITRs are provided in trans, the p5 remnant on its own activates the p40 promoter via DNA loops as previously reported, while the full-length p5 promoter is required for activation when ITRs are provided in cis. Further studies are warranted to understand the importance of the position of the p5 remnant relative to the position of the p40 promoter and how it would impact p40 promoter activation. Additionally, since the p5 remnant does not include the RBS, it would be interesting to see if the inclusion of the RBS on the p5 remnant would further enhance p40 activation. Studying the interplay of AAV viral genome elements in depth would help us better develop a system that can augment vector yields.

957. Massively Parallel In-Silico Protein Screening with AlphaFold and Molecular Docking for AAV and Therapeutic Payloads

Mark N. Miller, Andrey Smelter, Asher Baltzell, Jennifer Israel

Kriya Therapeutics Inc., Durham, NC

Identifying top candidates from a large library of protein variants is an essential task for the development of therapeutics, but the cost of synthesizing large libraries and experimentally screening their activity imposes a limit on practical library size and variant search-space. Generative deep-learning protein models and other in-silico approaches create libraries that far exceed biological library synthesis and in-vitro screening capacity, and these libraries can include variants with both potentially high activity and unusual sequence or structural features. These unusual features could bias traditional screens toward excluding variants despite the possibility of high activity. To rapidly identify promising protein variants while minimizing the cost of experimental screening, we built a computational framework to screen large protein sequence libraries in-silico based on modeled structure and binding to a ligand. Our system implements a massively parallel deep-folding (e.g. AlphaFold, ECMFold) deployment to rapidly generate protein structures from sequences, and subsequently uses this structure library as input to a parallel molecular docking system that models each variant's binding interactions with a ligand. The system's output is a per-variant score of predicted ligand-binding and protein stability, which can be easily used to identify a small number of candidates for experimental validation. Combining protein structure with predicted binding in a parallel compute environment enables rapid and practical screening of very large protein libraries as a tool to augment traditional library creation and screening approaches.

958. Stable Propagation of AAV2 Inverted Terminal Repeat (ITR) Elements in Plasmid Vectors

Vinod Jaskula-Ranga[1], Sheri Li[2], Fred Bunz[2]

[1]Hunterian Medicine, LLC, Cambridge, MA,[2]Johns Hopkins University School of Medicine, Baltimore, MD

Manufactured stocks of recombinant Adeno-Associated Virus (rAAV) typically contain a mixture of functional virions and defective particles, including empty capsids and virions that contain single-strand DNA genomes harboring deletions or contaminating sequences. The relative proportion of non-functional virions is typically significant. Moreover, the functional titer of viral preparations can vary among independently manufactured stocks. Homogeneity and consistency are particularly

important considerations when rAAV stocks are intended for clinical use. One probable source of rAAV heterogeneity is plasmid instability. Infectious rAAV particles are commonly rescued from plasmids that contain transgenes flanked by inverted terminal repeats (ITRs), which are the only genetic *cis* element required for packaging. The 145 base ITRs form stable, partial duplex hairpin structures that are critical for efficient genome encapsidation. In wild type AAVs, ITRs functionally contribute to virtually every stage of the viral life cycle. ITR instability was first observed in the original AAV2 isolates, which are ancestral to virtually all rAAV vectors currently in use. Propagation of these plasmids in standard bacterial strains results in the expansion of molecular subpopulations that contain ITR mutations, including deletions that are readily detectable by restriction digest. To minimize ITR instability, rAAV manufacturers frequently employ modified bacterial culture conditions that reduce saturation, such as growth under reduced temperature, and the use of specialized strains designed for the stable propagation of repetitive elements. We have employed advanced DNA sequencing methodology to rigorously investigate the basis for ITR instability. Unexpectedly, we observed that ITR instability in the founding AAV2 plasmids was asymmetric. While deletions could arise in either ITR, intermolecular heterogeneity was most prominent in the ITR positioned in closest proximity to the origin of replication (*ori*). By systematically positioning one or two ITRs in a variety of plasmid configurations, we were able to demonstrate that: 1) ori proximity was indeed the primary cause of ITR instability, and 2) instability was dependent on the presence of two ITRs. The latter finding suggests that recombination between ITR elements is a driver of plasmid instability rather than a consequence of instability. Most importantly, we have demonstrated that AAV2 ITR elements, when deliberately positioned in plasmid vectors, are inherently stable, even in standard bacterial strains grown under standard bacterial culture conditions. Many current rAAV vectors, which were ultimately derived from the original AAV2 isolates, harbor damaged ITRs. Among the most prevalent alterations is a recurrent 11-bp deletion. Indeed, a survey of rAAV2 plasmids submitted to Addgene revealed that a majority of vectors harbor this deletion. Our functional analysis of this mutant ITR suggests that its presence adversely affects critical aspects of vector manufacturing and function. Overall, our study highlights the importance of ITR stability for the safe application of rAAV therapeutics.

959. Increase AAV Productivity and Reduce Encapsuled Plasmid Backbone by Optimization of Plasmid DNA Usage During Upstream Process Development in AAVone Production System

Rongze Yang, Yuyan Wang, Zhen Shi, Yu Liu, Leming Wang, Cuiping Chen, Jiarui Liang, Daozhan Yu, Qizhao Wang

AAVnerGene Inc., Rockville, MD

Currently, the most used approach for manufacturing adeno-associated viral (AAV) vectors involves transiently transfecting mammalian cells with three plasmids. This method is versatile and relatively fast, but scaling up to meet the demands of clinical applications continues to be challenging. Total plasmid DNA (pDNA) amount and the ratio of the three plasmids are considered as important factors for achieving high productivity during upstream process. Although it may be different for different transgenes, a total pDNA amount of 0.75 to 1.0 μg is usually used for transfection of one million of cells. We previously reported a robust and highly efficient AAV production system, namely AAVone, in which all necessary components needed for AAV production in mammalian cells were consolidated into one plasmid with a backbone size around 13kb. Here we further optimized the plasmid dosage for transfection and found the AAVone system needs significantly lower amount of total pDNA to achieve higher productivity, which also results in significantly lower reverse packaging of plasmid backbone sequences into AAV capsids. The optimal total plasmid DNA amount needed for transfection is reduced to 0.25-0.30 μg for one million of HEK293T and 0.3-0.5 μg for HEK293 cells, about one half to one fourth of the amount used for triple-plasmid transfection system. The AAV productivity is increased up to 5-fold across different AAV serotypes compared to triple-plasmid transfection system for the same transgene. The reduced input plasmid in the AAVone system has also increased full-to-empty capsid ratio by ~10% (AAV2, from 30.02% to 38.48%) in the crude cell lysate, which is desirable for obtaining higher-quality AAV vectors with a higher proportion of functional, transgene-carrying capsids. Moreover, reduced input plasmid amount for transfection also reduces reverse packaged plasmid backbone sequences. In summary, reducing the input plasmid not only increases packaging efficiency, but also leads to increased full-to-empty ratios and reduced plasmid related impurities. AAVone represents a simple, cost-effective, and highly consistent AAV production system, particularly suitable for GMP-grade AAV production.

960. GMP (Good Manufacturing Practice) Testing Potential for Replication Competent Adeno-Associated Virus across Multiple Serotypes

Kaitlyn J. Knapp, Alexander Chiappini, Stacie Fichthorn, Marian L. McKee

Eurofins BioPharma Product Testing, Lancaster, PA

Replication competent virus testing is required by regulations for viral vector manufacturing to ensure the safety in resulting therapies. The regulations require that replication competent (rc) virus is monitored in virus seeds, unprocessed bulk (harvest), and drug substance (purified bulk). Adeno-associated virus (AAV) is a commonly utilized vector in many gene therapies. AAV vectors are designed to infect human cells and deliver the therapeutic genome in a specific area for the target condition without viral replication. Serotypes are key to the tissue selectivity. Vectors are modified to prevent replication, therapies must be monitored for the presence of replication-competent adeno-associated viruses (rcAAV), which could result in unintended side effects. Safety testing can be conducted to establish the presence of rcAAV in an intended sample, but many current methods are specified to AAV serotype 2 (AAV2) vectors. Serotype specificity is a challenge for methods which include a cell-based assay to amplify any replication competent virus present. We sought to explore methods for other AAV serotypes in order to offer an rcAAV method across multiple serotypes. For successful platform method development, understanding the infectivity of individual serotypes with the target cells used in the replication competent methods is required. To expand the scope of the

established rcAAV assays, AAV serotype 5 (AAV5), serotype 8 (AAV8), and serotype 9 (AAV9) were tested on cells from various tissue types. The standard for GMP testing with AAV2 is performed on HEK293 cells. Other cell lines were tested to expand testing alternatives. AAV serotypes expressing GFP (Green Florescent Protein) were used to infect HT1080, HeLa, and HEK293 cells. HT1080 cells acted as a control due to prior success across AAV5, AAV8, and AAV9. A range of Multiplicity of Infections (MOIs) for each serotype was tested to identify their individual infection sensitivity. Our results indicate that serotypes beyond AAV2 can infect cells that are suitable for rcAAV testing. These findings will expand rcAAV assay capabilities and the diversity of AAV serotypes that can be tested.

961. Scalable Cell-Based Assay of Tissue-Specific Regulatory Elements in Primary Human Tissues

Chris Stach, Ian Hill, Arturo Casini, Katelin Pratt, Jackie Thompson, Ben Gordon, Lila Wroblewska, Raja Srinivas, Alec Nielsen

Asimov, Boston, MA

The promise of adeno-associated viral (AAV) vector gene therapies relies on minimizing off-target effects of therapeutic payloads. One emerging approach is to steer gene expression toward specific tissues and cell types, using strategies such as engineering AAV capsids for targeted delivery, tissue-specific codon optimization of the payload, degradation of transcripts in off-target tissues with miRNAs, or by employing regulatory elements for tissue-specific expression. Previously, we reported a computational method to design tissue-specific promoters by applying artificial intelligence to multi-omics data, and validated its predictions using a reporter assay in mice, demonstrating greater than 100-fold dynamic range in expression between heart and liver tissues. The success of this design approach enables the design of thousands of candidate promoters, but screening at this scale is impractical in animal models. To address these challenges, we have developed a scalable cell-based assay that evaluates the specificity and activity of candidate regulatory sequences by testing their ability to drive a luciferase reporter across a panel of primary cells derived from human tissues. We demonstrate that AAV packaging, transduction, and luminescence assays can be performed in plate-based formats amenable to increased throughput. More importantly, by measuring tissue-specific promoters that we have previously characterized in mice, we show high correlation between the cell-based assay and the animal model. We further demonstrate that the assay can be extended to tissue-specific detargeting of payloads that incorporate sequences matching endogenous miRNAs. Together, these results indicate that our approach is well suited to accelerate the discovery of novel tissue-specific regulatory sequence designs by enabling screening of candidate sequences in large numbers in vitro before characterization in animal models.

962. Adapting a Replication Competent Adeno Associated Virus Assay for Commercial Manufacturing

Oxana M. Tsygankova[1], Leann Walsh[1], Brian Tomkowicz[2], Lana Sweet[1]

[1]Virology, Testing and Analytical Services, SK pharmteco - US, King of Prussia, PA,[2]Viral Vector Research & Development, SK pharmteco - US, King of Prussia, PA

Recombinant Adeno-Associated viruses (rAAVs)-based gene therapies are widely used for clinical purposes due to their unique characteristics. Unlike lentiviruses, they do not integrate into the host genome. Most manufacturing platforms for rAAVs includes a transient, triple-transfection of plasmid DNA into cells, mainly HEK-293, to produce viruses capable of infecting, but not self-propagating, in humans. However, the ability of otherwise replication incompetent viruses to acquire replication competence AAV (rcAAVs) has been observed. The assumption is that a recombination event occurs which swaps the *rep* and *cap* genes on one plasmid between the ITRs on the cis-plasmid. Subsequent packaging of these newly formed ITR-RepCap-ITR sequence will support replication of AAV *in vivo*. A universally applicable assay to monitor the emergence and estimate the frequency of recombination events during commercial manufacturing is required. Herein, we report on the development and application of a cell-based qPCR assay to monitor rcAAVs. Cell-based assays with a PCR endpoint are efficient assays and routinely used for rcAAV detection. Because all recombinant AAVs are use the AAV2-derived *rep* gene, our assay is built around Rep-targeting primer/probe sets to analyze test articles derived from transduced cells. To validate the assay, we use *cap* gene-specific qPCR. When applying this method for rcAAV detection on cells transduced with AAV1 or AAV2 serotypes we are able to detect rcAAV events at a limit of detection (LOD) of 10 Infectious Units. The incorporation of this assay to monitor the emergence of rcAAV for product release is necessary to ensure patient safety and provides a rapid assay for timely execution during manufacturing.

963. Seroprevalence of Liver Tropic AAV Capsids and the Evaluation of FcRN Inhibitors to Reduce Circulating AAV Antibodies

Yash Shah[1], Layth Awartani[1], Rohini Sheth[1], Charles Krause[1], Audry Fernandez[1], Angela Mote[1], Anna Tretiakova[1], Sherif Gabriel[1], Shari N. Gordon[1], Xiao Xiao[2], R. Jude Samulski[1,3]

[1]Asklepios BioPharmaceutical, Inc., Durham, NC,[2]Belief Biomed, Inc., Shanghai, China,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Pre-existing Adeno-associated virus (AAV) neutralizing antibodies prevent efficient AAV transduction and reduce therapeutic efficacy. The prevalence of serotype specific AAV neutralizing antibodies (NAb) varies due to testing methodologies, geographic location, and population of interest. Recently, an AAV8/ AAV6 chimeric capsid, referred herein as AAV8/6 chimera, has garnered interest due to its transduction efficiency, liver tropism and safety profile in the context of hemophilia B (Xue et al. 2022). We directly compared the seroprevalence of AAV8/6 chimera to its parental wild type vectors AAV8 and AAV6 and evaluated the ability of a neonatal receptor (FcRn) inhibitor to

remove infused human antibodies and facilitate AAV transduction in a humanized mouse model. A library of 100 human serum samples were sourced from various regions within the United States from individuals ages 18-71 of mixed gender and ethnicity. All 100 serum samples were first screened in a NAb assay at a dilution of 1:5 and 1:20. Any serum samples with more than 50% inhibition at a dilution of 1:5 was defined as NAb positive, and all positive samples were titered. We observed a similar seroprevalence for AAV8 (48%), AAV6 (43%), and AAV8/6 chimera (43%) however, there were significant regional differences in seroprevalence ranging from as low as 15% in the Northeastern regions to 58% in Southern states. These data suggest that AAV 8/6 chimera shares similar antibody recognition regions as parental capsids and confirms the need for strategies to remove pre-existing antibodies and increase patient eligibility in systemically administered gene therapy studies. Recently FcRn inhibitors have been gaining interest in the AAV field as they accelerate antibody catabolism reducing circulating immunoglobulin G (IgG) levels. The FcRn inhibitor is a monoclonal antibody that inhibits IgG binding to FcRn. We infused varying levels of human intravenous immune globulin (IVIG) into humanized FcRn transgenic mice to model high vs low titer pre-existing AAV NAbs. The ability of FcRn inhibitor to reduce circulating AAV antibodies and facilitate transduction of liver tropic capsids was evaluated. Our findings confirm and extend the potential use of FcRn inhibitors as a feasible strategy to reduce pre-existing low level antibodies and expand the pool of patients eligible for gene therapy, given the wide variation in AAV seroprevalence in the general population.

964. Suppressing Prior AAV-Mediated Gene Expression Using AAV Delivered Artificial microRNAs

Miguel de Mulder Rougvie, Mara R. Kebret, Youjun Wu, Katie M. Stiles, Ronald G. Crystal

Genetic Medicine, Weill Cornell Medical College, New York, NY

When administered to a non-proliferating cell population, adeno-associated virus (AAV) gene transfer vectors mediate persistent expression. While persistent expression following a single administration is ideal for treating chronic disorders, current technology does not provide a means of turning off expression should there be adverse effects from the transgene product. To design a permanent "off switch", we hypothesized that incorporation of unique artificial microRNA (amiRNA) target sequences into the AAV expression cassette would, if necessary, enable suppression of transgene expression with subsequent delivery of a different serotype AAV vector coding for the amiRNA cognate to the target sequence in the previously administered expression cassette. To test this hypothesis, we introduced 22 nt unique sequences not found in the human or mouse transcriptome into the 3' untranslated region (UTR) of the transgene of a therapeutic AAV expression cassette. Two tandem copies of the amiRNAs targeting the unique sequences were inserted into the 3'UTR of the mCherry reporter gene in the "off" AAV expression cassette. In vitro assessment of six amiRNA/target pairs using a dual luciferase reporter assay identified 4 amiRNAs that efficiently suppressed transgene luciferase expression. Cells co-transfected with target site 3 (TS3) and amiRNA-T3B showed the highest reduction (80%, $p<0.0001$) in luciferase activity and was selected for further studies. The "off-switch" system was evaluated in vitro with an AAV5-based therapeutic vector coding for anti-immunoglobulin E (IgE) (AAV5-TBG-anti-IgE-TS3, human thyroxine binding globulin promoter driving a recombinant DNA-derived humanized IgG1κ monoclonal antibody that binds to human IgE, designed to provide long-term expression of anti-IgE to protect against allergen-induced reactions such as peanut allergy). This vector includes a microRNA target site (TS3) for amiRNA for silencing. Co-transfection of HEK293T cells with both anti-IgE with the target site and targeting amiRNA-T3B pAAV expression plasmids significantly reduced expression anti-IgE mRNA and protein compared with control amiRNA ($p<0.0001$). Assessment off the "off switch" in vivo in Balb/c mice (n=5) was carried out by intravenous administration of the therapeutic vector coding for IgE (AAV5-anti-IgE-TS3; dose $3.2x10^{10}$ gc) followed 4 weeks later by the AAVrh.10-based miRNA "off" vector (AAVrh.10-TBG-amiRNA-T3B, dose $1x10^{11}$ gc). Control mice administered only the therapeutic vector (AAV5-TBG-anti-IgE-TS3) expressed human anti-IgE in the serum (anti-IgE serum levels 18.4±13.8μg/ml at 10 weeks). Mice administered the "off" vector (AAVrh.10-TBG-amiRNA-T3B) 4 weeks later had marked suppression at 10 weeks of the therapeutic anti-IgE (serum anti-IgE levels 0.3±0.15μg/ml, $p<0.0001$). In summary, this data provides a proof-of-concept for the use of AAV vector expressing amiRNAs to switch off transgene expression, a strategy that may improve the safety of AAV-mediated gene therapies.

965. The Extracellular Matrix as a Barrier to Adeno-Associated Viral Gene Delivery

Yahya Cheema[1], Gregg Anthony Duncan[1], Devorah Cahn[1], Matthew Wolf[2]

[1]Fischell Department of Bioengineering, University of Maryland, College Park, MD,[2]National Cancer Institute, Frederick, MD

Introduction: Despite its wide use, AAV delivery efficiency and biodistribution can be greatly improved. The extracellular matrix (ECM) is a major component of the tissue microenvironment which poses a significant barrier to AAV distribution, preventing delivery of genetic cargo. In disease states, the ECM often changes in both composition and quantity, which can hinder AAV gene delivery. This proposed research aims to identify strategies to increase the efficiency of AAV gene therapy by furthering our understanding of its interactions with the ECM microenvironment. We hypothesize that both the AAV serotype and ECM composition will impact AAV transport and gene delivery. Materials and Methods: AAV2, AAV6, and AAV8 viral vectors were fluorescently labeled and filtered to remove free dye using Sephadex columns. We formulated decellularized ECM (dECM) hydrogels by digesting lyophilized and cryomilled ECM and combining the digest with ECM components. Lung, liver, and small intestinal submucosal (SIS) dECM hydrogels were constructed with the gelation time and ratio of core ECM components varying depending on source type. We then characterized AAV serotype diffusion via insertion of the labeled viral vectors of each serotype into wells containing decellularized ECM and conducted multiple particle tracking (MPT) via fluorescence video microscopy. Mean squared displacement (MSD) as a function of time was calculated and was used to compute and characterize the overall movement of the AAV viral particles through the ECM hydrogels. The effect of both AAV serotype and ECM type were assessed. Additionally, we evaluated the effect of AAV serotype on cellular uptake in 2D and 3D in vitro models via GFP gene expression.

Results and Discussion: We characterized the diffusion of the serotypes when loaded into liver, lung, and SIS dECM hydrogels via MPT, and found that the serotypes displayed lower MSD values in each hydrogel when compared to a similarly sized 20 nanometer poly-ethylene glycol coated nanoparticle control (Fig. 1, Fig. 2). The lower MSD values seen in the serotypes when compared to the similarly sized 20 nm control indicate a greater level of hindrance of AAV diffusion due to surface interactions. While there was no clear tropism preference for AAV2, AAV6, and AAV8 that could be quantified or observed, there were trends observed in AAV serotype behavior. (Fig. 2) We found that AAV2 diffusion was least affected by the presence of ECM regardless of tissue type, and that AAV8 diffusion was most affected by the presence of ECM. Conclusion: This work demonstrates that dECM hydrogels can accurately model the increased surface interactions in the ECM microenvironment that hinder or slow the AAV capsids used in gene therapy delivery. These results suggest a decrease in biodistribution of AAV2, AAV6, and AAV8 in these microenvironments. Current studies are examining this effect in 3D dECM-incorporated in vitro models.

Adeno-associated virus (AAV) vectors have the potential to deliver the CRISPR-Cas system as a therapeutic drug. However, the size of AAV cargo is typically limited to less than 4.7 kb, which makes it challenging to deliver CRISPR/Cas gene editing machinery, especially with more than one guide RNA expression cassette. Administering multiple AAV vectors at once can reduce dose and effectiveness, while increasing safety risks. This study describes developing an improved all-in-one AAV-Cas vector configuration with high gene editing activity and AAV productivity. We designed 14 dual-guide, all-in-one AAV-SaCas9 configurations by modifying the composite, location, and orientation of the SaCas9 expression cassette and the expression cassettes of the two guide RNAs that target the viral long terminal repeats (LTR) and the Gag gene of HIV-1. We introduced a human beta-actin gene-derived stuffer sequence in the backbone of the AAV plasmids to minimize AAV backbone packaging. We prepared AAV crude lysates from the 14 all-in-one AAV-SaCas9 plasmids to transduce an HIV-1 knock-in reporter cell line and examined the HIV-1 excision efficiency induced by the paired HIV-1 guide RNAs. The seven most efficient AAV-SaCas9 plasmids were further co-transfected in Hela cells along with the HIV-1 plasmid pNL4-3. Two AAV-SaCas9 configurations showed the highest SaCas9 and guide RNA expression levels and the highest HIV-1 excision efficiency. Next, we conducted a manufacturability test using 2L bioreactors for one top AAV9-SaCas9 configuration (with an AAV vector size of 4.7 kb) and two top AAV9-PlmCasX configurations (both with an AAV vector size of 4.5 bp). Compared to our first-generation AAV construct, the three new AAV9 vectors showed a 3-10 fold increase in AAV yield and infectious titer. The AAV9 vectors also displayed high purity and high vector genome integrity. To profile the entire AAV vector genome as an intact molecule, we used

PacBio SMRT sequencing. For all three AAV9 vectors, over 90% of the PacBio sequencing reads were mapped to the vector genomes, and 70-80% of the sequencing reads contained the Rep binding element (RBE) sequence for both ITRs. In addition, the AAV plasmid backbone packaging for all three AAV9 vectors was below 1%. Overall, our results demonstrate that these newly engineered AAV configurations can effectively produce AAV vectors with high yield, purity, and AAV genome integrity. This optimization of the dual-guide, all-in-one AAV vector significantly enhances the potential of AAV vector as a delivery platform for CRISPR/Cas gene editing therapeutics.

Thursday Posters: AAV Vectors - Capsid Engineering

967. A Novel Platform of Chemically Modified AAV Vectors with Enhanced Functionality and Tropism

Paul Heppenstall[1], Daniela Hainberger[1], Elena Groppa[1], Irene Schiavo[1], Denise Ferrarini[1], Alessandro Barenghi[1], Sara Trifari[2], Niccolò Bacchi[2]

[1]SISSA, Trieste, Italy,[2]Borea Therapeutics, Milan, Italy

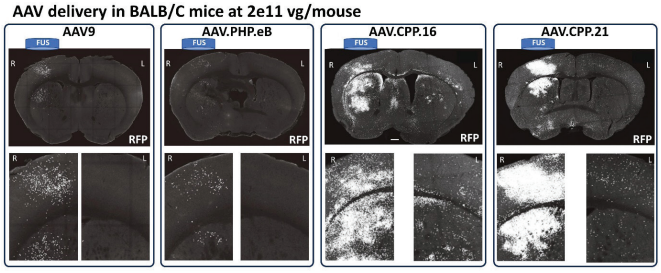
Enhancing AAV functionality through capsid engineering has become an area of enormous growth for gene therapy. The most common method to achieve this is to use genetic engineering, whereby sequences encoding short peptides are inserted into exposed loops of the capsid proteins. While many new AAV genetic variants have been described with potential for clinical applications, these approaches also have a number of shortcomings. First, genetic modification often reduces yield and potency of AAV vectors. Second, since only small peptides can be accommodated into the capsid structure, modified variants may have only weak or promiscuous binding to their cellular targets. Third, the cellular receptor(s) of genetically modified AAVs are generally not known a priori, making translatability across species difficult. Here we describe an alternative approach to capsid engineering based upon modification of the AAV capsid through biorthogonal chemistry. By implementing a post-manufacturing functionalization step, we can make virtually any AAV vector amenable to accept a ligand that will re-direct, modify or enhance its tropism. We show that our approach can accommodate multiple classes of ligands, from active peptides to full-length protein domains, allowing pre-determined human validated targets to be used as binding receptors, and resulting in enhanced AAV vector potency with no impact on yield. To illustrate the flexibility of our approach, we describe how, depending on the ligand we choose, we can add new functionalities to AAV, such as improving transduction across a variety of cell types, achieving cell-specific targeting, or increasing transport across the CNS. Furthermore, we provide functional evidence of the in vivo efficacy of our targeted vectors using an experimental pain model. Collectively, these data demonstrate that chemical modification of the AAV capsid can produce vectors with novel properties, circumventing limitations associated with genetic engineering. By applying optimized chemistry to clinically relevant AAV capsids, performance and specificity of AAV mediated gene therapy can be enhanced across highly coveted target tissues.

968. "Sortagged" AAV: A Novel Chemo-Enzymatic Approach for Site-Specific Ligand Conjugation on AAV Vectors

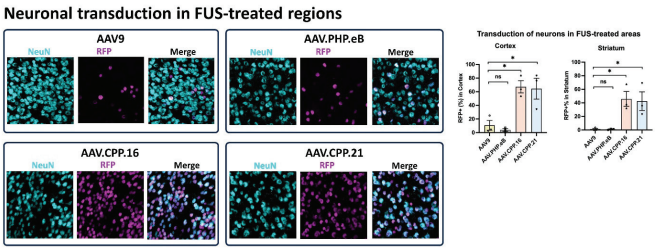
Irene Schiavo, Elena Groppa, Daniela Hainberger, Fernanda De Castro Reis, Paul Heppenstall

SISSA, Trieste, Italy

Adeno-associated virus (AAV) is a versatile viral vector that can be employed for gene delivery for the treatment of a variety of human diseases. AAV vectors have been extensively engineered at both the level of the transgene cassette, and at the capsid structural level to improve the efficiency of gene delivery. However, depending on the capsid engineering technique used, there are still disadvantages concerning, for example, the ability of the modified vector to assemble correctly, or the fact that even when variants with a more desirable tropism are identified in vivo, the target receptor is usually unknown, which carries the risk of poor translatability and off-target effects.In this study, a chemogenetic protein ligation technology, based on sortase-mediated ligation, was developed in order to couple AAV vectors with a ligand of interest. Sortase-mediated ligation relies on the enzymatic activity of the bacterial enzyme sortase (SrtA) that cleaves a specific amino acid motif (LPXTG) in a target protein, and then ligates a nucleophile to it. AAV variants were obtained by introducing the sortase motif in two surface-accessible variable regions of the AAV2 capsid. SrtA was then used to functionalize the "sortagged" AAV with a crosslinker-reactive moiety. This exposed moiety undergoes a click-chemistry reaction with an azide-modified protein of interest, thus covalently ligating such protein to the AAV surface. As result, the AAV is decorated with the ligand of interest specifically at SrtA-recognised sites. Different protein ligands can be chosen to either boost transduction efficiency or to redirect the viral vector to cells expressing the cognate receptor. Validation experiments have shown that chemogenetically-modified AAV2 vectors acquire new functional properties conferred by the conjugated ligand. This strategy is an innovative technique to engineer AAV capsid combining the accuracy of an enzymatic approach with the modularity of a click-chemistry reaction. Our approach allows to conjugate virtually any ligand of choice to an AAV vector, and therefore open the possibility to develop new therapies for currently untreatable disease.



969. Engineered AAV Capsids Combined with Focused Ultrasound Blood Brain Barrier Opening for Improved CNS Transduction Efficiency



Paige Nowlin[1], Xinyu Nie[1], Zhenghui Li[1], Yongzhi Zhang[1], Lilyan Garrett[2], Bernie Simone Owusu-Yaw[1], Fengfeng Bei[1], Nick Todd[1]

[1]Brigham and Women's Hospital, Boston, MA,[2]Northeastern University, Boston, MA

Background Genetic engineering of adeno-associated viruses (AAVs) has led to impressive improvements in central nervous system (CNS) transduction efficiency. However, current engineered AAV vectors given systemically still require a large systemic dose to achieve high neuronal transduction, which can lead to peripheral organ toxicity and carries substantial production costs. For systemically administered

AAV vectors to achieve clinical utility and commercial viability, strong BBB penetrance and high neuronal transduction must be achieved at a substantially lower systemic dose. The technology of focused ultrasound-mediated disruption of the BBB (FUS-BBB opening) can play a complementary role in further enhancing the CNS delivery of engineered AAVs. FUS-BBB opening temporarily increases the permeability of the BBB through mechanical forces on vessel walls created by the interaction of the ultrasound pressure wave and systemically circulating microbubbles. This physical approach offers an orthogonal set of BBB crossing mechanisms, that can be optimized in combination with the BBB crossing capabilities of genetically engineered AAV capsids. Here we demonstrate CNS transduction gains by combining FUS-BBB opening with two engineered AAV capsids, AAV.CPP.16 and AAV.CPP.21. **Methods** Experimental conditions in BALB/C mice were designed in a 4 x 2 fashion: AAV9 vs AAV.PHP.eB vs AAV.CPP.16 vs AAV.CPP.21; No FUS vs FUS (N=3 mice per condition). FUS-BBB opening was targeted to the right cortex and striatum, leaving the left cortex and striatum as the No FUS condition. Microbubbles were given by tail vein injection (Definity, 20 µL/kg) and FUS sonications were applied at 0.34 MPa intensity, 10 ms bursts and 1 Hz repetition frequency over 120 seconds. AAVs packaging nuclear red fluorescent protein (RFP) were given by tail vein injection immediately after FUS treatment at a dose of 2.0e11 vg/mouse (~8.0e9 vg/g). Mice were sacrificed 3 weeks after treatment for immunohistochemistry to quantify neuronal transduction. **Results** Figure 1 shows representative images of RFP signal for each AAV capsid. Greater RFP signal is seen in the FUS-treated right hemisphere for all capsids. Figure 2 shows representative NeuN, RFP and merged images from regions of interest within the FUS-treated right hemisphere and results quantifying the percent of neurons in cortex and striatum transduced for each AAV capsid. One-way ANOVA indicates a significant main effect over the AAV capsid type ($F = 12.47$ and $p = 0.0022$ for cortex; $F = 7.99$, $p = 0.0086$ for striatum), with post-hoc comparison showing significantly greater neuronal transduction for AAV.CPP.16 and AAV.CPP.21 (* $p < 0.05$) but not for AAV.PHP.eB. FUS-BBB opening improved delivery to the mouse brain for all AAV capsids tested. However, particularly strong delivery was seen for the novel capsids AAV.CPP.16 and AAV.CPP.21. Our next steps will be to characterize transduction efficiency as a function of AAV dose and demonstrate large-volume FUS-BBB opening can improve delivery to the whole mouse brain.

970. Deep Learning-Guided and Structure-Informed Multifunctional AAV Capsid Design Pipeline for Manufacturability and Redirected Tropisms

Cui Zhang[1], Zhuoyang Lv[2], Zhiwei Lu[1], Yongjian Zhang[1], Pengfei Yuan[1]

[1]EdiGene Inc., Beijing, China,[2]Department of Computer Science, Brown University, Rhode Island, RI

The recombinant adeno-associated virus (AAV) is a highly promising vector that is transforming the field of gene therapies for human diseases. Capsid engineering, which involves modifying the interactions between the capsid and cell surface receptors, has been achieved through a combination of knowledge-based design and iterative directed evolution. This approach has successfully produced AAV variants with notably altered biodistribution and other beneficial properties, such as improved manufacturability. Despite the capability of screening millions of capsid variants in a single library, conventional methods fall short in exploring the vastly larger combination pool and efficiently identifying the small fraction of vectors with the desired characteristics for clinical use. The process is also marred by the tedious and costly nature of multiple selection and testing rounds across different tissues. In response to these challenges, we introduce a comprehensive method that integrates deep learning-based models for sequence-to-characteristic predictions and a structural approach for capsid classification and clustering. This strategy simplifies the screening process and expedites the discovery of new capsids. Our method utilizes random 7-mer NNK insertional capsid libraries, with packaging and enrichment screening conducted across various tissues including the liver, muscle, and central nervous system (CNS). A deep-learning framework has been developed, capable of predicting manufacturability and tissue-specific targeting based on peptide sequences. From an initial experimental library of approximately 360,000 variants, representing a fraction of the 1.28 billion possible sequences, each peptide sequence was transformed into a one-hot encoded 7x20 two-dimensional array. A deep learning model was then trained for binary classification on production efficiency, supplemented by regression models to assess the enrichment scores for each target tissue. The integration of an attention mechanism to capture global sequence relationships and 1-D convolution for local context analysis has resulted in a classification model with an impressive 98% accuracy. Our regression model also consistently achieved over 70% accuracy in its predictions. By combining these models, we constructed a condensed, multi-trait capsid library of 300 manufacturable candidates targeting the CNS and muscle. This library was experimentally validated, with over 50% of the variants showing

targeted tissue enrichment—a success rate significantly higher than that achieved through traditional screening methods. Moreover, we utilized AlphaFold2 for predicting oligopeptide structures, facilitating the clustering of variants into distinct clades based on structural similarities. This approach aided in the deduplication and efficient classification of top candidates showing robust tissue enrichment in mouse models. Preliminary data from a non-PHP.eB-clustered variant demonstrated high and consistent CNS transduction in both C57BL/6 and BALB/c mice, underscoring the effectiveness of structure-based capsid classification. In summary, our proposed pipeline represents a significant advancement in AAV capsid engineering. It drastically narrows the search space for potential variants, reduces the number of screening and testing cycles needed, and demonstrates the powerful synergy of deep learning and structural analysis in expanding therapeutic possibilities.

971. Novel AAV Variants for Huntington's Disease Gene Therapy

Brian Lewandowski[1], David E. Leib[2], Yonghong Chen[1], Paul T. Ranum[2], Luis Tecedor[1], Sakshi Arora[1], Ashley Robbins[3], Bryan P. Simpson[2], Elena Lysenko[1], Megan S. Keiser[4], Xueyuan Liu[5], Jang-Ho Cha[2], Beverly L. Davidson[1]

[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]Latus Bio, Philadelphia, PA,[3]University of Pennsylvania, Philadelphia, PA,[4]Ohio State University Wexner Medical Center, Columbus, OH,[5]The Children's Hospital of Philadelphia, Philadelphia, PA

Huntington's disease (HD) affects a distributed network of brain areas including the basal ganglia and cerebral cortex. However, current state-of-the-art AAV capsids do not sufficiently target areas critical for HD therapy without large doses using prolonged surgery times. To overcome this challenge, we performed a screen of tens of millions of peptide-modified (PM) AAV capsid variants in adult rhesus macaques to identify novel variants that transduce relevant areas following a single focused low dose infusion. Our screen identified multiple variants with robust transduction across basal ganglia and cortical regions in rhesus. To test the across-species translatability of our PM-AAV screening approach, we took the top ~150 capsid variants identified after two rounds of screening in rhesus macaque and tested their performance in rhesus, African green monkey (AGM) and in mice. Capsid performance measured from next generation sequencing (NGS) results in rhesus and AGM was highly correlated, with a Pearson's correlation of 0.85. Similarly, there was enrichment of top capsid variants in mouse medium spiny neurons (MSNs) when assessed by single cell sequencing methods. One PM-AAV variant, DB-3, was consistently highly enriched in each round of selection. Biodistribution of AAV-DB-3 was characterized by native fluorescence of AAV-DB3. mTFP following relatively low dose injections in rhesus. We observed remarkably efficient transduction of basal ganglia regions and layer V/VI projection neurons across multiple cortical areas, including primary motor cortex. A critical target for HD gene therapy are MSNs in the basal ganglia. We assessed cell-type tropism in the caudate and putamen using RNAscope™ fluorescence *in situ* hybridization with probes targeted to MSN marker genes. DB-3 demonstrated high selectivity for MSNs, transducing ~50% of MSNs in both regions and only 5-20% of non-MSN cell types. We also assessed DB-3 transduction outside the nervous system. In digital droplet PCR of liver samples, DB-3 transgene levels were below the threshold of detection. To test whether DB-3 would exhibit similarly high transduction efficiency in human cells, we quantified transgene expression in neurons derived from human iPSCs using qPCR. At a dose of 5.0E3 vg/cell, DB-3 showed a ~5700-fold increase in transgene expression compared to the wild-type parental serotype. In summary, DB-3 exhibits remarkable tropism for therapeutically relevant HD-related brain regions and improved transduction efficiency in both human and NHP neurons at doses orders of magnitude lower than those currently in clinical use. DB-3 will be a powerful tool for the delivery of therapeutic transgenes for HD and other disorders affecting the brain.

972. Engineering Human-Translatable AAV Vectors with Receptor-Targeting Moieties for CNS Gene Delivery

Richard Alexander Martino, Ka Ying Sharon Hung, Mark Julian, Nadia D'Lima, Mengying Zhang, Xiaodong Lu, Cailtin Meeks, Samantha Desmarais, Aditya Utturkar, Shawn Kyle Bourque, Misha Chittoda, Harini Dhamodaran Sampath, Pete Clarner, Ankur Thomas, Bin Wang, Muccini Arnold, Samneet Kashyap, Quan Jin, Levi Griffin, Tania Seabrook, Emily Rouse, Yuting Liu, Adem Koksal, Benjamin Smith, Tom Cameron, Paul Weinreb, Junghae Suh, Joseph Arndt, Yuan Yuan

Biogen, Cambridge, MA

Treatments for neurological diseases would be expanded with adeno-associated virus (AAV) vectors capable of efficiently crossing the blood-brain barrier (BBB) and transducing cells of the central nervous system (CNS). CNS-targeting AAV vectors have been identified from selections of large AAV libraries in animal models, but these methods can produce vectors with species-specific activity due to a lack of phylogenetic conservation in cognate cell surface receptors. An alternative approach involves engineering AAV vectors that directly target desired human receptors, a strategy that would augment human translatability. In this work, we sought to improve AAV CNS transduction by inserting protein domains targeted to a human receptor into the AAV capsid. We first developed targeting domains cross-reactive to murine, cyno, and human receptor homologs. We then designed a cohort of genetic fusions with distinct sets of peptide linkers. We built a barcoded AAV library of these variants and screened in cynomolgus macaques as well as in a knock-in (KI) mouse model. Several variants emerged as attractive hits showing enhanced CNS transduction over AAV9 in both models. We further validated several variants in the humanized KI mouse model. One such variant was superior with significant improvement in transgene mRNA expression over AAV9, and robust neuronal transduction throughout the brain. In summary, we successfully engineered AAV capsids with targeting domain insertions that efficiently transduce the CNS through engaging with a human receptor. With a robust transduction profile in a humanized mouse model, these vectors hold clinical promise for the treatment of CNS diseases.

973. Discovery of TRACER AAV Capsids Escaping Pre-Existing Neutralizing Antibodies

Damien Maura, Jennifer Yu, Xiao-Qin Ren, Matthew Child, Rupinderjit Kaur, Zachary Thorpe, Jiachen Liu, Netsanet Gebremedhin, Daniel Henry Cox, Weitong Chen, Brett Hoffman, Tyler Moyer, Ambreen Sayed-Zahid, Johnny Yao, Charlotte Chung, Todd A. Carter, Mathieu E. Nonnenmacher

Voyager Therapeutics, Cambridge, MA

Adeno-Associated Virus (AAV) gene therapy shows great promise to treat a wide array of human genetic diseases. However, patient eligibility to receive AAV gene therapy is limited by the presence of pre-existing anti-AAV antibodies resulting from prior exposure to natural AAVs. These antibodies restrict AAV biodistribution and target tissue transduction, especially for systemically administered AAVs. Recent capsid engineering efforts have successfully improved AAV tissue tropism, and paved the way for enhancing other AAV properties. In this study, we leveraged our proprietary RNA-driven TRACER evolution platform to detarget our 2nd generation AAV9-derived CNS tropic capsids from neutralizing antibodies (NAbs). We evolved immunogenic capsid surface regions, and screened the resulting libraries *in vitro* in presence of monoclonal NAbs as well as human intravenous immunoglobulin (IVIG) to maximize the clinical relevance. Capsid libraries were also screened in marmoset and in a mouse passive immunization model with human IVIG. We identified several capsid families with specific amino acids enriched by IVIG selection pressure at several mutation hotspots. In pooled capsid library assays, top candidates evaded IVIG up to 20-fold better than the parental capsid in mouse while retaining over 50% brain transduction of the parent capsid in mouse & marmoset. Individual validation of these capsids in mouse confirmed that top candidates evaded human IVIG 10 to 30-fold better than AAV9. Most importantly, these capsids were able to complete evade ~40% of neutralizing human serum samples. Remarkably, combining mutations from different capsid regions further improved NAb evasion, with seroprevalence decreasing from 50% down to 20% in a panel of 50 human serums. Overall, this study identified a 3rd generation of bioengineered AAV capsids with mutations conferring evasion from pre-existing neutralizing antibodies while retaining the improved CNS tropism of their 2nd generation parent. These novel capsids have the potential to significantly improve a key bottleneck in AAV treatments by increasing patient eligibility to receive AAV gene therapies.

974. AAV9 Production Fitness Modeling with Machine Learning

Daniel H. Cox, Richard Lu, Hassan Gheisari, Netsanet Gebremedhin, Jiachen Liu, Mathieu E. Nonnenmacher, Weitong Chen

Voyager Therapeutics, Cambridge, MA

In the search for good vectors for viral-mediated gene-therapy, often large combinatorial libraries of mutant capsids are screened. The objective is to find capsids that will form novel viruses that both produce well and exhibit enhanced tropism toward a particular tissue. Typically, the sequence space represented by such libraries is much larger than the number of capsids that can be effectively screened in a single experiment, and it is common for a high percentage of the mutant capsids to fail to form viable virus. Thus, it would be useful to screen out such low-production-fit capsids in silico, at the design stage, to prevent wasted space in the subsequent experimental stage. To do this we have developed machine learning models to predict production-fitness from capsid sequence. Indeed, for capsid sequences consisting of 7 or 9 amino-acid insertions in variable region 8 of AAV9, we have developed classifiers that can distinguish between high and low production fit capsids with AUC values as high as 0.98 and regression models whose predictions correlate with measured values with r values ≥ 0.95. Furthermore, we have found these machine learning models to effectively guide the design of high-production-fit libraries as tested experimentally, and we have used hamming-distance constraints to spread test sequences as evenly as possible over the relevant search space. The theoretical limits of this approach will also be discussed.

975. Identification and Characterization of a Highly Conserved Cell Surface Receptor Utilized by Engineered BBB-Penetrant AAV Capsids with Enhanced Brain Tropism in Non-Human Primates and Mice

Brett Hoffman, Tatiana Knox, Tyler Moyer, Ishan Shah, Xiao-Qin Ren, Weitong Chen, Emily Rouse, Damien Maura, Mathieu Nonnenmacher

Voyager Therapeutics, Lexington, MA

Novel engineered blood-brain barrier (BBB)-crossing AAV capsids have demonstrated significant improvements in CNS tropism and thus increased therapeutic efficiency. However, the unpredictability of cross-species activity by engineered capsids has hampered progress to the clinic. Therefore, the identification of the receptors utilized by such novel capsids is important to predicting their utility in treating human conditions. For instance, the recent identification of receptors for multiple CNS-tropic capsids have explained their lack of cross-species activity as either due to lack of a human receptor ortholog or poor conservation of critical residues. Here we report the identification of a highly conserved brain vascular receptor specifically bound by the cross-species VCAP-101/102 engineered capsid class. This capsid family was previously reported to exhibit a 50-fold increase in BBB penetrance in both macaques and mouse. Ectopic overexpression of the human receptor isoform in cultured cells led to a significant increase in capsid binding and transduction while no difference was observed with the parental capsid, AAV9. Importantly, receptor isoforms from macaque, mouse, and pig also facilitated transduction by VCAP-102, highlighting the cross-species functionality of this capsid class. Neutralization of capsid-receptor interaction with anti-receptor antibodies or small molecule inhibitors completely reverted the gain of transduction by VCAP-102, further supporting a direct role in transduction. Additional studies in a transwell cell culture model demonstrated that the VCAP-102 receptor dramatically increased the transcytosis of capsids across polarized cells, strongly supporting a mechanistic role in capsid translocation across the BBB *in vivo*. Previous studies have demonstrated that expression of the VCAP-102 receptor significantly increases with age in both humans and rodents, and we observed a corresponding 2-fold increase of CNS transduction in aged mice relative to their young counterparts. Conversely, mice

pre-treated with a small molecule inhibitor of VCAP-102 receptor showed significantly reduced brain transduction, while no measurable effect was observed on liver transduction. Importantly, the CNS transduction by other capsids with a different receptor usage was unaffected by the inhibitor, ruling out the possibility of non-specific effects on viral transduction. Employing in silico structural modeling, we have further characterized the molecular mechanism governing the interaction between capsid and receptor. In summary, our discovery of a conserved cross-species receptor facilitating BBB passage by a novel engineered AAV capsid class represents a significant step forward in the development of targeted CNS therapeutics. Understanding the molecular mechanisms underpinning this interaction provides a foundation for the rational design of next-generation AAV vectors.

976. Establishment of a Predictive Transcytosis Model to Recapitulate Capsid-Receptor Interaction and Phenotype of BBB-Penetrant AAV Variants

Xiaoqin Ren, Ishan Shah, Tyler Moyer, Brett Hoffman, Elisabeth R. Knoll, Brian C. Ezell, Mathieu E. Nonnenmacher

Voyager Therapeutics, Cambridge, MA

Delivery of genetic payloads across the blood-brain barrier (BBB) remains a critical challenge for treatment of neurological diseases. Recent years have seen rapid progress in the engineering of BBB-penetrant viral and non-viral gene transfer vehicles, but questions remain regarding the translatability of these discoveries to human patients. In the absence of true in-human observations, translation between animal models and humans can be inferred from phenotypic equivalence across various primate and/or rodent species, or from the identification of the molecular mechanisms of BBB penetration, for example by identification of a vascular receptor. We have previously identified VCAP-102, an Adeno-Associated Virus (AAV) capsid variant showing improved BBB penetration in both primates (old world and new world) and rodents, and we were able to determine that VCAP-102 binds to a BBB surface receptor showing a high degree of conservation across species, including humans. In order to further characterize the mechanism of action of VCAP-102, we generated a transwell model using Madin-Darby Canine Kidney (MDCK) cells overexpressing VCAP-102 receptor and showed that this cell line allowed very efficient transcytosis of VCAP-102 capsids, but not the parental AAV9. Conversely, parental MDCK cells, which do not naturally express the receptor, were non-permissive to either capsids. We confirmed the receptor-mediated transcytosis of generation 2 capsids in our transwell model, consistent with their in vivo potency.

977. One Amino Acid Substitution Makes the AAV2 Capsid Mutant BR1 Permeable to the Murine Blood-Brain Barrier

Ayumu Konno, Hayato Kawabata, Hirokazu Hirai

Neurophysiology & Neural Repair, Gunma University, Maebashi, Japan

Adeno-associated viruses (AAVs) are small, non-enveloped DNA viruses that infect dividing and non-dividing cells. AAV vectors are promising for gene therapy because of their broad tissue and cell affinity, efficient gene expression, and minimal immune response. AAV serotypes, AAV9 and AAV2, are known to interact differently with brain microvascular endothelial cells (BMVECs). Namely, AAV9 is effectively transcytosed through BMVEC and leads to the transduction of brain parenchymal cells, whereas AAV2 barely crosses the endothelial barrier and transduces BMVECs. Because of these properties, the development of blood-brain barrier (BBB)-permeable AAV vectors such as PHP.B (Deverman et al., 2016) and AAV-F (Hanlon et al., 2019) has generally been based on AAV9. In this presentation, we report that AAV2-BR1, a capsid mutant derived from AAV2, has acquired BBB permeability by a single residue amino acid substitution.AAV2-BR1 is an AAV vector previously reported to enable specific and efficient transduction into BMVECs (Körbelin et al., 2016). This mutant has heptapeptide (NRGTEWD) insertions with a "stuffer" sequence (G and A) at both sides between amino acid positions R588 and Q589 of the AAV2 capsid protein. Importantly, BR1 has one more mutation from N to Q at position 587 (Figure). To produce the BR1 capsid for brain microvasculature transduction, we inserted 9 amino acids (7 insertions plus 2 stuffer amino acids) between R588 and Q589 of the AAV2 capsid, where an amino acid at position 587 was still asparagine (termed BR1N). Because we assumed that BR1N might be sufficient for BMVEC transduction, we produced BR1N capsid vectors and intravenously injected them into C57BL/6 mice. However, BR1N transduced cells of the central nervous system rather than BMVECs. Although BR1 and BR1N are presumed to use the same receptor for entry into BMVECs, the substitution of one amino acid (Q to N) may have resulted in a profound change in intracellular trafficking. This suggests that receptor binding alone does not determine the final outcome *in vivo* and that further improvements of capsids within predetermined receptor usage may open new avenues for capsid engineering.

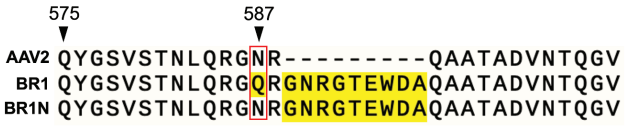


Figure. Amino acid sequence alignment of AAV capsids (AAV2, BR1, BR1N). BR1 and BR1N, AAV2 capsid mutants, have 7 amino acid (NRGTEWD) insertion with 'stuffer' sequence (G and A) at both sides in AAV2 capsid between positions 588 and 589. BR1 also has an asparagine (N) to glutamine (Q) substitution at position 587. Amino acids distinct from those of AAV2 are highlighted by a yellow background.

978. Characterization of Brain Targeting CereAAV™ Gene Transduction in Cynomolgus Macaque and Further Improvement of Gene Delivery Capability by Amino Acid Substitutions

Yoshinori Tanaka, Sayuri Ueda, Nozomi Okuda, Hiroaki Nariki, Sachiko Okamoto, Tatsuji Enoki

Takara Bio Inc., Kusatsu, Shiga, Japan

Recombinant adeno-associated virus vectors (AAVs) have been widely used as vehicles to deliver gene of interest for both research and therapeutic purposes. Zolgensma a treatment for spinal muscular atrophy, was approved by the US Food and Drug Administration (FDA) and numerous pre-clinical and clinical studies have been conducted using AAV2 and AAV9 serotypes to targeting brain diseases via local and systemic administration. In particular, AAV9 have been frequently used for gene delivery into the brain including central nervous system

(CNS), and several AAV9 derivatives such as AAV-PHP.eB, have been identified to transduce CNS efficiently. On the other hand, it has been reported that an AAV2 variant, designated AAV-BR1 efficiently transduced the Blood Brain Barrier (BBB) -associated endothelial cells by systemic administration. However, there is still no AAV2 variant is reported to transduce CNS across the BBB efficiently. To overcome the limitations of AAV2, we addressed to develop a novel brain-targeting AAV vectors based on AAV2 serotype. To date, we have demonstrated that CereAAV, which was obtained by directed evolution using random peptide-inserted AAV2 library, can efficiently transduce in mouse and marmoset brain by systemic injection. In this study, we aimed to assess the gene transduction efficiency of CereAAV in cynomolgus macaque and improve the transduction efficiency through capsid optimization of CereAAV in rodent model. We evaluated the gene transduction efficiency of CereAAV in a cynomolgus macaque using the AAV barcode library method and found that CereAAV also exhibited higher gene transfer efficiency to the brain compared to AAV9 in the non-human primate model. To elucidate the transduction mechanism of CereAAV, we performed alanine scanning of the insertion peptide of CereAAV capsid to identify the important amino acids for brain transduction. As a result, we found that the sixth amino acid residue in the inserted peptide of CereAAV plays a crucial role in gene delivery to the mouse brain by intravenous administration. Furthermore, we identified a novel CereAAVmt-6Y mutant with a specific and higher transduction efficiency in the mouse brain compared to CereAAV through a single amino acid substitution. The gene transduction in the brain of CereAAVmt-6Y was approximately 90-fold higher than that of AAV9 in luciferase reporter assay in rodent models. Recently, Kawabata et al. demonstrated that a single amino acid substitution, changing glutamine to asparagine at position 587 (AAV-BR1N) in the AAV-BR1 capsid, could increase the BBB permeability and redirect gene delivery form vesicular endothelial cells to neurons in the mouse brain. We have confirmed, the Q587N substitution also increased the gene transduction of CereAAVmt-6Y. Currently, further studies are underway to evaluate the transduction efficiency and characterize the transduction targets of CereAAV variants including Q587N substation, in rodent and non-human primate models.

979. Characterization of Engineered AAV Capsids for Improved Transduction Efficiency through Rational Design

Jingjie Hu[1], Panos Theofilas[1], Travis Bainbridge[2], Yoon Min Kim[2], Beyza Bulutoglu[2], Oded Foreman[3], Honglin Chen[1], Annalisa Lattanzi[1]

[1]Molecular Biology, Genentech, Inc., South San Francisco, CA,[2]Protein Chemistry, Genentech, Inc., South San Francisco, CA,[3]Research Pathology, Genentech, Inc., South San Francisco, CA

The engineering of adeno-associated virus (AAV) capsids for enhanced transduction and tissue-specific targeting is crucial for gene delivery and therapies. This would be beneficial for reducing vector dose, resulting in less immunogenicity and toxic effects. AAV9 serotype has become the preferred vector for systemic administration due to its ability to transduce a variety of tissues and organs. In this study, we tested AAV9-derived capsid mutants, engineered with a rational design approach for increased binding affinity to the universal AAV receptor (AAVR). The goal was to augment cell entry and intracellular trafficking, ultimately aiming to improve transduction efficiency. All AAV9 capsid mutants were packaged with an ITR-CAG-GFP-ITR payload for simplicity of imaging and flow cytometry analysis. We initially evaluated the *in vitro* transduction efficiency of the AAV9 capsid mutants in HEK293T and SH-SY5Y (neuroblastoma) cell lines. We observed 2- to 4-fold increases in transduction efficiency for two mutations and a synergistic enhancement up to 6-fold when they were combined. Their AAVR dependency was further confirmed in AAVR+/− and AAVR−/− HEK293T cell lines generated by CRISPR/Cas9 editing. Subsequently, we analyzed the transduction capability of the AAV9-derived capsid mutants in comparison to the wild-type control in C57BL/6J adult male mice via retro-orbital systemic injection or local brain injection. The systemic injection suggested slightly increased transduction in liver tissue and significantly detargeting from the heart for one of the two mutants that showed enhancement *in vitro*. We chose intracerebroventricular injection to test the differences in expression levels and biodistribution of these AAV9-derived capsid mutants compared to a wild-type control. Four weeks post-injection, the left hemisphere was harvested for DNA analysis of the AAV vector copy number (VCN). Meanwhile, the right hemisphere was processed in serial sections to evaluate the vector biodistribution using immunofluorescence for GFP reporter positivity. Our results revealed robust localized expression adjacent to the injection site for most mutants. Furthermore, the two capsid mutations with the best *in vitro* transduction ability also demonstrated an increased GFP signal intensity and a wider biodistribution area, which was consistent with the increased VCN quantification in the area of interest. Notably, in both *in vitro* and *in vivo* studies we found that mutants with the highest binding affinity to AAVR (30- to 50-fold) dramatically reduced their transduction ability. This suggests that an excessively high AAV-receptor binding affinity eventually results in an impaired vector's ability to enter the nucleus. Overall, this study demonstrates that the AAV9 capsid protein can be engineered to enhance its efficiency in transducing cells both *in vitro* and *in vivo*. Our findings suggest that these mutations can be utilized in future gene therapy research and be combined with other engineered AAV9 capsids.

980. Optimizing Cell-Type Specificity of AAV Gene Therapy Vectors for the Human Brain

JP McGinnis[1], Josh Ortiz-Guzman[2], Maria Camila Guevara[3], Sai Mallannagari[3], Daniel Curry[4], Ben Arenkiel[3]

[1]Department of Neurosurgery, Baylor College of Medicine, Houston, TX,[2]Rio Grande Urology, El Paso, TX,[3]Department of Human and Molecular Genetics, Baylor College of Medicine, Houston, TX,[4]Department of Neurosurgery, Texas Children's Hospital, Houston, TX

Molecular-based therapies promise to improve outcomes for our most frustrating pathologies. To date, however, we have no method that can deliver such sequence-based therapies selectively to the cell types involved. Virtually all prior work on adeno-associated viruses, the most common vector for neurological gene therapies, has studied capsid tropism in model organisms, primarily mice, despite abundant data that demonstrates a lack of translation across species. For this reason, we have developed an ex vivo organotypic system that uses surgically resected human brain tissue to screen libraries of AAV variants.We consent patients undergoing resective neurosurgical

procedures for any tissue not needed for clinical use. After sectioning the tissue, transducing with virus libraries, and allowing time in culture, we use both imaging and single-nuclei sequencing to characterize each variant's tropism.Resected human brain tissue is viable for up to four weeks, and is unaffected by addition of AAVs up to MOIs of 60,000. Appreciable transgene expression takes approximately 14 days. We find that transduction with 14 known AAV variants, including AAV2, the most common vector used in clinical trials, show quite low transduction of human neurons. Astrocyte transduction is better, in some cases as high as 50%. Ongoing work involves dissecting promoter behavior within human tissue in various cell types, along with large-scale library transduction.There is no prior work characterizing the cellular AAV tropism in human brain tissues, even those variants currently FDA-approved. This work shows the limited ability of animal models to predict the efficiency and specificity of AAV transduction, which relies on cell surface molecules that are known to be divergent between species and even strains of model organisms. These results provide the foundation for large-scale AAV gene therapy vector screening using human brain tissue, especially from diseases for which no durable therapy is currently available.

981. AAV Capsid Engineering for Improved AAVR Binding to Enhance Transduction Efficiency

Travis W. Bainbridge[1], Yoon Min Kim[1], Jingjie Hu[2], Panos Theofilas[2], Maciej T. Paluch[1], Oded Foreman[3], Honglin Chen[2], Annalisa Lattanzi[2], Beyza Bulutoglu[1]

[1]Department of Protein Chemistry, Genentech, South San Francisco, CA,[2]Department of Molecular Biology, Genentech, South San Francisco, CA,[3]Department of Research Pathology, Genentech, South San Francisco, CA

Immunogenicity and the consequent toxic side effects present major obstacles to broader AAV usage1, and this can become especially problematic with the highest doses used in the clinic (E13-E14 vg/kg). One way to overcome this is to improve the transduction efficiency of AAVs, which could allow for the use of lower doses, hence less immunogenic material. AAV transduction involves two key mechanistic events: i) AAVs binding to cell surface receptors followed by internalization, ii) intracellular trafficking of AAVs. The universal AAV receptor, AAVR, was identified as a key receptor for AAV infection, playing an important role in intracellular AAV trafficking.2 Recently, the protein-protein interactions between AAVR and AAV1, AAV2, AAV5, AAV9 were mapped, offering an opportunity to manipulate the affinity between the receptor and the AAV capsid.3,4. In this study, we engineered the AAV capsid to increase the affinity between the capsid proteins and AAVR for improved trafficking and cargo delivery to nucleus. We generated AAV9 virus-like particles and mutated the residues at the receptor-binding interface to all 20 amino acids. We then screened the variants bearing single point mutations as well as combinations of mutations via surface plasmon resonance (SPR), and identified AAV9 variants with improved AAVR affinity (Figure 1A). A handful of promising AAV9 variants carrying a GFP reporter gene were tested in vitro in HEK293T and SH-SY5Y neuroblastoma cells, where we observed up to 6-fold improvement in transduction efficiency. The transduced cells also showed a higher level of GFP expression, compared to the cells transduced with WT AAV9 (Figure 1B).We observed an optimal range for AAVR affinity improvement as AAV variants with highest AAVR affinity resulted in decreased transduction, compared to WT AAV9.

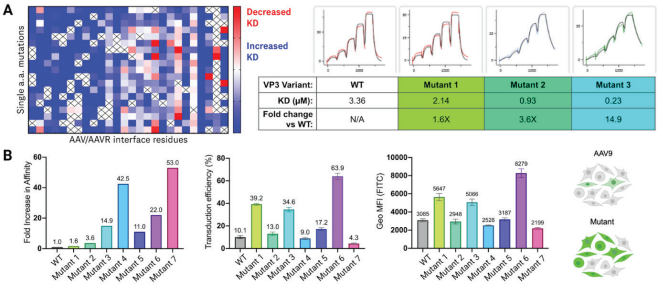

Figure 1. (A) Left: Heatmap demonstrating the AAVR fold-affinity change (relative to WT AAV9). Red denotes an increase in affinity (decreased KD). Blue denotes a decrease in affinity (increased KD). X denotes no capsid formation or WT residue. Right: Exemplary SPR sensograms. Point mutation-based engineering efforts resulted in variants with a wide range of fold increase in AAVR affinity. (B) When tested in vitro in SH-SY5Y neuroblastoma cell line, several AAV9 mutants performed better, compared to WT, both in terms of number of transduced cells as well as the intensity of the transgene (GFP) expression. In addition, we tested some of the AAV9 variants in vivo in C57BL/6J adult mice. Two variants with improved in vitro transduction ability, also demonstrated higher vg copy numbers in the brain tissue and wider biodistribution, compared to WT AAV9, when administered locally via intracerebroventricular injection (2E10 vg/mouse). These promising results demonstrated that engineering viral capsid proteins to modulate their binding affinity to the AAV-trafficking receptor AAVR can be advantageous. This approach can also be complementary to other capsid engineering efforts focusing on enhanced tropism, and can be used in a broad range of gene therapy applications. References: 1. Adeno-associated virus (AAV) capsids with improved central nervous system (CNS) tropism are needed to unlock the potential of AAV vectors for CNS diseases. In vivo screening of random peptide insertion

capsid libraries has identified novel AAV capsids with superior neural tropism compared to naturally occurring capsids. However, deconvoluting the transduction mechanism can be challenging, and engineered capsids can exhibit species-specific tropism, which potentially complicates their therapeutic utility. To overcome these limitations, we used an in vitro binding platform to select novel AAVs that bind to target human receptors with the potential to enable AAV trancytosis into the CNS parenchyma. We first selected 10-15 potential receptors based on either their ability to transcytose other cargo or other relevant factors. For instance, the transferrin receptor was included in our list of high-priority receptors based on its ability to transcytose antibodies and AAVs in animal models. The extracellular region of these receptors was then immobilized on beads as a fusion protein and used to affinity purify AAV capsids from diverse AAV9-based libraries with peptide insertions. A variety of capsid libraries were constructed, including those with random peptide insertions or designed to uniformly sample the vast sequence space. Through these screens, we identified a diverse collection of AAV variants that were both reproducible and unique to a given receptor. Importantly, peptide sequence motifs emerged from these binding hits for a given receptor, indicating specific receptor binding. Binding hits were then used to construct candidate libraries. To further diversify the experimental hits, we designed additional capsids using a deep learning-based modeling and sequence generation framework. The combined libraries were then tested in cell-based assays and animal models, including human protein knock-in mice and non-human primates. These studies resulted in the successful identification of novel AAV capsids with improved CNS tropism compared to AAV9 in animals, for more than one receptor. Structural modeling of the CNS-tropic capsids revealed similarities and differences in the putative binding conformation of the capsids with their cognate receptor. Based on the performance ranking of individual capsids in cell-based assay and animal models, several candidate AAV variants were selected for clonal studies in animals and for mechanistic studies. The results from these studies will be reviewed.

983. Optimization of a Generative Algorithm for Designing Novel rAAV Capsids with Enhanced Yields

Although AAV vectors are widely utilized in gene therapy, existing vectors lack optimization in terms of yield, specificity, and potency. In the pursuit of improving vector performance and exploring uncharted possibilities beyond the current library strategy, we have refined a generative algorithm for the exploration and testing of novel capsid sequences. This study utilizes publicly available data from AAV2 to train a generative algorithm employing a diffusion model to predict capsid assembly. We generated 8000 diverse AAV2 VP sequences and assessed their viability through DNase-resistant capsid assembly assays. Furthermore, we extended the algorithm's application to predict sequence migration and generation within the AAV9 domain, leveraging both similarities and differences. Envisioned sequences were synthesized, constructed, and compiled into a vector library to assess their actual survival rates. Results revealed that generated sequences exhibited a viability proportion exceeding 90% within a mutation range of 7 to 20. Importantly, selected sequences not only demonstrated enhanced yield but also exhibited a capacity for functional transduction. The mutation of additional sequences displaying high viability holds promise for generating innovative capsids tailored to specific targets and increased specificity.

984. Directed Evolution of AAV1, AAV5 and AAV9 Variants for Efficient Gene Delivery to Eye

Nachiket Pendse, Eduardo Magdaleno, Fabio Luna, Tan Ge, Steph Hintzen, Jake Hill, Cameron Mcelroy, Jayson Chen, Lawrence Tam, Eloise Hudry, Helen Booler, Kirsten Stoner, Kelley Penraat, Mark Hedgeland, Shraddha Babaria, John Walker, Scott Ellis, Fatih Ozsolak

Novartis Biomedical Research, Novartis Pharma AG, San Diego, CA

In recent years, adeno-associated viral (AAV) vectors have demonstrated efficacy and safety for ocular, neurological, musculoskeletal, and metabolic liver diseases in clinic. Naturally occurring AAV serotypes along with engineered capsids variants have been shown to enhance tropism to the neural retina and retinal pigment epithelium (RPE). The current FDA approved ocular gene therapy is for the treatment of RPE65-associated Leber congenital amaurosis (LCA) - an inherited retinal disorder (IRDs), utilizing sub-retinal delivery of AAV2 carrying the therapeutic cargo to the RPE. Despite its effectiveness, sub-retinal gene delivery is surgically complex and could only be accessible to a limited number of patients. Therefore, the development of platform capabilities including novel capsids and delivery methods may enable 'in-office' ocular gene therapies through broadening ocular tissue tropisms and expanding patient access. In the present investigation, we utilized our 'state of the art' Tangential Suprachoroidal (TS) Microinjector delivery device as well as previously described intra-vitreal (IVT) route for administration of AAV capsid libraries into non-human primates. To identify retinal specific capsids, we selected serotypes AAV1, AAV5 and AAV9 as the parental capsid. We utilized directed evolution approach by targeting the *CAP* gene of serotypes AAV1, AAV5 and AAV9 in variable loop VIII region and inserted randomized 7mer NNK library. Then, we administered such AAV libraries separately to non-human primate eyes via the suprachoroidal and IVT delivery routes. After one round of in-vivo selection and deep sequencing analysis, based on whole retina RNA enrichment scores, we identified key capsid candidate profiles of AAV1 and AAV5 with almost no virtual off-targeting in peripheral organs such as liver in NHPs. The results from our study demonstrate for the first time that TS Micro device mediated discovery of novel AAV1 and AAV 5 variants displayed high retina tropism and will enable the selection of ocular tropic variants with improved safety and efficacy profile for human ocular gene therapies.

985. Development of Blood-Brain Barrier Penetrant AAVs through Receptor-Targeted Capsid Engineering

Sangamo Therapeutics, Inc., Richmond, CA

The development of AAV capsids that cross the blood-brain barrier (BBB) has the potential to enable transformative genomic medicines for the treatment of neurological disorders. Previously we described SIFTER, a method for in vivo selection of AAV capsids that mediate improved central nervous system (CNS) delivery after administration into the vasculature or cerebrospinal fluid. This method has yielded highly efficient capsids for CNS delivery in non-human primates and can be coupled with receptor identification efforts to elucidate mechanisms by which AAV capsids cross the blood-brain barrier. Here we describe a complimentary engineering approach to develop AAV capsids targeting human receptors that are highly expressed in endothelial cells comprising the blood-brain barrier. AAV capsid libraries based on different parental serotypes, peptide insertion sites, and peptide sizes were first screened in vitro for enhanced binding to purified human BBB receptors. Library members with enhanced binding to the purified receptor were additionally screened for binding and transduction in cells engineered to overexpress these human BBB receptors. Two of the human BBB receptors we targeted for capsid evolution yielded especially notable results. The first receptor is highly conserved across species and abundantly expressed at the blood-brain barrier. Receptor-targeted library screening identified two capsid families with a differentially enriched amino acid motif that mediates enhanced receptor binding and transduction. This receptor interaction is preserved for both human and cynomolgus macaque orthologs, increasing the likelihood of translation between pre-clinical models and clinical applications. The second receptor is less well conserved across species but is likewise highly expressed in the human blood-brain barrier. We identified capsids with markedly improved binding and transduction in cells that overexpress this human BBB receptor. Based on these results we are evaluating these receptor-targeted capsids in vivo to assess CNS transduction efficiency and therapeutic potential for the treatment of neurological disorders.

986. Directed Evolution of Rationally-Engineered AAV Capsid Variants with Enhanced Central Nervous System (CNS) Tropism Following Systematic Administration

Hongxing Wang, Sha Zhu, Weiqun Zhang, Gabriela C. Toro, Na Liu, Lingzhi Zhao, Joan Shen

NeuShen Therapeutics, Lexington, MA

Clinicalsuccess in gene therapy has proven the potential of adeno-associated virus(AAV) as the leading viral delivery tool for in vivo therapeutics across manydisorders. Despite this, the inherent limitations of natural AAV capsids to crossthe blood-brain barrier (BBB) pose a significant clinical challenge,particularly in the context of neurological disorders. Recent efforts in AAVcapsid engineering have yielded some BBB penetrating AAV variants with enhancedCNS tropism and transduction in rodent and non-human primate (NHP), butnone of these new AAV variants have advanced to clinical stage, primarily dueto poor translatability across animal species or manufacturing/stability issueof novel AAV variants. Thus, there is an urgent need to develop novel AAVvariants with enhanced BBB penetrability, improved vector manufacturability anddesirable CNS tropism. At NeuShen Therapeutics, we employed structure-guidedpeptide insertion/substitution and amino acid mutagenesis approaches to rationallyengineer a total of 176 novel capsid variants, incorporating modifications tovariable regions (VR) 4, 5 and 8 of AAV9, AAV5 and AAVrh10. Additionally, weutilized 11 CNS benchmark capsids as reference controls. Each capsid variant wasindividually cloned and labelled with two specific barcodes. To assess the manufacturabilityof novel capsid variants, all variants were individually produced and vectortiter in cell lysate was assessed by quantitative PCR (qPCR). About 40% ofAAV9-derived and AAVrh10-derived variants exhibited better vector titer comparedto parental capsids. All capsid variants were pooled at equal vector genome andintravenously administered into rodent (C57BL/6 and BALB/c mice) and cynomolgusmacaque for 3-4 weeks of directed evolution. Specific barcoded DNA and RNA ofnovel capsid variants were recovered from multiple brain tissues and primaryperiphery tissues and analyzed by next generation sequencing (NGS). Based onNGS data from rodent evolution, a dozen of novel AAV9-derived variants andseveral AAV5-derived and AAVrh10-derived variants exhibited improved (up to70-fold) brain transduction and lower liver tropism in C57BL/6 or BALB/c micecompared to parental AAV9, AAV5 or AAVrh10. Some variants exhibited improvedCNS tropism in both rodent strains. Ongoing efforts involve furthercharacterization and validation of the most promising capsid variants. The NGSdata from NHP evolution will be expected in early March 2024, following whichthe data of CNS-tropic AAV variants from rodent and NHP will be aligned andintegrated. Taken together, our findings demonstrate the successfulestablishment of a capsid discovery platform for the development of CNS-tropiccapsid variants.

987. Structural Characterization of Engineered AAV Capsids and Their Interactors by Cryo-ET

Tyler Brittain[1], Seongmin Jang[1], Erin E. Sullivan[1], Timothy Shay[2], Ting-Yu Wang[1], Tsui-fen Chou[1], Viviana Gradinaru[3]

[1]Caltech, Pasadena, CA,[2]CLOVER Center, Caltech, Pasadena, CA,[3]California Institute of Technology, Pasadena, CA

Recombinant adeno-associated virus (AAV) vectors are the current optimum platform for therapeutic gene delivery. Despite this, clinical reports continue to call attention to the need for improved safety, potency, and cellular specificity. To address this, AAV capsids have been engineered on two fronts: (1) to evade antibody detection, thereby decreasing the immune response, and (2) to specifically target desired tissues and cell types. Understanding the interaction mechanisms of natural and engineered AAV capsids, enables structure-guided engineering of vectors with enhanced immunological and targeting properties. Structural analysis of AAVs has largely been restricted to single-particle Cryo-EM with few examples of Cryo-ET being utilized. Here we show across two different ligand-AAV interactions the limitations of single-particle can be overcome through sub-tomogram

averaging. Our lab identified murine carbonic anhydrase IV (Car4) as a receptor for two capsids, 9P36 and 9P31, enabling blood-brain barrier (BBB) crossing. Car4 is promising due to its conservation across rodent and primate species. Here we present the single-particle Cryo-EM structures of the two engineered capsids with and without their receptor. Inherent flexibility within their interaction prevents resolving Car4 through single-particle methods, which can be overcome and visualized using sub-tomogram averaging. Structural analysis of the 9P36/9P31-mCar4 interaction provides a framework from which to engineer future BBB-crossing vectors. Separately, a cell micro-array screen found a novel interaction between the cytokine interleukin-3(IL3) and all AAV9-based capsids. XL-MS/MS and site-directed mutagenesis was used in tandem with cryo-ET to reveal the binding location on the surface of AAV9. This structural analysis hints at a larger role in destabilizing core AAV interactions. The methodology herein shows how cryo-ET and sub-volume averaging can outshine traditional single-particle methods for small complexes bound to large symmetric particles. Additionally, the information learned has far-reaching implications for engineered BBB crossing vectors in primates & all AAV9-based capsids.

988. Expression-Based Selection Identifies a Microglia-Tropic AAV Capsid for Direct CSF Routes of Administration in Mice

Miguel Santoscoy[1], Paula Espinoza[1], Killian S. Hanlon[2], Carrie Ng[1], Suzanne Hickman[1], Rachel E. Bennett[1], Casey A. Maguire[3]

[1]MGH, Charlestown, MA,[2]Harvard Medical School, London, United Kingdom,[3]The Massachusetts General Hospital, Charlestown, MA

Microglia, resident myeloid-lineage cells of the central nervous system, exhibit a range of heterogeneous phenotypes due to their context-dependent functionalities in brain parenchyma. *In vivo* targeting of microglia using gene delivery systems is crucial for studying brain physiology and developing gene therapies for dementia and other brain disorders. However, they have been extremely resistant to transduction by viral vectors, including adeno-associated virus (AAV) vectors. This may be due to several factors, including the phagocytic nature of these immune cells and the ability to degrade pathogens such as viruses. Another challenge of microglia transduction may relate to the natural neuronal tropism of AAV and the relatively low percentage of microglia (~10%) compared to other cell types in the brain. The combination of this tropism "sponge" towards neurons and unfavorable stoichiometry may impact whether a given AAV particle is able to interact with microglia. Fortunately, in the past two years, there has been some progress demonstrating the feasibility and potential of using AAV to transduce microglia after direct intraparenchymal vector injection. Data suggests that combining specific AAV capsids with microglia-specific gene expression cassettes to reduce neuron off-targeting will be key. However, no groups have developed AAV capsids for microglia transduction after intracerebroventricular (ICV) injection. The ICV route of administration has advantages such as increased brain biodistribution while avoiding issues related to systemic injection. Here, we developed and validated a variant of the AAV transgene-expression selection system, iTransduce, combined with an AAV9 peptide display library for microglia transduction in mice after ICV injection. For the first round of selection, we injected CX3CR1-GFP mice ICV with the AAV9 library and rescued capsid DNA from flow-sorted GFP+ microglia. To select capsids that could transduce microglia over other cell types in the brain, we engineered an AAV-CD68-Cre-p41-Cap-7mer cassette to allow Cre expression in microglia. In the second round, we injected Ai9$^{CAG\text{-}FS\text{-}tdt}$ x CX3CR1-GFP mice. Expression of Cre in microglia resulted in tdTomato expression, and we flow-sorted GFP+/tdTomato+ microglia and GFP+ only microglia and performed sequencing to assess unique peptide inserts. We chose one variant, MC5, which was in the top 5 reads for the highest presence in the GFP+/tdT+ fraction. Interestingly MC5's peptide sequence has high identity with a domain within Syndecan-4, which may provide insight into its microglia-tropic properties in the future. The ability of MC5 for specific and efficient microglia transduction was validated with a head-to-head comparison with reported microglia-specific capsid MG.1.2 and parental capsid, AAV9, using a previously reported microglia-selective AAV transgene expression cassette, AAV-Iba1-GFP-WPRE-mir9.T4x-mir129.T4x. In preliminary stereological quantitation in the cortex and immediately surrounding the ventricles, MC5 showed a trend towards improved transduction efficiency of microglia when compared to the reported microglia-selective MG1.2 capsid as well as AAV9. MC5 and MG1.2 showed similar transduction specificity towards microglia over other transduced cells. AAV9 showed the poorest specificity. In conclusion, our *in vivo* selection strategy has identified a new AAV capsid capable of improved and more specific transduction of microglia after ICV injection. MC5 can serve as a valuable research tool, and a potential therapeutic candidate.

989. Engineering Human-Translatable CNS-Targeting AAV Capsids through Differential Directed Evolution in a Humanized Mouse Model

Mengying Zhang, Nadia D'Lima, Quan Jin, Samneet Kashyap, Margaret Kelemen, Emily Rouse, Pete Clarner, Maria Bloom, Ming Liu, Fu-Chia Yang, Xiaodong Lu, Ankur Thomas, Bin Wang, Kate Henry, Aissatou Diallo, Merilla Michael, Darryna Guy-Williams, Joe Arndt, Thomas O. Cameron, Caitlin Meeks, Benjamin Smith, Mark Julian, Taras Tuczkewycz, Daniel Ferretti, Junghae Suh, Yuan Yuan

Biogen, Cambridge, MA

Safe and efficient gene delivery remains a major challenge for central nervous system (CNS)-targeted gene therapy. Recombinant adeno-associated viruses (rAAVs) have emerged as promising engineering scaffolds for CNS-targeting vectors, as demonstrated by a myriad of blood-brain barrier (BBB)-crossing and neurotropic vectors engineered through directed evolution in mouse and non-human primates (NHPs). While enabling selection of novel capsid variants capable of transducing target CNS cells through diverse mechanisms, most CNS-targeting directed evolution approaches produce capsids with uncertain human translatability due to genetic differences between human and model organisms. To overcome this limitation, we developed Differential Directed Evolution, a species-specific receptor-targeted approach to engineer CNS-targeting capsids with human translatability. We evolved in parallel a peptide insertion AAV library in WT mice and a humanized knock-in (KI) mouse

model, and bioinformatically identified human receptor-dependent CNS-targeting capsid candidates with significantly and reproducibly higher CNS transduction in humanized KI mice compared to WT controls. A number of peptide motifs emerged in the candidate pool, indicating a robust selection pipeline. To validate top candidates, we confirmed human receptor-dependent transduction in CHO cells as well as enhanced CNS transduction in humanized KI mice for a subset of variants. We selected several top hits and further evaluated them in singleton format in the humanized KI mouse model, and observed that all top capsids led to superior and widespread CNS transduction in KI mouse brains. In summary, we established Differential Directed Evolution as a novel approach combining directed evolution and humanized mouse models to engineer human-translatable AAV vectors. Through this method, we identified potent human receptor-targeted CNS capsids, which may facilitate therapeutic gene delivery for a variety of neurological disorders.

990. Identification of a CNS-Targeting AAV Capsid Family with NHP and Human Cross-Reactivity through Directed Evolution

Jin Quan[1], Ka Ying Hung[1], Samneet Kashyap[1], Emily Rouse[1], Margaret Kelemen[1], Xiaodong Lu[1], Misha Chittoda[1], Harini Dhamodaran Sampath[1], Samantha Desmarais[1], Shawn Kyle Bourque[1], Aditya Utturkar[1], Davide Gianni[1], Gregory Dillon[2], Sueon Sim[2], Nam-Kyung Yu[2], Kurt Cox[3], Bekim Bajrami[3], Anh Nhu[2], Pete Clarner[1], Richard Alexander Martino[1], Caitlin Meeks[4], Jimmy Tran[5], Amit Kumar[5], Tania Seabrook[1], Kate Henry[1], Jinkuk Choi[1], Shuyun Deng[1], Joseph Cabral[1], Junghae Suh[1], Yuan Yuan[1]

[1]Gene Therapy Accelerator Unit, Biogen, Cambridge, MA,[2]Genetic and Neurodevelopmental Disorders Research Unit, Biogen, Cambridge, MA,[3]Chemical Biology & Proteomics, Biogen, Cambridge, MA,[4]Biologics Drug Discovery, Biogen, Cambridge, MA,[5]Nonclinical Safety, Biogen, Cambridge, MA

The most promising route to achieve widespread therapeutic gene delivery to central nervous system (CNS) is by overcoming the blood-brain barrier (BBB). Directed evolution of peptide insertion AAV libraries has yielded a myriad of novel capsids capable of crossing the BBB and transducing CNS cells in mouse and non-human primates (NHPs). However, it remains to be demonstrated whether capsids evolved in model organisms are suitable for clinical applications, as cross-species genetic differences may impact engagement between capsids and cognate BBB receptor homologs. The key to unraveling the uncertainty around human-translatability, therefore, lies in identifying cognate BBB receptors followed by affinity comparison between capsids and receptor homologs. We have identified a CNS-targeting AAV capsid through three rounds of directed evolution in cynomolgus macaques. In adult cynomolgus macaques treated with immunosuppressants (n=3), this novel AAV capsid led to widespread, significantly higher CNS transduction compared to AAV9, with deep brain nuclei and brain stem showing highest overall transgene expression. In addition, the AAV capsid was well tolerated with minimal safety or pathology findings. To further improve the potency of this novel capsid, we screened in NHP a saturation mutagenesis AAV library carrying a conserved motif, and identified additional variants with further enhanced CNS and neuronal tropism.

991. Human CA4-Targeting AAV Capsids Efficiently Transduce the CNS in Humanized Mice

Nuria Roxana Botticello-Romero, Jason Wu, Qin Huang, Thomas Beddow, Ken Y. Chan, Pamela Brauer, Fatma Elzahraa Eid, Alina Chan, Benjamin E. Deverman

Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA

The development of adeno-associated viruses (AAVs) that efficiently target the human central nervous system (CNS) promises to boost the impact of gene therapies for neurological disorders. We engineered a suite of peptide-modified AAV9 capsids to cross the blood-brain barrier (BBB) by directly binding to the human GPI-linked enzyme Carbonic anhydrase IV (hCA4). Using our recently described receptor-targeting approach, we identified three capsids with distinct sequences, BI-hCA4-1, BI-hCA4-2, and BI-hCA4-3, that more efficiently transduce hCA4-expressing cells compared to wild type AAV9. When systemically injected into mice that express hCA4 on the brain microvasculature, the BI-hCA4 capsids transduced cells throughout the CNS more efficiently than AAV9 (Fig. 1). This enhanced tropism was not observed in wild type mice. We are now using site-saturation mutagenesis and a generative machine learning model paired with an AAV production fitness model to further improve the ability of the capsids to bind hCA4 and cross the BBB *in vivo*. In summary, we demonstrate that human CA4 is a promising new target for engineering CNS-directed gene delivery vectors.

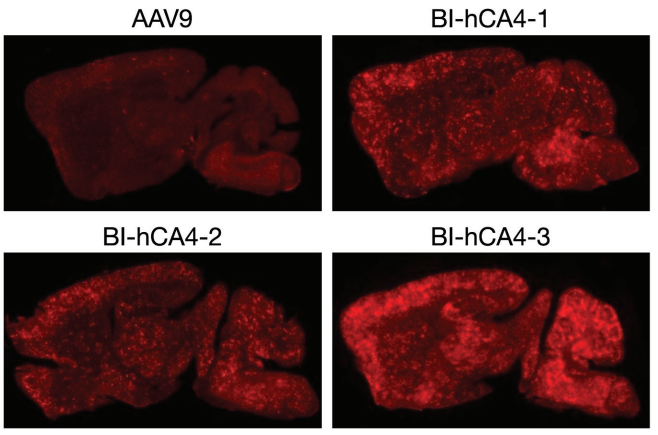

Figure 1. Human CA4-targeted capsids achieve efficient gene delivery to the CNS. The hCA4 gene was first delivered to the CNS endothelium by intravenous administration of AAV-BI30:CAG-hCA4-miR122-WPRE. Next, AAV9 or BI-hCA4:CAG-mScarlet-P2A-Luciferase-SV40pA were administered intravenously. Representative images show AAV transduction in sagittal brain sections of mice three weeks after the delivery of the hCA4-binding AAV.

992. Directed Evolution of AAV2 Libraries Yields Capsids with Improved Performance in the Central Nervous System and Cross-Species Translatability

Xiaojing Shi, Sean Gross, Michelle Ling, Reem Elteriefi, Zach Mason, Caden Holloway, Yixi Wang, Mark Chin, Christopher Octeau, Kimberly McDowell, Brandon Wheeler, Nicholas Flytzanis, Nick Goeden, Susan Catalano

Capsida Biotherapeutics, Inc., Thousand Oaks, CA

Central nervous system (CNS) disorders represent an area of major unmet medical need. The delivery of genetic therapies to the CNS is a significant challenge, particularly in the context of broad delivery throughout the brain and/or spinal cord. Intravenous delivery of engineered Adeno-Associated Virus (AAV) capsids capable of crossing the blood-brain barrier (BBB) is an attractive strategy for achieving broad and uniform transduction of the CNS. Current efforts to engineer AAV capsids for improved transduction of the CNS have largely focused on AAV9, primarily due to its ability to cross the BBB more efficiently than other serotypes. However, the use of AAV9 is limited by its high transduction of the liver and the resulting toxicity. Alternative AAV serotypes may offer distinct advantages regarding tropism, manufacturability, and safety profile. In light of this, we aimed to investigate other AAV serotypes for CNS tropism engineering, with a particular focus on AAV2, which has been extensively studied and utilized in clinical trials, providing a wealth of structural information that can aid in engineering efforts. We modified surface-exposed loops of AAV2 that are known to be important for brain and liver tropisms and employed our high-throughput, non-human primate (NHP)-based AAV engineering platform to evolve for capsids with CNS enrichment. Following two rounds of screening in NHPs, we identified three capsid families, defined by distinct consensus sequence motifs, that showed notable BBB-penetrance and liver de-targeting capabilities. Subsequent pool studies of the top capsids from each family in both NHPs and rodents highlighted one family with remarkably improved brain performance across species. Further characterization of a specific novel capsid from this family revealed a 50-fold increase in vector biodistribution in the brain and a 20-fold decrease in the liver compared to wild-type AAV9 in cynomolgus monkeys, along with extensive brain transduction in rodents. Continued engineering of this novel capsid yielded next-generation variants with up to 80-fold enhancement in CNS transduction relative to the parent novel capsid in NHPs. Taken together, our work identified AAV2-derived capsids with a combination of desirable characteristics, including robust CNS penetrance, cross-species translatability, and an improved safety profile due to reduced liver viral load. The identified variants have the potential to be utilized in future gene therapy applications for CNS disorders.

993. Unveiling Novel AAV Variants for Blood-Brain Barrier Crossing through Computational-Guided Directed Evolution

Eunhyun Ji, Eunji Lee, Kye Il Joo

Ewha Womans University, Seoul, Korea, Republic of

Adeno-associated viruses (AAVs) have emerged as common gene delivery vehicles for treating numerous human diseases. Gene therapy using AAV in neurological disorders is a leading platform because they are considered safe, low immunogenic, and long-term persistency. However, enabling the noninvasive transportation of AAVs across the blood-brain barrier (BBB) poses a substantial challenge in achieving optimal clinical applicability. In this study, we employed an integrated approach that combines experimental selection strategies and computational modeling to synthesize chimeric AAV capsid variants and predict their ability to traverse the BBB through AAV capsid-receptor binding. To discover the novel AAV capsid candidates with improved tissue- or cell-specific tropism for brain targeting, we generated a library of engineered AAV capsids using directed evolution techniques, including AAV capsid DNA shuffling and peptide display. A Next Generation Sequencing (NGS) analysis was conducted on the tissues and cells infected by the generated AAV library to isolate AAV candidates capable of penetrating the BBB. Concurrently, computational modeling was utilized to evaluate the binding affinity of the newly discovered AAV capsids to BBB-related receptors, facilitating a comparative analysis with experimental data. Taken together, these results enable the discovery of AAV capsid variants capable of crossing the BBB, primarily by quantifying their receptor binding affinities, through a comprehensive approach that integrates AI-enhanced structural prediction and molecular modeling. The outcomes of this investigation have the potential to guide the application of noninvasive, customized gene therapy for brain disorders.

994. AAV(BBB): A Novel AAV Variant Targeting the Central Nervous System with Super-High Efficiency and Specificity

Bing Wang, Yu Liu, Yuyan Wang, Leming Wang, Qizhao Wang, Daozhan Yu

AAVnerGene Inc., Rockville, MD

Treating diseases of the central nervous system (CNS) is notably challenging, largely because the blood-brain barrier (BBB) restricts the entry of many therapeutic drugs. Utilizing AAV vectors in gene therapy offers a potential solution to overcome this barrier. AAV9 is recognized for its ability to breach the BBB and is commonly employed for CNS delivery. Numerous studies have utilized AAV9 as a template to develop new AAV vectors with improved BBB-crossing capabilities, examples of which include AAV-Php.eB and AAV-Mac. Using our ATHENA I platform, we verified that AAV9 outperformed other AAV serotypes in brain tissue of C57B6 mice. However, AAV9 also shows significant transduction in heart, kidney, lung and liver. AAV-Php.eb, which is derived from AAV9, has also been reported to express highly in various tissues. Furthermore, the ability to cross the blood-brain barrier (BBB) varies among species. AAV-Php.eb, developed using the C57B6 mouse model, is effective only in this specific strain and not in others like B6C3, 129/SV or non-human primates (NHPs). Consequently, there is a significant demand for new AAV variants

with enhanced targeting to the central nervous system (CNS). In this context, we have engineered a new AAV capsid, named as AAV(BBB), based on the data of our ATHENA I evolution studies. AAV(BBB) shows a remarkable increase at RNA level by approximately 20-fold and at DNA level by 26-fold in mouse brain, Compared to AAV9. More importantly, AAV(BBB) demonstrates a specific affinity for the mouse brain, with ultra-low DNA accumulation and RNA expression in other organs including liver. Thus, AAV(BBB) has the potential to drastically increase the drug efficacy, and decrease AAV dose, side effects and cost for gene therapy of CNS disorders.

Thursday Posters: AAV Vectors - Preclinical and Proof-of-Concept In Vivo Studies

995. Optimizing AAV Dosing for *In Vivo* Screens in the Mouse Brain

Alex Lenail
MIT, Cambridge, MA

In vivo, AAV-driven CRISPR and ORF perturb-seq screens are emerging as powerful techniques to assay gene function in organismal contexts. In order to perform an in vivo perturb-seq screen, AAVs carrying CRISPR constructs or transgene open reading frames are delivered to an organism, with some method of targeting the organ system under study. The ideal dose of AAV yields as many study-relevant cells expressing a single AAV payload as possible per animal - too low a dose requires more animals, and too high a dose results in too many multiplets from which it is very challenging to garner useful data. The relationship between AAV dose and infected cells is relatively straightforward in vitro, where "poisson loading" results in a characteristic relationship between AAV dose and infection. However, in the case of an organism, cells may be differentially vascularized, differentially or susceptible to infection, resulting in the need for empirical measurement of cargo expression at different AAV dosages in the in vivo cells under study. We performed a dose-escalation experiment to ascertain the optimal dose of AAVs to perform efficient in vivo perturb-seq screens in the murine brain by systemic injection of AAV capsid PHP.eB. We found that infectivity in different brain regions differed substantially, in agreement with known vascularization patterns. We found strikingly diminishing returns with increasing AAV dosage. Finally, we found no evidence for cooperativity among AAV infections, providing a green light for perturb-seq screens in the murine CNS.

996. Gene Therapy Development for DDX3X Syndrome

Andrea Boitnott, Anjala Jiji, Yuhui Hu, Xin Chen, Steven J. Gray
UT Southwestern Medical Center, Dallas, TX

DDX3X syndrome is a neurodevelopmental disorder first described in 2015, and today it is thought to be one of the leading known genetic causes of intellectual disability in females. The syndrome is caused by mutations in the Dead-Box Helicase 3 X-Linked gene (*DDX3X*), an abundant and ubiquitously expressed RNA helicase. Despite the clinical burden of DDX3X syndrome and the known genetic cause, no study to date has determined whether gene-based therapies have the potential to treat this disorder. Our hypothesis is that DDX3X gene reinstatement, after altered DDX3X function during prenatal development, will restore proper protein function and, therefore, ameliorate disease symptoms preclinically in a timepoint dependent manner that is sensitive to the level of DDX3X. To determine preclinically if gene replacement therapy for DDX3X syndrome is beneficial, we developed a first generation AAV9 gene therapy to test in mice. In this vector, a functional copy of *DDX3X* is expressed from a relatively weak ubiquitous promoter. Mice modeling DDX3X syndrome, as well as littermate controls, were dosed at postnatal day 1 (P1) via two routes of administration—bilateral intracerebroventricular or lumbar intrathecal—and behavior phenotypes were assessed across development from P2-20 and as adults, at 3 and 12 months. The treated DDX3X syndrome mice showed limited evidence for benefit in a subset of all tests conducted, including time in center of an open field and gait analysis. Conversely, some behaviors became worse, such as decreased rotarod performance. Our results suggest that the dosage of DDX3X is important for behavior, where not enough or too much expression could each lead to altered behavior. To further test the dose-sensitivity of DDX3X, we treated mice with an AAV9 vector that overexpressed DDX3X from a strong ubiquitous promoter, and this resulted in rapid death of mice as early as 1-week post-injection when dosed at P1. Our results clearly demonstrate that overexpression of DDX3X is detrimental, even relatively subtle overexpression that can occur with a deliberately weak promoter. These studies suggest that there could be beneficial outcomes with a DDX3X gene therapy approach, but only if expression can be carefully regulated to avoid transgene overexpression.

997. A Novel Approach to Treat Stuttering: Preclinical Gene Therapy in Animal Studies

Camryn Bragg, Ruli Zhang, Shahriar SheikhBahaei
Neuron-Glia Signaling and Circuits Unit, National Institutes of Neurological Disorders and Stroke, Bethesda, MD

Stuttering is a neurodevelopmental disorder that affects nearly 70 million adults worldwide. People who stutter exhibit repetition, prolongation, pauses, or hesitations in their speech. Recently, it has been shown that specific mutations in the gene that codes for N-acetylglucosamine-1-phosphate-transferase subunits α,β, *GNPTAB*, cause stuttering symptoms in humans and rodents. Yet, the cellular and physiological consequences of the causal mutation are still unclear. Previously, our efforts to characterize the disorder in genetically engineered, *Gnptab*-mutant mice have shown effects on rhythmic motor behaviors, including breathing, grooming, and vocalization. In the present study, we evaluate the effectiveness of a gene therapy method to improve these motor behaviors in the mutant mice. Here, we used viral vectors to introduce a functional copy of the gene in P0 mice via intracranial injections. Our preliminary analysis suggests that pre-clinical gene therapy has improved vocal behaviors in the mutant animals. This study can be used as proof of principle that gene and cell therapies may be a possible avenue for the treatment of neurodevelopmental motor control disorders.

999. Allele-Specific Silencing of Mutant ATXN3 Mitigates Motor Deficits and Neuropathology in a Severely Impaired Mouse Model of Spinocerebellar Ataxia Type 3 (SCA3)

Ana Carolina Silva, Carina Henriques, Diana Lobo, Ana Rita Fernandes, Miguel Lopes, Dina Pereira, Sonia Duarte, Rafael Baganha, Sara Lopes, Magda Santana, Rui Jorge Nobre, Luis Pereira de Almeida

Center for Neuroscience and Cell Biology, Coimbra, Portugal

Spinocerebellar Ataxia Type 3 (SCA3), also recognized as Machado-Joseph Disease (MJD), stands as a dominantly inherited and fatal neurodegenerative disorder characterized by the aberrant repetition of CAG trinucleotides within the ATXN3 gene. This anomalous expansion leads to a toxic gain-of-function in the ATXN3 protein, inducing neuropathology and neurodegeneration, particularly in the cerebellum. Presently, there exists no therapy capable of modifying disease progression.Consequently, our investigation delved into the therapeutic potential of an AAV encoding artificial microRNAs (miATXN3) precisely targeting the mutant ataxin-3 allele. We administered this therapy via intra-cisterna magna (ICM) in severely impaired transgenic SCA3 mice.Motor performance analysis unveiled significant and robust enhancements in coordination, balance, and gait at 5-, 8-, and 11-weeks post-injection, as assessed through rotarod performance, beam-walking testing, and CatWalk XT analysis. Importantly, histological analysis indicated an improvement in neuropathology, evident through a reduction in the number of ATXN3 inclusions and the prevention of layer thickness shrinkage within the cerebellar lobules of AAV9-miATXN3-injected mice when compared with vehicle-treated counterparts. These outcomes were reinforced by a dose-dependent reduction in mutant ATXN3 mRNA levels in the cerebellum. Furthermore, the end-of-experiment assessment (13 weeks post-ICM injection) revealed widespread detection of AAV genome copies and miATXN3 levels in disease-relevant brain regions. In summary, our findings endorse an AAV-based therapy for SCA3, marking a significant stride toward imminent clinical translation for SCA3 patients.

1000. Developmental Age Effects for AAV9/SLC6A1 Gene Therapy in Heterozygous and Homozygous SLC6A1 KO Mice

Weirui Guo, Matthew Colby Rioux, Frances Shaffo, Yuhui Hu, Steven J. Gray

University of Texas Southwestern Medical Center, Dallas, TX

The human SLC6A1 gene encodes the highly conserved gamma-aminobutyric acid (GABA) transporter GAT-1, a protein crucial for GABAergic signaling in the central nervous system (CNS), and thus crucial for maintaining the excitatory/inhibitory signaling balance in the brain. A subset of patients presenting with rare forms of infantile encephalopathy with intellectual disability (ID) have been shown to be heterozygous for loss-of-function mutations in SLC6A1.To test our hypothesis that broad delivery of the human SLC6A1 gene across the CNS using adeno-associated virus type 9 (AAV9) to restore normal GABAergic signaling can provide an effective treatment and long-term therapeutic benefit for SLC6A1-Related Disorder, we designed two AAV9 vectors with different promoters (one is a weak universal promoter - JeT; the other is a neuronal-specific promoter - MeP229) and conducted preclinical gene therapy studies using heterozygous and homozygous SLC6A1 KO mice at different developmental ages. Both vectors were well-tolerated when administered to WT mice intrathecally (IT), at either post-natal day (PND)7-10 or PND28, out to 6 months and 1-year post-injection, respectively. The two AAV9/SLC6A1 vectors were tested separately via intracerebroventricular (ICV) administration in neonatal mice, lumbar intrathecal (IT) administration at the age of postnatal day (PND) 5, 10 or 28, and intravenous (IV) administration of AAV-PHP.eB at PND23. Neonatal ICV administration of both vectors ($3x10^{11}$ vg per mouse) resulted in significantly reduced seizures assessed by EEG in heterozygous and homozygous SLC6A1 KO mice, as well as improvement in several behavioral phenotypes of homozygous SLC6A1 KO mice. IT administration of both vectors ($5.6x10^{11}$ or $1.12x10^{12}$ vg per mouse) at PND5 showed near-complete normalization of EEG patterns in $SLC6A1^{+/-}$ heterozygous mice at either dose. Interestingly, the abnormal EEG patterns were not rescued in the homozygous $SLC6A1^{-/-}$ KO mice, suggesting that complete absence of GAT1 through early postnatal development makes them refractory to treatment rescue. Likewise, IT administration to PND10 $SLC6A1^{-/-}$ KO mice showed modest and statistically non-significant improvements in nest building and rotarod, but no improvement in EEG. The PHP.eB/SLC6A1 (IV) administration at PND23 ($2x10^{10}$, $2x10^{11}$ or $1x10^{12}$ vg per mouse) failed to reduce EEG seizures in heterozygous or $SLC6A1^{-/-}$ KO mice, and the $2x10^{10}$ or $2x10^{11}$ vg doses only showed a moderate nest building behavioral improvement (the 1 $x10^{12}$ vg group wasn't assessed). Treatment at PND 28 in $SLC6A1^{-/-}$ KO had no apparent treatment benefit. When administered ICV to PND1 mice, the JeT vector resulted in approximately 50% early mortality and some sporadic adverse effects while the MeP229 vector resulted in 17% early morality also with some sporadic adverse effects. No adverse effects were observed across all the IT or IV treated animals, except for some possible sporadic events in the JeT PND5 injection group (<5% of animals). Overall, our data demonstrate compelling treatment activity when mice are treated at an early development age (neonatal and PND5). We also identified that outside of the neonatal treatment window, the severe homozygous KO model is refractory to treatment, whereas the heterozygous mice that genotypically match human patients have displayed remarkable treatment activity. Treatment of heterozygous mice older than PND5 is ongoing, but the lack of rescue at PND23 with PHP.eB suggests that early intervention is critical for this disorder.

1001. Dorsal Root Ganglion Pathologies and Responses to Gene Therapy in Mice with Sialidosis

Wuh-Liang Hwu[1,2], Yu-Han Liu[1], Karine Chang[1], Hao-Chun Wang[1], Ni-Chung Lee[3], Yin-Hsiu Chien[3]

[1]Nation Taiwan University Hospital, Taipei, Taiwan,[2]Center for Precision Medicine, China Medical University Hospital, Taichung, Taiwan,[3]National Taiwan University Hospital, Taipei, Taiwan

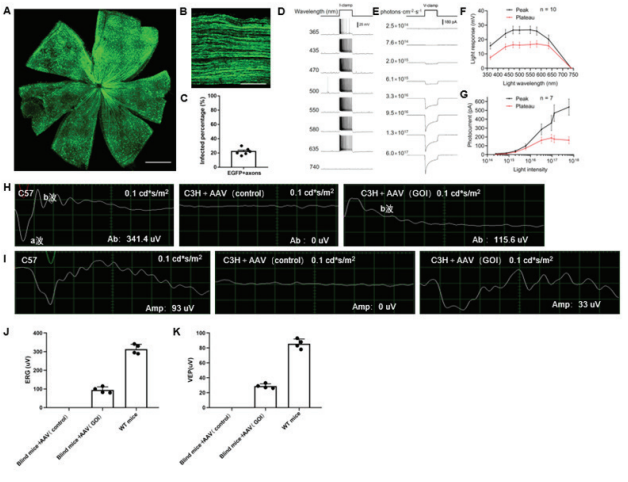
Patients with sialidosis (mucolipidosis type I) type I typically present with myoclonus, seizures, ataxia, cherry-red spots, and blindness because of mutations in the neuraminidase 1 (*NEU1*) gene. Although ataxia is one of the main symptoms of the disease, there is no loss

of cerebellar Purkinje neurons in the disease. We created a *Neu1* knockout (*Neu1*$^{-/-}$) mouse model of sialidosis, and the homozygous *Neu1*$^{-/-}$ mice exhibited impair rotarod performance. We examined the dorsal root ganglia (DRG) of *Neu1*$^{-/-}$ mice. Grossly, DRG of *Neu1*$^{-/-}$ mice were larger than those of wild-type mice. H&E staining of the affected DRG revealed vacuolation of small cells (microglia) and pale cytoplasm of large cells (neurons). Immunofluorescence staining was performed for the storage material LAMP1. DRG neurons of *Neu1*$^{-/-}$ mice exhibited a variable, homogeneous increase in LAMP1 staining intensity, while microglia exhibited strong and clumping LAMP1 stain. However, the shape and number of peripherin (nociceptor) or neurofilament (mechanoreceptor) positive neurons looked similar between the wild-type and *Neu1*$^{-/-}$ mice. Ultrastructure of DRG was further elucidated by electron microscopy. Microglia were found to contain large vacuoles. On the contrary, neurons were filled with small vacuoles more homogeneous in size with depletion of rough endoplasmic reticulum, but the morphology of mitochondria still looked normal and there was no degeneration of nuclei. We have developed an adeno-associated viral (AAV) vector AAV9-P3-NP which included the human *NEU1* promoter, *NEU1* cDNA, IRES, and *CTSA* cDNA. In *Neu1*$^{-/-}$ mice received neonatal injections of AAV9-P3-NP, LAMP1 accumulation decreased in both the neurons and microglia of DRG. Therefore, DRG-related symptoms of sialidosis may be treatable by AAV-mediated gene therapy.

1002. Gene Editing Strategies to Treat Spinocerebellar Ataxia Type 1

Kelly Fagan[1], Guillem Chillon[1], Ellie Carrell[2], Beverly L. Davidson[2]

[1]University of Pennsylvania, Philadelphia, PA,[2]Children's Hospital of Philadelphia, Philadelphia, PA



Spinocerebellar ataxia type 1 (SCA1) is a dominantly inherited neurogenetic disease caused by expansion of the polyglutamine repeat region in *ATXN1*. Normal *ATXN1* alleles contain 6-42 CAG repeats with interspersed CAT nucleotides, while disease alleles have 39-100+ uninterrupted CAG repeats. SCA1 patients present with cerebellar Purkinje cell (PC) loss, progressive loss of motor coordination, respiratory issues and eventual death. Currently there are no disease modifying treatments; however, previous work from our laboratory has demonstrated the potential of gene therapy as a treatment modality, specifically RNAi. Here, we tested two CRISPR-Cas9 strategies aimed to reduce *ATXN1*; a single guide RNA (gRNA) that targets near the exon-exon junction to induce nonsense mediated decay and a second approach which employs a dual guide system to excise the CAG repeat region. Both single and dual gRNA strategies significantly reduced *ATXN1* RNA by 56% and 57%, respectively when screened in HEK-Cas9 cells. Next, we tested for editing in human cells and in mice models. SCA1 patient iPSCs and unaffected matched sibling donors were differentiated into neuronal progenitor cells and transgenes expressing *Sp*Cas9 and dual gRNAs were delivered via AAV1. Treated experimental cells showed full CAG deletion. In B05 mice, a transgenic model of SCA1 that expresses human *ATXN1* (*hATXN1*) with 82 uninterrupted CAG repeats under a PC-specific promoter, co-delivery of Cas9 and gRNA reduced ATXN1 mRNA levels by 36% (dual gRNAs) and 54% (single gRNA), respectively. Additionally, rotarod performance by B05 mice treated with the single gRNA strategy was significantly better than vehicle-treated B05 mice and not statistically different from wild-type animals. Importantly, there was no increase in inflammatory markers in treated animals. In combination, these data present CRISPR-Cas9 as a potential approach for SCA1 therapy.

1003. Optogenetic Therapy Partially Restores Vision in Blind Mice

Xiaohu Wei[1], Lingjie Cui[1], Shanzhong Zhang[1,2], Cheng Xie[1], Sijie Sun[1], Xiaohua Liu[1], Zhiping Cui[1], Shijun Weng[3]

[1]Ugenex Therapeutics Ltd.Co, Suzhou, China,[2]Otovia Therapeutics, Shanghai, China,[3]Institute of Brain Science of Fudan University, Shanghai, China

Retinal neurodegenerative diseases, such as retinitis pigmentosa (RP) and age-related macular degeneration (AMD), eventually lead to degeneration of photoreceptor cells, resulting in blindness. We are dedicated to restoring vision in patients through optogenetic therapy, utilizing the expression of photosensitive ion channel proteins in the remaining neurons of the retina. Our designed photosensitive ion channel products and their various variants, delivered via AAV2/7m8, induce the generation of electro-retinogram (F-ERG) in blind C3H mice under normal white light stimulation. Additionally, Visual evoked potentials (F-VEP) are recorded in the brain's visual cortex, indicating the restoration of the complete visual pathway. These products exhibit long-term expression for at least 14 months without adverse effects. Enhanced photosensitivity and photodynamics, significantly lower photosensitivity thresholds, increased light response speed, and maximum response frequency are observed in these products and their variants. Covering the visible light spectrum, with optimal absorption wavelength in the safe red-shifted range, the products demonstrate minimal phototoxicity, surpassing other photosensitive ion channel protein products. Given the favorable efficacy and advantages in light sensitivity, photodynamics, and wavelength characteristics observed in blind mice, these products hold significant potential in the treatment of retinal neurodegenerative diseases.

(A), In C3H mice with photoreceptor cells degenerative blindness at 12 weeks of age, intravitreal injection of AAV was performed, and retinal wholemount 7 weeks post-injection revealed efficient expression of the product in retinal ganglion cells (RGCs), with axons converging at the

optic nerve (B). Approximately 20% of RGCs were infected (C). (D), Whole-cell current-clamp recording RGCs in UGX-GOI-treated C3H retinal wholemount, the light-evoked spiking traces of GOI-expressed RGCs with 2 s light pulses at different light wavelengths under about 3×10^{17} photons/cm^{2}s. (E), Voltage-clamp recording RGC, the light-evoked current traces of GOI-expressed RGCs with 2 s light pulses at 580 nm under different light intensities measured as photons/cm^{2}s.(F), The light wavelength and voltage response relationship were measured at peak and plateau currents. n = 10. (G), The light intensity and current response relationship were measured at peak and plateau currents. n = 7. (H), F-ERG data were collected using a light intensity of 0.1 cd*s/m^2. Compared to the control group, the experimental group expressing our product exhibited recorded ERG signals. The a-wave, specific to photoreceptor cells, was minimal, while the b-wave, specific to inner layer cells, was relatively high, indicating restoration of the visual pathway in the eye region. Statistical analysis is represented in panel (J) n=4. (I), VEP data were also collected using the same light intensity, revealing recorded VEP signals in the experimental group expressing our product compared to the control group. This implies that the visual pathway in the eye region has been restored, and signals can be further transmitted to the visual cortex. Therefore, partial restoration of vision was observed in blind mice after expressing our product. Panel (K) presents the VEP statistical analysis, n=4.

1005. Validation of TDP-43 Splicing Repression as a Therapeutic Strategy for ALS and FTD

Tianyu Cao, Aswathy Mallika, Irika Sinha, Meghraj Baghel, Katie Irwin, Jonathan Ling, Philip C. Wong
Pathology, Johns Hopkins University School of Medicine, Baltimore, MD

Nuclear depletion and cytoplasm aggregation of Tar RNA-binding protein 43 (TDP-43) is a major pathology underlying amyotrophic lateral sclerosis (ALS), frontotemporal dementia (FTD) and many neurodegenerative diseases. Previous findings showed that the major function of TDP-43 is splicing repression, which serves to protect the transcriptome by preventing aberrant splicing. Lossing TDP-43 in the nuclear leads to mis-splicing of cryptic exons, and especially depletion of a critical gene for synapse function, UNC13A. However, whether restoring splicing repression can be a therapeutic strategy for neurodegeneration is still under investigation. Here we show that a previously characterized chimeric repressor (termed CTR), which possesses only splicing repression of TDP-43, is effective for TDP-43 loss of function. We found that in vivo delivery of CTR by AAV to a mouse model lacking TDP-43 in forebrain neurons showed a rescue of CA2/3 neurons loss and hippocampus shrink, together with a significantly reduced expression of the cryptic exons than the AAV GFP injected group, including the cryptic UNC13A expression in the hippocampus. Our results demonstrate that TDP-43 loss of function mediated cryptic splicing, calcium channel disruption and neurodegeneration can be effectively restored by CTR. This finding may provide preclinical evidence for the treatment of ALS/FTD.

1006. scAAV9.hGAMT Results in a Durable and Dose-Dependent Correction of the Biochemical Phenotype in a Mouse Model of Guanidinoacetate Methyltransferase (GAMT) Creatine Deficiency

Robyn T. Binsfeld[1], Troy B. Webster[1], Ilona Tkachyova[2], Emahnee Cover[3], Tesla Peretti[1], Brianna M. Quinville[1], Melissa Mitchell[4], Andreas Schulze[2,5], Jagdeep S. Walia[4,6]
[1]Centre for Neuroscience Studies, Queen's University, Kingston, ON, Canada,[2]Peter Gilgan Center for Research and Learning, The Hospital for Sick Children, Toronto, ON, Canada,[3]Faculty of Arts and Science, Queen's University, Kingston, ON, Canada,[4]School of Medicine, Department of Pediatrics, Queen's University, Kingston, ON, Canada,[5]Departments of Pediatrics and Biochemistry, University of Toronto, Toronto, ON, Canada,[6]Kingston Health Sciences Centre, Kingston, ON, Canada

Guanidinoacetate methyltransferase (GAMT) is an essential enzyme in the biosynthesis of creatine, a small molecule that plays an important role in energy metabolism. Creatine deficiency disorders are inborn errors of metabolism resulting in several neurological manifestations including developmental delay, intellectual disability, and epilepsy, emphasizing the importance of creatine's role in the brain. Endogenous synthesis of creatine takes place through the enzymatic function of arginine:glycine amidinotransferase (AGAT) to form guanidinoacetate (GAA) which is then converted to creatine by GAMT. GAMT-deficiency is an autosomal recessive disorder resulting in little to no available intracellular creatine accompanied by an accumulation of the potentially neurotoxic metabolite, GAA. Current treatments for GAMT-D focus on diet intervention to supplement creatine and reduce GAA production, however this does not restore creatine or GAA levels in the brain, leaving many of the symptoms unattended. Previously we presented a proof-of concept study showing that the *scAAV9.hGAMT* vector had the potential to restore expression and function of GAMT in murine models of GAMT-D following intrathecal administration at 7 weeks post-treatment. Here, for the first time we now show the dose-response following treatment with *scAAV9.hGAMT* resulting in durable expression detected at 5-months post-treatment. *scAAV9.hGAMT* was administered intrathecally at three doses ranging from $6.25e^{10}$ to $2.5e^{11}$vg/mouse. A dose-dependent increase in creatine and decrease in GAA accumulation was detected in several tissues and the serum of treated mice including the central nervous system. Monthly blood collections showed these metabolites stabilized at 6 weeks post-treatment and were maintained until the long-term endpoint of 20 weeks post-injection in the serum. GAMT protein was restored and detectable by western blotting in the liver at both short and long-term endpoints in a dose-dependent manner. Overall, we have shown that *scAAV9.hGAMT* represents a promising therapeutic for the treatment of GAMT creatine deficiency and is under further investigation for safety and dose optimization for better translation for clinical use.

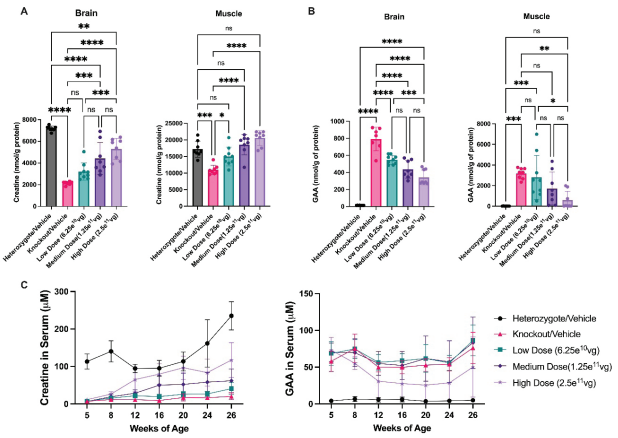


Figure 1. Creatine and GAA levels are corrected in a dose-dependent manner in treated animals compared to untreated controls. A. Creatine is significantly increased in animals treated with the medium and high doses compared to untreated knockouts in both the brain and muscle tissues. **B.** GAA levels are significantly decreased in the brain at all three doses however this is only evident at the high dose in the muscle tissues. **C.** Creatine increased over time in the serum with the greatest increase observed at the highest dose and no differences seen with the lowest dose. This increase stabilized at 6 weeks post injecton and remained for the duration of the study until the endpoint at 20-weeks post-treatment. GAA accumulation decreased over time following the same trend as the increase in creatine, however there was no observable differences in the medium or low doses compared to untreated knockouts. (* p<0.05, **p<0.01, ***p<0.001, **** p<0.0001)

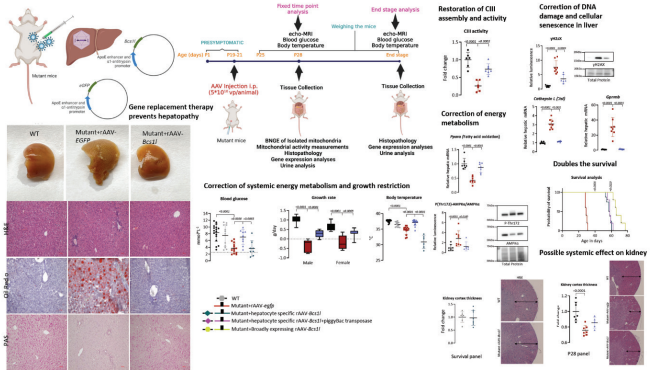
1007. Considerations for Species Differences in Pre-Clinical Gene Therapy Development

Meghan Eller, Krishanna Knight, Rachel M. Bailey

UT Southwestern Medical Center, Dallas, TX

For gene therapy proof-of-concept studies, cell and animal models are used to demonstrate safety and therapeutic benefit, which typically involves expressing human genes in a non-human species. For many genes, this cross-species approach is well tolerated due to high homology, however species compatibility can still be an issue even in well-conserved genes. In this study, we aimed to determine the species compatibility between human and mouse *ECHS1*, a gene that encodes short-chain enoyl-CoA hydratase (ECHS1) with 88% species homology. ECHS1 functions within mitochondria to catabolize branched chain amino acids and fatty acids, supporting energy production within cells. Loss-of-function variants in ECHS1 cause a Leigh-like syndrome, and the feasibility of developing a gene replacement therapy for this disorder has yet to be explored. Towards this, 2 self-complementary AAV9 constructs were developed, which both contained codon optimized human *ECHS1* cDNA driven by a weak ubiquitous promoter. The second vector transgene was also CpG depleted in an effort to reduce immunogenicity. Prior to virus production, both plasmids were confirmed to express ECHS1 at similar levels following transfection of cells. To assess toxicity in vivo, wildtype (WT) mice were treated with high and low doses of each virus via intrathecal lumbar puncture at post-natal day 10. There were no differences in weight or survival across treatments or compared to vehicle, however, 70% of mice that received a high dose of the CpG-depleted transgene developed progressive hindlimb clasping that did not resolve up to 1-year post-injection. This behavior was not associated with any histopathological abnormalities across tissues at 2 months post-injection, but animals that developed clasping had significantly higher ECHS1 expression than animals without clasping. This suggests that overexpression of human ECHS1 is not well-tolerated in mice, although it is unknown whether this is due to species differences or to ECHS1 itself. To further investigate potential species incompatibility with ECHS1 overexpression, human (HEK293T) and mouse (N2A) cell lines were used. Cell viability and ATP levels were used as indicators of overall cell health and ECHS1 function. When ECHS1 is reduced by genetic knock-out or siRNA, ATP levels are significantly decreased in both mouse and human cells. Interestingly, when human ECHS1 was overexpressed in mouse cells, viability was not affected but ATP levels were significantly reduced. In contrast, ATP levels were not impacted by mouse Echs1 overexpression in mouse cells. Further, overexpression of human ECHS1 in human cells led to a two-fold increase in ATP levels, suggesting improved cell health and/or increased ECHS1 function. Taken together, these results support that overexpression of ECHS1 may not be inherently toxic, and rather there is species incompatibility. As ECHS1 functions as a homohexamer, co-expression of human and mouse ECHS1 may have a dominant negative effect and reduce functionable ECHS1 complexes. Experiments to overexpress mouse ECHS1 in human cells are ongoing and will be reported. Future studies will develop AAV9 constructs to overexpress mouse Echs1 in WT mice, which we hypothesize will be well tolerated. These findings emphasize the importance of considering species compatibility in pre-clinical studies, and caution scrutiny of the impact of human transgene expression in different model systems.



1008. Effective Treatment of Complex III Deficient Mice with Hepatocyte-Targeted Gene Therapy

Rishi Banerjee, Janne Purhonen, Vineta Fellman, Jukka Kallijärvi

Faculty of Medicine, University of Helsinki, Helsinki, Finland

Mitochondrial disorders comprise a large group of monogenic inborn errors of metabolism, typically with compromised respiratory chain (RC) function, leading to a wide spectrum of manifestations from myopathies to encephalopathies and multi-organ disease. Mutations in the RC complex III (CIII) assembly factor gene *Bcs1l* are the most common cause of CIII deficiency (1). The most severe of them is GRACILE (Growth Restriction, Aminoaciduria, Cholestasis, liver Iron overload, Lactic acidosis, and Early death) syndrome, described in Finland (2). Our group generated a GRACILE mutation knock-in (Ser78Gly mutation in Bcs1l) mouse model that recapitulate most of the clinical manifestations (3, 4). The *Bcs1l*$^{p.S78G}$ mice show a severe juvenile-onset disease with growth restriction, kyphosis, and decreased bone mineral density and fat mass. Early histopathology and CIII deficiency are mainly seen in the liver and kidney. It is not known to which degree the concomitant systemic and metabolic phenotypes growth restriction, loss of adipose tissue and hypoglycemia dependent on the liver. Therefore, to interrogate the contribution of the metabolically compromised hepatocytes, we used recombinant adeno-associated viruses (rAAVs), serotype 9 and a hepatocyte-specific human ApoE enhancer and α1-antitrypsin promoter, to express wild-type BCS1L in the *Bcs1l*$^{p.S78G}$ liver starting at presymptomatic age (P21). . Along with the expression cassette, the vector also has flanking PiggyBac transposon recognition sequences, which ensures efficient integration. To ensure persistent expression, we used this novel bi-virion AAV system, which consists of the vectors carrying *Bcs1l* and PiggyBac transposase, and the survival was analyzed. In the juvenile mice, a single intraperitoneal injection of rAAVs improves CIII assembly and activity and normalizes mitochondrial alterations in mutant liver. Moreover, the gene replacement therapy prevented lethal hepatopathy, like lipid accumulation, glycogen depletion in juvenile mice. It also prevented cell proliferation, DNA damage and cellular senescence in liver.

Moreover, it also rescued all the metabolic error, critical for systemic effect by liver. Strikingly, the liver-targeted gene therapy was sufficient to correct systemic phenotypes like hypoglycemia, hypothermia and decreased growth. Lastly, it dramatically increases the survival of these animals by two fold. Thus, we propose that liver-targeted gene therapy is an effective strategy to treat mitochondrial disease phenotypes with mainly visceral manifestations, such as GRACILE syndrome. Reference 1. 1009. NGGT006, an Advanced Gene Therapy Vector for Treating Familial Hypercholesterolemia

Shengmei Wen[1], Hai Zhang[1], Yufeng Guo[1], Qingzhou Wang[1], Yiting Liu[2], Guang Qu[1,2], Lixin Jiang[1,2]

[1]NGGT (Suzhou) Biotechnology Co., Ltd., Suzhou, Jiangsu, China,[2]NGGT, Inc, Walnut Creek, CA

Introduction: Homozygous Familial Hypercholesterolemia (HoFH) is a rare and devastating genetic metabolic disorder characterized by absent or severely reduced capacity to catabolize circulating Low density lipoprotein (LDL) particles by the hepatic LDL receptor (LDLR). HoFH patients present abnormally high total plasma LDL-cholesterol (LDL-C) levels, resulting in severe atherosclerosis and often leading to early onset of cardiovascular disease. Treatment aimed to reduce plasma LDL-C level for these patients is therefore essential. Unfortunately, most HoFH patients are unresponsive or respond very poorly to the existing therapies which cannot overcome the deficiency of LDLR. Thus, functional replacement of the defective LDLR via AAV-based liver-directed gene therapy could be a valuable approach to treat HoFH. **Methods/Results:** Using an optimized expression cassette combined with a high liver-tropism AAV vector, we have developed NGGT006, an rAAV8-based vector expressing human LDLR (rAAV8-hLDLR). In the hepatocyte line Huh7 cells infected with different multiplicities of infection (MOIs) of NGGT-006, dose-dependent increases of the expression of hLDLR protein as well as the activity of LDL-C particle uptake were observed, indicative of an effective in vitro biopotency of hLDLR delivered by NGGT006. In the LDLR-deficient mice on Western Diet containing 0.21 % cholesterol and 40% fat, a single intravenous (IV) injection of NGGT006 significantly corrected hypercholesterolemia at the dose as low as of 8.0E10 vector genome (vg)/kg. At the dose of 4.0 E11 vg/kg, 12 weeks after injection, NGGT006 effectively reduce the area of atherosclerotic deposition with substantially reduced LDL-C and total cholesterol (TC) in the peripheral blood. Furthermore, NGGT006 demonstrated therapeutic effects in LDLR gene depleted golden syrian hamsters, another rodent model of FH. It has been reported that coronary atherosclerosis in the aged LDLR null hamsters exhibit similar lipid metabolic profiles as those in humans. In these hamsters on normal chow diet, NGGT006 at 1.5E13 vg/kg significantly and sustainedly reduced serum LDL-C during a 32-week period after a single jugular vein injection. In LDLR null hamster fed on a high fat chow diet (containing 0.5 % cholesterol and 33% fat) with abnormally high serum LDL-C induced, NGGT006 at 1.25E13 vg/kg also achieved a robust 50% reduction of serum LDL-C and TC from 2-week post injection and maintained the effect for at least 27 weeks. In addition, when injected into LDLR +/- hamsters on normal chow diet, NGGT006 at 1.5E13 vg/kg significantly and stably reduced the level of serum LDL-C for 20 weeks. **Conclusions:** These studies demonstrate the therapeutic efficacy of liver-directed gene therapy approach of hLDLR gene replacement and support the further development of NGGT-006 in treating FH.

1010. NGGT003, an Advanced Gene Therapy Vector Carrying a New FVIII Variant for Treating Hemophilia A

Qing Cao[1], Qingzhou Wang[1], Yufeng Guo[1], Shengmei Wen[1], Yiting Liu[2], Guang Qu[1,2], Lixin Jiang[1,2]

[1]NGGT (Suzhou) Biotechnology Co., Ltd., Suzhou, Jiangsu, China,[2]NGGT, Inc, Walnut Creek, CA

Introduction: Hemophilia A (HA) is an X-linked bleeding disorder caused by a deficiency of coagulation factor VIII (FVIII), resulting in extensive bleeding tendencies, hematomas and joint deformities. A common treatment for hemophilia A is protein replacement with recombinant or plasma-derived coagulation FVIII. However, this therapy requires lifelong medication. AAV-based gene therapy for hemophilia A could achieve a lifetime cure by a single dose. Roctavian was recently approved for treating HA at a dose as high as 6E13 vg/kg. In order to improve the treatment efficiency and reduce the potential risks caused by high doses, we developed NGGT003, an rAAV8 based vector carrying a new human FVIII (hFVIII) variant, hFVIII-L1, aiming to increase plasma hFVIII level compared to the commonly used hFVIII-SQ and to reduce the treatment dose. **Methods/Results:** In HepG2 cells overexpressing the AAV receptor (HepG2-AAVR), 5- to 24-fold higher activity of hFVIII was detected in the supernatant of cells infected with NGGT003 (AAV8-hFVIII-L1) than AAV8-hFVIII-SQ at different multiplicities of infection (MOIs). In the FVIII -/- mouse model, 6 weeks after tail vein injection of vectors at a dose of 4E12 vg/kg, plasma hFVIII activity mediated by NGGT003 was 7.1-fold higher than that by AAV8-hFVIII-SQ, as well as a shorter bleeding

time. NGGT003 significantly reduced the bleeding time at the dose as low as 8E11 vg/kg. **Conclusions:** These in vitro and in vivo results demonstrated that NGGT003 achieved higher efficacy at a low dose, suggesting that it has a great potential to improve the treatment for HA patients at a much lower dose to ensure the safety.

1011. *In Situ* Gene Editing of Hematopoietic Stem Cells via AAV-Delivered CRISPR Guide RNAs

Alborz Karimzadeh[1], Rebekah Kim[1,2], Vivian Garcia[2], Michael Florea[2], Bryan Peacker[2], Shio Kobayashi[1], Drake Watkins[1], Kathleen Messemer[2], Jing Zeng[3], Daniel E. Bauer[3], Thomas F. Serwold[1], Amy Wagers[1,2]

[1]Joslin Diabetes Center, Boston, MA,[2]Harvard University, Cambridge, MA,[3]Boston Children's Hospital/Harvard Medical School, Boston, MA

Hematopoietic stem cells (HSCs) are the self-renewing, multipotent, and engraftable source of all cells in the blood system. Accordingly, hematopoietic stem cell transplantation (HSCT) has been utilized as a definitive cure for hematological disorders. Although HSCT has been improved upon for decades, complications associated with HSCT still relegate it to a last-resort option in many cases. Efficient gene editing of HSCs while they remain in the body has the potential to eliminate the requirement for HSCT while still leveraging the potency of HSCs for blood cell repopulation in treating monogenic blood disorders. Towards this goal, in this study, we aimed to optimize adeno-associated virus (AAV) vector design and delivery to achieve CRISPR guide RNA (gRNA) mediated *in situ* HSC gene editing in *Sp*Cas9-expressing mice. Using Ai9;*Sp*Cas9 reporter mice, which carry a broadly expressed *Sp*Cas9 transgene together with a Lox-STOP-Lox (LSL)-TdTomato reporter cassette, we first tested whether systemic administration of AAVs carrying *Sp*Cas9-compatible gRNAs designed to target sequences 5' and 3' of the LSL cassette would result in excision of the STOP codons and expression of TdTomato in HSCs. In adult mice, administration of single-stranded AAVs (ssAAVs) carrying one copy of the 5' gRNA and one copy of the 3' gRNA ("1x gRNAs") yielded rare, but readily-detectable, TdTomato+ HSCs, demonstrating the sensitivity of this system to reveal gene-editing events at the single-cell level, even in rare HSCs. We then leveraged this platform to identify modifications that might improve HSC editing rates. Substitution of a self-complementary AAV (scAAV) format improved editing rates by ~6-fold compared to ssAAV-1xgRNAs. Inclusion of an additional copy of each gRNA also boosted HSC editing rates by ~25%. Vectors incorporating both these modifications achieved editing rates of more than 5% TdTomato+ HSCs in adult animals injected with scAAV-2xgRNAs. Notably, CFU and transplantation assays confirmed that such *in situ* AAV-CRSIPR edited HSCs sustain intact multi-lineage engraftment potential. We also evaluated the adaptability of our platform to earlier intervention strategies by systemic delivery to neonatal Ai9;*Sp*Cas9 animals. Excitingly, we observed HSC editing rates exceeding 20% of the total HSC pool in mice injected within the first 3 days of life with scAAV-2xgRNAs and, for the first time, documented multi-vector transduction of HSCs *in situ* upon dual AAV delivery of separated CRISPR machinery. Finally, we tested the potential therapeutic utility of *in situ* CRISPR editing using gene-modified mice carrying the constitutive *Sp*Cas9 transgene in which the mouse hemoglobin A (HBA) and HBB genes had been replaced with human HBA, HBG, and HBB or HBS (sickle HBB). Systemic delivery of scAAV carrying gRNAs targeting the BCL11A binding motif, located within the HBG promoter, effectively targeted this motif in HSCs, resulting in ~40% modified reads and modest induction of fetal hemoglobin (HbF). Taken together, this study introduces a new and effective platform for AAV-mediated *in situ* modification of HSC genomes in mice, delineates multiple design features that promote robust gene editing in these cells, and offers initial proof-of-concept for the therapeutic application of this approach to hemoglobinopathies and potentially other congenital blood disorders.

1012. AAV-hTREM2 Reduces Pathological Amyloid-Beta in 5xFAD Mouse Model

Jessica Willen[1], Carter Daniels[2], Jeremiah Hendricks[2], Milankumar Kothiya[2], Priyam Raut[2], Lindsay Carter[3], Neda Masoudi[4], LiChin Wong[2], Sitharthan Kamalakaran[2], Ben Shykind[5], Franz Hefti[2], Mansuo Shannon[2], Anindya Sen[4]

[1]Preclinical Research and Development, Eli Lilly, New York, NY,[2]Eli Lilly, New York, NY,[3]Eli Lilly, Indianapolis, IN,[4]Prevail Therapeutics, New York, NY,[5]Prevail Therapeutics/Eli Lilly, New York, NY

TREM2 (Triggering receptor expressed on myeloid cells-2) is a cell surface transmembrane glycoprotein expressed primarily in cells of myeloid lineage, including microglia. TREM2 directly binds to amyloid-beta, facilitating microglial congregation around plaques, limiting plaque accumulation and promoting plaque removal *TREM2* mutations associated with increased risk of AD decrease microglial response to amyloid plaques. In mouse models of AD, increasing TREM2 levels enhances microglia activation, promoting their clustering around plaques, amyloid-beta uptake and plaque compaction. AAV-hTREM2 is a gene therapy candidate designed to reduce deposition and toxicity of amyloid-beta in AD by increasing TREM2 levels. The hTREM2 vector was packaged in two different capsids, AAV9 and AAV-PRV, a novel capsid which shows broader CNS biodistribution and an increased microglial transduction compared to AAV9. In the 5xFAD mouse model of AD, we evaluated the effects of AAV9-hTREM2 and AAV-PRV-hTREM2, administered by intracerebroventricular (ICV) injection. Post-treatment, animals were assessed for biodistribution, TREM2 protein levels, and amyloid-beta levels. hTREM2 dosing in this model resulted in broad biodistribution and dose-dependent increases in TREM2 protein levels for both capsids, but significant reduction of amyloid-beta isoforms and aggregates only in mice treated with the AAV-PRV capsid. This study demonstrates the potential of a TREM2-based therapy for AD and highlights the critical importance of the optimal capsid for targeting disease-associated cell types.

1013. AAV-hTREM2 Gene Therapy, a Disease Modifying Treatment for ALSP Associated with CSF1R Mutations (ALSP-CSF1R)

Neda Masoudi[1], Jessie Willen[1], Carter Daniels[1], Beverly Ann Jenkins[1], Ellen Conceicao Furber[1], Milankumar Kothiya[1], Michael Banjoko[1], Raghu Gowda[1], Jeremiah Hendricks[1], Yi-Ya Fang[1], Priyam Raut[1], Adnan Arnaout[2], Fares Bassil[1], LiChin Wong[1], Garrett Daniels[1], Jorge Francisco Haller[1], Sitharthan Kamalakaran[3], Travis Lewis[3], Theresa Day[1], Ben Shykind[4], Mansuo Shannon[1], Franz Hefti[1], Anindya Sen[5]

[1]Preclinical Research and Development, Eli Lilly, New York, NY,[2]Eli Lilly and Company, New York, NY,[3]Eli Lilly, Indianapolis, IN,[4]Prevail Therapeutics/Eli Lilly, New York, NY,[5]Eli Lilly, New York, NY

Adult-onset Leukoencephalopathy with axonal Spheroids and Pigmented glia (ALSP) is a rare neurological disorder characterized by demyelination of white matter, spheroidal axons, and pigmented glia. Mutations in the colony stimulating factor 1 receptor (CSF1R) gene, a transmembrane tyrosine kinase receptor that expresses in brain microglia have been linked to the majority of ALSP cases. CSF1R function is necessary for the development and maintenance of microglia. Similar to CSF1R, TREM2 (Triggering receptor expressed on myeloid cells-2) is a receptor expressed in brain microglia, sharing an overlapping signaling pathway with CSF1R to activate microglia. Thus, we have developed PR009, a rAAV gene therapy to deliver a functional h*TREM2* gene, as a disease-modifying, one-time treatment for ALSP-CSF1R. PR009 is designed to enhance microglial function by increasing cellular TREM2 levels to compensate for CSF1R loss-of-function and ameliorate ALSP-CSF1R-associated pathophysiology. To test the efficacy of PR009, we developed *in vitro* and *in vivo* CSF1R-inhibition models to mimic CSF1R loss observed in patients. In a CSF1R-inhibition mouse model, treatment of PLX3397, a CSF1R inhibitor, resulted in depletion of the microglial pool. PR009 ICV dosing resulted in broad biodistribution throughout the CNS, dose-dependent increase in hTREM2 expression, effective attenuation of microglial depletion and maintenance of microglial health. Ongoing safety and tolerability studies in NHPs and rodents will provide valuable safety profile of this drug candidate. Currently, there is no disease-modifying therapy for ALSP-CSF1R and the use of available drugs is limited to managing disease associated symptoms. Our findings suggest that PR009 has the potential to treat the underlying cause of ALSP-CSF1R by expressing hTREM2 in the microglia of patients, resulting in restoration of microglial function and survival.

1014. The Postnatal Injection of AAV9-FOXG1 Rescues Corpus Callosum Agenesis and Other Brain Deficits in the Mouse Model of FOXG1 Syndrome

Shin Jeon[1,2], Jaein Park[2,3], Shibi B. Likhite[4], Ji Hwan Moon[2,5], Dongjun Shin[2,3], Liwen Li[2,3], Kathrin Meyer[4], Jae W Lee[2,3], Soo-Kyung Lee[2,3]

[1]Systems Pharmacology & Translational Therapeutics, Institute of Immunology, University of Pennsylvania, Philadelphia, PA,[2]FoxG1 Research Center, University at Buffalo, Amherst, NY,[3]Biological Science, University at Buffalo, Amherst, NY,[4]Nationwide Children's Hospital, Columbus, OH,[5]Samsung Genome Institute, Seoul, Korea, Republic of

Heterozygous mutations in the *FOXG1* gene manifest as FOXG1 syndrome, a severe neurodevelopmental disorder characterized by structural brain anomalies, including agenesis of the corpus callosum, hippocampal reduction, and myelination delays. Despite the well-defined genetic basis of FOXG1 syndrome, therapeutic interventions targeting the underlying cause of the disorder are nonexistent. In this study, we explore the therapeutic potential of adeno-associated virus 9 (AAV9) mediated delivery of the *FOXG1* gene. Remarkably, intracerebroventricular injection of AAV9-FOXG1 to *Foxg1* heterozygous mouse model at the postnatal stage rescues a wide range of brain pathologies. This includes the amelioration of corpus callosum deficiencies, the restoration of dentate gyrus morphology in the hippocampus, the normalization of oligodendrocyte lineage cell numbers, and the rectification of myelination anomalies. Our findings highlight the efficacy of AAV9-based gene therapy as a viable treatment strategy for FOXG1 syndrome and potentially other neurodevelopmental disorders with similar brain malformations, asserting its therapeutic relevance in postnatal stages.

1015. OCU410ST (AAV5-h*RORA*) Modifier Gene Therapy Rescues Retinal Degeneration in a Mouse Model of Stargardt Disease

Monica Akula[1], Pushpendra Singh[2], Neena Haider[3], Arun Upadhyay[4]

[1]Research and Development, Schepens Eye Research Institute, Massachusetts Eye and Ear, Department of Ophthalmology, Harvard Medical School, Boston, MA,[2]Research and Development, Ocugen, Malvern, PA,[3]Research and Development, Schepens Eye Research Institute, Massachusetts Eye and Ear, Department of Ophthalmology, Harvard Medical School, Boston, Massachusetts, USA, Boston, MA,[4]Ocugen, Inc., Malvern, PA

Background: Stargardt disease (STGD) affects ~ 1 million individuals globally. This rare disease is clinically characterized by slow loss of central vision in both eyes from early childhood. Underlying common cause involves >1,200 variants in gene mutations in the ABCA4 gene, which follows an autosomal recessive pattern of inheritance. Mutations of the ABCA4 gene lead to defective processing and transportation of all-trans retinaldehyde, from the photoreceptors to retinal pigment epithelium (RPE) cells. Our preclinical studies revealed that Retinoic acid related orphan receptor alpha (RORA), a nuclear hormone receptor, regulates the inflammatory response pathways that are impacted in Stargardt's disease demonstrating its therapeutic potential.
Methodology: We evaluated AAV5-*hRORA* as a modifier gene therapy

for STGD using the *Abca4*$^{-/-}$ mouse, an established model for STGD. A Low (1×10^8 vg/eye), Medium (1×10^9 vg/eye) or high (4×10^9 vg/eye) dose of AAV5-*hRORA* was administered subretinally in the *Abca4*$^{-/-}$ mice at one month of age. Fundus Blue Light Autofluorescence (BAF) imaging was used to measure the presence of lipofuscin deposits, Electroretinogram (ERG) analysis was performed to measure the retinal function. Immunohistofluorescence (IHF) was done to detect the presence of several molecular biomarkers. Follow -up assessments were performed at 1-, 4- and 7-months post-treatment. **Results:** Three different doses of *RORA* transgene delivered through AAV5-*hRORA* at 1 month (1M) showed reduced sub-retinal and RPE lipofuscin deposits in *Abca4*$^{-/-}$ treated eyes compared with untreated eyes correlating with improved photoreceptor function as assessed with electroretinography (ERG) analysis. Furthermore, *RORA*-treated *Abca4*$^{-/-}$ mice showed restored *CD59* expression at 4M and 7M and attenuated expression of amyloid precursor protein (APP) that gives rise to β-amyloid a drusen component, compared to untreated eyes. **Conclusions:** AAV5-*hRORA*-treated retinas demonstrate improvement in multiple clinical, functional, and molecular markers in *Abca4*$^{-/-}$ mice. This is the first study evaluating the impact of AAV5-*hRORA* in rescuing retinal degeneration associated with Stargardt disease. Ocugen, Inc. is currently conducting phase 1/ 2 safety and efficacy study for OCU410 in Stargardt patient (NCT05956626).

1016. Two Years Study of Safety and Efficacy of AAV Vaccine in a Preclinical Spontaneous Canine Model of Oral Melanoma

Ester Molina[1], Caitlin Yung[2], Colin Caine[1], Hisae Yoshitomi Kuoch[3], Karina Krotova[1], Antonella Borgatti[2], George Aslanidi[4]

[1]The Hormel Institute, Austin, MN,[2]University of Minnesota, Minneapolis, MN,[3]Hormel Institute University of Minnesota, Austin, MN,[4]University of Minnesota, Austin, MN

We previously demonstrated the possibility of using capsid and expression cassette optimized AAV vectors as cancer vaccine. Multivalent AAV vaccine which carry three melanoma antigens, glycoprotein 100 (Gp100), tyrosinase (Tyr) and tyrosinase related protein 1 (TRP1) proved its effectiveness in mice model. Oral melanoma (OM) is an aggressive disease that often courses with metastasis in distant organs, such as lungs and lymph nodes which eventually cause the death of the patients. The mainstream therapy is surgical removal of the primary tumor followed by intense chemotherapy or radiotherapy. The therapy is rarely effective and associated with serious adverse effects for the patients. Dog's immune system is much similar to humans, and they develop spontaneous OM with higher frequency than humans, which make them an ideal pre-clinical model to test our vaccine. 8 companion dogs with confirmed early stages of OM were vaccinated with equal amount of the 3 different AAV expressing human tumor antigens (Gp100, Tyr and TRP1). Some dogs have undergone surgery and radiotherapy prior injection of AAV vaccine. 5 males and 3 females were enrolled in the study with ages range between 6.5 and 14.3 years. 5 dogs received dose of $3x10^{12}$ vg/ dog and 3 animals received $9x10^{12}$ vg/ dog. Animals were followed for up to 9 months. On each visit animals were evaluated for blood biochemistry and hematological analysis, and chest radiography to track metastatic spared in the lungs. Additionally, blood samples were collected to analyze in our lab to determine the immune reaction against both the viral capsid and the encoded antigen(s). Globulins and white blood cell (WBC) count were tracked for a sign of inflammatory responses and 3 dogs presented high values 2 weeks after AAV vaccine administration. 4 of the dogs displayed high values for liver enzymes (alanine transaminase (ALT), alkaline phosphatase (ALP) and aspartate aminotransferase (ALS)). However, baseline values for these parameters were on the high end before vaccination, suggesting that their increased cannot be a consequences of the treatment. The results showed that none of the animals had measurable an adverse reaction against AAV vaccine. The selected inflammatory markers (IFN-γ, TNF-α, interleukin 6 (IL-6), MYD88, and TLR9) showed that at least 2 dogs presented a significant increase in all markers, suggesting acute immune system activation. The IFN-γ ELISPOT analysis demonstrated that at least 1 out of 4 dogs presented a significant increase in antigen-specific $CD8^+$ T cells against all three tumor antigens (Gp100, Tyr and TRP1). All dogs enrolled into study were tested for presence of neutralizing antibody (NAb) against AAV6 and met eligibility requirement of titer 1:2-1:8. Post vaccination monitoring showed that all animals presented elevated NAb titers with peak between 1 and 4 weeks after AAV administration. 4 animals presented a slight increase in NAb titer 1:14- 1:21, while three animals presented a significant reaction with NAb titer 1:88-1:182. However, NAb titer declined at later time points for most of the dogs suggesting the possibility of vector re-administration. The variable survival time making impossible to definitely evaluate efficacy of AAV vaccine. However, significantly, 3 dogs are currently disease-free and 2 dogs survived over 560 days after vaccination. Our study presents for the first time the attempt of using AAV cancer vaccine in large spontaneous animal model of OM closely recapitulating human disease development. Our results indicate that AAV vaccine based on tumor antigens is safe in dogs, which open possibility to expand repertoire of diseases beneficial from AAV vectors based therapy.

Thursday Posters: AAV Vectors - Product Development Manufacturing and Approval Considerations

1018. Avoiding Host and Viral (Non-Viral Genomic) DNA/RNA Contamination in Viral Particles Produced for Clinical Applications Under GLP/GMP and Profiling of RNA/DNA Packaged Inside Viral Particles

Praveensingh B. Hajeri, Masato Yamamoto, Adam Herman

Department of Surgery, University of Minnesota, Minneapolis, MN

Background: Viruses are increasingly being used as vectors for delivering therapeutic cargo. Often, viruses themselves are used as therapeutic agents for, e.g., oncolytic viruses. In all such cases, efficient amplification and purification of viral particles is an essential step. It includes designing, producing, testing, and validating viral particles that meet the standards of GLP, GMP, and standards of impurities. Viral particle assembly and packaging in cells is an organized process.

The process differs between different viruses based on whether they are enveloped, the type of genome, the structure of the protein capsids, etc. There are several reports that mention host and viral RNAs (non-genomic) get packaged in mature and empty virus particles, which may have functional importance to the virus infection cycle in general. It is not completely clear if all the host and viral non-genomic RNAs found in viruses are of functional importance or if they get packaged randomly. Most importantly, the experiments used in several such reports were not stringent enough to rule out the possibility of such RNAs bound outside the viral particles rather than getting packaged inside. So, at least in some viruses, it still remains to be investigated if host and viral RNAs get packaged inside viral particles at all using very stringent and efficient methods. For clinical applications, such impurities may affect the quality of the viruses (prepared under GLP and GMP) and may lead to many unwanted and untargeted effects on patients. Several reports suggest that some host/viral RNA contamination is unavoidable in adenoviruses and AAVs. The standards for testing such contaminants and how much contamination is acceptable are not very clear and are still being debated. ***Materials and methods:*** We tested viruses (AdV and AAVs) prepared with current state-of-the-art methods and standards and observed significant host and viral DNA/RNA contamination. Viruses were prepared using ultracentrifugation. We deployed robust DNA/RNA extraction methods and next-gen sequencing methods to identify if there are RNAs and to determine the sequences, if any, are present. We used current state-of-the-art methods available through our genomics core facilities and also our novel NGS library prep methods, which are more sensitive than others. ***Results:*** We could identify most of such contamination is only from outside of the viral particles rather than inside. We could not detect any of the transcripts (host / viral) reported earlier to be packaged inside viral particles, and also, no new transcripts were detected. This is contradictory to several earlier reports. We also devised novel methods to remove DNA/RNA contaminants from AdV particles, which seem to be mostly from outside. We hope our study and recommendations can be implemented to prepare better-quality viral particles with no contamination of nucleic acids from hosts. This will help in meeting zero contamination levels for clinical applications and manufacturing.

1019. Automated Alkaline Lysis System for cGMP Production

Baoyu Zhu

OBiO Technology (Shanghai) Corp., Ltd., Shanghai, China

Background: Supercoiled plasmid is a key raw material for gene therapy, cell therapy, nucleic acid vaccine and other fields. It is usually obtained by high-density fermentation of Escherichia coli. How to improve the lysis efficiency of supercoiled plasmid in large-scale plasmid extraction process to obtain gram scale high-purity supercoiled plasmid is a key technical bottleneck in the industry. Methods: In order to break through the technical bottleneck of the industry, OBiO independently designed a large-scale plasmid Lysis system suitable for the platform process. It consists of four parts: front/back weighing and mixing unit, group pumps, unit mixer and program console. The speed ratio of the power group pump is accurately adjusted by the program algorithm, so that the weight ratio of the material and liquid can be quickly and accurately controlled, so that the two-phase material and liquid can be accurately mixed in the mixer to ensure uniform lysis effect. During the lysis process, the contact time of alkaline solution, acid neutralization time, stirring speed and stirring time in the process of plasmid lysis can be accurately controlled to ensure consistent production between batches; The lysis production adopts single-used consumables under the laminar flow hood to minimize the risk of contamination to the environment. By this optimized process of the platform, 50-100L fermentation broth could be processed per batch in large-scale production, and 4-6g of supercoiled plasmid stock solution could be produced in the following purification process. The yield of supercoiled plasmid from SEC pool to fermentation pool could be more than 40% after purification, and the HCD residue Could be < 0.2%, and the plasmid lysis efficiency Could be stable above 90%. Keywords: Cell and gene therapy, Plasmid lysis, Automated alkaline lysis system, Supercoiled plasmids

1020. Improving rAAV Functionality through Chromatographic Enrichment of Full Capsids

Hannah Mosheim[1], Douglas Steinhauff[2]

[1]Gene Delivery Process and Analytical Development, Bristol Myers Squibb, Seattle, WA,[2]Bristol Myers Squibb, Seattle, WA

Recombinant adeno-associated virus (rAAV) is one of the most commonly used delivery vectors in gene and cell therapy development. Significant research has been done towards understanding AAV biology and the development of scalable and robust manufacturing processes and technologies. Despite advances in vector production, vector supply and potency remain obstacles for commercial viability. One of the main challenges of rAAV production is the formation of empty rAAV particles, which do not contain the gene of interest and reduce vector quality. To resolve this, anion exchange chromatography (AEX) can be used to selectively enrich full rAAV particles. The initial study used fractionation of AEX elution to generate rAAV pools with a range of full capsid concentrations and measured transduction frequency (TF) using a primary T cell assay. The results showed that increasing the fraction of full capsids led to higher transduction frequency and required a lower volume of vector to reach saturation for gene expression. A subsequent study investigated AEX process parameters with the aim of increasing selectivity for full rAAV particles. The ionic strength of the wash step was identified as a key process lever for increasing selectivity. Enriched rAAV pools recapitulated the trends in higher TF at reduced vector input. This data illustrates the value of AEX chromatography for reducing product-related impurities and improving vector functionality.

1021. Scalable Purification of Adeno-Associated Virus Produced in the Gibco™ CTS™ AAV-Production System

Nils Williston[1], Natalie Glover[1], Collin Rasmussen[1], Natalie Miller[1], Emily Jackson-Holmes[2], Chao Yan Liu[1], Kenneth W. Thompson[1], Jonathan Zmuda[1]

[1]Thermo Fisher Scientific, Frederick, MD,[2]Thermo Fisher Scientific, Carlsbad, CA

Given the tremendous interest in the use of viral vectors for gene therapy applications, there is a critical need to scale AAV manufacturing processes to deliver products able to fulfill clinical and commercial needs. As the AAV gene therapy space continues

to grow the speed with which sponsors look to move their therapies into clinical testing has accelerated. Also, large quantities of AAV are needed per dose with a maximum dosage of 1.5x 10^{17} vector genomes per kilogram of body weight for systemic treatment. To provide a scalable upstream solution for commercial-grade AAV production using the triple transfection method, we previously developed the Gibco™ CTS™ AAV-MAX Production System. Here, we present data on the downstream purification of an anti-CD19CAR-AAV6 produced using the AAV-MAX system at the 20L scale in a single-use Wave bioreactor system including detailed procedures for each step of the downstream process: 1) cell lysis and nuclease treatment, 2) clarification by depth filter train, 3) concentration and buffer exchange by hollowfiber tangential flow filtration, 4) affinity chromatography using the POROS™ CaptureSelect™ AAVX Affinity Resin, 5) full capsid enrichment by anion exchange chromatography, 6) final concentration and buffer exchange by hollowfiber tangential flow filtration, and 7) sterile filtration. Using droplet digital PCR with primers and probes targeting the anti-CD19CAR we determined viral genome titers and achieved 40% overall recovery throughout the entire purification process. Analysis of the purified AAV by mass photometry determined that 75% of the capsids were full and ex vivo transduction of T cells demonstrated the biological activity of the resultant AAV. We also provide data on vector quality including host cell DNA and protein clearance as well as residual plasmid DNA levels in the final product. To further demonstrate scalability of the AAV-MAX System in stirred tank reactors, we produced the same anti-CD19CAR-AAV6 at the 50L scale in Thermo Scientific DynaDrive single use bioreactors with associated downstream purification. This work demonstrates the scalable, end-to-end production and purification of AAV vectors using the AAV-MAX Production system and provides guidance to those looking to manufacture highly purified AAV at clinical and commercial scales.

1022. Evaluating Three Genes of Interest in an Adeno-Associated Viral Vector Platform Process

Catherine Ludolph, Hannah Seo

Gene Delivery Process Development, Bristol Myers Squibb, Seattle, WA

Recombinant adeno-associated virus (AAV) vectors for cell and gene therapies are commonly produced via triple transient transfection in suspension HEK293 culture, utilizing replication and helper plasmids, as well as a plasmid containing the gene of interest to be expressed (pGOI). With a robust AAV platform, the GOI plasmid can be changed with minimal upstream process optimization, allowing for accelerated development. In this work, we aimed to demonstrate the robustness of our internal upstream AAV platform. With the same upstream process, we can produce AAV with high vector genome titers and a high fraction of full capsids, despite changing the GOI. Of the many key parameters that influence AAV vector production, we focused on the total concentration of plasmid DNA introduced into the system, the viable cell density at the time of transfection (VCD), and the ratio of DNA to transfection reagent (N:P). The maximum achievable vector genomes and percent full capsids produced vary with GOI; however, there is consistency in the optimal values for the process parameters investigated, suggesting a robust platform. As more GOI are developed in this upstream platform, the targets identified provide a reliable starting point for optimization and the opportunity to continue outlining a robust design space for transfection.

1023. Digital PCR-Based Assays for AAV and VCN Quantification

Dirk Vollenbroich[1], Christoph Mueller[2], Ali Kaan Aldere[2], Nicole Paland[2]

[1]Minerva Biolabs Inc., Skillman, NJ,[2]Minerva Biolabs GmbH, Berlin, Germany

Gene and cell therapies for treating patients with uncurable diseases or genetic disorders have been rapidly evolving over the last decade. Manufacturing of gene therapy products involves process development to ensure more efficient therapeutics and analytical development to ensure the therapeutics' quality, efficacy, and safety. Gene and cell therapies include in vivo and ex vivo approaches. In vivo approaches locally or systemically deliver gene editing reagents or genes directly to the target site. In contrast, ex vivo approaches involve altering the patient's cells outside the organism and re-applying the modified cells to the patient. To ensure efficacy and to avoid toxicity effects of the final product, the therapeutic dose before administration must be determined. We have developed two quantification assays for the determination of the titer of adeno-associated virus (AAV) vectors, commercially available as MiQuant® AAV Kit, as well as for the determination of the vector-copy number (VCN) for CAR T-cell therapy, available as MiQuant® CAR T Cell Kit. Quantification is based on the novel PCR quantification technology, digital PCR (dPCR). dPCR is based on the distribution of the bulk reaction into thousands of partitions, so an individual end-point PCR amplification is undergone in each partition. This makes dPCR less vulnerable to PCR inhibitors, less dependent on the efficiency of the primers, and more precise, especially for lower concentrations of the target. Both quantification kits are designed to allow multiplexing of up to five relevant targets that the customer can compile from a range of provided targets, including adding custom-designed primer/probe systems according to their requirements. Determination of the AAV titer can be combined with investigating residual DNA if desired or needed. For ease of use of both kits from the laboratory to the result, software will be provided, enabling the fast and reliable calculation of the AAV titer and the VCN determining the lentiviral integration into CAR T cells. The efficacy of gene and cell therapy therapeutics and the patient's safety relies on the exact determination of viral titers for in vivo and ex vivo approaches. Our quantification kits combine ease of use with innovative quantification methods and fast-forward results.

1024. Development Considerations in Transfection Process for Gene Therapy Viral Vector Production

Mukesh Mayani, Oliver Meade, Nicole Nohilly, Kevin Keating, Yvette Valenzuela, John F. Kerwin

Gene Therapy Development, National Resilience, Inc., Waltham, MA

Transient transfection represents a crucial yet complicated process in the manufacturing of adeno-associated (AAV) and lentiviral (LVV) vectors. The transfection process is often sensible and prone to high variability, particularly when conducted at a large scale for manufacturing

vector drug substance. Achieving higher vector productivity pivots on the precise and consistent preparation of transfection complexes involving plasmid DNA (pDNA) and transfection agent. Factors such as transfection cocktail composition, mixing time, hold time, particle size and stability significantly impact cell transfection, viral vector titer and infectivity attributes. In this presentation, we will highlight important distinctions and discuss crucial observations of transfection processes in manufacturing of both AAV and LVV vectors. Further, this presentation discusses essential small- and large-scale considerations for preparing the transfection cocktail, examining influential variables such as the pDNA to transfection agent ratio, pDNA quantity and HEK293 cell density that result in remarkable 4-6-fold increase in vector productivity, achieving titer values of upper e11 vg/mL for AAV and upper e7 TU/mL for LVV, respectively.

1025. Analysis of Recombinant Adeno-Associated Viral Vectors Using Charge Detection Mass Spectrometry

Anisha Haris[1], Rebecca D'Esposito[2], Kevin Giles[1], David Bruton[1], Chris Wheeldon[1], Alistair Schofield[1], Keith Richardson[1], David Eatough[1], Steve Preece[1], Matthew Lauber[2]

[1]Waters Corporation, Wilmslow, United Kingdom,[2]Waters Corporation, Milford, MA

Recombinant adeno-associated virus (rAAV) has emerged as a suitable delivery vehicle for gene therapy products. With AAV-based gene therapy continuing to evolve, there is an increasing need to provide improved analytical tools to better characterise the therapeutics and to facilitate their production. Analytical focus is placed on full, partial, and empty capsid characterization and impurities due to the potential impacts that they may have on clinical efficacy, safety, and immunogenicity. Charge detection mass spectrometry (CDMS), using an electrostatic linear ion trap (ELIT), is an ultra-high mass technique, which provides direct mass measurement of individual ions through simultaneous determination of their mass-to-charge ratio (m/z) and charge (z). We aim to demonstrate the potential of CDMS for analysis of rAAVs and their product-related impurities including the detection of empty and partially filled capsids, where it can be a challenge for current methodologies and conventional mass spectrometry. AAV empty and full capsid samples of various serotypes (AAV1, AAV2, AAV5, AAV6, AAV8 and AAV9) were purchased from different commercial suppliers. The samples were buffer exchanged into 200 mM aqueous ammonium acetate solution with 0.001 % Pluronic F-68 (Gibco) using size-exclusion columns (Bio-Rad). Ions were generated in positive ion mode using nanoelectrospray ionisation and mass analysis was performed using a prototype CDMS instrument. Data processing and visualisation was achieved using in-house software. AAV capsids consist of 60 copies of three viral proteins VP1, VP2, and VP3 which are assembled in a range of stoichiometries (nominally 50:5:5 respectively) with an average mass around 3.7 MDa. The average mass of a full capsid (empty capsid plus genome) is typically in the 4-6 MDa range. CDMS data were obtained for the empty and full capsid samples of various AAV serotypes. The measured average masses were in good agreement with the theoretical values of the empty and full AAV capsids. Interestingly, low molecular weight species with distinct ion populations (< 1 MDa) were observed for all the empty AAV capsids, with the exception of AAV5. Additionally, for the full AAV samples, empty particles were detected in AAV1, 2, 5, 8, and 9 with partial/intermediate particles detected in AAV1, 5, 6, and 9. These data highlight the ability of CDMS to readily distinguish between empty, full, and the partially filled/intermediate capsids. Partially filled capsids as well as an increase in the empty capsid ion population were detected for an AAV8 full capsid when stored at 4 °C instead of -80 °C, indicating that storage conditions of AAVs can have a significant impact on their stability, and ultimately affecting the potency of the product. Relative quantitation of empty and full capsids for AAV8 were also investigated for mixtures ranging from 100 % empty to 100 % full, in increments of 25 %. The data were plotted as mass peak area vs. % full capsids and a linear response and correlation were observed (R^2> 0.99), highlighting the utility of CDMS for this type of work. The results presented herein demonstrate the potential of CDMS to provide valuable mass information about large and complex biotherapeutic agents, going well beyond the realm of conventional mass spectrometry. Distinguishing between empty, partial, and full particles in manufactured AAV formulations can be readily achieved, including the relative quantification of empty and full particles based on the peak area ratios of the average masses detected. Characterization of additional critical quality attributes of AAVs are also provided, such as the presence low molecular-weight impurities.

1026. Unveiling the Prolonged Performance and Reusability of AVIPure Resin for rAAV9 Purification

Junping Li, Dandan Wang, Xiaoyan Wang, Xin Xin, Wei Hu

Hangzhou Exegenesis Bio Ltd., Hangzhou, China

The purification of Recombinant Adeno-Associated Virus (rAAV) heavily relies on affinity chromatography for capsid capture. However, the substantial costs associated with resins underscore the importance of maximizing their longevity and reusability to reduce the overall cost of goods for commercialization. While various commercially available rAAV affinity resins exist, Repligen's AVIPure AAV9 resin distinguishes itself through its alkali-tolerant synthetic peptide design, coupling chemistry, and high binding capacity of 1E14 vp/mL at a 1-minute residence time and >1E15 vp/mL at a 4-minute residence time. The pressure flow performance is 3 bar at >300 cm/hr. This comprehensive study evaluated the performance and cycle time of AVIPure AAV9. A total of 21 purification cycles were executed using the same rAAV9-containing clarified harvest as the load, with 0.1M NaOH clean-in-place after each cycle. The results showcase remarkable consistency in both rAAV recovery and impurity clearance, indicating minimal loss of binding capacity after 21 cycles (see Figure 1). The average recovery of viral particles was 97% (see Figure 2). Notably, levels of host cell DNA, residual packaging plasmids, and leachable peptide ligand remained consistently low throughout all cycles. These findings demonstrate the remarkable stability and cleanability of AVIPure AAV9's peptide ligand in the presence of the strong and effective cleaning reagent NaOH, thereby extending the operational life of the resin and contributing to a reduced cost of goods for commercialization.

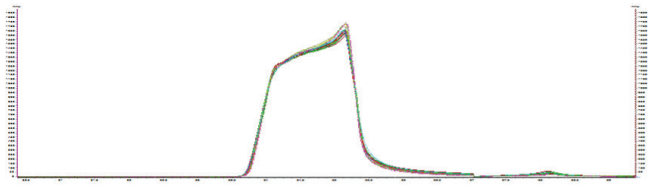

Figure 1: AVIPure affinity chromatography Elution Peak Overlay

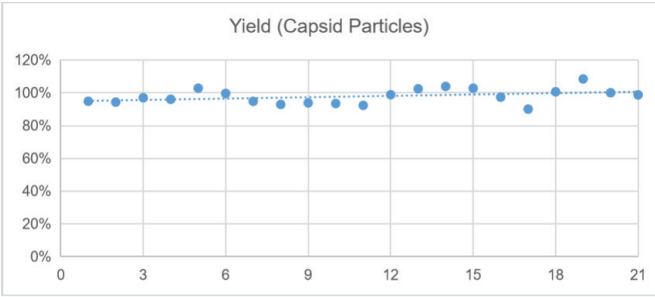

Figure 2: AVIPure affinity Chromatography Step Recovery in Capsid Particles

1027. A Commercially Producible Non-Lethal Virus Insect Cell Line

Shixian Zhang, Yan Wu, Yujing Liu, Yangyang Sheng, Xin'an Lu

Beijing Cygenta BioTechnology Co., Ltd, Beijing, China

The baculovirus expression system stands out as a robust tool for producing recombinant proteins, vaccines, and AAV vectors. In 2014, the FDA reported contamination of commercially produced baculovirus cell lines sf21 and sf9 cells with rhabdovirus, emphasizing the need for rhabdovirus-free insect cells to ensure the safety of biological products. In this study, we successfully established a rhabdovirus-free Sf9 (RVF-Sf9) insect cell line using a monoclonal screening method with antiviral reagents. The RVF-Sf9 cell line, cultured for 44 passages, exhibited no rhabdovirus detection, maintaining stable doubling time and cell viability across passages. Baculovirus titers at different passages showed no significant differences. Genomic copies of Adeno-Associated Virus Vectors (AAV2-VEGF) produced in RVF-Sf9 and SF9 (with rhabdovirus) cells were comparable. Further production of AAV-VEGF in 200-liter batches demonstrated a higher crude harvest yield of 5X10^14 vg/L using RVF-Sf9 cells compared to 3X10^14 vg/L with SF9, with no discernible differences in purity or product characteristics. Our results showcase the successful creation of a stable rhabdovirus-free cell line, providing a safer platform for commercial baculovirus system production.

1028. Rapid Optimization of AAV9 Production in Suspension HEK293 Cells to Develop a Scalable Process for Clinical Supply

Oliver Meade[1], Cuitla Chavez-Pena[1], Xiaotong Fu[1], Mukesh Mayani[2]

[1]Resilience, Inc., San Diego, CA,[2]National Resilience, Inc., Chelmsford, MA

Recombinant AAV has proven to be one of the most promising options for treatment of devastating neuromuscular rare diseases. While AAV platform processes can greatly reduce time to the clinic compared to bespoke approaches, transient transfection performance can vary within an established platform based on serotype and transgene attributes. In this study, a toolbox of rapid optimizations was used to augment the incumbent triple transient transfection platform and significantly improve production vg titer while maintaining % full particles of v1.0 of the process. Using high throughput tools such as the ambr250 bioreactor and Tecan EVO liquid handler, the vg titer of AAV9 encoding a short-length transgene (< 3 kb) for the treatment of a rare neuromuscular disease was improved 2.5-fold at small scale. The resultant process was successfully scaled to 10L pilot reactors in advance of engineering and GMP batches. The process development case study illustrates the effective interplay of platform unit operations with rapidly implementable process improvement levers, achieving clinical supply targets for rare diseases requiring high vg/kg doses.

1029. Analytical Comparability of Four Alternative AAV9 Downstream Processes

James Michael Hatfield[1], Rok Zigon[2], Austin Smith[3], Greg Boyd[4], Stephen Ollosi[3], Ales Strancar[5], Andrew Knudten[6], Maja Leskovec[2], Joseph Balleydier[1]

[1]Research and Development, Advanced Medicine Partners, Durham, NC,[2]PC3, Sartorius BIA Separations, Ajdovscina, Slovenia,[3]Analytical Development, Advanced Medicine Partners, Durham, NC,[4]Process Science, Advanced Medicine Partners, Durham, NC,[5]Sartorius BIA Separations, Ajdovscina, Slovenia,[6]Advanced Medicine Partners, Durham, NC

Improved analytical methods allow us to better understand the capsid heterogeneity in AAV therapeutic preparations. This better understanding allows us to develop manufacturing processes that produce AAV therapeutics with fewer non-functional capsids. We will present the results of a four-arm AAV-9 comparability protocol that includes three alternative 2-column downstream processes at 50-L scale and one ultracentrifugation (UC) process at 200-L scale. We consider the UC process the gold-standard for functional-capsid purification. Simplified process descriptions for the capture and empty/full (E/F) separation steps are listed below. 1. **Capture:** CEX monolith (NaCl gradient), AEX filter (flow-through) **E/F:** UC 2. **Capture:** CEX monolith (NaCl gradient), **E/F:** AEX monolith (NaCl gradient) 3. **Capture:** CEX monolith (pH gradient), **E/F:** AEX monolith (NaCl gradient) 4. **Capture:** Affinity resin (pH step gradient), **E/F:** AEX monolith (NaCl gradient). The analytical-comparability of the drug substance lots will include: Vector yields (vg/mL and capsids/mL), host-cell protein (HCP), plasmid-DNA (pDNA), and host-cell DNA (hc-DNA); Empty, partial, and full capsid content by SV-AUC (Sedimentation-velocity Analytical Ultracentrifugation), CDMS (Charge Detection Mass Spectrometry), and Mass Photometry; vector protein purity by SDS-PAGE and CE-SDS (capillary electrophoresis); aggregation by SEC (size exclusion chromatography); vector DNA purity by DNA gel, long-read and short-read Next Generation Sequencing; potency by *in vitro* eGFP expression; and capsid protein charge heterogeneity by icIEF (capillary isoelectric focusing). AUC analysis will show that the UC method produces highly purified AAV9 Drug Substance with > 90% full capsids while the two-column processes with AEX empty-full separation produce Drug Substances with > 85% full capsids.

1030. Low Endotoxin Control Strategy for an AAV-Based CNS Gene Therapy

Stephen Stephansky, Li Chen, Ying Cai
Ultragenyx Pharmaceutical Inc., Bedford, MA

Bacterial endotoxin is known to cause low to severe inflammatory reactions in patients. Health authorities has established guidelines for the endotoxin test methods and limits in the injectable drug product and medical devices. Medicinal products delivered to the central nervous system (CNS) especially demand a very low level of Endotoxin, which has become a major challenge for the manufacturing process. In developing AAV CNS gene therapies, it is important to understand the potential sources of endotoxin in able to establish a comprehensive control strategy. Raw materials, process solutions, product containers and ancillary supplies must all be scrutinized for low endotoxin levels to minimize potential introduction to the process or product. A robust downstream process with adequate endotoxin clearance capability is equally important to mitigate potential material risks. The endotoxin test method could be optimized to improve its sensitivity and limit of quantification (LOQ). In this work we present a new process improvement to enhance endotoxin control for an AAV based CNS gene therapy. The rAAV gene therapy is produced with the platform Producer Cell line (PCL) process at Ultragenyx. The upstream process consists of cell expansion into a 2000L bioreactors and infection via helper virus adenovirus Type 5 (Ad5). The downstream process consists of depth filtration, chromatography steps, heat inactivation and final formulation and concentration. While the process was demonstrated successful to deliver several 2000L batches, it was noted that solutions used in the final formulation and concentration step require extremely low level of endotoxin, nearly 10-fold lower than assay LOQ. To improve overall endotoxin control strategy, several endotoxin reduction techniques were evaluated, with one endotoxin reduction filter selected and studied. The study demonstrated several logs of additional endotoxin clearance capability for process solutions. Implementing this endotoxin reduction filter has minimal impact to the existing AAV manufacturing process, yet significantly improved process robustness to meet low endotoxin limit required for the CNS Gene Therapy.

1031. Increased Reproducibility in a Critical Downstream Processing Step Allows for Speed to Commercialization of Gene Therapy Product to Treat Leber's Hereditary Optic Neuropathy (LHON)

Scott A. Jeffers
GenSight Biologics, Paris, France

Gene therapy is one of the promising areas in the search for treatments for rare diseases like Leber Hereditary Optic Neuropathy (LHON). Without gene therapy, patients may find themselves afflicted with a disease with few or no options for efficacious treatment. In LHON, this means progressing to legal blindness within a year of first noticing defects in one's central vision. But to be approved, a gene therapy must not only prove itself in clinical trials; it must also have a manufacturing process that can be reliably executed to the highest level of quality. The affinity step in the downstream portion of the manufacturing process is particularly critical for the final drug substance: the step must deliver the recovery and purity of viral vector and must not fail, thereby nullifying the previous steps that had been executed successfully. Choosing the right equipment is a key success factor in getting the affinity step right. For Lumevoq (GS010), this has meant taking specific factors into account, such as reproducibility, monitoring of critical parameters, and ease of use. This talk will focus on this critical downstream step and how GenSight has solved this issue.

1032. Unraveling Impact of Manufacturing Process-Related Stresses on AAV Stability, Aggregation, and DNA Release

Saba Ghazvini, Michelle Jones, Michael Everton, Benson Gikanga, Madhura Som, Sandeep Yadav
Sangamo Therapeutics, Brisbane, CA

As gene therapy use continues to expand, substantial investment has been directed toward the adeno-associated virus (AAV) platform, recognized as one of the most promising delivery vehicles. Since material availability and cost are two of the main challenges of early-stage development, there is a significant need to clearly define the specific assays needed for stability evaluation to minimize material, time, and resources. In this study, we have investigated the impact of some common stress types on the stability of a model AAV6, including thermal, freeze-thaw, exposure to ambient and UV light, agitation, pH variation, and oxidation. To gauge AAV6 stability comprehensively, we employed a diverse array of analytical techniques, including Size Exclusion Chromatography coupled with Multi-Angle Light Scattering (SEC-MALS), Field Flow Fractionation coupled with Multi-Angle Light Scattering (FFF-MALS), Subvisible Particle Characterization using laser obscuration technique and Micro-Flow Imaging (HIAC and MFI), Dynamic Light Scattering (DLS), Free DNA detection via dye binding, and fluorescence measurements during thermal ramping to assess aggregation (Tagg). Results showed that thermal stress had the most significant impact on monomer loss, followed by UV light and low and high pH. Agitation created subvisible particles but not measurable aggregates. Freeze-thaw and exposure to visible light had a minor impact on the monomer loss or aggregate formation. Incorporating separation techniques with MALS furnished additional insights, enabling the quantification of capsid and vector genome (vg) titers suitable for stability screening. Our data provide a deeper understanding of the intricate interplay between stress conditions, aggregation, and particle formation. Notably, detecting aggregation or subvisible particles by HIAC/MFI or DLS in isolation proved insufficient to resolve the overall stability impact. Lastly, the addition of free DNA assay and correlation with SEC-MALS/FFF-MALS provides a more comprehensive picture of the release of DNA and aggregation to enable risk ranking different stresses on AAV stability.

1033. Development and Scale Up of Adeno Associated Virus Transient Transfection Manufacturing Process with Improved Productivity and Product Quality

Ying Liu

CMC, Genomic Medicine Unit, Sanofi, Waltham, MA

Rapidly increasing growth potential of gene therapy requires scalable, efficient and cost-friendly AAV production process. However, manufacturing AAV is not simple, with multiple complex challenges ranging from critical raw material (e.g. plasmids) generation and ensuring high titers of viral vectors, to purification and full capsid enrichment, where not all AAV particles may contain the intended genetic payload. In this presentation, we report our recent advances tackling these challenges. The first improvement was made via changing the packaging system from traditional triple plasmids (Adhelper, Gene of Interest, and Rep/Cap) to a two-plasmids system. This change allowed for 2-3 fold improvement in productivity and an increase of the full vectors generated in cell culture. Interestingly, coupling with an optimized cell feed, we achieved 10-fold increase on AAV productivity across all scales. To ensure a scalable transfection procedure, we employed single use mixing container in the procedure with optimized timing of DNA complex formation and addition. The recent large-scale batch demonstrated the consistency and scalability of the optimized process. Overall, recent advances led to significant improvements on multiple challenges, which enhances our process to yield a high-titer and high-quality AAV. Collectively, these technological breakthroughs will lead the next generation of AAV vector production process which can accelerate the timeline to the clinics and increase accessibility of gene therapy product through reduced COGs.

1034. Analytical Comparison of AAV Manufactured with Triple-Plasmid Transfection/HEK293 and Double-Baculovirus Infection/Sf9 Processes

Shreya Ahuja, Stuart Nelson, Adnan Arnaout, Mary Ng, Garrett Daniels, Andrew Pla, Shital Kakkar, Priyam Raut, Kaavya Maganti, Diogo de Oliveira Pessoa, Sitharthan Kamalakaran, Ilan McNamara, Mansuo L. Shannon, Jorge F. Haller

Prevail Therapeutics, a wholly owned subsidiary of Eli Lilly and Company, New York, NY

Adherent HEK293 triple-plasmid transfection and Sf9 double-baculovirus infection are two widely used GMP AAV manufacturing processes. However, direct comparison between the two platforms, using clinical manufacturing processes with the same vector sequence, has not been well studied. We recently completed an *in vitro* comparability exercise in which these two manufacturing processes were evaluated based on product quality attributes, including release testing, characterization testing, and stability. Final products from both processes showed comparable analytical attributes regarding safety, purity, identity, achievable strength, biological activity, and stress stability. Furthermore, both processes yielded AAV product comprised of viral capsid proteins with identical mass and similar post-translational modifications. In addition, differences in the process residuals, which are inherent to the processes, were observed. Overall, the baculovirus/Sf9 process consistently presented higher levels of full viral capsids, with significantly less AAV partials and empty viral particles. Additionally, the products derived from the baculovirus/Sf9 platform contained less total DNA impurities compared to triple-plasmid transfection/HEK293 process. The main contributor to residual DNA in the triple-plasmid transfection/HEK293 process was plasmid DNA. In contrast, no detectable infectious baculovirus or particle associated Sf9-Rhabdovirus RNA were present in the Sf9 produced drug substance. In conclusion, the double-baculovirus infection/Sf9 process was able to upscale AAV production and deliver a comparable AAV product to the AAV material manufactured from the triple-plasmid transfection/HEK293 adherent process.

1035. Development of HEK293 Cell Line for Optimal Production of Novel Capsids with Enhanced Brain Tropism

Zeynep Guillemin, Varshini Venkatesan, Amanda Ibe-Enwo, Christian Gagnon, Shamik Sharma, Kumar Dhanasekharan

Voyager Therapeutics, Inc., Lexington, MA

Voyager has developed-novel AAV capsids with significantly enhanced brain tropisms and achieved transgene expression that is superior to conventional AAV serotypes in non-human primates. These capsids have the potential to increase the safety and effectiveness of AAV gene therapy. In order to accelerate clinical studies of therapeutic candidates using novel capsids, rapid process development leading to a cost effective manufacturing process is the next challenge. HEK293 cells are the most widely used cell-line for rAAV production and Voyager has internally developed a HEK293 cell line to support our portfolio of AAV gene therapy assets. The VYGR-293 cell line was developed by adapting a serum-fed adherent cell line to a serum-free suspension culture. Further, VYGR-293 cells were optimized for maximum productivity throughout the production process from cell seeding to lysis. Triple transfection parameters of total plasmid amount, cell density at transfection, plasmid to transfection reagent ratio and molar plasmid ratio (Transgene: Rep-Cap: Helper) were tested using Design of Experiment (DOE) studies. Optimal parameters that enabled the highest productivity and %Full capsids were thus selected. The upstream process was further developed by examining optimal N-1 to N split ratios, amino acid utilization during production and time of harvest studies. In addition, multiple additives and commercial transfection additives are explored. VYGR-293 cells achieved 2-4x increase in volumetric titer after these optimization studies, reaching above 2E11 vg/mL. rAAV obtained from VYGR-293 cell line had good product quality profile including high % full capsids. In summary, this cost-efficient cell line provides a good foundation for the development of an AAV expression platform to produce drug candidates for neurological disorders.

1036. An Innovative Affinity Chromatography Approach for Effective Removal of Empty Capsids in Recombinant AAV Products

Tao Wu, Lijun Wang

CoJourney Bio Ltd., Lower Gwynedd, PA

Ensuring the safety and regulatory compliance of recombinant adeno-associated virus (rAAV)-based gene therapy requires the meticulous removal of product-related impurities, particularly empty capsids, from rAAV preparations. While ultra-centrifugation using density gradient is an effective polishing step for rAAV, its scalability is limited. Anion exchange chromatography (AEC) offers satisfactory separation of empty and full capsids, but conventional affinity resins typically lack effectiveness in removing empty capsids. This study introduces a novel affinity chromatographic approach designed for the efficient removal of empty capsids from genome-containing viral particles. The method leverages the differential binding affinity of empty capsids compared to full capsids. We present a comprehensive method for the purification of the rAAV9 vector utilizing POROS CaptureSelect AAVX affinity resin, which holds promise for application across various rAAV serotypes to achieve consistent empty and full separation. Chromatographic enrichment of rAAV9 full particles is accomplished through linear gradients based on Tris buffer at an optimal pH, supplemented with additives. The composition of the affinity column fractions is evaluated using UV and analytical ultracentrifugation, revealing a substantial enrichment of full capsids. This innovative affinity chromatography approach not only enhances the downstream purification process but also holds potential for improving the overall quality and safety of rAAV-based gene therapy products.

1037. Comparing CsCl Density Gradient Ultracentrifugation and Anion Exchange Chromatography for Full Capsid Enrichment of a Novel Adeno-Associated Viral Vector

Roberto Facendola[1], Kavitha Bodige[1], Jacob Guzman[1], Patrick Carroll[1], Kevin Nguyen[1], Tom Elich[1], Shamik Sharma[1], Kumar Dhanasekharan[2]

[1]Voyager Therapeutics, Cambridge, MA,[2]Voyager Therapeutics, Inc., Cambridge, MA

A key challenge in manufacturing recombinant Adeno-Associated Viruses (rAAV) for gene therapy applications is the removal of capsids which do not contain the complete transgene of interest, otherwise known as "empty" or "partially full" capsid impurities. It is common for triple transfection processes using Human Embryonic Kidney (HEK) 293 cell lines to produce more empty capsids than full, which lead to low percent full ratios in the cell culture harvest. Since empty capsids cannot transduce any target cells in a patient, their presence lowers the efficacy of an rAAV mediated genetic therapy. Therefore, robust processes are needed to remove empty and partially filled capsids from rAAV drug product. One technique is cesium chloride density gradient ultracentrifugation which separates empty and full particles by mass. This process is agnostic to capsid structure and can therefore separate full rAAVs from empty rAAVs regardless of the serotype (including modified or engineered serotypes) using standard protocols. The major drawbacks to this method are long process times, lack of scalability, manual product collection, and low step yields. Recently, chromatographic techniques have been emerging as a more efficient method to separate empty capsids. One common chromatographic mode used for this is Anion Exchange (AEX) chromatography. This approach exploits slight charge differences between full and empty capsids to separate them from one another in a bind-and-elute mode. AEX chromatography methods are more scalable and require less process time than ultracentrifugation. However, since AEX purification depends heavily on capsid surface charges, development time is needed to optimize a specific protocol for each serotype and/or engineered capsid. Furthermore, in addition to capsid surface properties, characteristics of the packaged transgene may also impact AEX purification performance. Here, we present data for both ultracentrifugation and chromatographic separation methods for rAAV polishing, and compare performance in terms of full capsid enrichment, process yield, residual impurity clearance, and process time. The cumulative data helps to identify the appropriate purification strategy for a range of biomanufacturing scenarios. Additionally, a review of data generated for multiple capsids and transgene constructs offers interesting insights to the relative influence of capsid and transgene properties on AEX purification.

1038. Separation of Empty and Full Engineered Adeno-Associated Virus Capsids Using a Weak Anion Exchanger

Varun Gejji[1], Hari Acharya[2]

[1]Capsida Biotherapeutics, Thousand Oaks, CA,[2]Capsida Biotherapeutics, Inc., Newbury Park, CA

Gene therapy, using recombinant adeno-associated virus (rAAV) as the delivery vehicle, has shown promising results to treat genetic disorders. To expand the therapeutic space, engineered AAV capsids with improved tissue tropism and transduction efficiency are being developed. As the need to manufacture highly specific engineered capsids grows, several challenges to process scale up persist. One of the key challenges is separating full capsids containing the gene of interest (GOI) from empties. Currently, full and empty capsid separation often relies on ultracentrifugation, however, scaling ultracentrifugation is not feasible. In this work, we explore full enrichment of engineered capsids using anion exchange chromatography. We examine several process parameters including binding conditions (pH and salt), elution conditions (pH, salt concentration, gradient elution, step elution, and hybrid elution profile), loading rates, and resins. Resins screened range from weak to strong exchangers with varying charge densities. Our studies indicate that the binding strength of engineered capsids can significantly differ from the wild type. Elution over different anion exchangers in the presence of various salts or over a range of pH did not yield better separation, likely due to the nature of engineered capsids. We identified several control variables that enabled full capsid enrichment.

1039. Next-Generation Sequencing as a Multi-Attribute Method for Monitoring Critical Quality Attributes of Gene Therapy Products

David Killen[1], Thipa Asvarak[1], Sarah Berger[2], Thomas Hartsch[2]

[1]Genedata Inc., Lexington, MA,[2]Genedata AG, Basel, Switzerland

Developing and producing Advanced Therapy Medicinal Products (ATMPs), such as gene therapies, is a challenging task that involves designing complex vectors, using high-quality cell lines, and complying with strict regulatory guidelines. While these therapies have shown remarkable results, some have caused unexpected problems and delays during clinical trials. To prevent this, it is essential to test the Critical Quality Attributes (CQAs) of the desired therapeutics, which include identity, integrity, and safety. Regulatory agencies, such as the FDA or EMA, can request thorough information from the biopharmaceutical companies about the CQAs of the product during the IND application. For this reason, having a simplified set of tests and the proper technology to measure simultaneously various CQAs of these therapeutics would be highly beneficial. Next Generation Sequencing (NGS) has become a powerful tool for biopharmaceutical companies to automate CQAs testing of gene therapy products. By harnessing the power of NGS technology, high-quality gene therapy products that meet both good manufacturing practice (GMP) requirements and clinical standards can be developed. With automated NGS workflows, biopharmaceutical organizations can speed up the development and manufacturing of gene therapy products and lower the cost of testing their CQAs.

1040. Recombinant Adeno Associated Virus Full Particle Enrichment Using Affinity Chromatography and Scalable Continuous Flow Ultracentrifugation: A Scalable, Flexible and Cost Effective Approach

Gael Mbele[1], Eleonora Leggiero[1], Sara Fabbricino[1], Miriam Centrulo[1], Fabio Perini[1], Bill Vestal[2], Sandra Merino[3]

[1]Innovavector, Pozzuoli, Italy,[2]Alfa Wassermann B.V, Ijsselstein, Netherlands,[3]Alfa Wassermann B.V., Ijsselstein, Netherlands

Adeno-associated virus (AAV) is one of the most promising gene therapy vectors due to their low immunogenicity and large tropism. A robust, reliable and scalable purification process for AAV vectors is essential to the gene therapy industry. To date, manufacturing purification methods for AAV vectors are mostly based on affinity chromatography, for rAAV particles capture, and ion-exchange for full particles enrichment. Purified rAAV vectors, resulting from such biomanufacturing process, still vary according to the packaged genome sizes, including full-genome, intermediate, and empty particles. As empty capsids are thought to reduce transduction efficiency and can induce unexpected immune responses, there is an exponentially increasing demand for improved purification strategy with the aim of lowering the empty particles content to properly support rAAV-based preclinical and clinical studies. In addition, IEX ion exchange chromatography steps can be time-consuming to develop because they depend on the serotype being used. Alfa Wassermann scalable continuous flow ultracentrifuges meet all the demands of cGMP manufacturing for viral vaccines and viral vector gene therapy products and provide a scalable solution to move from laboratory tube rotors to industrial scale ultracentrifugation. Here we report an approach, based on density gradient ultracentrifugation that combines concentration and purification in a single step, reducing the total number of process steps and process time. This directly increases the overall yield, production capacity and product quality with the benefit of remaining flexible for multi-product purification as the separation methodology is serotype independent. Therefore, we reasoned that coupling affinity chromatography with a centrifugation polishing step can be a fast, efficient and cost-effective approach to provide high yield of purified rAAV with a high content of full particles. Here, we report a side-by-side comparison of rAAV8 product profiles obtained either by; 1) 2 steps chromatography (affinity and IEX) based approach and 2) affinity chromatography followed by continuous flow ultracentrifugation.

1041. Bioprocess Optimization for Improved AAV Titer and Percent Full Capsids with a Sf-Rhabdovirus-Negative Insect Cell Line and CD Insect Cell Medium

Sandra McNorton

MilliporeSigma, Lenexa, KS

The resurgence of gene therapies is providing lifesaving options to patients with otherwise untreatable diseases, leading to increased demand for large amounts of high-quality viral vectors. Adeno-associated virus (AAV) is one of the leading viral vector platforms. The insect cell based Baculovirus Expression Vector System (BEVS) based on baculovirus infections for production and Baculovirus Infected Insect Cell system (BIICs) based on infected cells for production are being utilized by biopharmaceutical companies to achieve large volumes of high-quality recombinant adeno-associated virus (AAV) to treat genetic diseases. *Spodoptera frugiperda* (Sf) cell lines are widely used as hosts for BEVS and BIIC. However, the majority of Sf9 and Sf21 cell lines contain a Sf-rhabdovirus which is considered a process contaminant and must be eliminated from the product. To improve the safety profile of the BEVS and BIIC production methods, we developed a high performing Sf-rhabdovirus-negative (Sf-RVN®) Platform, composed of an Sf9 rhabdovirus-free cell line with an optimized chemically-defined medium (EX-CELL® CD Insect). In this study, we optimized the MOI and RepCap:ITR-GOI ratio for AAV production with the BEVS and BIIC systems using our GMP Sf-RVN® insect cell line (developed by GlycoBac LLC) cultivated with our chemically defined medium to achieve high titers in bioreactor tubes, and further increased AAV production and percent full capsids with the BIIC system using post-infection feeds.

1042. Comparison of AAV Downstream Purification Process Using Chromatography and Density Gradient Ultracentrifugation

Smriti Mishra[1], Matthew Kuc[2], Lori Mullin[2], Joe S. Orlando[2]

[1]Virus and Gene Therapy Bioprocessing, MilliporeSigma, Bedford, MA,[2]MilliporeSigma, Bedford, MA

Recombinant adeno-associated viral (rAAV) vectors provide an efficient and effective tool for therapeutic gene delivery. During genome packaging in host cells, a heterogeneous population of vectors is produced consisting of full, empty, and partially full capsids. An excess of empty capsids in a therapeutic dose can trigger unintended immune responses; therefore, therapeutic potency requires the removal of empty capsids for final formulation. Empty and full capsids are similar in their physical characteristics and vary slightly in isoelectric point (pI) and density which makes separation challenging. Here we compare two methods for the separation of empty and full capsids based on the mentioned characteristics. A cesium chloride (CsCl) density gradient ultracentrifugation (DGUC), that is AAV-serotype independent and a chromatographic method utilizing AEX resins. We demonstrate the capabilities, efficiencies, and challenges of two methods using models AAV2 and AAV5 in downstream vector processing. Both methods are evaluated from similar start material using affinity capture chromatography feed. Our findings demonstrate the deeper understanding and importance of the two methods in terms of their usage depending on the requisites of the final formulation. Each method provides flexibility based on the therapeutic drug product's production scale, availability of instruments, raw materials, and technical expertise.

1043. Optimization of Scalable rAAV Production for Gene Therapy - Leveraging At-Line Amino Acid Measurements for Bioprocess Modeling-Driven Approaches

Prasanna Srinivasan[1], John Joseph[1], Tam N. T. Nguyen[2], Graziella Piras[3], Ji Young Anderson-Czajkowski[3], Milla Neffing[3], Scott Miller[3], Anthony J. Sinskey[4], Richard D. Braatz[5], Jackie Wolfrum[1], Paul W. Barone[1], Stacy Springs[1]

[1]Center for Biomedical Innovation, Massachusetts Institute of Technology, Cambridge, MA,[2]Research and Development, BioNTech, Cambridge, MA,[3]908 Devices, Boston, MA,[4]Department of Biology, Massachusetts Institute of Technology, Cambridge, MA,[5]Department of Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA

Impact: Utilising mechanistic models for HEK293 rAAV production and at-line spent media analysis for data-driven process intensification and yield improvement by cell culture media and feed optimisation. **Introduction:** rAAV viral vectors (VV) used for *in vivo* gene therapy are commonly produced using transient transfection of HEK293 cells. Although this method is well established, challenges remain in achieving high VV titer and a high ratio of full-to-empty capsids. Our aim is to build a mechanistic understanding and knowledge of amino acid (AA) consumption to guide the development of advanced manufacturing processes. The resulting model-driven approach is used to design, predict, test, and optimize VV production processes - scaling up and transferring to a continuous process at bioreactor scale. Media optimization can be a laborous process involving multiple DoEs. Rapid and simple analytical tools at the point-of-use are required to quickly assess key-nutrient consumption and provide feedback to optimize feed and supplement addition strategies. In this study, we performed data-driven media screening and optimization experiments leveraging a fast, at-line amino acid analyser, REBEL. **Methods/Approach:** For initial experiments, rAAV was produced via transient transfection in a fed-batch 300 mL mini-bioreactor and in the shake flasks. Samples were collected to identify potential AA depletion that may impact capsid titre. **Results:** Asn is an important AA building block and constitutes ~10% of capsid protein composition. Results show clear differences in fluxes of Asn and Asp, which were reported previously as candidate AAs for producing viral particles. Other essential AA also exhibited strong depletion, indicating opportunities to optimize cell culture conditions. With subsequent experiments, the impact of AA addition to the cell culture was assessed with the goal of improving vector titre. **Conclusion:** This work is relevant to addressing key challenges of rAAV production platforms via process engineering and optimization of cell culture conditions to scale-up vector production and development of continuous bioprocessing of rAAVs. The technology used uniquely enables at-line AA measurements, leading to deeper insights and informed feeding strategy optimization.

1044. Harnessing the Power of High-Throughput Virology and Design of Experiment for Rapid Vector Production Process Optimization

Jean-Simon Diallo, Jondavid De Jong, Keara Sutherland, Tianxiao Yang, Andrea Vervoort

Virica Biotech, Ottawa, ON, Canada

Introduction: Biomanufacturing of cell and gene therapies is a complex process, hampered by variability in yield, quality, and scalability of manufacturing platforms. Production parameters can be key drivers for vector quality, quantity and cost, making them prime process optimization targets. However, assessing all possible variables and understanding their interactions with product output and each other can be a convoluted and time-intensive task when using traditional one-factor-at-a-time (OFAT) process optimization strategies. **Methods/Approach:** A high-throughput, 96-well format virology platform using transduction-based quantification of luciferase reporters allows for rapid quantification of various produced viral vectors. We developed transfection-based production and quantification assays for AAV (suspension 293) and lentivirus (adherent 293T) and used DoE statistical methods to optimize up to six different production parameters simultaneously. This approach of combining high-throughput virology assays with DoE is amenable to various vector production platforms, including replicating viruses, reverse genetics and inducible systems. **Results:** AAV production in suspension HEK293s was optimized, with the methodology allowing simultaneous optimization of up to six factors, including total DNA, nucleic acid type, cell count, transfection reagents, and addition of small molecule enhancers for optimization of AAV production. Additionally, LV production optimization in adherent HEK293T by full factorial combination of various plasmid ratios was performed. Importantly, the optimized conditions identified at small scale were translatable to larger-scale formats, demonstrating scalability. **Conclusion:** We demonstrate that combining high-throughput assays with the statistical power of DoE enables process optimization of multiple factors in time-frames not achievable through traditional OFAT methods. Furthermore, we exemplify how the output data can be used to optimize processes for various factors, including transduction signal, TU/mL,

vg/mL or even cost/vg. The flexibility of optimizing different outputs from a single data set unlocks the potential for data-driven decisions to maximize production processes based on strategic needs.

1045. Increased Viral Vector Yield: Development and Scale-Up Validation of Small Molecule Enhancers

Jean-Simon Diallo, Jondavid de Jong, Keara Sutherland, Andrea Vervoort

Virica Biotech, Ottawa, ON, Canada

Manufacturing gene and cell therapy vectors are complex and expensive, often resulting in insufficient yields to satisfy commercial demand. While advancements have been made in manufacturing strategies, the industry faces major challenges in production consistency and yield. It is also important to understand the key cost drivers of these production processes, which are crucial to creating more accessible and affordable therapeutics. An often overlooked bottleneck in cell culture-based manufacturing is the presence of cellular innate antiviral defenses that remain intact in producer cells. These well-conserved pathways are triggered via the detection of foreign nucleic acid and/or molecular by-products of viral replication/assembly, resulting in blunted viral vector yields in infection and transfection-based manufacturing strategies. Virica's Viral Sensitizers (VSEs™) encompasses a proprietary collection of small molecules that enhance the growth of viruses by transiently and efficiently dampening cellular antiviral defenses. Leveraging high-throughput methods, Virica has assembled a library of over 130 small molecules that enhance viral production by transiently antagonizing a broad range of innate cellular antiviral pathways. Owing to different molecular mechanisms, VSEs can be combined and formulated for specific uses across various viral and cellular platforms. Here we describe the development of custom small molecule formulations for enhanced production of therapeutically relevant vectors, including AAV (Adeno-Associated Virus) and lentivirus, using high-throughput methodologies. We present validation data supporting the scalability of AAV8-specific custom formulations yielding multi-fold increases (>2x) in genomic titer, capsid titer, as well as full to empty ratio in formats representative of large-scale commercial platforms, including the Ambr®15 microbioreactor system and bioreactor systems up to 5L working volume. Applicability of VSE technology in commercially relevant non-transfection based systems for lentivirus production is also shown; the addition of VSEs in a fully inducible suspension-based HEK293 system demonstrated over 3-fold enhancement in functional lentivirus titer. Finally, Virica uses bioprocess modelling to offer insights into manufacturing cost drivers to inform the long-term feasibility of various production strategies. Considering key modelling output metrics such as global, economic and environmental impact allows for more informed decision-making when considering multiple manufacturing strategies to increase yield. Ultimately, this data supports the broad applicability of small molecule enhancers, such as Virica's VSEs, and their use as a novel and economically feasible solution for increased production of viral vectors at scale.

1046. Finding the Needle in the HEKstack: Media Screening for AAV Production in HEK293

Pia Brinkert, Kathrin Teschner, Alyssa Buve, Vera Ortseifen

Sartorius Xell GmbH, Schloß Holte-Stukenbrock, Germany

Adeno-associated viruses (AAVs) are the leading platform for *in vivo* gene therapy. To date, transient transfection of HEK293 cells is state-of-the-art for AAV production. Despite extensive research, low productivity is limiting a broader clinical application. To overcome this, it is essential to approach and improve AAV production from multiple angles. For instance, the choice of culture medium has a major impact on AAV yield. Hence, we developed a cell culture medium tailored to the needs of AAV production, i.e., allowing for transient transfection, high growth rates, and high AAV titer. In addition, the medium was sought to contain a minimum number of components to reduce the variance and complexity in raw materials, to increase process robustness, and to reduce downstream interference. Initially, a minimal medium was produced which however did not allow for stable growth of HEK293 cells at shake flask scale. The medium was refined in a design of experiment (DoE) approach using MODDE®. Monitoring cell growth in shake flasks led to the identification of a group of essential vitamins. To assess the benefits for AAV production, three media variants were used in a transient transfection process with FectoVIR®-AAV. One media variant resulted in higher AAV genomic titer compared to the reference medium. To further increase AAV yields, this variant was supplemented with components selected based on AAV biology. Addition of a translation regulator led to a more than 100% increase in AAV genomic titer compared to the reference. Importantly, such titer increase was reproducible in a regulated system such as the Ambr®15. In conclusion, the combination of a DoE approach together with a rational design enabled the development of a lean HEK medium for stable HEK293 cell growth and high AAV titers. Thereby, it will contribute to overcome the current limitations of AAV production processes.

1047. A Novel Cell Lysis Solution with Advantageous Use Characteristics for rAAV Manufacturing That Can Lead to Greater Downstream Recovery by Minimizing Upstream Loss

Nandu Deorkar, Courtney O'Dell, Lori Fortin, Nima Sedaghat, Breanne Schwing, Rejean Wang, Jungmin Oh, Arvind Srivastava

Avantor, Radnor, PA

Many gene therapies and viral vaccines rely on a high dose of recombinant adeno-associated virus (rAAV) to deliver therapeutic DNA to patient cells, which may be challenging. Improving titer during the upstream process is important but recovering the titer during the harvest process is critical. Recovery of assembled rAAV particles can be challenging as their cytoplasmic localization requires release through cell lysis and separation from resulting cellular debris. Chemical lysis is the industry favored method of lysis to retrieve rAAV due to its scalability as well as other factors; however, variable recovery and

need for environmental regulatory compliance has led to continuous development and testing of chemical solutions. In this presentation, we will demonstrate the benefits of using a novel cell lysis solution which can rapidly rupture cell membranes across a wide range of operating conditions, is compatible with traditional DNA removal agents and also provides preferential yield and titer of rAAV. The features of this cell lysis agent, along with ease-of-use qualities such as relatively low viscosity and room temperature stability at storage conditions, make it the optimal solution to improve the overall viral vector manufacturing process by providing robust and efficient cell lysis that may allow for high titer rAAV recovery.

1048. In-Line and On-Line Monitoring of Key Cell Culture Parameters for Robust Cell and Gene Therapy Bioprocess

Christopher D. Brown[1], Colin Gavin[1], Stephen Driscoll[1], Wolfgang Kuennecke[2], Michael Hartlep[2], Milla Neffling[1], Boris Aleynik[1], Graziella Piras[1]

[1]908 Devices, Boston, MA,[2]908 Devices, Braunschweig, Germany

Over the last 20 years the industry has achieved remarkable success with mAb-based therapeutics, and extraordinary advances in mRNA-, cell- and gene-based therapeutics are becoming everyday news. However, predictive bioprocess development and control is (still) hard, especially with patient-specific therapies. Technologies for near real-time bioprocess characterization have rapidly advanced in recent years, expanding the panel of readily accessible process and product attributes. Fundamental chemical and physical engineering factors (dissolved gases, pH, temperature) have been measurable in/on-line for some time. Biological activity assays are conducted frequently, but are labor intensive, and some too slow to be actionable for improving therapy outcomes. Gene therapy manufacturing know-how has advanced in recent years due to increased efforts to tackle the many challenges in viral vector bioproduction. However, the HEK293 process is still dependent on key cell culture components and feeding strategy optimization. HEK293 nutrient (such as glucose) control to avoid the accumulation of toxic metabolites (such as lactate), is a key consideration in intensified and extended manufacturing processes. Parameters that influence cell culture viability, transfectability and resulting viral vector titer and quality are critical to understanding and control in an efficient manner. We discuss a novel Raman-based analytical solution that does not require any chemometric modeling for implementation. We describe the automated control of glucose with plug-and-play in-line monitoring and feedback loop. Cell therapy manufacturing needs efficiency and robustness to consistently produce products with improved treatment outcomes in patients. The cell therapy manufacturing process is dependent on multiple stages of cell manipulation, throughout which cell growth and health are imperative. Continuous, automated (on-line) measurement of process key components, lactate and glucose, enable data-driven decisions to be made for an effective cell product manufacturing process. However, this has been challenging due to the low level of analyte measurements required, small batches, and processing bioreactors and methods currently used. We discuss an automated on-line, biosensor-based analytical solution for various cell therapy bioprocess scales and processes. We will discuss recent advances in these cell and gene therapy bioprocess analytical technology regimes, approaches to real-time analytical modeling/calibration of these systems, and how their informing power can be leveraged for predictive bioprocess optimization.

1049. AAV-Based Gene Therapy Development: Some Real Concerns, Some 'Empty' Threats

Rajiv Gangurde

Cell & Gene Therapy, Regulatory Strategy, Parexel, Newton, MA

With five FDA-approved products and more than 130 ongoing clinical trials, AAV-based gene therapy has come a long way as a modality to challenge a wide variety of diseases. Long-term efficacy has been demonstrated in different organs, including liver, eye, and the central nervous system. However, some concerns, challenges, and threats continue to loom over the use of AAV vectors. Related to CMC, off-target transduction, immunogenicity, and residual impurities pose safety concerns. Manufacturing strategies for high-dose, systemic delivery products continue to be a challenge. The threat of empty capsids, whilst debate-inducing, remains elusive and poorly understood. Of the 33 clinical holds imposed by the FDA on cell and gene therapy products during 2020 - 2022, 15 are for AAV-based gene therapies. While majority of these holds are for clinical reasons, CMC deficiencies, such as lack of device compatibility, manufacturing inconsistencies, and product instability, are some of the main culprits according to the FDA. This talk focuses on these critical areas from a CMC and regulatory perspective, with specific examples of AAV serotypes in clinical trials, evolving regulatory guidance, and the need for analytical harmonization across the industry. Phase-appropriate CMC strategies to mitigate known risks for AAV gene therapy development are discussed.

1050. Enabling Commercial AAV Manufacturing by Xcite® AAV Stable Producer Cell Lines

Gang Li[1], Chien-Ting Li[1], Khanh Ho[2], Friedrich Michael Haller[1], Leila Aneke[1], Jiasong Jiang[1], Peng Wang[1], Tam Duong[1], Senthil Ramaswamy[1], Bingnan Gu[1]

[1]Research & Development, Lonza Houston Inc., Houston, TX,[2]Process Development, Lonza Houston Inc., Houston, TX

The superior safety profile and transduction efficiency make AAV an excellent viral vector for human gene therapy. However, current AAV manufacturing suffers from low productivity and scalability, high raw material cost and supply chain complexity, and high batch-to-batch variation. To overcome these limitations and industrialize AAV manufacturing, we have generated a high-performing, helper virus-free, Xcite® AAV stable producer cell line (PCL). The cell line is built upon our proprietary high-producer HEK293 cells used for AAV transient transfection platform, grown in chemically defined, serum-free, ADCF medium in suspension. The DNA expression vectors are designed to tightly control viral gene expression via engineered inducible promoters, and stably integrated into the cell genome in one step by our VS *piggyBac*™ transposon system, which markedly increase the efficiency of cell line construction. Upon small chemical doxycycline induction at regular cell density, our selected PCL clones outperform transient transfection method with even higher AAV

titer (>1E12 vg/mL) and comparable AAV genome packaging (>30% full capsids) at harvest. Moreover, these cells maintain the stability of AAV productivity and packaging over 30 cell passages corresponding the scale far beyond 2000 liters. Taken together, our Xcite® AAV stable PCL represents a next-generation platform that can enable high-quality commercial AAV manufacturing at large scale with significantly reduced cost and process complexity.

1051. Developing Faster and Easier AAV Purification Protocols with the AAVone System and Purpose-Built Ultracentrifuge Rotors

Cuiping Chen[1], Aparna Jasti[2], Yuyan Wang[1], Yu Liu[1], Leming Wang[1], Shawn M. Sternisha[2], Qizhao Wang[1], Daozhan Yu[1]

[1]AAVnerGene Inc., Rockville, MD,[2]Beckman Coulter Life Sciences, Indianapolis, IN

At AAVnerGene, we have developed a novel one-plasmid adeno-associated virus (AAV) production system called AAVone, which allows for greatly enhanced productivity, simpler protocols, higher consistency, reduced production time, and dramatically lower costs. It makes providing on-shelf AAV vectors for researchers more realistic. However, downstream purification is often the bottleneck in AAV production. Although chromatography offers some advantages, the purest and safest AAV products are generated using ultracentrifugation. Most common rotors can only hold 6 or 8 tubes, making sample purification throughput limited and tedious. Here, we developed faster and easier protocols using two high capacity rotors, the VTi 50.1 and Type 45 Ti. The VTi 50.1 can hold 12 tubes and each tube has 39.5 mL loading capacity, enabling more samples to be processed in a single run. The Type 45 Ti rotor can hold six tubes of approximately 100 ml each, which makes it perfect for processing large volume samples. We used both rotors to develop better protocols for small or large volume AAV productions with either cesium chloride or iodixanol gradients. The new protocols require fewer steps, simple sample preparation, lower ultracentrifuge run time and less effort. The purified AAV exhibits high yield, quality, infection and expression. In conclusion, optimization of the ultracentrifugation step can speed up the AAV production and reduce the cost, facilitating AAV gene therapy research and drug development.

1052. Process and Formulation Development for a Novel Blood-Brain Barrier Penetrant AAV Capsid

Taeho Kim[1], Zelong Xie[1], Saba Ghazvini[1], Jada Padilla[1], Alex M. Ward[2], Matthew R. Tiffany[2], David Ojala[2], Nikul Patel[1], Anthony Chikere[1], Phillip Ramsey[1], Sandeep Yadav[1]

[1]Sangamo Therapeutics, Brisbane, CA,[2]Sangamo Therapeutics, Inc., Richmond, CA

Recombinant adeno-associated virus (AAV)-based vectors for therapeutic gene delivery have shown great promise due to their excellent safety profile, ability to target a wide range of tissues, stable transgene expression, and may offer significant clinical benefits. However, conventional AAV serotypes have limited ability to cross the blood-brain barrier (BBB) and deliver therapeutic cargo to the central nervous system (CNS). Capsid engineering approaches have the potential to improve AAV delivery and tissue specificity including the ability to cross the BBB and deliver therapeutic cargo for CNS indications. The successful progression of these engineered capsids through clinical development will require a robust manufacturing process and stable formulation that enables large-scale production of these novel AAV vectors. In this study, we report the development of a scalable process for the production and purification of a recently identified engineered AAV capsid with the ability to cross the BBB in nonhuman primates. Further, a stable formulation was developed to enable optimal shelf-life and DP presentation aligned with the target product profile for CNS indication. Critical quality attributes such as titer, empty/full ratio, aggregation, purity, and potency were evaluated to demonstrate process and formulation performance. Both suspension HEK293 and *Sf*9 production platforms were evaluated and optimized to maximize capsid yield and purity. The HEK293 triple transfection process was optimized for various process parameters including transfection reagent to DNA ratio, cell density, total DNA amount, and transfection incubation time. Furthermore, a purification process was developed using a combination of scalable affinity capture and ion-exchange chromatography steps. Purification parameters such as pH, salts, and flow velocity were optimized to maximize recovery of the engineered AAV capsid variant and separate empty and full capsids. The optimized process parameters deliver a robust and scalable manufacturing process and formulation with product quality attributes critical to advancing novel viral vectors and genomic medicines in CNS applications.

1053. Evaluation of Cell Growth and AAV Production in a Fixed-Bed Bioreactor to Streamline Process Development

Anne MacIntyre, Nathan Hazi, Andrew Laskowski, Michelle Olson Peabody

Cytiva, Westborough, MA

The demand for viral vector-based gene therapies continues to grow as FDA approvals accelerate and the number of potential indications increase. To remain competitive, companies must streamline viral vector development timelines using advanced systems and efficient processes. For adherent cell culture processes, the iCELLis Nano bioreactor is an automated, single-use, fixed-bed bioreactor that facilitates excellent cell growth and volumetric productivity and offers high flexibility for gene therapy development. We evaluated how select process parameters affected cell attachment, cell growth and distribution, and recombinant adeno-associated virus serotype 5 (rAAV5) production in the iCELLis Nano bioreactor. We performed a series of growth and rAAV5 production cell culture runs using a HEK293 cell line. We evaluated the impact of linear speed and presence of Pluronic F-68 on cell growth and distribution. We also evaluated the impact of linear speed, cell density, and total DNA concentration during transient transfection on rAAV production. Pluronic F-68 exhibited no impact on cell growth, while linear speed was shown to influence cell growth and overall cell distribution. At the time of transfection, the cell density and total DNA concentration displayed an effect on rAAV production yield, while linear speed did not. The results highlight areas

of process robustness when using the iCELLis Nano bioreactor. They also suggest focus areas for process development when evaluating cell growth and rAAV production.

1054. Novel Solutions for Quality Control in Gene Therapy Viral Vector Development

Andrea O'Hara[1], Crystal Richardson[1], Chris Mozdzierz[1], Haythem Latif[1], Ginger Zhou[2]

[1]Azenta, Burlington, MA,[2]Azenta Life Sciences, Burlington, MA

Interest in gene therapy-based disease prevention and treatment has grown rapidly over the last decade. While lentivirus has historically been the viral vector of choice for gene therapy, recombinant adeno-associated viral (rAAV) vectors have seen widespread application in recent years due to the non-integrating ability. Baculoviruses are emerging as a highly adaptable vector with a broad tissue and host tropism. Regardless of vector, extensive quality control (QC) throughout the entire development and manufacturing process is essential. A robust QC process expedites safe and effective commercialization of the final product. While Sanger sequencing can be ideal to verify and validate plasmid sequences pre-packaging, next generation sequencing (NGS) combined with post-viral production methodologies such as CE analysis and transmission electron microscopy offer an effective high-throughput approach for monitoring AAV quality, from initial construct assembly to analysis of the encapsulated product. Both Illumina® short-read and PacBio® long-read sequencing technologies offer distinct advantages including sequencing of the entire viral genome, with detection of potential mutations, truncations, and contaminants. Here we describe our novel proprietary vector-agnostic workflows, for use in lentiviral, AAV or baculovirus settings. Starting with high quality synthesis of either vector plasmid or region of interest, full-length plasmid sequence is confirmed. Depending on these results, correction or new synthesis of plasmid options are applied. Following packaging within the viral vector system of choice, QC results using both short- and long-read NGS platforms are supported with a regulatory-compliant Sanger assay. State of the art synthesis reduces potential upstream errors. Sanger ITR sequencing and sequence correction upstream alleviates potential downstream issues in viral packaging. High-quality viral packaging ensures robust viral titers for downstream use. The combined NGS approach post-packaging alleviates current constraints for high throughput AAV sequencing and thereby enhance the overall QC process. Our Good Laboratory Practices (GLP) Sanger sequencing method extends read lengths through the entire ITR regions, allowing for rapid sequence confirmation of the final AAV product. The combination of these approaches enables a comprehensive solution, ideal for sequence confirmation of both transfer plasmid and final packaged product for improved viral vector gene therapy manufacturing in advance of FDA or EMA filings.

1055. Establishment of a Scale-Down Model for Robust and Cost-Effective Adeno-Associated Virus Process and Analytical Development and Characterization

Berenice Carrillo, Ran Li, Swathi Kuppireddy, Karina Cabrera, Gabrielle Huang, Alexa Truong, Weijie Yao, Liying Yang

PackGene Biotech Inc, Houston, TX

Adeno-associated virus (AAV)-based gene therapy has emerged as a promising approach for treating a wide range of genetic disorders. Despite advancement of innovative technologies and methodologies, AAV gene therapy is still facing a series of CMC challenges including those in upstream three-plasmid transient transfection and downstream empty/full viral particle separation, necessitating the development of robust and scalable manufacturing processes. For enhancement of process robustness, scalability and cost-effectiveness, we have established an integrative scale-down model for AAV manufacturing process development and optimization. The platform includes cell culture, transfection and lysis in a multi-well (MW) plate for upstream viral production, as well as cell lysate clarification, virus capture and elution with a spin filter column/plate for downstream crude purification. Multiple samples can be generated from different unit operations during the platform execution for AAV analytical characterization including titer, identity, purity, impurity and potency . We have shown that cell culture performance in MW plates have demonstrated a growth profile similar to that in shake flasks and bioreactors. Cell transfections performed in MW plates and shake flasks also result in comparable viral titers and empty/full ratios. After lysate clarification and optimized affinity purification with the spin filter column/plate, the purified viral samples can be subjected to more sensitive assays for characterizing critical quality attributes including process- and product- related impurities such as residual host cell DNA (HCD), protein (HCP), E1A oncogene and plasmid. In summary, the scale-down model developed in this study provides a cost-effective and efficient platform for process optimization and analytical characterization of AAV manufacturing process, and serves as a valuable tool for researchers and bioprocess engineers to investigate impact of various process parameters in AAV production process and critical quality attributes.

1056. Optimizing the Scalable Production of Recombinant Adeno-Associated Viral Vectors for Gene Therapies

Evan Tan, Patric Chua, Nurul Atiqah Herman, Alif Sufiyan Ali, Nur Izzati Soonaan, Wei Zhang, Say Kong Ng

Animal Cell Bioprocessing, A*STAR Bioprocessing Technology Institute, Singapore, Singapore

Background and novelty. Viral vectors based on adeno-associated virus (AAVs) have shown safety and efficacy as gene delivery vehicles. Viral vector production remains challenging as current production methods are not scalable. rAAVs are typically produced by the transient transfection of adherent HEK293 cells in serum-containing media and purified using ultracentrifugation. Upstream production

processes utilising serum-free suspension-based transfection process coupled with centrifugation-free downstream purification process allows for a scalable and efficient purification platform, essential for producing high-quality AAV vectors. Here, we describe an optimised serum-free suspension-based transient transfection process and a centrifugation-free downstream purification process capable of producing >10^{14} vg/L, post-purification. **Experimental approach.** rAAVs were produced by transfecting cells, in suspension, using PEI-MAX with plasmids pHelper, pAAV_RC2, and pAAV_GFP. Transfection process was optimised using DoE, with cell density at transfection and the concentrations of each plasmid as variables to be optimised. The optimised transfection process was validated in flask-scale production and the scalability of transfection process was demonstrated in 2L stirred-tank bioreactors. Lysis of the rAAV-containing culture was performed via a chemical-based approach utilizing Tergitol™ and nuclease. The lysate was then clarified using depth filters and then concentrated with ultrafiltration and diafiltration (UFDF). The primary capture step was performed using affinity column chromatography, whereas subsequent polishing was performed on anion exchange column chromatography for the separation of empty and full capsids. The final stage involved another round of UFDF to carry out buffer exchange, resulting in the final formulation of the AAV for use or storage. **Results and discussion.** rAAV titers obtained could be improved 2.3-fold after DoE optimization. In flask-scale productions, our current process yields rAAV titers comparable to commercially available workflows. Volumetric titers obtained in 2L STB are comparable to flask-scale productions. Similarly, we demonstrated a scalable, chromatography-based purification process as opposed to ultracentrifuge-based method. Enrichment of full capsids, assessed using a combination of TEM, PCR and ELISA assays, was up to 4-fold. Sufficient removal for impurities i.e., residual host cell protein and DNA, nuclease, and endotoxins, was also achieved. In addition, we have developed a streamlined and improved qPCR method for AAV quantification which performs comparably with dPCR.

1057. How to Resolve Vector-Based Therapeutics Major Manufacturing Pain Points by Innovation-Driven Collaborations

Rachel Legmann[1], Rene Gantier[2], Keen Chung[2], Kathleen Mihlbachler[3], Ganesh Krishnamoorthy[4], Frank Agbogbo[5]

[1]Gene Therapy, Repligen, Waltham, MA,[2]R&D, Repligen, Waltham, MA,[3]Systems, Repligen, Waltham, MA,[4]PD DSP, Forge Biologics, Grove City, OH,[5]PD, Forge Biologics, Grove City, OH

With increasing approvals of viral vector-based gene therapies, the industry is shifting its focus to the expansion of viral vector manufacturing to meet the demands of the growing number of therapies on the market. The higher complexity of viral vectors compared to monoclonal antibodies or recombinant proteins creates additional production and purification challenges to overcome. Therefore, collaboration, better fit innovative platforms and expertise are crucial for rapid continuous improvements in the efficiency of viral vector production to meet demand and get lifesaving therapies to patients quickly. This must be carefully balanced with consistency and quality of the final product. Multiple applications and technologies to address current manufacturing challenges and solutions to increase overall viral vector yield throughout development will be explored. Collaborative case studies will be presented to demonstrate the progress associated with entire process intensification and optimization from benchtop development to large-scale commercial manufacturing. Upstream process intensification strategies using the KrosFlo® tangential flow depth Filtration (TFDF®) technology, a perfusion platform for lentivirus and AAV high production and clarification will be presented. Two experimental upstream studies illustrate the next generation manufacturing process for AAV and LV viral vector intensification using HEK293 cells in suspension. In both experimental studies, the TFDF, a perfusion platform, was integrated into the bioreactor to intensify AAV8 viral vectors and in the second study lentivirus (LV) was intensified. The TFDF, a perfusion integrated platform, increased the HEK293 cell density by 3 X fold at time of transfection led to increase up to 10 X fold of total titer of rAAV8 and rAAV9. The cell retention filters enabled the continuous harvest clarification of secreted AAV8 particles into the media during the virus production, demonstrating the potential for continuous upstream-downstream processing of secreted AAV vectors. The TFDF platform increased lentivirus (LV) yield up to 86 X through synergism between high cell density, higher specific productivity, and continuous harvest approach. Overall, the TFDF platform enables manufacturers to meet high vector demand and potentially reduce the cost per dose. We will also present the collaborative effort with a gene therapy CDMO that involved a detailed evaluation of scaling up the affinity chromatograph step for AAV9 from a 1-L benchtop chromatography scale to a 167-L industrial scale using the innovative single-use advanced KRM™ Chromatography System. The large-scale tests were sequentially executed with the benchtop-scale tests in parallel. All process fractions were analyzed by Droplet Digital PCR. It also demonstrated high reproducibility between the scale-up runs without compromising quality product attributes such as empty and full ratio, endotoxin, residual host cell protein and aggregation. This successful AAV scaleup demonstrated a 240-fold increase in the overall viral recovery that is 1.4 X fold higher than predicted, as well as good reproducibility of the scale-up runs. The innovative KRM™ Chromatography Systems enabled high productivity and cost-effective manufacturing of viral vectors, including AAV and lentivirus, through novel design features like low hold-up volumes, gentle internal flow paths, and accurate pump performance. The results of this case study will further demonstrate the capabilities to scale-up form 500-L to 5000-L manufacturing scale bioreactors.

1058. Whole Genome High-Throughput Screen Identified microRNAs Enhancing rAAV Production

Bettina Finkbeiner[1], Madina Burkhart[2], Sabrina Reichl[1], Rupert Derler[1], Andreas Schulze[1], Florian Sonntag[1], Kerstin Otte[2], Markus Hoerer[1]

[1]Ascend, Planegg, Germany,[2]Institute for Applied Biotechnology, Biberach University of Applied Sciences, Biberach an der Riss, Germany

Recombinant adeno-associated viruses (rAAV) have become the leading vector for gene therapy in recent years. However, manufacturing bottlenecks pose a severe challenge to provide the required high quality rAAV amounts for increasing clinical and commercial demands. Scale-up of vector manufacturing and additional capacities are now commonly observed. However, further increase in cell-specific and

volumetric rAAV productivity are still neglected strategies to drive rAAV yields and beyond that potentially rAAV quality. MicroRNAs are short non-coding RNAs playing a crucial role in the regulation of gene expression during virtually all cellular processes and were already successfully exploited to boost the manufacturing of classical biologics. Therefore, microRNAs are considered a useful tool to overcome critical bottlenecks in rAAV vector production that, if addressed, could drive rAAV production efficiency towards the required levels. Based on the Ascend HEK293 cell line and split two plasmid system we have developed a robust modular suspension platform process for rAAV production, that is optimized towards yield at best possible and consistent quality from bench to 200 L scale. For a systematic identification of host cell factors that significantly impact rAAV productivity of our HEK293 cells, we performed a high-throughput screen using a genome-wide library of human microRNA mimics. With this approach, 160 microRNAs increased rAAV yields by more than 2-fold while over 1000 microRNAs decreased rAAV yields. The effect of the most promising microRNAs was confirmed using a multi-parallel microbioreactor system as down-scale model of our production platform. In summary, the top microRNAs identified from the genome-wide screen provide a very promising platform to further improve rAAV vector yields.

1059. AAV Capsid ELISA Automation for High-Throughput AAV Titer Determination

Silja Syrbe, Dana Holzinger, Caroline Odenwald, Christina Sonnek, Katharina Hammer

PROGEN, Heidelberg, Germany

The AAV gene therapy community is facing major challenges like the competitive go-to-market time pressure as well as increasing numbers of samples that need to be processed and analyzed within a very limited time span. Consequently, there is a growing demand for more time-efficient solutions with less hands-on time for analytical characterization of AAV samples. Enzyme-Linked Immunosorbent Assay (ELISA) is an industry standard in AAV gene therapy, well-known for its accuracy and reliability. Nevertheless, the time-consuming nature may hinder rapid analysis, which is essential for meeting tight production schedules or addressing urgent quality control issues. An automated ELISA processing system might significantly reduce potential human errors and variability while allowing fast and high-throughput analyses. To show that AAV capsid ELISA is suitable for high-throughput processing, we transferred the manual AAV9 ELISA (PRAAV9) to a fully automated system. We analyzed plate homogeneity, intra- and inter-assay variance, as well as recovery obtained by the automated system and compared the data to the same key performance indicators obtained by manual processing. Using a fully automated system significantly reduced hands-on time and allowed higher sample throughput, whilst maintaining robustness and accuracy of the conventional AAV ELISA. With this data we show a high-throughput protocol for our AAV ELISAs, thus can support the CGT users to accelerate efficiency of AAV titer determination.

1060. Determination of Full-Empty Ratio of AAV Standard Material by Orthogonal Methods

Lisa Mutz[1], Robert Mildner[2], David Goloka[2], Benjamin Draper[3], Catia Crespo[4], Katharina Hammer[1], Caroline Odenwald[1], Dana Holzinger[1]

[1]PROGEN, Heidelberg, Germany,[2]Waters | Wyatt Technology, Dernbach, Germany,[3]Megadalton Solutions, Bloomington, IN,[4]Refeyn Ltd., Oxford, United Kingdom

Today, AAV-based gene therapy is one of the most promising and fastest growing branches of modern medicine. Moving forward to a more clinical focus in this field, the use of reliable AAV standards and orthogonal methods is indispensable to meet current FDA guidelines. Since the production of comprehensively characterized, internal standard material is not feasible for a large number of companies and a lack of commercially available reference material, we now offer AAV standard material for the most commonly used AAV serotypes. We have established a comprehensive characterization process for these commercially available standards. Besides testing several characterization parameters (e.g. vg and capsid titer, filling grade, purity and aggregation), this process also contains the analysis with a set of suitable orthogonal methods ensuring the utmost level of accuracy and reliability of the data. Here, we present our study on current orthogonal methods for determining the full-empty ratio and their comparability using our eGFP-filled AAV standard material (AAV2, AAV5, AAV8 and AAV9). The study includes the full-empty analysis using Charge Detection Mass Spectrometry (CD-MS), Size Exclusion Chromatography - Multi-angle Light Scattering (SEC-MALS), Mass Photometry (MP), and a combination of Dynamic Light Scattering/ Static Light Scattering and Ultraviolet and Visible Light Measurements (DLS/SLS-UV/vis). Depending on the serotype and the method, some variations were observed regarding the filling grades. The average filling grades across serotypes were measured by DLS/SLS-UV/Vis, CDMS, SEC-MALS, and MP. The results obtained from CDMS and MP showed in average the highest correlation, while a little higher and lower full-empty ratios were observed using SEC-MALS and DLS/SLS-UV/Vis, respectively. The use of reliable standards within diverse orthogonal methods ensures not only the most accurate result but also the safety of the final product in compliance with current FDA requirements. Therefore, we present the reliability of our characterization process for AAV standards, thus demonstrating their reliability and suitability for biophysical and immunological applications, respectively.

1061. Quadplex dPCR as a Tool to Analyze Genome Integrity and Heterogeneity for Gene Therapy Drug Products

Ryan Massopust[1], Annabelle Phillips[1], Nejc Košir[2], David Dobnik[2], Sarang Brahma[1], Maria Belousova[1], Andrea R. Moore[1], Joshua Grieger[1]

[1]Asklepios Biopharmaceutical Inc., Research Triangle Park, NC,[2]Niba Labs, Ljubljana, Slovenia

Cell and gene therapies are transformational treatments with high numbers of IND-filings and product approvals in recent years. This rapid growth presents a need for improved product-specific analytics. Critical quality attributes, such as viral genome (VG) or viral particle (VP) titer, do not consistently correlate with drug potency or safety,

demonstrating a lack of genome-specific analyses. It is hypothesized that the heterogeneity of packaged genomes is a potential cause for this inconsistency. Therefore, there is a pressing need to improve characterization of packaged genomes for their heterogeneity and integrity. Our approach employs quadplex digital Polymerase Chain Reaction (dPCR), utilizing four primer probe sets that span the genome from promoter to poly(A) signal sequence, covering the critical elements of the AAV cassette. Novel genome integrity analysis utilizing the quadplex dPCR data allows calculation of both the absolute number and distribution (heterogeneity) of the target based AAV genome variants. The results presented here demonstrate that the number of intact genomes and the proportion of intact genomes relative to truncated variants changes across different lots of the same drug product. Thus, this novel assay may provide impactful insights into variable potencies and packaging efficiencies of gene therapy products. Results from dPCR genome integrity analyses may be utilized throughout the drug development pipeline, informing research and development all the way through patient dosing. We believe, in combination with orthogonal analytics such as Next Generation Sequencing and Analytical Ultracentrifugation, multiplex dPCR assays will serve as a core component of genome integrity and heterogeneity analytics packages.

1062. Production of AAV Vectors Using Synthetic, Enzymatically Produced Linear DNA

Celine Winckler, Florent Fordoxel, Angel Picher, Heikki Lanckriet, Amy Walker

4basebio, Cambridge, United Kingdom

Adeno-associated virus (AAV) remains a popular vector for gene therapy. However, AAV manufacture faces several challenges to keep pace with the demand for large scale, high quality batches. The standard plasmid triple-transfection presents several issues including availability and cost of GMP grade plasmid, sequence fidelity of the inverted terminal repeats (ITR), and safety concerns over non-specific encapsidations. 4basebio has developed a proprietary, scalable synthesis process for the production of linear closed DNA constructs via its Trueprime™ amplification technology. The hpDNA™ produced is devoid of any bacterial backbone and circumvents cumbersome fermentation processes required for plasmid DNA. Here, we compared the production of AAV vectors using hpDNA™ encoding for the typical Adenovirus helper functions, *rep* and *cap* genes, and an expression cassette consisting of AAV2 ITRs and a reporter gene driven by an ubiquitous promoter. Conventional plasmid triple-transfection was used as a control. We achieved equivalency in viral genome titres, full:empty ratios and infectivity between the two production methods. We have demonstrated that functional AAV vectors can be produced using hpDNA™, which could greatly accelerate therapeutic development of gene therapy programmes. The technology could overcome the difficulties associated with complex ITR structures required for AAV production, which are inherently difficult to synthesise via bacterial propagation systems. Moreover, the lack of plasmid backbone sequences such as antibiotic resistance genes enhances the safety profile of the AAV product.

1063. Transcriptomic Analysis Identifies Differential Expression Patterns in Cellular Stress Response, Signal Transduction, and Extracellular Matrix Proteins During AAV Production

Joshua Tworig[1], Francis Grafton[1], Markus Hörer[2], Chris A. Reid[1], Mo Mandegar[1]

[1]Ascend Gene and Cell Therapies, Alameda, CA,[2]Ascend Gene and Cell Therapies, Munich, Germany

Recombinant adeno-associated virus (rAAV) is a widely used viral vector for gene therapy. Despite its clinical efficacy, the manufacturing of rAAV faces challenges in productivity and vector quality, leading to high costs and limited availability of gene therapies. To meet the growing clinical and commercial demand, mechanistic understanding of the cellular response to rAAV production is required to develop next-generation rAAV production processes. In this study, we performed transcriptomic analysis at multiple stages of rAAV production to better understand the pathways altered during this process. RNA-sequencing was performed on suspension-adapted HEK293 cells originating from two polyclonal populations during rAAV9 production. Polyclonal and clonally derived cells were included in our analysis to identify robust transcriptional signatures independent of clonal differences. Differential expression analysis across timepoints revealed that heat shock and inflammatory proteins, as well as Golgi organization, spindle assembly, and other cytoskeleton-associated components were among the most significant upregulated genes, while inhibitors of DNA-binding proteins were most consistently downregulated during AAV9 production. A variety of extracellular matrix-associated proteins also exhibited significant changes in expression across AAV production. These data uncover novel and previously identified pathways that may affect rAAV productivity, potentially enabling a path to engineer improved processes and cell lines for higher yields and better quality rAAV production.

1064. Ministring DNA (msDNA™): Maximizing Quality of Novel DNA Vectors

Steven J. Hersch[1], Siddarth Chandrasekaran[1], Jamie Lam[1], Peyman Mokarami[1], Roderick A. Slavcev[1,2], Nafiseh Nafissi[1,2]

[1]Mediphage Bioceuticals, Toronto, ON, Canada,[2]School of Pharmacy, University of Waterloo, Waterloo, ON, Canada

Gene and cell therapy have elevated DNA vectors to crucial roles as starting or intermediate products in genetic medicine pharmaceuticals. The quality of DNA material is paramount in determining the ultimate product quality and its compliance with regulatory approvals. Ministring DNA (msDNA™) emerges as a novel DNA platform technology, generating a linear, covalently closed (LCC) DNA vector exclusively containing the sequence of interest. Produced through a simple *in vivo* reaction in *E. coli* cells, msDNA™ incorporates essential components for viral vector production, mRNA production, or non-viral gene therapy. Distinguishing itself from conventional plasmid-based systems, the msDNA™ is entirely free of undesirable contaminating bacterial backbone sequences. This positions it as an advantageous choice for a variety of gene and cell therapy applications.

In vivo manufacturing methods for msDNA yield pure, endotoxin-free, high-quality DNA. Many bacterial sequence-free or LCC DNA vectors are synthetically produced *in vitro* via polymerase-based manufacturing platforms. However, since bacteria encode mutation-reduction mechanisms, such as mismatch repair, our investigation into DNA production *in vivo* in *E. coli* focused on enhancing DNA fidelity. Commonly used next-generation sequencing approaches face limitations in sensitivity, making them insufficient to observe the low mutation rates predicted for *E. coli* in the literature. To address this challenge, we introduce a novel assay based on loss-of-function (LOF) mutations in the conditionally toxic sacB gene. Our findings reveal that DNA production in *E. coli* results in significantly fewer LOF mutations (80- to 3000-fold less) compared to enzymatic/polymerase DNA synthesis using PCR and rolling circle amplification (RCA). This study emphasizes that DNA synthesized *in vivo* in *E. coli* exhibits significantly fewer mutations than enzymatically-produced DNA, potentially enhancing the quality, fidelity, potency and yield of final pharmaceutical products. In summary, msDNA™ stands out as a scalable, high-quality, and high-fidelity LCC DNA vector with promising implications for advancing genetic medicine.

1065. Developing Fed-Batch Strategy to Optimize Plasmid DNA Production in Escherichia Coli DH5alpha for Cost-Effective Manufacturing

Jacob T. Hromyak, Carson G. White, Dylan J. Vasconcelles, Dennis O. Concepcion, Mahajoub B. Bello Roufai

Research and Process Development, Akron Biotech, FL, Sarasota, FL

Demand for high-quality plasmid DNA (pDNA) has greatly increased in recent years due to its myriad applications across therapeutic modalities - including gene therapies, vaccines, and mRNA. This increased demand poses a challenge to pDNA manufacturers, which must continue to increase yield and productivity without compromising on rigorous standards for purity, and ultimately, safety. Productivity in pDNA manufacturing is heavily influenced by host strain, plasmid type and size, growth medium and growth conditions. A widely used culture medium, TB (Terrific Broth) offers high cell density cultures but lacks the capacity to generate large quantities of pDNA (>60 ng/µl). In understanding the significance and effect of peptones in TB a proprietary chemically defined media was designed to increase pDNA titers. This abstract captures efforts to create a high yielding and scalable fermentation process, involving the evaluation of various strategies in Escherichia coli DH5α transformed cells. The development of the process was driven by a three-level single-factor experimental design focused on media composition, temperature, concentration of peptone and carbon source. Improvements in small- and large-scale pDNA yield during fermentation, resulting from media selection and optimization are summarized. The results revealed that a chemically defined media used in conjunction with a nutrient-dense feed supported high cell density cultures and increased pDNA yield and specific productivity when compared to conventional exponential fed batch cultures in TB media. The feed approach developed was optimal for the three plasmids tested and constitute a robust pDNA yield optimization platform established at Akron enabling the production of cost effective pDNA for advanced therapies. This feed-based optimization platform is being tested with various E. Coli Stains and plasmid sizes for fitness and possible strain specific optimizations.

1066. AAV-2 Production with Suspension HEK293 Cells in Scale-X Achieves High Productivity, High Full-to-Empty Capsid Ratio and Low Contaminants

Floriane Cohen

Univercells Technologies, Nivelles, Belgium

Adeno-associated viruses (AAV) are the vector of choice for a wide range of gene therapies, with a focus on rare diseases but increasingly shifting towards higher prevalence indications. This trend combined with varying dose requirements, sometimes exceeding 10E15 vg, means that manufacturing capacity will increasingly become a bottleneck. While stirred tank bioreactors (STRs) offer the hope of large-scale manufacture, they possess inherent limitations which means that scaling from the bench to commercial scale will always be an iterative and risky process with potential delays in the time to market. The next generation fixed-bed bioreactors such as the scale-X offer a low-volume, low-footprint, high-concentration alternative which not only reduces scale-up challenges for processes with suspension and adherent cell lines but also lowers the cost of goods. In this study, it is demonstrated that a suspension HEK293F cell line is successfully grown at high cell density in serum-free media in the scale-X bioreactor achieving the following results compared to the reference suspension process: - 3-fold increase in AAV-2 productivity - 3-fold increase in full-to-empty capsid ratio - A 10-fold reduction in HC-DNA and 5-fold reduction in HCP in the cell culture harvest A drug substance cost of goods reduction ranging from 25 to 52% process

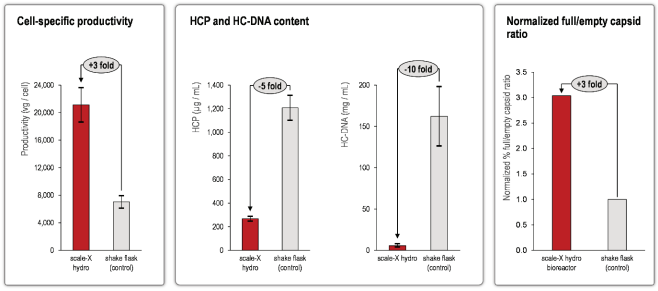

Figure 1. Cell-specific productivity (left), contaminants (centre) and full-to-empty capsid ratio (right) compared to reference shake flask

1067. A Novel, Synthetic DNA Alternative for rAAV Manufacturing

Ileana Guerrini, Roxanne Lourman, Martin Cusack, David Wilson, Luca Distefano, Ivana Pastierikova, Marco Guarrera, Alexander Pekarsky, Jorge Omar Yanez Cuna, Joel de Beer

Anjarium Biosciences AG, Schlieren, Switzerland

The number of FDA-approved gene therapy products using recombinant adeno-associated virus (rAAV) has grown rapidly in the last few years and highlights the key role this vector will play in future gene therapies. However, current manufacturing constraints

pose challenges in meeting the increasing demand for rAAV-based therapies. A fundamental challenge is the sourcing of large quantities of plasmid DNA, the essential starting material for conventional rAAV production, which entails long turnaround times and a high probability of alterations in the AAV-specific ITR sequences during the fermentation-based production processes. Furthermore, the bacterial sequences can potentially be packaged, risking the safety profile of the AAV product. We have developed a novel, optimized synthetic linear double-stranded DNA with customizable hairpin-ended structures for use in rAAV manufacturing. Our production process has several advantages over that of plasmid DNA since it is a one-pot, enzymatic, cell-free, scalable reaction with high yields and rapid production times. The final DNA product is characterized by superior purity and quality, and better product homogeneity. Interestingly, our customized hairpin-ended structures seamlessly integrate with the function of each synthetic DNA construct. To replicate and package the GOI without the need for any additional unwanted sequence, the hairpin ends of our GOI construct were designed as AAV2 ITR-like hairpins for single strand AAV (ssAAV) or self-complementary AAV (scAAV). To prevent the packaging of AAV structural and replication sequences, the hairpin ends of our RepCap and Helper were designed with synthetic hairpin structures. The absence of bacterial sequences in our DNA material reduces the risk of unwanted DNA sequences in the resulting rAAV product. Here we show that our synthetic DNA is suitable as input for ssAAV or scAAV manufacturing with a range of serotypes in a conventional triple transfection set. Triple transfection with plasmid constructs was used as reference. We show all rAAV produced from our synthetic DNA to be functionally equivalent to rAAV produced from plasmid. In addition, rAAV production from our novel DNA was comparable or better in yield, percentage of full:empty ratios, particles and infectivity. Altogether, our results point to our synthetic DNA as a superior alternative for starting material for AAV production compared to conventional plasmid DNA because of the speed and scalability of our process and the reliability and performance of our product.

1068. A Mechanistical Understanding of Producer Cell Line (PCL) Approaches for AAV Production Using Metabolomics

Swetha Kumar[1], Adhvait Shah[1], Laura Parisi[2], Lilu Guo[2], Bailin Zhang[2], Darrick Yu[1], Madhuresh Sumit[1], Jeong Lee[1]

[1]Genomic Medicine Cell Culture Process Development, Sanofi US Services Inc, Waltham, MA,[2]Research and Development, Sanofi US Services Inc, Cambridge, MA

With more than 30 CGT FDA product approvals, gene therapy is emerging rapidly and provides much promise in the treatment of rare neurological diseases. To have a state-of-the-art process that helps improve patient access to life-saving care, it is imperative that we gain a mechanistical understanding of manufacturing processes that increase productivity while maintaining acceptable product quality, particularly AAV based processes that are most employed for gene therapy manufacture. In the era of 'Big Data', we have employed metabolomics in our biopharmaceutical manufacturing process to enable data-driven process design and optimization. Using an in-house developed PCL, we employed metabolomics to identify differences in cellular response and AAV production upon wild-type Ad5 (wtAd5) infection. The conditions were run as biological replicates in batch and perfusion modes, at different cell densities in Sartorius Ambr250® systems. Supernatant samples collected at multiple time-points over the first 48 hours post infection were analysed on Flex2, Cedex BioHT, LC-MS/MS for metabolome profiling. AAV, Ad5 titer were quantified upon harvest. Differences in metabolite profiles between conditions with different AAV productivities, from pathways that are both cell specific and wtAd5 infection specific, were observed. Functional analyses, including KEGG and Gene Ontology (GO), of the metabolome data suggests accumulation of metabolite by-products that could potentially inhibit AAV production in batch cultures, removal of which could lead to increased productivity. We hypothesize that by gaining a deeper understanding of cellular response to wtAd5 infection, we can manipulate AAV processes to higher productivity and product quality. Using the power of 'Big Data', we can identify process switch-points, challenges and biomarkers that can guide scientists to design bioprocesses with superior cellular performance and process productivity.

1069. AAV Process Development in Culture Biosciences' 250mL Bioreactors

Rebecca Du, Hannah Monroe, Kris Tyner, Jean-Marc Guedon, Kat Kozyrytska, Elena Cant, Darcy Birse

Culture Biosciences, South San Francisco, CA

Adeno-associated viruses (AAVs) have emerged as an extremely promising and widely-used delivery vehicle for gene therapy. However, a major hurdle in the development of AAV-based gene therapy is the high cost of manufacturing AAV on the clinical and commercial scale due to the difficulty of scale-up and the inherently high variability during AAV production. Using triple transfection in suspension HEK293 has been shown to yield viral genome titers in excess of $1x10^{14}$ genomes/L. However, the percentage of filled AAV capsids and genome titers can range widely across batches and adjustments in upstream and downstream processing are required for each unique AAV serotype, making it difficult to standardize AAV production. Additionally, AAV production processes are not particularly robust; even after optimization, simply switching plasmids or transfection reagents can result in order-of-magnitude differences in viral titers, necessitating additional rounds of process optimization. These challenges are difficult to overcome when running just a few experiments at a time and are exacerbated by the high variability of AAV processes, which can mask the effect of the parameters being tested. However, they can be addressed through high-throughput, intentional exploration of design space using sufficient replicates to confidently identify critical process parameters that drive efficient and robust AAV production. Here we show production of multiple AAV serotypes in our 250mL bioreactors and demonstrate how running multiple small-scale bioreactors in parallel enabled us to quickly identify transfection reagents, complexation conditions, and bioreactor process parameters to improve overall yields.

1070. UpTempo℠ AAV Platform: Enhanced Process Development to Produce High Quality, High Yield AAV

Elena Andreeva-Gurnev, Casey Vanderheyden, Janna Q. Wisniewski, Mourad Mellal, Arthur Rostovtsev, Gunjan Andlay, Qin Guo, Brian Howard, Elena Prikhodko
Catalent Cell & Gene Therapy, Baltimore, MD

Catalent's UpTempo AAV platform provides a streamlined path from process development to drug product manufacturing for AAV gene therapies, addressing a bottleneck in time to a clinic for early-phase products. Multiple aspects drive product quality and speed, including a platform manufacturing process, Catalent's off-the-shelf (OTS) plasmids, and Catalent's clonal HEK293 cell line (Cell Line). In the UpTempo AAV process, recombinant AAVs are produced via transient transfection of HEK293 cells, cell lysis, and clarification, concentrated via tangential flow filtration (TFF), and purified by affinity chromatography, anion-exchange chromatography, and final formulation. UpTempo AAV process development includes product-specific optimization for yield and quality. Data will highlight recent platform updates including a Design-of-Experiments (DOE) approach to establish optimal transfection parameter design space, an improved harvest strategy to reduce processing time and reduce feed stream impurity levels, and screening of additional compounds that increase production titer up to 3-fold. In addition, 2L production and purification data were obtained across an extended set of AAV serotypes (1, 2, 5, 6, rh10) using Catalent OTS plasmids and Cell Line. Regardless of serotype, 2L yields measured up to 3 x 10^{11} vg/ ml, purity up to 99%, full capsids in the range of 75%, and empty capsids in the range of < 10%, assessed by analytical ultracentrifugation. Improved quality attributes were observed including reduced residual host cell DNA compared to AAVs produced with competitor tools. Scaling data indicates comparable yield, quality, and recovery, confirming that the UpTempo℠ platform process offers a robust solution for AAV manufacturing.

1071. How Does ICH Q5A R2 Impact Viral Clearance Studies for Non-Enveloped Gene Therapy Vectors?

Danielle Hickman
MilliporeSigma, Rockville, MD

Viral contamination of a manufacturing process for a biological product has wide implications from the manufacturer to the patient, resulting in many consequences such as drug shortages and the high cost of investigation, cleanup, and corrective actions. To avoid viral contamination, manufacturers implement a three-fold viral safety strategy: 1) Preventions: sourcing safe raw materials, other starting materials, and facility design; 2) Detection: testing cell banks and process intermediates; and 3) Removal/Reduction: evaluating downstream purification steps for their potential to inactivate or remove a contaminating virus. This has been a successful strategy, because although contamination events have occurred, viral contaminants have not been detected in the drug product. ICH Q5A R2 includes guidance for non-enveloped gene therapy vectors that are amenable to viral clearance. The scope of a viral clearance study is dependent on the stage of process development, with studies to support early-stage clinical trials smaller in scope than studies to support a late-stage clinical trial or a BLA. In this presentation, stage specific viral clearance study requirements and strategies will be discussed. In addition, data will be presented that demonstrates that non-enveloped gene therapy vector products have virus removal or inactivation capacity in their manufacturing processes.

1072. Development of a Serum-Free Suspension HEK293 Cell Line for AAV Production with High Yield and Low Encapsidated DNA Impurities

Hairui Yang
OBIO TECH, Shanghai, China

Adeno-associated virus (AAV) has emerged as a successful tool in gene therapy, with different serotypes exhibiting remarkable efficiency in targeting specific organs and tissues. The escalating demand for large-scale manufacturing of various AAV serotypes, particularly for pre-clinical and clinical trials, underscores the need to enhance the packaging capacity of producer cells, thereby optimizing the productivity of AAV vectors. This study delves into the growth characteristics and AAV packaging titer of a high-yield monoclonal cell line derived from HEK293. The findings reveal a substantial increase in the packaging titer of these high-yield HEK293 monoclonal cells—ranging from 17% to an impressive 435% when compared to the VPC2.0. Concurrently, the residual host cell DNA was notably reduced by 50% to 70% in comparison to the VPC2.0. To validate the scalability of the selected high-yield monoclonal HEK293 cell line in a manner more representative of current Good Manufacturing Practice (cGMP) standards, AAV production was assessed in bioreactors ranging from 15L to 50L to 200L. Consistent with the trends observed at 15L and 50L, the results from the 200L bioreactors demonstrated a remarkable 1.6-fold increase in genome productivity, coupled with comparable capsid production and consistent levels of residual host cell DNA. These data affirm that the chosen high-yield HEK293 cell line exhibits linear scalability across diverse production scales, maintaining consistent results. The demonstrated consistency in up to 200L bioreactors establishes the viability of cell line development for commercial supply, opening avenues for applications in indications with larger patient populations. More Importantly, this method is not only applicable to AAV production but can also be extended to other types of cell screening, demonstrating its broad application value.

Thursday Posters: Metabolic Diseases

1073. Modeling ABCD1 Deficiency in Adrenocortical Cells by CRISPR and Correction viaAAV-Mediated Gene Delivery

Yi Gong[1], Vasileios Kreouzis[1], Ann Moser[2], Casey A. Maguire[3], Florian Eichler[1]
[1]Massachusetts General Hospital, Boston, MA,[2]Hugo W Moser Research Institute, Baltimore, MA,[3]The Massachusetts General Hospital, Charlestown, MA

X-linked Adrenoleukodystrophy (X-ALD) is a debilitating monogenic disease caused by pathogenic variants in *ABCD1* that affects both males and females. The *ABCD1* gene localizes to Xq28 and encodes an ATP-binding cassette (ABC) transporter that mediates the transport of very long chain fatty acids (VLCFA) from cytosol to peroxisome where β-oxidation takes place. Thus, accumulation of VLCFA is the biochemical hallmark of X-ALD. With a birth incidence of about 1:14700, X-ALD is considered the most common peroxisome disorder. There is no clear genotype phenotype correlation in X-ALD, and the clinical spectrum ranges from devastating cerebral inflammatory demyelination (CALD) to a slowly progressive myeloneuropathy affecting spinal cord and peripheral nerve. The adrenal glands are commonly affected with a lifetime risk of adrenal insufficiency in ~80% of ALD males with VLCFA accumulation being the likely culprit of pathology within the adrenal cortex. In the present study, significant accumulation of VLCFA was detected in adrenocortical cells (HAC15) following ABCD1 silencing with a consequent notable reduction of cortisol levels in vitro. Lipid treatment has no clear impact on adrenal cortisol function in nontargeting (NT control) HAC15 cells. In contrast, ABCD1 deficient cells displayed further inhibited adrenal cortisol production following VLCFA treatment, suggesting the additive impact of genetic and environmental factors. In HAC15 cells we employed 2sgRNAs to mediate a large fragment deletion in *ABCD1* using CRISPR-Cas9. This led to profound accumulation of VLCFA in vitro. Most importantly, AAV9 mediated ABCD1 gene delivery to HAC15 knockout cells at 1E6 gc/cell significantly alleviate the VLCFA accumulation. While AAV9-mediated ABCD1 intrathecal delivery in the X-ALD mouse model has demonstrated efficacy in treating neurological features of ALD and has led to a current clinical trial to address the myeloneuropathy of X-ALD, our proof of concurrent AAV9-ABCD1 transduction in adrenal cortex provides a rational for AAV mediated gene therapy in the treatment of adrenal insufficiency.

1074. Correction of Arginine:Glycine Amidinotransferase (AGAT) Creatine Deficiency through a Novel Bicistronic AAV9 Construct

Tesla A. Peretti[1], Troy B. Webster[1], Robyn T. Binsfeld[1], Ilona Tkachyova[2], Michael B. Tropak[2], Andreas Schulze[2,3], Jagdeep S. Walia[1,4]

[1]Queen's University, Kingston, ON, Canada,[2]The Hospital for Sick Children, Peter Gilgan Center for Research and Learning, Toronto, ON, Canada,[3]Departments of Pediatrics and Biochemistry, University of Toronto, Toronto, ON, Canada,[4]Departments of Pediatrics, Queen's University, Kingston, ON, Canada

Creatine is a small molecule that plays an important role in energy metabolism and is required for overall health and neurodevelopment as seen from creatine deficiency syndromes (CDS). CDS are inborn errors of metabolism which result in neurological manifestations including intellectual disability, developmental delay, and seizures emphasising the importance of creatine in brain function. Endogenous production of creatine begins through the enzymatic function of arginine:glycine amidinotransferase (AGAT) to form guanidinoacetate (GAA) which is then converted to creatine by guanidinoacetate methyltransferase (GAMT) enzyme. AGAT-deficiency (AGAT-D) is an autosomal recessive disorder caused by loss of function mutations in the *GATM* gene encoding the AGAT protein preventing endogenous creatine production. Currently, the only treatment for AGAT-D relies on daily creatine supplementation, however this is not curative and does not restore AGAT function or normal creatine levels in the brain, leaving many symptoms untreated. We have performed a proof-of-concept *in vitro* study using two plasmid constructs- *phGATM* and *phGATM-GAMT*, through transfecting AGAT knockout HAP1 cells. Results demonstrate restoration of AGAT protein and creatine production. HAP1 cells were cultured in specialized media so that any creatine quantified would have to be produced by the cells. The cell lysates were analyzed for guanidino compounds such as creatine and GAA through liquid chromatography tandem mass spectrometry. Both constructs were able to restore creatine production, however in the *phGATM* treated cells, GAA levels were significantly elevated which could lead to potential neurotoxic effects likely due to relative GAMT-D, while the *phGATM-GAMT* treated cells received both enzymes for the pathway preventing GAA accumulation. These results have inspired the *in vivo* proof-of-concept study that is currently underway using *AAV9.hGATM* and *AAV9.hGATM-GAMT* vectors in murine models of AGAT-D. Further studies will aid in determining optimal efficacy and safety of the vectors for translation into clinical use for AGAT-D and potentially other diseases.

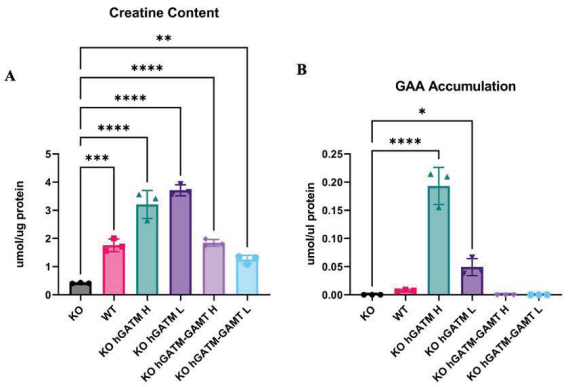

Figure 1. Intracellular creatine and GAA content of knockout (KO) *GATM* cells following high dose and low dose transfection of *phGATM* and *phGATM-GAMT*. Untreated (GFP transfected) KO cells represent the negative control and untreated (GFP transfected) wildtype (WT) cells represent the positive control. **A.** Treatment of *GATM* KO cells with high (3.75μg) and low (1.25μg) doses of *phGATM* and *phGATM-GAMT* significantly increased the intracellular creatine levels compared to KO levels (**** $p < 0.0001$, ** $p < 0.01$). Treatment with high dose (3.75μg) of *phGATM-GAMT* restored intracellular creatine levels to that of untreated WT HAP1 cells. **B.** Treatment of *GATM* KO cells with a high dose (3.75μg) of *phGATM* significantly (**** $p < 0.0001$) raises GAA levels to that of *GAMT* KO cells (unpublished Walia Lab data) leading to potentially toxic effects. Treatment of *GATM* KO cells with a high dose (3.75μg) and low dose (1.25μg) of *phGATM-GAMT* does not result in any GAA accumulation.

1075. From Rare Challenges to Results: Lessons Learned in Gene Therapy Development for Ultra-Rare Disorder

Julia Taravella

Rare Trait Hope Fund, New Olreans, LA

Aspartylglucosaminuria (AGU) (OMIM #208400) is an ultra-rare lysosomal storage disorder caused by pathogenic mutations in the AGA gene. This leads to a deficiency in aspartylglucosaminidase enzyme responsible for breaking N-linked glycoproteins. The deficiency results in the accumulation of these compounds, impairing bodily functions, particularly in the central nervous system. Patients present with speech/language and cognitive developmental delays, often diagnosed as autism, followed by a slow and steady decline in motor function

and cognitive abilities. Individuals remain dependent on caregivers for the entirety of their lives before succumbing to premature death around 35 years of age. Currently, there are no curative therapies for AGU. The inheritance pattern of AGU is autosomal recessive, and its prevalence varies across different populations. A significant majority of the research was conducted in Finland in 1970-1990s due to the disease higher presence in the Finnish population. These early efforts to develop a cure for AGU included promising gene and enzyme replacement therapies studies in animals. However, challenges such as securing sufficient funding and scaling up production posed significant obstacles, resulting in stalled research efforts. By 2013, while funding remained a hurdle, scientific advancements had led to a more standardized approach in the development of gene replacement therapy using AAV (Adeno-Associated Virus). This scientific progress marked a significant step forward in the potential treatment of AGU that was recognized by Rare Trait Hope Fund. This presentation discusses the development of gene therapy for AGU, from diagnosis, to pre-clinical development, to clinical trials, highlighting the unique challenges and strategies needed to make gene therapy a feasible option for ultra-rare disorders such as AGU. Emphasis will be placed on cost management, the need for multi-party collaboration, and understanding the nuances of developing treatments for rare diseases. This comprehensive overview aims to illustrate the process of bringing gene therapy from concept to clinical application for an ultra-rare diseases. The presentation will further discuss key takeaways from each stage of AGU treatment development. This includes insights from pre-clinical studies, the pre-IND phase, the nuances of gene therapy drug manufacturing, GLP toxicology studies, and the processes involved in IND submissions and related activities. Additionally, the keys to success for a patient foundation driving treatment development will be covered, including: - Hands on and active project involvement. - Maintaining regular communications with researchers/developers. - Adoption of standard(s) (vector, manufacturing, etc.) and common(s) with other developments (models, cultures, RoA) to save time, resources, and funding. - Frequent advice-seeking to reviews of key assumptions, leveraging collaborations and free research tools.

1076. Preclinical Assessment of the Efficacy and Safety of AAV9-HGSNAT Gene Replacement Therapy for MPS IIIC

Xin Chen[1], Thomas Dong[1], Merve Emecen Sanli[1], Anjala Jiji[1], Srikanth Singamsetty[2], Jill Wood[2], Steven J. Gray[1]

[1]UT Southwestern Medical Center, Dallas, TX,[2]Phoenix Nest Biotech, Brooklyn, NY

Mucopolysaccharidosis type IIIC (MPS IIIC or Sanfilippo syndrome Type C) is caused by the mutations in the heparan-alpha-glucosaminide N-acetyltransferase (HGSNAT) gene. It is an autosomal recessive disorder characterized by the lysosomal storage of heparin and heparan sulfate in the central nervous system that causes progressive destruction of nerve cells, with no specific treatment. The severity of the disease can range from mild to severe, even among affected individuals in the same family. MPS IIIC patients manifest with neuropsychiatric problems (hyperactivity, aggressiveness, and autistic features) followed by developmental delay, hearing loss, and childhood dementia. Most patients become paraplegic during adolescence and die before adulthood, but some survive until the fourth decade of life with progressive dementia and retinitis pigmentosa. Our group is evaluating the efficacy and safety of an adeno-associated viral 9 (AAV9)/HGSNAT vector in a mouse model of MPS IIIC *Hgsnat*^{P304L} developed by the team of Dr. A. Pshezhetsky, CHU Ste-Justine, Montreal, Canada. These mice were reported to show some biochemical and histological features of the disease starting around 2 months of age, behavioral phenotypes starting at 4 months of age, and average time to humane euthanasia endpoint around 10 months of age. Mice were randomized into treatment groups (vehicle, 1E11 vg/mouse, or 4E11 vg/mouse) and injected by a lumbar intrathecal route of administration at 7-10 days old or 120 days old. Study mice are weighed weekly up to 1 month old, then monthly thereafter. Urine is collected from all mice at 3, 6, 9, 12, 15, and 18 months of age, as well as at necropsy. A blood sample is collected at 2 months post-injection and will be collected again at necropsy for evaluation of markers of liver and kidney toxicity, as well as for evaluation of biomarkers of MPS IIIC. At 4, 6, 9, and 12 months old, all mice undergo behavioral phenotyping (open field, elevated plus maze, and novel object recognition). All mice are tested on the Y-maze at 6 months old only. Interim study results will be presented on treatment outcomes of the mice up to 6 months old.

1077. Enhancing Islet Isolation Techniques to Improve Digestion Efficacy: A Breakthrough for Pediatric Islet Auto-Transplantation in Fibrotic Chronic Pancreatitis

Masoumeh Asadi, Krishna K. Samaga, Ahad A. Kodipad, Chandrashekar B. Revanna, Jaimie D. Nathan, Appakalai N. Balamurugan

Islet GMP Facility, Center for Clinical and Translational Research, Nationwide Children's Hospital, Ohio State University, Columbus, OH

Introduction: Among improved islet isolation techniques, utilizing ideal combination of collagenase-protease enzyme blend is important. In this study, our primary objective was to utilize recombinant collagenases (rC1rC2) based on percent parenchymal mass for effective digestion of chronic pancreatitis pancreas to release islets followed by pediatric islet cell auto-transplantation. The dose and composition of the collagenase enzyme blends (CEB) used in the islet isolation process is a critical factor that impacts the number and quality of islets released from chronic pancreatitis pancreases (CPP). In this study, recombinant Clostridium histolyticum class I (rC1) and class II (rC2) collagenase on human pancreas digestion efficacy in combination with P. polymyxa protease (BP-protease) enzyme blend (rCEB) was assessed. **Methods:** No animal components were used in the generation of the raw material or purification of rC1, rC2, or BP-Protease. In our initial studies, we tested rCEB in 22 human research pancreases utilizing split lobe and full lobe models. In the current study, we introduced rCEB for clinical islet auto-transplantation (n=11). we also tested this enzyme blend in two validation islet isolations (n=2) perior to introduction in the clinic clinical. Collagenase was used at >19 Wunsch units/gram pancreas (20-40 unit) and proteas were used at >14.000 unit/gram pancreas (15,000-53,000 unit). Dosing of rCEB was based on percent parenchymal tissue mass in each chronic pancreatitis pancreas. Human islets were isolated according to our standard clinical islet isolation protocol. rCEB enzyme blend was injected into the pancreatic duct and digestion was done in

the Ricordi chamber. Pancreas digestion profiles (islet number, IEQ, islet/acinar morphology, tissue pellet volume, undigested pancreas) were carefully monitored and compared to isolations performed with traditional enzyme formulations. **Results:** Before introducing the rCEB for clinical islet auto-transplantation procedure, the effectiveness and optimal dosage of the recombinant enzyme (rCEB) were determined, and the functions of the islets were closely monitored to ensure their proper performance. Assessing percent parenchymal mass by visual and histology methods guided us to select the correct enzyme dosing. The digestion efficacy of rCEB in all five isolations were >90%, the undigested portion of pancreases were <10%. The digestive profiles of the pancreas exhibited normal characteristics and the final islet viability was >70% in all preparations. The final islet per gram pancreas was comparable to our previous islet isolation performed with traditional collagenase enzyme blends. **Conclusions:**. In summary, dosing rCEB based on percent parenchymal mass successfully digested the entire fibrotic pancreas and released all islets. The application of purified P. polymyxa protease in combination with rC1rC2 collagenases proved effective in maximizing islet yield for clinical islet auto-transplantation in fibrotic chronic pancreatitis cases.

1078. Macrophage-Based Therapy to Improve Surgical Outcomes of Urogynecologic Mesh Implantation in Patients with Diabetes

Rui Liang

University of Pittsburgh, Pittsburgh, PA

Synthetic meshes are often used to augment surgical repairs of pelvic floor disorders, prevalent conditions in aging women. We previously showed that diabetes induces macrophage dysfunction in the vaginal host response to mesh, possibly accounting for the prolonged and increased inflammation at the mesh site. Here we aimed to define the role of macrophages in the mesh-associated inflammation and address whether macrophage-based therapies can rectify the adverse effect of diabetes on the host response to mesh. Middle-aged inbred female Lewis rats were used for diabetes induction (n=14) with a single doze streptozotocin injection via tail vein (35 mg/kg), or as non-diabetic controls (n=11). Subgroups underwent mesh implantation without interventions (n=3-4 per group), with/without monocyte/macrophage ablation (n=3 per group), and with/without healthy monocyte treatment (n=4-7 per group). For mesh implantation, a light weight polypropylene mesh was implanted on the vagina via sacrocolpopexy following supracervical hysterectomy. For cell ablation, lyposome-encapsulated clodronate (LEC) solution (0.5 ml ip and 0.5ml iv for consecutive 3 days before surgery) was used. The effect of LEC on eliminating circulating monocytes and tissue residential macrophages was pre-tested and verified in a non-diabetic rat. Healthy monocytes (~1 - 2 x 10^6) isolated from healthy donor rats were infused to the mesh-implantation sites during surgery and injected via tail vein immediately following surgery. Inflammation outcomes were obtained via histomorphology analysis (Hematoxylin & Eosin and Trichrome staining) and flow cytometry. A mixed-effects model was used for statistics. We found that macrophages directly contributed to the scales of mesh-associated inflammation under normoglycemic conditions. Specifically, the cell ablation significantly decreased macrophage recruitment to the mesh site and the inflammation scale, while monocyte therapy restored the cell number and inflammation back to normal (all $p<0.05$). Under diabetic conditions, the positive relationship between mesh load and inflammation was disturbed, while the cell ablation and monocyte therapy reinstated the relationship (Figure). These findings suggest that macrophage-based therapies may normalize the host inflammatory response to medical devices (e.g., meshes), thus improving surgical outcomes in patients with diabetes.

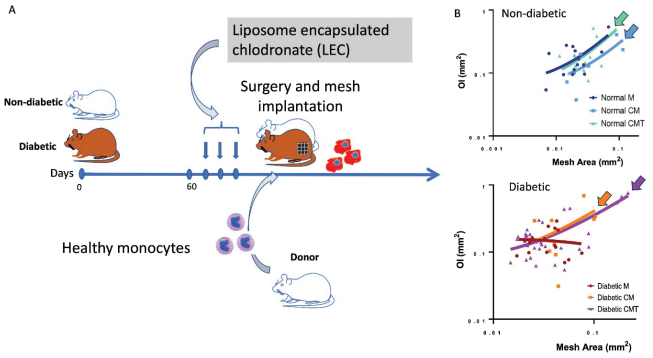

Figure. (A) Schematic drawing showing the flow of healthy monocyte therapy (CMT) following macrophage/monocyte ablation with chlodronate (CM) and mesh implantation (M) in diabetic vs. nondiabetic rats. (B) Inflammation analysis: Under normoglycemic conditions, the overall inflammation (OI) increased with mesh load (dark blue). Macrophage/monocyte ablation decreased the OI (light blue) while monocyte treatment (Green) returned the response back to normal (all $p<0.05$), proving that macrophages play determining roles in the mesh-elicited inflammation. Under diabetic conditions, the normal positive OI-mesh load relationship was disturbed (brown), which were restored by macrophage/monocyte ablation (orange) as well as monocyte treatment (purple).

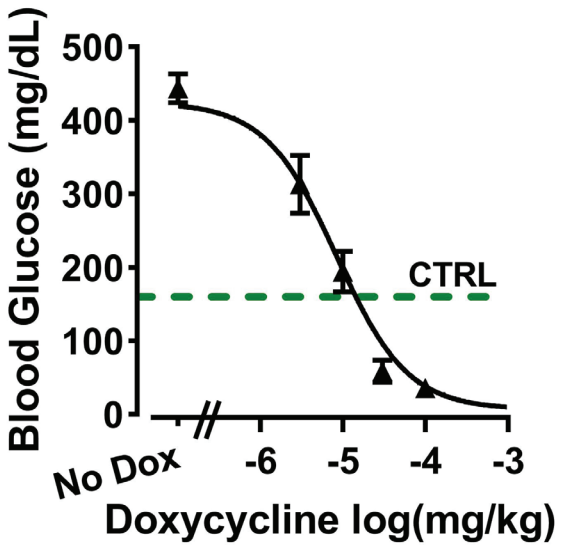


1079. Insulin Replacement Gene Therapy Using a Novel Glucose- and Drug-Inducible Adeno-Associated Virus

Aleksandra Maciejczuk[1], Stefan Hargett[1], Igor R. C. Rocha[1], Iuliia Vitko[1], Jun Xie[2], Guangping Gao[2], Thurl Harris[1], Edward Perez-Reyes[1]

[1]Pharmacology, University of Virginia, Charlottesville, VA,[2]UMass Chan Medical School, Worcester, MA

Objective: To develop AAV-based gene therapies that can be activated by the FDA-approved drug doxycycline (Dox). We present proof-of-concept studies using diabetic mice that show effective delivery and pharmacological regulation of an insulin gene replacement therapy. **Methods:** Glucose-inducible promoters have been developed by incorporating the DNA sequences that bind the carbohydrate response element binding protein, ChREBP. We developed a novel promoter with multiple repeats of ChREBP binding motif 1 and motif 2 (Jeong et al., 2011). For Dox regulation we engineered a single AAV to contain both components of the 3G Dox-on system (Clontech): 1) the reverse tetracycline transactivator (rtTA), whose expression is controlled by the glucose-inducible promoter; and 2) the tet operator, where the rtTA binds in the presence of Dox to induce the expression of recombinant insulin. Recombinant AAV8 pseudovirions were injected into the tail vein of diabetic mice (streptozotocin model). Blood glucose levels were monitored after a 4 hour fast and after an intra-peritoneal glucose tolerance test (GTT). Insulin production was monitored using serum samples and an ELISA directed against the human C-peptide produced by the rAAV. Expression of recombinant insulin mRNA was also validated using RT-qPCR. AAV delivery was confirmed by either qPCR or ddPCR on liver DNA. **Results:** Design of the AAV targeting plasmid was guided by in vitro studies measuring the expression of the fluorescent reporter, Fusion Red. In vitro experiments showed 2- to

5-fold regulation of expression by glucose and robust regulation by doxycycline (Dox) with a large dynamic range (100-fold). All in vivo experiments were blinded and included 4 groups of mice (C57Bl/6, n=4-5 each): Group 1 were control (CTRL) mice (not diabetic, no AAV); Group 2 were negative controls (diabetic, null AAV); while Groups 3 and 4 tested variations of the rAAV-Insulin gene therapy (1.0E+13 VG/kg). Baseline studies established that STZ-treated mice lost their ability to control blood glucose. Strikingly, administration of Dox normalized glucose handling in groups 3 & 4 to similar levels as observed in the control group. We then performed dose response studies varying the concentration of Dox in the chow (Figure). Very high doses of Dox (100 mg/kg) actually lowered blood glucose below levels observed in CTRL Titration down to 10 mg/kg Dox in chow restored blood glucose in diabetic mice to the control level. Taking into account chow consumption, this dose is half of that used in human patients during antibiotic therapy. **Significance:** The human insulin replacement market has been estimated at $42 billion dollars. Most commonly used strategies rely on the patient monitoring of their blood glucose and daily subcutaneous injections of recombinant insulin. These studies demonstrate that a drug-inducible AAV therapy can be used successfully to titrate insulin replacement by varying doxycycline dosing.

1080. The Highly Immunodeficient SRG Rat for the Development of Cell-Based Diabetes Therapeutics

Grace Walton, Fallon Noto, Diane Begemann, Cynthia Dunn, Lauren Keach, Darrell Robertson, Cassandra Scutchfield, Chris Brenzel, Michael Schlosser
Hera BioLabs, Lexington, KY

Immunodeficient rodents are vital for pre-clinical development of cell-based diabetes therapeutics. The SRG rat (Sprague Dawley Rag2-/-, Il2rg-/-) is normoglycemic under standard conditions and lacks mature B, T, and NK cells. The SRG rat offers several size-based advantages compared to mice, including more human-like physiology, easier surgeries, and ability to collect larger blood volumes on a more frequent basis. Compared to athymic nude rats, the SRG is more permissive to a wider range of human xenografts due to a lack of B and NK cells, which are still present in the nude rat. Given these advantages, we determined whether the SRG could serve as a model of streptozotocin-induced (STZ) Type 1 Diabetes or diet-induced obesity (DIO) Type 2 Diabetes. We compared blood glucose in SRG versus wild-type Sprague Dawley (SD) male rats following STZ treatment. Rats were administered vehicle, STZ 40 mg/kg, or STZ 65 mg/kg. Six days after low dose STZ, non-fasting glucose was 262 ± 41 (SEM) mg/dL in SD rats and 565 ± 64 (SEM) mg/dL in SRG rats. Six days after high dose STZ, non-fasting glucose was 679 ± 23 (SEM) mg/dL in SD rats and 505 ± 72 mg/dL in SRG rats. Compared to SD rats, weight loss associated with hyperglycemia was more pronounced in SRG rats. To induce obesity, insulin resistance, and T2D, SRG rats were fed control or high fat diet (60% kcal from fat). Body weight and food intake were recorded weekly. Glucose tolerance testing was performed after 10 and 24 weeks of high fat diet and insulin tolerance testing was performed after 11 weeks of high fat diet. Compared to low fat diet, DIO rats had increased caloric intake and body weight throughout the study. After 10 weeks, DIO rats had impaired glucose tolerance without elevated fasting insulin. Insulin tolerance did not differ at 11 weeks. At 24 weeks, glucose tolerance did not differ between diet groups, but DIO SRG rats displayed elevated fasting insulin ($P < 0.01$). In conclusion, SRG rats are more sensitive to 40 mg/kg STZ versus SD rats, with rapid weight loss and hyperglycemia. The SRG rat glycemic response to DIO showed temporal changes. These data demonstrate that the SRG Rat, a model with high-take rates for human xenografts, is a potential model for development of cell-based diabetes therapeutics.

1081. SKG0702, an AAV Gene Therapy Product for the Treatment of Wilson Disease

Li Wang, Yanqun Shu, Yanjun Shen, Ruojie Wang, Yuwen Du, Liuye Yao, Ruoyan Hu, Huimin Kong, Peilu Li, Bing Wu, Jinxin Deng, Lingling Zhao, Hao Luo, Zheng Luo, Yue Zhang, Shihua Cao, Yu Wu, Xia Liu, Yao Qiu, Xiaorui Bian, Hui Liu, Carol Huang, Jay Hou
Skyline Therapeutics, Cambridge, MA

Wilson disease, an autosomal recessive disorder caused by mutations in a copper-transporting P-type ATPase (*ATP7b*) gene, causes severe liver damage. Currently this disease is treated with the lifelong copper chelation therapy, which has many side effects and does not fix copper metabolism. To address these challenges, we developed SKG0702, a one-time gene therapy with adeno-associated virus (AAV) vector expressing an engineered codon-optimized version of the human mini-*ATP7b* transgene driven by a liver-selective promoter. AAV5 is the common capsid for liver targeting gene therapy. On the other hand, a different AAV (AAV_L) capsid has been drawing some attention in non-clinical/clincal stage liver targeting gene therapy programs recently. Here, we packaged mini-*ATP7b* transgene into AAV5 (SKG0701) and AAV_L capsid (SKG0702), respectively and did a head-to-head comparison of the transduction efficiency of the vectors in HepG2 cells, *Atp7b*$^{-/-}$ mice (Wilson disease model), and cynomolgus monkeys. We demonstrated that SKG0702 is superior in transducing hepatocytes compared to SKG0701 in both *in vitro* and *in vivo* studies. SKG0702 drove ~25-fold higher mini-ATP7b protein expression than

SKG0701 in HepG2 cells at the same multiplicity of infection. The dose range finding study in *Atp7b*$^{-/-}$ mice showed dose-dependent vector distribution and mini-*ATP7b* expression in the liver. However, intravenous (IV) delivery of SKG0702 mediated higher vector genome (vg) copy number in the liver and was more efficient in reducing hepatic copper accumulation than SKG0701. In addition, SKG0702 resulted in mini-ATP7b expression in >70% of hepatocytes and ~50% reduction of hepatic copper level in *Atp7b*$^{-/-}$ mice at the dosage of 2E12 vg/kg. Furthermore, IV delivery of SKG0702 in cynomolgus monkeys led to more vector distribution and transcription products in the liver than SKG0701. At the dosage of 5E12 vg/kg, SKG0702 mediated mini-*ATP7b* transcript expression in >60% of hepatocytes and was well-tolerated without any histopathological findings. In summary, SKG0702 is clinically advantageous with efficient hepatocyte transduction and is a promising gene therapy candidate for reducing liver damage and correcting copper metabolism in Wilson disease.

1082. Determinants of AAV Persistence in a Mouse Model of Glycogen Storage Disease Type III

Justine Nozi[1,2], Hanadi Saliba[1,2], Youssef Krimi Benchekroun[1,2], Jeremy Rouillon[1,2], Gianni Tavella[1,2], Valle Montalvo-Romeral[1,2], Bérangère Bertin[1,2], Louisa Jauze[1,2], Helene Jammes[3,4], Alice Jouneau[3,4], Coralie Pecquet[1,2], Louis Bergantz[1,2], Andrés F. Muro[5], Giulia Bortolussi[5], Sylvain Fisson[1,2], Nathalie Daniele[1], Laetitia Van Wittenberghe[1], David A. Gross[1,2], Tiziana La Bella[1,2], Antoine Gardin[1,2], Giuseppe Ronzitti[1,2]

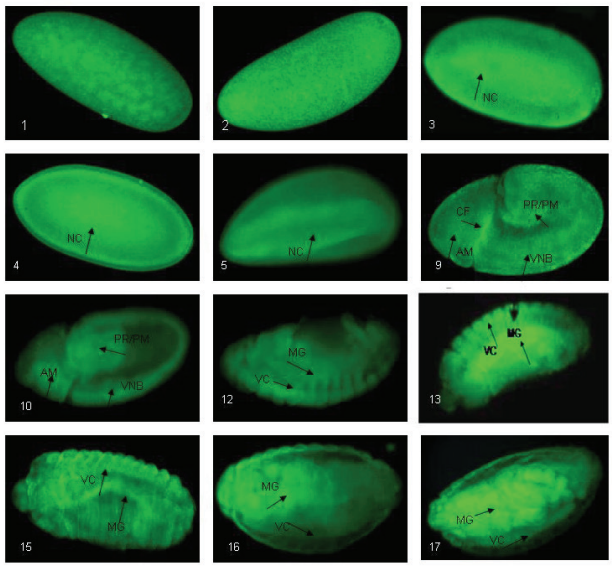
[1]GENETHON, Evry, France,[2]Université Paris-Saclay, Univ Evry, Inserm, Genethon, Integrare Research Unit UMR_S951, Evry, France,[3]Université Paris Saclay, UVSQ, INRAE, BREED, Jouy en Josas, France,[4]Ecole Nationale Vétérinaire d'Alfort, BREED, Maisons-Alfort, France,[5]International Centre for Genetic Engineering and Biotechnology (ICGEB), Trieste, Italy

Liver-directed gene transfer with Adeno-associated viral (AAV) vectors demonstrated long-term efficacy in a large number of clinical trials and relevant preclinical animal models (D'Avola D, 2016; Weber ND, 2023). However, transgene expression loss was reported for some individuals without any evident correlation with the development of an immune response (Konkle BA, 2021) suggesting that other mechanisms might be responsible of this phenomenon. Importantly, this loss of transgene expression is poorly recapitulated by the current rodent models, since long-term expression is usually achieved in mouse liver in absence of significant liver damage (Ronzitti G, 2016). In this study, we hypothesized that subclinical liver conditions, such as fibrosis or hepatocyte metabolic impairment, may have an impact on the persistence of AAV liver gene transfer. To model such conditions, we used a mouse model of glycogen storage disease type III (GSDIII), which displays features of chronic liver damage as well as a mild progressive fibrosis. The relatively low level of fibrosis observed in this model did not impact gene transfer efficacy at short-term while, at long-term efficacy loss was observed with a kinetic similar to the one observed in humans. Importantly, the reduction of CpG dinucleotides in the transgene sequence and in the promoter of the expression cassette resulted in longer transgene expression stability and correction of the metabolic phenotype in the majority of the AAV-treated GSDIII mice. Interestingly, despite this optimization some of the mice showed robust transgene expression loss associated with transcriptional inactivation that was further characterized. Among mechanisms potentially affecting vector stability and persistence over time, we showed that hepatocytes proliferation, if not corrected, can lead to transgene expression loss due to AAV dilution starting from three months after treatment. Interestingly, in the same experimental setup, we identified differential methylation of the promoter sequence occurring specifically in GSDIII mice suggesting a deregulation of the epigenetic mechanisms in this mouse strain. Finally, adaptive immune responses triggered by the capsid or by the transgene were investigated highlighting an enrichment of non-conventionally activated effector/memory CD8+ T cells and an increase of CD8+ T cell infiltrates in the liver of Agl-/- mice one month after vector injection. The characterization of the role of these T cell infiltrates in the loss of correction observed over time is still undergoing in our model. In conclusions, our work suggests the involvement of multiple mechanisms in the long-term persistence of AAV genome and transgene expression in the mouse GSDIII liver. These findings support the hypothesis that the variable efficacy and long-term persistence observed in the clinical trials may be related to the presence of an underlying subclinical metabolic impairment, proliferation associated with fibrosis and/or the presence of a pro-immunogenic environment. These mechanisms should be investigated in patients enrolled in liver-targeted gene therapy clinical trials to better understand their contribution in humans and improve the outcome of liver gene therapy.

1083. LY-M003: Advancing Wilson Disease Treatment through Copper-Responsive Gene Therapy

Yuzhe Peng, Guofang Yan, Yixiong Chen, Qing Lin

Lingyi Biotech Co., Ltd., Shanghai, China



Wilson disease (WD), a rare autosomal recessive disorder, stems from mutations in the ATP7B gene, culminating in diminished ATP7B activity and the subsequent systemic accumulation of copper, predominantly affecting the liver, brain, and kidneys. This accumulation leads to severe organ damage, highlighting the critical need for therapeutic interventions that restore ATP7B protein function. LY-M003, an innovative adeno-associated virus (AAV8)-based gene therapy, is at the forefront of this challenge, designed to synthesize a modified ATP7B^{LY} protein in a copper-dependent manner through its Copper Responsive Engineering of ATP7B Expression (CREATE) system. The ATP7B^{LY} protein, engineered to mirror the functionality of its wild-type counterpart, forms the core of LY-M003's therapeutic strategy. In vitro studies showcase LY-M003's proficiency in expressing ATP7B^{LY}, coupled with a robust capacity for copper exportation. Preclinical efficacy evaluations in *Atp7b*$^{-/-}$ and *Atp7b*$^{M1/M1}$ mouse models—characterized by detrimental hepatic copper accumulation, heightened urinary copper excretion, and compromised serum ceruloplasmin activity—revealed LY-M003's potential. Notably, a 13-week treatment regimen in male *Atp7b*$^{M1/M1}$ mice with LY-M003 correlated with a dose-dependent decrease in tissue copper levels, normalization of urinary copper and serum ceruloplasmin levels, and a marked alleviation of liver lesions. Moreover, extensive toxicology assessments of LY-M003 in both CD-1 mice and Cynomolgus macaques underpin its safety and tolerability, offering a promising therapeutic

outlook. The amassed preclinical data robustly advocate for LY-M003's safety and therapeutic efficacy in both mice and non-human primates (NHPs), providing a solid foundation for the forthcoming human clinical trials.

1084. Aminopeptidase P (DAP) Expression Pattern in *Drosophila Melanogaster*

Suneeta Gireesh Kumar
Microbiology, Dr. D. Y. Patil Arts, Commerce and Science, College, Pimpri, Pune, Maharastra, India

Aim: Aminopeptidase P (APP) is an enzyme that has specificity for proline, can specifically cleave Xaa-Proline peptides and is a metallo-aminopeptidase. The bonds nearby to the imino acid proline are tough to be cleaved by many peptidases but APP can specifically break peptide bonds engaged with proline. Membrane-bound form and a cytosolic form are the two forms in which this enzyme exists. The exact physiological function of APP remains unclear and hence the present work attempts to determine it. Methods: In present study, expression pattern of cytocolic Aminopeptidase P (DAP) was determined in all the embryonic stages and larval stages of wild type Drosophila, by using polyclonal monospecific antibodies. To show the presence of DAP RNA in embryonic and larval stages, RNA in situ hybridization was performed. DAP *promoter-LacZ* fusion reporter gene vector was used to construct transgenic embryos to study the regulation pattern of DAP. To study the DAP expression profile, a transgenic fly consisting of DAP promoter with β-gal and GFP reporter genes in front of it was constructed. Results: DAP protein expression was observed in neuroectodermal cells, posterior midgut primordium, proctodeum, ventral neuroblast and primordial stomatogastric nervous system. It was observed in the ventral cord and midgut in the stage 12. The completely developed embryos showed intense occurrence of it in the ventral cord and gut region. The eye-antennal disc, wing disc and leg disc also showed the presence of DAP protein. LacZ expression in transgenic embryos also showed same pattern. Conclusion: Similar to various known multiple functional proteins, DAP could be one with different functions at different stages and in different cells. Data presented here designates DAP functions in the early embryonic and imaginal disc differentiation and development, suggesting that it may be required for the metabolism of proteins like neuropeptides, and tachykinins.

Thursday Posters: Liver Genetic Diseases

1085. Engineering of a High-Activity FVIII-BDD Gene Therapy Vector with High AAV-Packaging Efficiency for Hemophilia A

Qu Bin, Na Li, Xi Zhu, Wenjing Luo, Hongyu Li, Xingyu Yang, Shin-Shay Tian, Xiaoping Zhao
Shanghai Vitalgen Biopharma Co Ltd., Beijing, China

Hemophilia A is an X-linked recessive genetic disease caused by a deficiency or dysfunction of the clotting factor VIII (FVIII). We have developed a highly active FVIII-BDD AAV expression cassette and demonstrated its superior efficacy in mouse and non-human primate models The FVIII-BDD coding sequence was first codon optimized for enhanced human hepatic expression with reduced CpG to minimize silencing *in vivo*. Then, different regions of FVIII-BDD were mutated, such as the F309S mutation, the deletion of the furin recognition site 1645-1648 in the SQ sequence, the insertion of 5 glycosylation sites in the middle of the SQ, and combination mutations of the above described to further optimize hepatic protein expression. Since the A1 domain sequence affects the secretion and expression of FVIII-BDD, we replaced the A1 domain sequences with those of the pig FVIII, An53 and other proteins known for their high expression and secretion. We designed a series of X2 (two amino acid mutations), X4 (four amino acid mutations) and X5 (five amino acid mutations) to further improve the hepatic expression and secretion of FVIII-BDD. In addition, we also performed extensive promotor screening to obtain a short 175bp liver-specific promoter. By combining the above optimized elements, we generated several AAV expression cassettes and packaged into AAV8 for validation *in vivo,* together with two FVIII-AAV benchmark controls, BMN-270 and SPK-8011. While the benchmark BMN-270 group was found to have an average FVIII activity of 85.9 IU/mL,

our optimized expression cassettes were all performed significantly better, with the best one R216 showing an average FVIII activity of 1149.2 IU/mL. R216 expression cassette was selected and packaged into AAV5 for evaluation in non-human primates, using BMN-270 (also packaged in AAV5) as a benchmark control. We again observed significantly higher FVIII expression by R216 in comparison to BMN-270. The large size of FVIII has always presented a major challenge to develop an effective AAV gene therapy. After optimizing our vectors and selecting the smallest elements, we managed to reduce the R216 vector size to 4,917nt. At this size, there were still significant packaging and purification challenges. To address this, we have implemented measures such as inserting the lambda II filling sequence outside the ITR sequence, screening for the optimal RC and helper plasmid combination, and extensive optimization of the purification processes. We have successfully increased the packaging efficiency and virus yields and in addition, controlled the residual plasmid and Host Cell DNA (HCD) at very low levels, laying a solid foundation for advancing our FVIII gene therapy into clinical trials.

1086. The Combination Strategy of Lipid Nanoparticle-Encapsulated rAAV and Triamcinolone Acetonide Enables Enhanced and Successful rAAV Multi-Administration

Chunmei Gan[1], Mi Leng[1], Yu Liu[1], Zhaoyue Zheng[1], Siyuan Dong[2], Lei Gao[2], Jingya Ye[2], Hoi Yee Chow[1], C. Alexander Valencia[2], Biao Dong[2]

[1]National Clinical Research Center for Geriatrics and State Key Laboratory of Biotherapy, West China Hospital, Sichuan University, Chengdu, China,[2]Sichuan Real and Best Biotech Co., Ltd., Chengdu, China

The multi-administration of recombinant adeno-associated virus (rAAV) is limited, in part, by immunological barriers in vivo. Herein, a novel strategy, named lipid nanoparticle-encapsulated rAAV combined with triamcinolone acetonide (LNP-rAAV + TAC), has been described. We demonstrated that both lipid admixing and LNP encapsulation enhanced liver-targeted transduction at initial administration. Also, successful tri-trafficking was achieved by LNP-rAAV2; however, weak expressions were observed following second and third transductions. In addition, triamcinolone acetonide administration, which modulated the immune response, permitted rAAV2 re-administration yet deaths were observed at higher-dose groups. Furthermore, the combined strategy of LNP-rAAV + TAC was tested in the tri-trafficking of rAAV2, which enabled powerful achievements in eradicating anti-rAAV antibodies and enhancing expression in the second and third transductions with a safe performance compared to their independent approaches. Thus, this combination strategy could be an attractive candidate for reducing immunogenicity and enabling multi-dosing of rAAV vectors.

1087. CRISPR Base Editing for *In Vivo* Correction of Severe Hemophilia a Missense Variant

Yuanyi Xu[1], Chun-Yu Chen[1], Meng-Ni Fan[1], Xiaohe Cai[1], Barbara A. Konkle[2,3], Carol H. Miao[1,4]

[1]Seattle Children's Research Institute, Seattle, WA,[2]Division of Hematology and Oncology, University of Washington, Seattle, WA,[3]Washington Center for Bleeding Disorders, Seattle, WA,[4]Department of Pediatrics, University of Washington, Seattle, WA

Hemophilia A (HA) is a genetic bleeding disorder in which patients are not able to produce sufficient functional coagulation factor VIII (FVIII, *F8* as the gene of FVIII). The identification and correction of the patient's *F8* pathogenic variant represents a personalized gene therapy approach to rescue FVIII production and therefore treat HA. We aim to use CRISPR cytosine base editing (CBE) to target the HA missense variant to achieve high editing efficiency and low bystander effects, resulting in phenotypic and genotypic improvements. Among *F8* variants identified in our patients with HA, we selected the T535C variant and designed sgRNA with mutation site T·A to C·G on C8. To examine the in vivo base editing, we constructed a B-domain-deleted mutant human FVIII (hFVIII) expressing plasmids encoding the T535C variant and used a wild-type hFVIII as a control. Subsequently, we proceeded with cloning the CBE plasmid by incorporating the U6 promoter and specific sgRNA targeting the mutant site into pCMV-BE4m vector backbone. The CBE plasmid, along with T535C mutated FVIII plasmid were hydrodynamically injected into an exon 16 deletion-HA murine models. The FVIII activities were determined by activated partial thromboplastin time assay. Treated mouse livers were harvested for genomic DNA extraction, followed by PCR of the target region and Sanger sequencing to evaluate the editing efficiency. We observed 18-28% overall editing rate and a wide editing window from the initial testing of base editing of the specific *hF8* variant using the parent CBE plasmid. Subsequently, we enhanced our CBE constructs by switching the CMV promoter to the stronger CAG promoter and explored existing CBE variants to increase targeting specificity. New combinations of mutated T535C hFVIII and CBE variants plasmids were administered by hydrodynamic injection and the editing efficiency was examined with the same methods. One of the highly active CBE variants driven by CAG promoter demonstrated the highest FVIII activity, exceeding 50% FVIII activity of the wild-type FVIII plasmid treated mice on day 7. DNA sequencing result also indicated 50% of *in vivo* correction of mutant C·G to normal T·A on day 7. Minor bystander effects did not significantly impact the functional FVIII activity recovery. The results suggest CRISPR base editing tools in combination with specific sgRNA can efficiently correct the missense mutation and provide effective phenotypic correction of mutant FVIII plasmid *in vivo*. We are currently testing the base editing tools to correct point mutations in primary human cells.

1088. Development of an AAV Gene Therapy Vector FT-004 for Hemophilia B

Zhong-Dong Shi[1], Chinmay Patkar[1], Yiling Fang[1], Chao Ren[2]

[1]Frontera Therapeutics, Bedford, MA,[2]Frontera Therapeutics, Shanghai, China

Hemophilia B is an inherited X-linked rare recessive genetic bleeding disorder caused by insufficient levels of a blood protein called factor IX (FIX). Using AAV vectors to deliver FIX expression cassettes to the patient's liver is a promising method to treat the disease. However, several early programs have failed likely due to low activity of wildtype FIX or loss of transgene expression. A high number of CpG dinucleotides in the transgene could stimulate innate immune response which might result in loss of durability. To develop a novel durable AAV gene therapy vector for treating as many hemophilia B patients as possible, we designed 6 vectors in either scAAV or ssAAV form containing a codon-optimized human FIX Padua variant driven by different liver-specific promoters. FIX-Padua is a natural hyperactive FIX variant whose activity is ~7-fold that of wild-type FIX. To reduce potential immunogenicity, the CpG count on the codon-optimized FIX Padua variant was reduced to 0. AAV5 capsid was used to target a broader patient population given its low seroprevalence. We tested the vectors for FIX expression and activity in vitro using the Huh-7 cell line, followed by further comparing them in an *F9* KO hemophilia B mouse model. We nominated the design that gave the highest potency according to one-stage clotting assay as our drug candidate - FT-004. Further in vivo preclinical study showed that FT-004 specifically targeted *F9* KO mouse liver and provided a high level of FIX expression, and the FIX antigen concentration in the plasma was stable from week 4 to week 8. Both FIX activity and aPTT time changes displayed a clear dose-dependent manner. FT-004 could reduce bleeding duration, decrease bleeding area, and increase survival rate. The minimum effective dose (MED) was determined to be 5E12 vg/kg. FT-004 produced at different scales (from 0.2 L, 50 L, and 500 L) showed a comparable potency in the hemophilia B mice. A 13-week GLP safety study in NHPs (cynomolgus monkeys) showed that FT-004 had no local or systemic toxic effects at all tested doses up to 9.7E13 vg/kg (NOAEL). Furthermore, administration of FT-004 also resulted in potent hFIX protein expression in NHPs in a dose-dependent manner. Vector genome copies were persistent from Day 29 to Day 92 post vector injection in NHPs, which may indicate that codon-optimized and CpG-removed FIX-Padua gene sequence did not elicit a strong immune response. Overall, the vector durability, efficacy, and safety data we generated from preclinical studies support further clinical development for FT-004.

1089. Optimized F8-X5 Variants Improve hFVIII Activity and Durability of Expression

Shiyong Wu[1], Matthew Chrzanowski[2], Kentaro Yamada[1], Sreevani Arisa[1], Jiahe Tian[3], Roland W Herzog[1], Weidong Xiao[1], Junping Zhang[1]

[1]Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN,[2]Nikegen LLC, Wynnewood, PA,[3]Department of Molecular Biology and Genetics, Cornell University, Ithaca, NY

Previously we developed a human FVIII variant FVIII-X5, which significantly improves AAV based gene therapy efficiency by enhancing hFVIII secretion. Due to AAV packaging capacity limitation, only shorter promoters can be used to regulate FVIII expression. Here we sought to develop better promoter/enhancer/intron cassettes to further improve AAV based gene therapy efficiency. New expression cassettes were constructed based on B domain deleted factor VIII (BDD-FVIII). The expression plasmids were tested by hydrodynamic injection into Hemophilia A mice. The hFVIII activity was measured by APTT assay. Five of these constructs showing significant better factor VIII expression level were further tested in AAV8 vector system using one of the BDD-FVIII, BDD-FVIII-X5 and a new BDD-FVIII-X5-LK genes. They were compared with AAV8-TTR-BDD-FVIII-X5, AAV8-hATT-codon-optimized BDD-FVIII (CoFVIII), and AAV8-TTR- CoFVIII. All AAV8 vectors were injected into HA mice (B6;129S-F8$^{tm1Kaz/J}$) at the dose of 4×10^{11} or 1×10^{11} vg/mouse, 5-7 mice/group. hFVIII activity was detected by chromogenic assay. Anti-hF8 IgG and anti-AAV8 IgG in serum were measured by ELISA. Even with a smaller promoter less than 200bp, the hFVIII activity reached a peak of 130% after one week. The newly designed mini-intron significantly enhance factor VIII expression. The hFVIII activity approached 220% at two weeks with an intron addition. We observed that hFVIII activity dramatically dropped after achieving a peak at later time points. Meanwhile, the anti-hFVIII IgG expression greatly increased accordingly. These results suggest that the expression cassette with an efficient mini-promoter-enhancer-intron combination lead higher hFVIII expression but does result in increased inhibitor formation in mice. For the factor VIII with a new heavy chain and light chain link FVIII-LK, the expression exhibited a unique pattern, the hFVIII activity showed a slight increase from day 7 to day 14 and achieved a dramatically high level at 220% from day 21 to 28. Interesting, no anti-hFVIII-IgG expression was detected in this vector group. In addition, we systemically characterized the genome integrity of the new AAV-FVIII produced. Alkaline gels showed that the packaged genomes size in 4906 bases, 4874 bases, 5080 bases exhibited an intact band while the packaged genomes of 5493 base and 5210bases show varying truncated bands. In conclusion, these optimized hFVIII-X5 expression variants are promising candidates for hemophilia A gene therapy.

1090. Development and Optimization of Factor VIII Transgene Cassettes for Hemophilia A Gene Therapy with AAV Vectors

Kentaro Yamada[1], Miguel Gonzalez[1], Zhouji Chen[2], Maite Munoz[1], Sreevani Arisa[1], Bridget Brian[1], Ype De Jong[3], Weidong Xiao[1], Randal J. Kaufman[2], Roland W. Herzog[1]

[1]Herman B Wells Center for Pediatric Research, Indiana University, Indianapolis, IN,[2]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA,[3]Weill Cornell Medical College, New York, NY

Liver-directed adeno-associated viral (AAV) vector-based gene therapy drugs have recently received regulatory agencies for the treatment of the X-linked bleeding disorder hemophilia. However, large vector doses are used to treat hemophilia A (deficiency in coagulation factor VIII, FVIII). Furthermore, FVIII is not normally expressed in hepatocytes and may induce cellular stress responses. More efficacious vectors expressing better secreted forms of FVIII are desirable. To generate superior FVIII transgene cassettes, we tested AAV8 vectors harboring different cassettes expressing CpG-depleted, codon-optimized, B domain-deleted (BDD) human FVIII in hemophilia A mice (C57BL6/129 F8e16-/-). AAV vectors were administered iv at the dose of 1.0E+11 vg/mouse. Initially, we compared a limited number of published elements and found a construct utilizing the hepatocyte-specific HLP promoter, which drives FVIII expression in the commercial product roctavian, achieved ~55% of normal FVIII

activity at week 2. We next introduced amino acid changes that may enhance FVIII secretion. These variants included F309S, X5 (a variant in which 5 amino acids had been replaced with porcine residues for improved secretion), and a combination of these. While F309S failed to improve FVIII activity in circulation, introduction of X5 showed about 4-fold higher FVIII activity (~190%). Combination F309S/X5 showed the similar FVIII activity (~221%) compared to X5 alone. Analysis of AAV copy numbers and hF8 mRNA levels measured in livers at 6 weeks showed overall a good correlation between AAV copy numbers, F8 mRNA levels and FVIII activities for individual mice. Next, we replaced the HLP promoter with the transthyretin (TTR) promoter, which is utilized in a different product under commercial development and similar in size to the HLP promoter. This change consistently increased FVIII activity by ~2-fold for all constructs, resulting on average in 118% activity for WT FVIII and 112%, 414% and 354% for F309S, X5 and F309S/X5, respectively. When normalized for vector copy number in the liver, results suggested that inclusion F309S in WT FVIII or X5 variant modestly improved systemic FVIII expression by 2- and 1.4-fold, respectively. Thus far, all constructs expressed the "SQ" version of BDD-FVIII. Since the QS linker sequence contains a proteolytic cleavage site that may decrease FVIII stability, we deleted the SQ linker, which increased FVIII activity by 1.5- to 1.8-fold, with the additional advantage of further reduced the size of the vector genome. We are now testing whether performance of the X5 variant can be further enhanced by combination with linker deletion or mutations that reduce FVIII inactivation in circulation. In conclusion, FVIII can be rationally engineered to develop AAV gene therapy that is effective at reduced vector doses. We postulate that improved secretion combined with reduced burden of FVIII per hepatocyte will result in more stable gene therapy for hemophilia A.

1091. A Novel Factor VIII Variant That Yields Improved Secretion and Reduced ER Stress for Second Generation AAV-Mediated Gene Therapy for Hemophilia A

Jonathan R. Lindgren[1], Marie Seleme[1], Allysen Henriksen[1], Giang N. Nguyen[1], Denise E. Sabatino[1,2]

[1]Division of Hematology and The Raymond G. Perelman Center for Cellular and Molecular Therapeutics, The Children's Hospital of Philadelphia, Philadelphia, PA,[2]Department of Pediatrics, Division of Hematology Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

An AAV gene therapy product was recently approved for the treatment of patients with severe hemophilia A (HA). Ongoing clinical studies have shown promise, however, it is unclear whether long term FVIII activity within a therapeutic-to-curative range can be achieved for all patients. There remains a need to develop 2nd generation products that achieve durable levels of FVIII expression at lower vector doses. Most products in clinical development make use of a B-domain deleted (BDD) human factor VIII (hFVIII) transgene. Our group has identified a unique hFVIII-BDD protein variant, hFVIII-Δ3-SP/DE, that is secreted more efficiently and expressed at higher levels after gene therapy when compared to hFVIII(Nguyen et al 2023). In vivo studies of AAV delivery of the hFVIII and hFVIII-Δ3-SP/DE showed that the variant expressed 2-4-fold higher levels of protein in the plasma which inversely correlated with intracellular FVIII protein levels. To further understand the mechanism for the increased FVIII levels in the plasma after AAV gene therapy, we investigated the secretion of hFVIII-Δ3-SP/DE in vitro. Using established stable BHK cell clones, we determined the ratio of intracellular to secreted FVIII by comparing clones expressing hFVIII or hFVIII-Δ3-SP/DE. The ratio of intracellular FVIII to secreted FVIII from stable BHK clones expressing hFVIII (4.7 ± 1.3) was significantly higher than hFVIII-Δ3-SP/DE (1.6 ± 0.3, $p < 0.001$). This demonstrates that the hFVIII-Δ3-SP/DE variant is secreted more efficiently than hFVIII. Previous studies have shown that overexpression of FVIII may activate ER stress pathways. We hypothesized that hFVIII-Δ3-SP/DE may reduce cellular stress responses since it is secreted more efficiently. Stable BHK clones expressing hFVIII and hFVIII-Δ3-SP/DE were evaluated for transcriptional activation of ER stress response elements using the Cignal ERSE-Reporter Dual-Luciferase Assay. Two independent stable clones expressing the hFVIII-Δ3-SP/DE variant expressed significantly lower levels of ERSE-driven luciferase activity (0.53 ± 0.24 and 0.51 ± 0.25 RLUs) compared to clones expressing hFVIII (1.11 ± 0.34 RLUs) ($p < 0.05$, Dunnets multiple comparisons test). Stable clones were further assessed for relative mRNA expression of the unfolded response element marker, BiP. Clones expressing hFVIII had significantly increased levels of BiP expression compared to clones expressing hFVIII-Δ3-SP/DE, at similar levels of hFVIII mRNA (3.2 vs 0.95, respectively, 2-sided unpaired t-test $p = 0.0002$). Furthermore, the normalized amount of BiP expression per copy of FVIII mRNA was higher in BHK clones expressing hFVIII vs hFVIII-Δ3-SP/DE (2.8 vs 1.8, respectively, two-sided unpaired t-test $p = 0.044$). The hFVIII-Δ3-SP/DE variant has reduced ER stress induction, compared to hFVIII, possibly due to the improved secretion efficiency of the variant protein. In conclusion, the hFVIII-Δ3-SP/DE variant shows enhanced secretion both in vitro and in vivo, leading to higher FVIII levels in plasma and reduced ER-stress, showing that this variant overcomes a key barrier in AAV gene therapy for hemophilia A.

1092. The Impact of Anti-Platelet Antagonists on the Hemostatic Efficacy of Platelet-Specific FVIII Gene Therapy in Hemophilia A Mice

Hongyin Yu[1,2], Jocelyn A. Schroeder[1,2], Jeremy G. Mattson[2], Qizhen Shi[1,2]

[1]Dept of Pediatrics, Medical College of Wisconsin, Milwaukee, WI,[2]Blood Research Institute, Versiti Wisconsin, Milwaukee, WI

Hemophilia A is a prime model for gene therapy. Recently, the FDA has approved AAV-mediated liver gene therapy to treat patients with hemophilia A. However, pediatric and adult patients with severe liver disease or neutralizing antibodies to AAV, which are present in 30-50% of the population, are excluded from AAV liver gene therapy. Our previous studies have demonstrated that platelet-targeted FVIII expression (2bF8) is effective in rescuing the bleeding phenotype of hemophilia A ($F8^{null}$) mice even in the presence of anti-FVIII inhibitory antibodies (inhibitors). Currently, our gene therapy approach is in Phase I clinical trial. Since antiplatelet drugs are commonly used in the clinic, it is important to investigate how platelet antagonists affect the clinical efficacy of platelet-derived FVIII. Here, we evaluated two categories of platelet antagonists: one is the antibody (Leo.H4) that specifically blocks the αIIbβ3 complex, and the other is the drug (Clopidogrel, Plavix) that inhibits the $P2Y_{12}$ subtype of the ADP

receptor to investigate how anti-platelet medications impact the clinical efficacy of platelet-derived FVIII. Hemostatic properties of platelet-FVIII were assessed by *ex vivo* ROTEM and native whole blood TGA (nWB-TGA) analysis of whole blood and *in vivo* $FeCl_3$-induced carotid artery injury model, lateral tail vein transection (TVT) injury model, and tail tip bleeding test (TTT). In $2bF8^{Tg}/F8^{null}$ mice with a platelet-FVIII level of 6.89±0.65 or 12.32±0.73 mU/10^8 platelets, all parameters from ROTEM analysis were comparable to those in WT control mice. However, all parameters, including clotting time, clot formation time, maximal clot firmness, α-angle, and A10 were significantly impaired in the presence of Leo.H4 compared to native samples from 2bF8 mice. In contrast, in samples from WT mice, only α-angle and A10 were significantly tempered in the presence of Leo. H4. Interestingly, peak thrombin and endogenous thrombin potential determined by nWB-TGA were significantly enhanced in the presence of Leo.H4 compared to native samples from $2bF8^{Tg}/F8^{null}$ mice, but there were no significant differences in other parameters. Leo.H4 did not impact the hemostatic parameters determined by nWB-TGA in WT mice. Complete occlusion occurred in the $FeCl_3$-induced carotid injury in all 2bF8 and WT mice, but none occluded when Leo.H4 was infused. In the TVT injury model, when Leo.H4 was infused, none of the $2bF8^{Tg}/F8^{null}$ mice stopped bleeding in the 10-minute bleeding test, and animals lost a significant amount of blood (525.98±92.06 µL). In contrast, when animals were infused with IgG isotype control, the bleeding time was 0.99±0.05 min, and blood loss was 17.05±9.37 µL. There were no significant differences in the bleeding time and blood loss between the 2bF8 and WT groups infused with IgG in the TVT test. When mice were treated with Plavix, all 2bF8 and WT animals bled the entire 10 minutes during the TTT test, which was significantly different compared to the control vehicle-treated animals, in which the bleeding time was 0.88±0.39 and 1.43±1.19 min, respectively. The blood loss in the Plavix-treated animals was 84.1±68.18 and 56.74±49.16 µL in the 2bF8 and WT groups, respectively. The blood loss in these animals was 13- and 16-fold more than those lost in vehicle-treated control animals (6.4±6.19 and 3.5±4.67 µL, respectively, in the 2bF8 group and WT group). In conclusion, our results demonstrate that platelet aggregation is critical in maintaining the clinical efficacy of platelet-derived FVIII in hemophilia A and anti-platelet medications can impede the hemostatic efficacy of platelet-FVIII

1093. Peptide-Based Nanoparticles Mediated mRNA Rescue of Factor VIII; a New Approach to Treat Hemophilia A

Gilles Di Vita[1,2], Nathalie Durany[1,2], Veronique Josserand[3], Melanie Guidetti[4], Neil Desai[2]

[1]DIVINCELL, Nimes, France,[2]AADIGEN, Pacific Palisades, CA,[3]IAB, Grenoble, France,[4]IAB, Genoble, France

Hemophilia A is an X-linked bleeding disorder caused by the deficiency of coagulation Factor VIII. Hemophilia A patients are currently treated with costly and inconvenient replacement therapy of short-lived factor VIII (FVIII) protein. Although safe and efficient delivery of therapeutic mRNAs for protein replacement therapies offers great promise, it remains challenging. We have developed a new peptide-based platform that can potently deliver functional mRNAs encoding Factor VIII to the liver. ADGN technology constitutes a biocompatible and scalable system to efficiently package and deliver mRNA to the target site. ADGN technology is based on short amphipathic peptides that form stable nanoparticles with nucleic acids through non-covalent electrostatic and hydrophobic interactions. The chemistry of ADGN-nanoparticles can be tuned in order to target specific organs and to induce robust mRNA expression in the targeted tissue. Here we selected ADGN-peptide with a liver tropism and able to target liver and lymph nodes. ADGN/mRNA nanoparticles are stable both in solution and in dry powder formulations, with an average size of 100 nm and a high encapsulation efficiency (> 90%) We demonstrated that Intravenous (IV) and subcutaneous (SQ) administration of ADGN-carrying mRNAs encoding human FVIII (ADGN-F8) into a Hemophilia A mouse model, using different dosing regimens (ranging from 0.2 to 1.0 mg/Kg), results in a rapid pulse of FVIII protein expression (within 12h) and a recovery of the Factor VIII level in the blood. The expressed FVIII protein is therapeutically effective, like the recombinant human factor VIII protein, that is the current standard of care. The FVIII protein expression and activity remained above therapeutic levels up to 30 days post-injection (>50% of the reference range) and slowly declined thereafter. Repeated IV (0.2 mg/Kg) and SQ (1.0 mg/kg) injections of ADGN-F8 once every two weeks produced consistent expression of FVIII over time IV SQ , and maintained protein level and FVIII activity above clinically relevant threshold (>50% of the reference range). ADGN-F8 was redosed every 2 weeks over 3months without inducing liver toxicity, inflammation or chronic alteration as determined by histology. Cytokine, histology and liver enzyme profiling showed that repeated SQ and IV administrations of the ADGN-F8 did not cause any adverse innate or adaptive immune responses in immune-competent, hemophilic mouse model. Our study showed the potential of ADGN as a safe and effective platform of new mRNA therapies for Hemophilia A. ADGN-F8 treatment produced rapid and prolonged duration of FVIII expression that could be a therapeutic alternative for current Hemophilia A treatments. Similar strategies could be applied to other clotting disorders and for other hepatic diseases.

1094. *In Vivo* CRISPR Mediated Editing of PCSK9 Using Peptide-Based Nanoparticles Durably Lowers Cholesterol in Mice

Gilles Di Vita[1,2], Nathalie Durany[1,2], Veronique Josserand[3], Melanie Guidetti[3], Neil Desai[1]

[1]AADIGEN, Pacific Palisades, CA,[2]DIVINCELL, Nimes, France,[3]IAB, Grenoble, France

Atherosclerotic cardiovascular disease remains the leading cause of death worldwide. A major contributor to the development of atherosclerosis are elevated low-density lipoprotein cholesterol concentrations. Hypercholesterolemia is a highly prevalent genetic disorder and mutations *PCSK9 gene*, encoding proprotein convertase subtilisin/kexin type 9 (PCSK9) was identified to cause hypercholesterolemia. Inhibitors of PCSK9 have emerged as a promising new class of cardioprotective drugs *and b*ase editing strategies to permanently disrupt the *PCSK9* gene in the liver are currently being evaluated in Phase 1 clinical trial.By delivering an mRNA encoding for the Cas9 protein with guide RNAs (sgRNA) for a gene of interest it is possible to permanently knock out a pathogenic gene mutant in a target cell, curing otherwise incurable genetic diseases. However, *in vivo* administration CRISPR components remains a limitation to the overall potency and for the therapeutic application of

the CRISPR-CAS9 system. We have developed a new delivery platform that can potently deliver active CAS9 mRNA/gRNA complexes *in vivo* and selectively silence PCSK9 gene in mouse liver. ADGN technology constitutes a biocompatible and scalable system to efficiently package and deliver CAS9mRNA/gRNA to the target site. ADGN technology is based on short amphipathic peptides that form stable nanoparticles with RNAs. The molecular composition and sequences of ADGN nanoparticles have been rationally designed for selective organ targeting of functional RNAs and to overcome off target accumulation. *PCSK9* being preferentially expressed in the liver, we have selected ADGN-peptide with a liver tropism and able to target liver i*n vivo*. ADGN/RNAs nanoparticles exhibit stable physicochemical properties both in solution and in dry powder formulations, with an average size of 100 nm, a slightly negative charge surface and a high encapsulation efficiencies (> 90%).We demonstrated that intravenous administration of ADGN/Cas9mRNA:gRNA nanoparticles resulted in mRNA accumulation in the liver with CAS9 protein expression starting 6 hrs after administration with an optimal expression after 24 hrs, and slowly declined thereafter.ADGN has been used for the co-delivery of mRNA encoding for Cas9 and a guide RNA targeting exon 1 of mouse *PCSK9*. We showed that a single administration of ADGN-PCSK9 induced in a permanent alteration of PCSK9 in mice. We observed nearly 50 % of knockdown of *PCSK9* gene in the liver at various doses down to 0.5 mg/Kg. ADGN-PCSK9 treatment resulted in a stable reduction of circulating PCSK9 plasma levels by ca. 75% and reduction of plasma cholesterol level by ca. 55%. All of these alterations remained stable for at least 2 months after a single-dose treatment. Cytokine, histology and liver enzyme profiling showed that ADGN-PCSK9 administration does not induce liver toxicity, inflammation or chronic alteration and any adverse innate or adaptive immune responses in immune-competent mice. No off-target were detected with a 0.5 mg/kg dose and no modification in PCSK9 and cholesterol levels was observed when using control ADGN nanoparticles containing mRNA Cas9 and a control gRNA targeting GFP. ADGN nanoparticles constitute a new platform for CRISPR editing of PCSK9 in order to reduce low-density lipoprotein cholesterol as a treatment of atherosclerotic cardiovascular disease. Our results provide a proof-of-concept for how ADGN technology can be successfully applied to make precise CRISPR gene editing in therapeutic target genes in the liver.

Thursday Posters: Lysosomal Storage Disorders

1095. Preclinical Therapeutic Efficacy of Novel Bicistronic Adeno-Associated Virus Vectors for GM2 Gangliosidosis Gene Therapy

Ali Ramezani, Anna Leigh Lynch, Juliette Hordeaux, James M. Wilson

Gene Therapy Program, University of Pennsylvania, Philadelphia, PA

Background: Tay-Sachs disease (TSD) and Sandhoff disease (SD) arise from mutations in the *HEXA* and *HEXB* genes, respectively, that result in reduced or complete loss of the heterodimeric enzyme β-N-acetylhexosaminidase (HexA). A deficiency of functional HexA prevents degradation of its substrate, GM2, meaning GM2 accumulates in neurons where it causes lysosomal dysfunction, neurotoxicity, and death. No cure or effective therapy is currently available for either TSD or SD. Research has shown that gene therapy can confer substantial therapeutic benefits in animal models, with adeno-associated virus (AAV) vector-mediated *HEXA* gene delivery and expression emerging as one of the most promising approaches for treating TSD and SD. Objective: Generating functional HexA heterodimers requires co-expression of the α- and β-subunits within the same cell; given the limited transgene capacity of AAV vectors, previous work has explored the co-delivery of two separate monocistronic AAV vectors, albeit with limited success. Our objective was to develop bicistronic AAV vectors that co-express both subunits of HexA and identify the optimal design. Methods: We developed novel bicistronic AAV-hu68 vectors co-expressing the *HEXA* and *HEXB* complementary DNA using a 2A peptide or bidirectional (BD) promoter strategy. We evaluated several different viral 2A peptides (2A-1 to 2A-5), as well as novel and naturally occurring short BD promoters with or without the cytomegalovirus enhancer, ranging in size from 131 bp to 869 bp (BD-1 to BD-6). We identified vectors with the most efficient 2A peptides following in vitro transfection and Western blot analysis of *HEXA-HEXB* double knockout (AB-KO) human embryonic kidney (HEK293) cells. To test the BD promoters, we constructed AAV vectors with enhanced green fluorescent protein and mCherry fluorescent biomarkers flanking the promoters and tested these vectors in vitro in 293T cells and in vivo in C57Bl6 mice. We evaluated the therapeutic efficacy of selected AAV-hu68 vectors with the best-performing 2A peptides or BD promoters in 4- to 6-week-old SD mice (*Hexb*$^{-/-}$) following intracerebroventricular (ICV) administration of 1E11 genome copies/mouse. Results: AAV vectors with 2A-1 and 2A-2 exhibited the highest expression, near-complete peptide cleavage, and highest enzyme activity in transfected AB-KO HEK293 cells. Among the BD promoters, AAV vectors with BD-1, BD-2, and BD-3 conferred the highest transgene expression and enzyme activity in transfected AB-KO HEK293 cells. Following ICV dosing in adult SD mice, we detected HexA enzyme activity in the blood of all dosed animals on day 7 at levels that reached or exceeded wild-type levels. Moreover, all AAV vectors significantly improved survival compared to untreated SD mice. The median survival increased post dosing from 10.3 weeks for untreated SD mice to 15.7 weeks for AAVhu68-HEXB-[BD-3]-HEXA vector-dosed SD mice ($p<0.01$), 17.6 weeks for AAVhu68-HEXA-[2A2]-HEXB vector-dosed mice ($p<0.005$), and an undefined survival for AAVhu68-HEXA-[2A1]-HEXB vector-dosed mice, as 50% of the treated SD mice in this group survived past 22 weeks post-dosing (the experimental endpoint). Histological analysis of SD mice brains stained with an anti-GM2 antibody demonstrated that all vector-treated SD mice exhibited decreased GM2 buildup compared with untreated SD mice; we observed the greatest reductions (85% and 67%) in GM2 accumulation in the brain in SD mice treated with AAVhu68-HEXA-[2A2]-HEXB and AAVhu68-HEXB-[BD-3]-HEXA vector, respectively. Conclusion: Upon ICV administration in SD mice, our novel bicistronic AAV vectors achieved high HexA expression and activity levels, ameliorated brain GM2 accumulation, and conferred significant survival benefits. These data highlight the potential efficacy of bicistronic AAV vectors for treating GM2 gangliosidoses such as TSD and SD.

1096. Development of Systemic AAV Gene Therapies for Neuronopathic Gaucher Disease

Tae Un Han[1], PamelaSara Head[2], Adenrele Gleason[1], Bahafta Berhe[1], Akhil Kulkarni[1], Tiffany Chen[1], Charles P. Venditti[2], Ellen Sidransky[1]

[1]Medical Genetics Branch, NIH/NHGRI, Bethesda, MD,[2]Metabolic Medicine Branch, NIH/NHGRI, Bethesda, MD

Introduction: Gaucher Disease (GD) is an autosomal recessively inherited disorder resulting in the deficiency of the lysosomal enzyme glucocerebrosidase (GCase). The disorder has a spectrum of both neuronopathic and non-neuronopathic manifestations, with varying levels of severity. Current treatments (enzyme replacement therapy and substrate reduction therapy) are effective for non-neuronopathic GD, but do not reverse neuronopathic symptoms, as these therapies do not cross the blood-brain-barrier. Our aim was to develop novel viral gene therapies and evaluate their efficacy in a murine model of neuronopathic GD (nGD). **Methods:** Codon adjusted and optimized *GBA1* genes were developed and tested for expression in human HEK 293T cells and a H4 neuroglioma *GBA1* knock-out cell line (H4 *GBA1-/-).* The *GBA1* construct, co*GBA1.1* demonstrated highest GCase expression was cloned as a transgene under the control of the EF1S promoter and produced supraphysiological GCase activity in H4 *GBA1-/-* cells. Next, *coGBA1.1* was used to produce single stranded AAV EF1s *coGBA1.1* HPRE vectors packaged in AAV9 and AAVrh10 capsids. The recovery of GCase expression was evaluated in H4 *GBA1-/-* cells via infection with the *GBA1* AAVs followed by Western Blot analysis. Then the AAV-*GBA1* constructs were tested *in vivo* using a K14-lnl skin-recovery knock-out mouse model of nGD. The AAV-*coGBA1.1* vectors were delivered at varying doses via facial vein (FV) infusions or retro orbital (RO) injections in P1 neonatal K14-lnl pups and survival was evaluated. We are also developing a model of delayed onset nGD using a tamoxifen-induced *gba1* knock-out strategy, where symptoms are induced by oral administration of tamoxifen in older mice. **Results:** Both AAV9 and AAVrh10 EF1s *coGBA1.1* HPRE vectors restored GCase levels in a dose dependent fashion in H4 *GBA1-/-* cells. K14-lnl animals treated with a 4×10^{11} GC dose of the AAV9-EF1s *coGBA1.1* HPRE prevented neurological and systemic manifestations of nGD and extended lifespan (>300 days), with grossly normal behavior, development, weight gain, clinical appearance, and fertility while the untreated K14-lnl mice had weight loss, an abnormal gait, seizures, Gaucher cells in visceral organs and severe neuroinflammation at two weeks of age. Treatment of three K14-lnl mice with AAVrh10- EF1s *coGBA1.1* HPRE the same dose also prevented the development of symptoms. The tamoxifen-induced *gba1* knock-out model developed neurological findings and neuroinflammations similar to those in K14-lnl mice at age 10~14 weeks, depending on when tamoxifen was administered. **Conclusions:** The EF1s *coGBA1.1* HPRE transgene, when packaged into an AAV9 or AAVrh10 capsid, demonstrated potent *in vivo* activity in a severe model of nGD, a devastating genetic neurodegenerative disorder currently without any effective therapy. After dosage optimization in mouse models of nGD, we will explore the feasibility of a clinical trial in patients while we further develop conditional, inducible models of nGD.

1097. Long-Term Functional Benefits of Treating MPS IH with a Compact Self-Complementary AAV9-ΔIDUA^{op} Vector

Tierra A. Bobo[1], Hyouk-Bum Kwon[2], Xinyu Cao[2], Michael Robinson[2], Allen Zheng[3], Haiyan Fu[1]

[1]Pediatrics Genetics and Metabolism, The University of North Carolina at Chapel Hill, Gene Therapy Center, Chapel Hill, NC,[2]Gene Therapy, The University of North Carolina at Chapel Hill, Gene Therapy Center, Chapel Hill, NC,[3]NeuroGT, Inc., Chapel Hill, NC

MPS I is a devastating LSD caused by mutations in the iduronidase (IDUA) gene. The disease manifests in all organs, with profound neurological impairments in the majority of patients. No treatment is currently available for the neurological disorders of MPS I. Addressing this unmet need, this study develops an effective self-complementary (sc) gene therapy vector for treating MPS I using the trans-BBB-neurotropic AAV9 via systemic delivery. We constructed a gene replacement vector, scAAV-Δh*IDUA*^{op}, containing the codon-optimized human *IDUA* cDNA (h*IDUA*^{op}) to enhance the transgene expression. To accommodate the limited packaging capacity of scAAV vector, we engineered the vector genome to 4,850bp by using a 228bp truncated miniatur CMV promoter, a 16bp SNRP1 Poly A signal, and miniaturized h*IDUA*^{op} cDNA (Δh*IDUA*^{op}). We tested scAAV-Δh*IDUA*^{op} vector *in vitro* to assess rIDUA expression, secretion, and scAAV packaging. *In vitro* studies showed that codon-optimization of h*IDUA* cDNA resulted in >2-fold increase in rIDUA expression. The deletion of 15 bp non-conserved 3' untranslated sequence from h*IDUA*^{op} not only enabled the packaging of scAAV-Δh*IDUA*^{op}, but also further enhanced rIDUA expression and secretion. The scAAV9-ΔhIDUA^{op} viral vector was tested in 1-2m-old MPS I mice via an IV injection at 2e12vg/kg, 5e12vg/kg and 1e13vg/kg to determine the therapeutic potential. The vector treatments resulted in rapid and persistent IDUA expression, the clearance of lysosomal storage pathology throughout the CNS, PNS and periphery tissues, and amelioration of neuroinflammation, leading to significant behavior improvement and extension of survival (ongoing) in MPS I mice. Notably, 2e12vg/kg was identified as the minimal effective clinical dose. This study demonstrates the promising clinical potential of the systemic scAAV9-ΔhIDUA^{op} gene delivery for treating neuropathic MPS I. The 4,850bp vector genome allows the packaging into scAAV vector, which is slightly beyond the previously defined size limit (~4,700bp).

1098. Development of a Best-in-Class AAV Gene Therapy for Fabry Disease with Enhanced a-Gal A Expression and Cellular Uptake by Protein Engineering and Promoter Evolution

Lu Guo, Zihui Zhao, Wenjing Luo, Jing Ma, Xi Zhu, Xiaoping Zhao, Shin-Shay Tian

Vitalgen BioPharma, Shanghai, China

Fabry disease (FD, OMIM 301500) is an X-linked, dominantly inherited genetic disorder caused by the deficiency or absence of lysosomal α-galactosidase A (EC 3.2.1.22, α-Gal A), resulting in pathogenic deposit of globotriaosylceramide (Gb3 or GL-3) and its derivatives globotriaosylsphingosine (lyso-Gb3) in heart, kidney and other tissues.

The enzyme replacement therapies (ERT) approved for FD require repeat dosing and patients run the risk of developing neutralizing antibodies that reduce the therapeutic efficacy over time, supporting the need for a better treatment. One of the main limitations for FD ERTs is the poor cellular uptake efficiency of the α-Gal A protein by the relevant tissues, e.g., heart and kidney. The limited expression of the mannose-6-phosphate (M6P) receptor (M6PR), which mediates α-Gal A cellular uptake, limits α-Gal A uptake and its efficacy. Based on the association of M6P with protein glycosylation, α-Gal A mutants with increased N-linked glycosylation sites were designed to increase the numbers of M6P in the expressed α-Gal A protein. The mutants were evaluated in several liver (HepG2, Hep3B & Huh7) and kidney (A-498, ACHN &769-P) cell lines for their secreted protein expression (liver cell supernatants) and uptake (kidney cells) levels. Among the 13 mutants evaluated, mutant M7 showed the highest levels of cellular uptake, increasing up to 6-fold over the wild type α-Gal A. M7 and the wild type control were packaged into AAV8 for further evaluation in GLA$^{-/Y}$ mice at the doses of 5×10^{11}, 5×10^{12} and 5×10^{13} vg/kg. The activities of α-Gal A in the plasma, liver, heart and kidney at day 28 were measured and the levels of plasma lyso-Gb3 were analyzed. The results confirmed that in comparison to the wild type control group, the M7 group achieved higher α-Gal A enzyme activities in the liver and heart and further more, significantly better lyso-Gb3 lowering in the plasma. In parallel, the AAV expression cassette was optimized by introducing various *cis*-regulatory elements to the promoter. Based on the *in vitro* liver cell protein expression and *in vivo* efficacy studies in the GLA$^{-/Y}$ mice, P18 was identified as the best candidate. A final AAV expression cassette P18-M7 was generated and packaged into AAV8 for evaluation in the GLA$^{-/Y}$ mice at the doses of 1×10^{11}, 1×10^{12} and 1×10^{13} vg/kg. The results showed that AAV8-P18-M7 effectively down-regulated the plasma, liver, heart and kidney lyso-Gb3 to the wild type levels at 28 days after AAV administration, significantly more effective than the several benchmark constructs used for comparison. To summarize, by optimizing α-Gal A protein cellular uptake and obtaining a chimeric promoter to drive stronger liver-specific protein expression, we have developed a significantly improved AAV-based gene therapy for treating Fabry Disease.

1099. Preclinical Development of ZS805, a Favorable Liver-Directed rAAV Gene Therapy for Fabry Disease

Fuqin Fan[1], Siwu He[2], Ming Zhang[1], Yu Liu[2], Zhaoyue Zheng[2], Siyuan Dong[1], Lei Gao[1], Jingya Ye[1], C. Alexander Valencia[1], Hoi Yee Chow[2], Biao Dong[1]

[1]Sichuan Real & Best Biotech Co., Chengdu, China,[2]National Clinical Research Center for Geriatrics and State Key Laboratory of Biotherapy, West China Hospital, Sichuan University, Chengdu, China

Fabry disease is a rare X-linked recessive lysosomal storage disease caused by dysfunctional mutations in the alpha-galactosidase A (*GLA*) gene, leading to systemic accumulation of the deleterious substrates, namely, Gb3 and Lyso-Gb3, within various tissues and organs. Progressive substrate buildup results in the development of cardiovascular and cerebrovascular symptomology, such as heart failure, stroke, end-stage renal disease and even premature death. The current standard treatment for Fabry disease is enzyme replacement therapy (ERT). While ERT has demonstrated the ability to slow the progression of the disease, its significant drawbacks, including limited efficacy, immune intolerance, immunogenicity of recombinant alpha-galactosidase A (α-Gal A) and need for lifelong infusions, have been observed by a number of studies. Herein, we present ZS805 as a rAAV5 vector harboring an expression cassette featuring a novel liver-specific promoter, a modified signaling peptide (SP21) sequence and a codon-optimized human GLA cDNA. In the investigational new drug-enabling preclinical study, we showed that in the α-Gal A KO mouse model a single intravenous injection of ZS805 (dose ranging from 2.0×10^{12} vg/kg to 2.0×10^{13} vg/kg) led to a substantial and persistent increase in the plasma α-Gal A protein and activity in a dose-dependent manner. Crucially, the plasma α-Gal A protein and activity reached supraphysiological level at a dose value of 2.0×10^{12} vg/kg, with about a 90% clearance rate of the Gb3 and lyso-Gb3 substrates in the plasma. At the end of study (Day 92), α-Gal A protein expression and α-Gal A enzymatic activity persisted, the levels of Gb3 and lyso-Gb3 significantly decreased in all examined tissues, including the liver, spleen, heart, kidney, lung, gastrocnemius muscle, brain, and dorsal root ganglia.

1100. Evaluation of AAV.GMU1 Biodistribution via Intravenous Administration for Treatment of Gaucher Disease

Swathi Ayloo[1], Shih-Ching Chou[1], Jae Ryu[1], Charles Miller[1], Jie Bu[1], Tracy Lacson[2], Mariana Gonclaves[2], Lilu Guo[2], Shelley Naas[1], Bradford Elmer[1], Catherine O'Riordan[1], Martin Goulet[1], Christian Mueller[1], Shyam Ramachandran[1]

[1]Genomic Medicine Unit, Sanofi, Waltham, MA,[2]Precision Medicine and Computational Biology, Sanofi, Cambridge, MA

Our previous work with AAV.GMU1 has demonstrated broad CNS (central nervous system) tropism in non-human primates (NHPs). We also observe that lower viral load of AAV.GMU1 capsid yields higher transgene expression compared to other capsids. Bi-allelic mutations in *GBA1*, the gene encoding glucocerebrosidase (GCase) are causative for Gaucher disease (GD). GD is a lysosomal storage disease characterized by excessive lipid build-up in macrophages across multiple peripheral tissues, including liver spleen, as well as muscle. GCase is a lysosomal enzyme that catalyzes the hydrolysis of glycolipids glucosylceramide (GL1) and glucosylsphingosphine (Lyso-GL1). Reduction or loss of GCase activity leads to the accumulation of substrates, disrupting lipid homeostasis. Here we evaluate biodistribution of AAV.GMU1 with intravenous (IV) doing in rodent and NHPs and establish efficacy of our engineered *GBA1* payload for effective lipid clearance for the treatment of type 1 GD. We first examined biodistribution of AAV.GMU1 in NHPs three weeks post IV dosing and observed robust transduction of several peripheral organs such as liver, spleen, heart, and muscles such as diaphragm, quadriceps, and gastrocnemius. We then examined biodistribution of AAV.GMU1 with IV dosing in rodents in the context of GD using our engineered lead *GBA1* variant. Consistent with broad transduction of several peripheral organs in NHPs, we observe similar transduction in rodents. We also performed functional efficacy studies in mice pre-treated with CBE, a covalent inhibitor of GCase. In contrast to vehicle-injected mice, we observe increased GCase activity as well as robust clearance of lipids in AAV.GMU1-GBA injected mice. Importantly, we observed reversal of lipid

accumulation even in tissues that received little to no AAV vector indicating robust cross-correction by our engineered lead construct. Collectively, our data demonstrate that AAV.GMU1 via IV dosing has broad biodistribution in multiple peripheral organs including muscle tissues. The biodistribution in combination with our lead *GBA1* construct engineered for cross-correction establishes a gene therapy platform for the treatment of GD Type 1 with IV dosing.

1101. Comparing Efficacy of AAV Capsid Serotypes for the Treatment of Feline GM1 Gangliosidosis

Courtney Garrett[1,2], Amanda L. Gross[1], Heather L. Gray-Edwards[3,4], Miguel Sena-Esteves[3,5], Douglas R. Martin[1,2]

[1]Scott Ritchey Research Center, Auburn University College of Veterinary Medicine, Auburn, AL,[2]Department of Anatomy, Physiology, & Pharmacology, Auburn University College of Veterinary Medicine, Auburn, AL,[3]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[4]Department of Radiology, University of Massachusetts Medical School, Worcester, MA,[5]Department of Neurology, University of Massachusetts Medical School, Worcester, MA

Introduction. Feline GM1 gangliosidosis is a fatal neurodegenerative disease caused by a deficiency of lysosomal β-galactosidase (β-gal). The feline disease faithfully emulates the pathology of GM1 in humans, making cats an ideal animal model for studying this disease. Adeno-associated viral (AAV) gene therapy for GM1 aims to restore β-gal activity and minimize disease progression. Choosing the appropriate AAV serotype and delivery route is critical for GM1 therapy since the vector must display tropism for cells that can achieve therapeutic effect and reach the areas most affected, such as the cerebellum. Intracranial injection of AAV into the thalamus and deep cerebellar nuclei resulted in a 7.5-fold increase in the lifespan of GM1 cats, but the procedure is invasive and requires a craniotomy for delivery to the brain parenchyma. Injection into the CSF via the cisterna magna (CM) is less invasive and could potentially improve biodistribution to certain parts of the CNS and peripheral organs. This study compares the effects of AAV serotype on survival, β-gal distribution, viral distribution, and disease progression in GM1 cats following CM injection using serotypes AAV9 and AAVrh10. Methods. Each cohort received 1.5e13 vector genomes/kg body weight at 2.2 ± 0.3 months of age (symptom onset occurs at ~4 months). 4-MU enzyme assays were used to assess β-gal enzyme activity in CNS tissue samples as well as several peripheral organs. The same CNS samples were also stained with X-gal to visualize β-gal activity. 7T Magnetic resonance imaging was used to track disease progression across cohorts. Immune response to the capsid was also evaluated using ELISA-based serum antibody titers. Results. β-gal activity increased in the cerebellum and the spinal cord for both treatment cohorts, but not the cerebrum - untreated animals exhibit little to no β-gal activity in the brain and spinal cord (Figure 1). Both cohorts also displayed improved β-gal activity in peripheral tissues, such as the heart and cervical dorsal root ganglion. MRI showed delayed neurodegeneration in both cohorts, which correlated with delayed clinical symptoms such as inability to stand (Figure 2). Ultimately, untreated GM1 cats (n=9) survived 7.9 ± 0.3 months, GM1+AAV9 (n=3) cats survived 13.9 ± 1.9 months, and GM1+AAVrh10 (n=3) cats survived 11.9 ± 0.9 months. Statistical significance was found between the survival of untreated GM1 cats treated cats in both cohorts (p=0.0089) but there was no statistical significance found between AAV9 and AAVrh10 treated cats (p=0.1966). Conclusions. This study indicates efficacy of AAV therapy in both treatment cohorts and suggests that CM-injected AAV9 delays disease progression compared to AAVrh10 for the feline model.

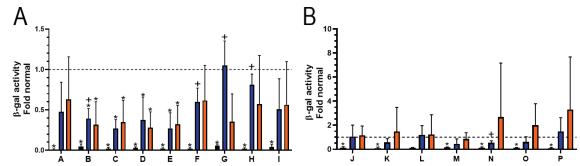


Figure 1. β-gal activity. Enzyme assays were performed to assess β-gal restoration in the CNS of treated cats when compared to untreated GM1 cats. * p<0.05 vs Normal, + p<0.05 vs GM1

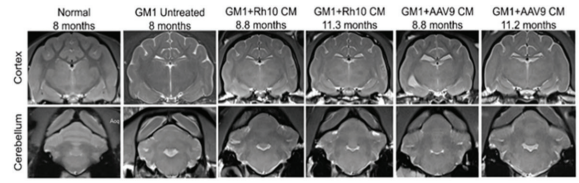

Figure 2. 7T MRI analysis. When compared to normal cats at 8 months, untreated GM1 cats have isointense (equal intensity) gray and white matter. The two treatment cohorts showed preservation of white matter at approximately 8.8 months. By endpoint, neurodegeneration and atrophy also progressed in both cohorts to a similar degree, as demonstrated by isointensity of the parenchyma and increase in CSF (bright white) around the brain, respectively.

1102. Pioneering Gaucher Disease Treatment: Preclinical Efficacy and Safety Study of LY-M001

Xiaojing Sheng, Yingying Cai, Tianqi Jiang, Chenming Lu, Yixiong Chen, Qing Lin

Lingyi Biotech Co., Ltd., Shanghai, China

Gaucher disease (GD), a prevalent lysosomal storage disorder, arises from mutations in the GBA1 gene, leading to deficient activity of glucocerebrosidase (GCase). This deficiency triggers the accumulation of glucosylceramide (GlcCer) and glucosylsphingosine (Lyso-GL1) in lysosomes, causing multisystemic organ damage. LY-M001, a novel rAAV serotype 8 vector-based therapy, aims to rectify this deficiency by delivering a codon-optimized *GBA1* gene, driven by a hybrid hepatic-specific promoter, and expressing a modified GCase ($GCase^{LY}$). This study evaluates LY-M001's potential as a therapeutic agent for GD. Employing the LY-Vector™ platform, over 500 AAV vector candidates were meticulously crafted and screened through rigorous in vitro and in vivo analyses, leading to the selection of LY-M001. Preclinical efficacy assessments in $Gba^{M1/M2}$ Gaucher model mice demonstrated remarkable restoration of GCase activity and substantial reduction of GlcCer and Lyso-GL1 in key organs post a single intravenous dose of LY-M001. Correspondingly, a reduction in Gaucher cells across vital tissues was observed. Long-term stability of GCase activity was confirmed in C57BL/6J mice over 10 months, with no adverse effects noted. Additionally, a 13-week GLP toxicology study in Cynomolgus monkeys endorsed LY-M001's safety profile, exhibiting exceptional tolerability and absence of toxicity. The convergence of these comprehensive preclinical data underscores LY-M001's profound potential in revolutionizing the therapeutic landscape for Gaucher disease, heralding a new era of treatment possibilities.

1103. Gutless Adenovirus-Mediated Gene Transfer of NEU1 Sialidase Rescues Sialidase-Deficient Mice

Suleiman A. Igdoura[1], Allyson Peek[2], Maria Athanasopoulos[2]

[1]Biology and Pathology & Molecular Medicine, McMaster University, Hamilton, ON, Canada,[2]Biology, McMaster University, Hamilton, ON, Canada

Sialidosis, an inherited primary deficiency of lysosomal sialidase, is an autosomal recessive lysosomal storage disease, characterized by the accumulation of sialylated glycopeptides and oligosaccharides in tissues and body fluids, leading to a range of clinical manifestations, including visual disturbances, ataxia, and myoclonus. Currently there is no treatment for Sialidosis, while there has been some success reported for the treatment of several lysosomal storage diseases using enzyme replacement therapy or bone marrow transplantation. Helper-dependent gutless adenoviruses (HD-Ad) have been studied as potential gene therapy vehicles for the treatment of genetic diseases. To this end, a full-length lysosomal sialidase gene and promoter was cloned into a HD-Ad vector and were tested in vitro and in vivo in sialidase-deficient cells and mice respectively. Following HD-Ad infection, lysosomal NEU1 sialidase enzymatic activity and mRNA levels in cultured deficient cells were dramatically increased and sustained for 20 passages. After an intravenous administration of HD-Ad NEU1 vector in sialidase deficient mice, mice were terminated at one, two and six- and 18-weeks post infection. Our in vivo results show that HD-Ad NEU1 demonstrated a sustained expression of sialidase beyond four months post-infection. The HD-Ad NEU1 also corrected sialidosis-associated phenotype. The in vitro and in vivo preclinical studies presented herein using helper-dependent adenovirus sets the stage for clinical trials in Sialidosis patients.

1104. Advancing Neuronopathic Gaucher Disease Modeling Using Microglia-Containing Brain Organoid

Yi Lin[1], Benjamin Liou[1], Jason Hammonds[2,3], Stuart Adler[1], Ying Sun[1,3]

[1]Division of Human Genetics, Cincinnati Children's Hospital, Cincinnati, OH,[2]Division of Infectious Diseases, Cincinnati Children's Hospital, Cincinnati, OH,[3]Department of Pediatrics, University of Cincinnati School of Medicine, Cincinnati, OH

Mutations in *GBA1*, encoding the lysosomal acid β-glucosidase (GCase), cause neuronopathic Gaucher disease (nGD). To model the impact of *GBA1* mutations on human midbrain development, we derived human 3D midbrain-like organoids (MLOs) from a nGD patient fibroblasts-derived induced pluripotent stem cells (iPSCs) and a gene-corrected isogenic control iPSCs created by CRISPR/Cas9 system, as well as healthy human iPSCs. The nGD MLOs closely resembled key phenotypes associated with nGD. However, the major challenge of a physiological nGD MLO model is the lack of resident microglial cells, which play pivotal roles in brain homeostasis and pathogenesis in nGD. To address this barrier in nGD modeling, a healthy human iPSC line with a knocked-in PU.1 inducible cassette was generated using CRISPR/Cas9 gene editing. PU.1 is a critical transcription factor for controlling myeloid/microglia lineage commitment. We have developed a culture strategy involving the combination of PU.1-knocked in iPSC and unmodified iPSC, resulting in the spontaneous generation of microglia containing MLOs (mcMLOs) with doxycycline induction. These mcMLOs contained microglia-like cells expressing typical microglia markers (Iba1+PU.1+), without apparent impact on the formation of midbrain enriched dopaminergic neurons in neuroectoderm differentiation conditions. Importantly, mcMLOs demonstrated a responsive chemokine system showing increased expression of *CD11b*, *LGALS3*, *IL-1β* to the inflammation stimulation induced by lipopolysaccharide, confirming microglial functionality. Pharmacological inhibition of GCase using conduritol B epoxide resulted in a complete loss of GCase activity in healthy mcMLOs, and consequently, elevated expression of microglia activation related genes, mimicking inflammation phenotype in nGD. These results provide compelling evidence supporting the modelling of nGD using mcMLOs. Meantime, we have knocked in an inducible PU.1 expression cassette into iPSCs derived from nGD patients, including both type 2 and type 3 GD, and corresponding isogenic lines. We aim to employ this innovative microglia-containing brain organoid platform using nGD patient and isogenic iPSC lines to study the role of microglia in neural development and neurodegeneration associated with nGD.

1105. Single vs Dual Transgene *Ex Vivo* Gene Therapy for Multiple Sulfatase Deficiency

Vi Pham[1,2], Lucas Tricoli[2], Parith Wongkittichote[2], Xinying Hong[1,2], Lars Schlotawa[3], Stefano Rivella[1,2], Rebecca Ahrens-Nicklas[1,2]

[1]University of Pennsylvania, Philadelphia, PA,[2]Children's Hospital of Philadelphia, Philadelphia, PA,[3]University Medical Center Goettingen, Goettingen, Germany

Multiple sulfatase deficiency (MSD) is an ultra-rare, inherited lysosomal storage disorder characterized by the functional deficiency of all sulfatase enzymes. MSD is caused by mutations in the gene *SUMF1*, encoding a sulfatase modifying factor that activates 17 downstream sulfatases. MSD patients present with combined multisystemic features of single-sulfatase disorders such as the mucopolysaccharidoses and metachromatic leukodystrophy (MLD), including neurologic regression, respiratory complications, liver enlargement, bone abnormalities, cardiac dysfunction, and hearing loss. Currently, there are no disease-modifying therapies for MSD. We aimed to develop *ex vivo* gene therapy with hematopoietic stem cell transplant for MSD, as this approach has proven successful for related lysosomal disorders. We designed lentiviral vectors encoding either 1) *SUMF1* or 2) a downstream sulfatase *ARSA* that is greatly implicated in the disease. *ARSA* ex vivo gene therapy is approved by the EMA for MLD and has the potential to be repurposed for patients with MSD. *In vitro*, MSD patient fibroblasts transduced with the lentiviral vectors demonstrated improved biochemical phenotypes including rescue of sulfatase activities and glycosaminoglycan accumulation. *In vivo,* the *SUMF1* lentiviral vector proved efficacious in rescuing biochemical and behavioral phenotypes in MSD mice that underwent hematopoietic stem cell transplant with *ex vivo* gene therapy. To further augment outcomes, we designed a novel lentiviral vector that co-expresses both *SUMF1* and *ARSA*. This dual vector greatly enhanced biochemical

rescue *in vitro* and augmented disease phenotypes *in vivo* as compared to the single vectors. We will present the results of our ongoing work optimizing the co-expression of both *SUMF1* and *ARSA* transgenes.

1106. Engineering and Characterization of CLN3 Disease (Juvenile Neuronal Ceroid Lipofuscinosis) iPSC Cells

Devin Burris[1,2], Livia Sitori[2], Jeet Singh[2], Rebecca Ahrens-Nicklas[1,2]

[1]University of Pennsylvania College of Medicine, Philadelphia, PA,[2]Children's Hospital of Philadelphia, Philadelphia, PA

CLN3 disease (also known as Juvenile Neuronal Ceroid Lipofuscinoses (JNCL)) is a form of lysosomal storage disease which arises from mutations in the *CLN3* gene, which encodes CLN3 protein. CLN3 disease is a rare, pediatric genetic neurodegenerative disorder characterized by progressive vision loss onset at ages 4-7, seizures at approximately age 10, parkinsonism, problems walking, difficulty with speech and language, and death between ages 15-30. Loss of CLN3 function leads to lysosomal storage, the accumulation of cellular debris, hypothesized to disrupt neuronal function. CLN3 is a lowly expressed transmembrane lysosomal protein with unreliable antibodies for protein analysis and no final 3D structure, so indirect perturbations of protein function mainly inform the field. CLN3 was recently hypothesized to be a lipid species transporter, but its function is yet to be robustly supported. Unclear mechanism makes *CLN3* a good candidate for gene-level therapeutics. We have generated a patient-derived iPSC line from a rare attenuated CLN3 disease patient. The patient had preserved cognition and only experienced vision loss well into their 30s. This patient is compound heterozygous for the severe 1.02 kB deletion of exons 7 and 8 seen in 70-80% of cases and an intron 6-exon 7 splice acceptor variant. This patient line demonstrates an intermediate level of CLN3 transcript between WT and KO cells. We are using genome editing tools to generate and validate an isogenic control for future characterization of disease intensity in various iPSC derived cell types. We aim understand the impact of CLN3 and its splice variants on disease progression, cellular electrophysiology, and lysosomal storage when considering Gene Therapy approaches.

1107. AAV-HEXA-HEXB-Mediated Gene Therapy Reverts Sandhoff and Tay-Sachs Diseases

Sara Marcó[1,2,3], Gemma Elias[1,2], Miquel Garcia[1,2,3], Xavier Sánchez[1,2], Carles Roca[1,2,3], Albert Ribera[1,2,3], Víctor Sánchez[1,2], Joan Bertolin[1,2], Jennifer Pérez[1,2], Maria Molas[1,2,3], Xavier León[1,2], Fatima Bosch[1,2,3]

[1]Biochemistry and Molecular Biology, Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain,[2]Cbateg, Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain,[3]CIBERDEM, Madrid, Spain

Tay-Sachs (TSD) and Sandhoff (SD) diseases are two rare autosomal recessive lysosomal storage diseases that results from the deficiency of the heterodimer β-Hexosaminidase A (HEXA), encoded by *HEXA* (TSD) and *HEXB* (SD) genes. Defective HEXA enzyme leads to progressive accumulation of GM2 ganglioside within lysosomes. TSD and SD patients exhibit severe, progressive neurodegeneration with indistinguishable devastating pathology and premature death. Currently, there is no cure for these diseases. Here, using mouse models of SD and TSD, we demonstrated therapeutic efficacy at short- and long-term of a novel gene therapy approach based on a single intra-cerebrospinal fluid (intra-CSF) administration of an adeno-associated (AAV) vector encoding simultaneously both *HexA* and *HexB* genes (AAV-*HexA*-*HexB*). AAV-mediated gene transfer resulted in widespread, even expression of a new covalently linked β-Hexosamindase A in the whole Central Nervous System (CNS) of TSD and SD mouse models. In addition, AAV-treated SD mice showed reversion of CNS lysosomal pathology, leading to correction of myelinization, autophagy and neuroinflammation. Moreover, intra-CSF administered AAV-*HexA*-*HexB* vectors efficiently transduced the liver, allowing the secretion of HEXA enzyme into the bloodstream, which completely corrected peripheral lysosomal pathology of SD disease. Reversion of pathological alterations were paralleled to normalization of behavioral deficits. More remarkably, treatment of SD mice with the single AAV-*HexA*-*HexB* vector significantly extended lifespan, compared to the co-administration of AAV-*HexA* and AAV-*HexB* vectors or the delivery of AAV-*HexA*-P2A-*HexB* bicistronic vector to SD mice. Altogether, our pre-clinical data clearly demonstrated that a single intra-CSF administration of AAV-*HexA*-*HexB* vectors resulted in efficient production of the new covalently linked β-Hexosamindase A, leading to whole-body correction of both CNS and peripheral pathology. These results provide strong rationale for the future clinical translation of the AAV-*HexA*-*HexB* gene therapy to treat Tay-Sachs and Sandhoff patients.

1108. Characterizing the Phenotypic Abnormalities of a Mouse Model of Inborn Error of Polyamine Metabolism for Gene Therapy Development

Oluwaseun Akinyele[1], Anushe Munir[1], Marie Johnson[1], Megan Perez[1], Yuan Gao[1], Jackson Foley[2], Yijen Wu[1], Tracy Murray-Stewart[3], Robert Casero[3], Hulya Bayir[1], Dwi U. Kemaladewi[4]

[1]Pediatrics, University of Pittsburgh, Pittsburgh, PA,[2]Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Johns Hopkins University School of Medicine, Baltimore, MD,[4]Children's Hospital of Pittsburgh, Pittsburgh, PA

The polyamines (putrescine, spermidine, and spermine) are essential for normal cellular functions and are subject to strict metabolic regulations. Mutations in the gene encoding spermine synthase (SMS) lead to the accumulation of spermidine in an X-linked recessive disorder known as Snyder-Robinson syndrome (SRS), which manifest with a spectrum of symptoms including intellectual disability, developmental delay, thin habitus, and low muscle tone with no available treatment. Development of therapeutic intervention for SRS would require a mutation-specific animal model that recapitulates many of the abnormalities observed in affected individuals. Here, we study the molecular, behavioral, and neuroanatomical features of a

mouse model with a missense mutation in the *Sms* gene that results in a glycine-to-serine substitution at a position 56 (termed G56S) of the SMS protein and evaluate gene therapy as a treatment approach for the disease. This mouse was modeled after patients with the severe form of the disease. We showed that the G56S mice exhibit almost complete loss of SMS protein and elevated spermidine/spermine ratio in the skeletal muscles and the brain, as well as increased anxiety, impaired learning, and decreased explorative behavior. Furthermore, these mice fail to gain weight over time and exhibit abnormalities in brain structure and bone density. Transcriptomic analysis of the cerebral cortex revealed downregulation of genes associated with ribosomal protein synthesis and mitochondrial oxidative phosphorylation, which were functionally recapitulated in embryonic mouse hippocampal cells and primary fibroblasts isolated from the mice. Collectively, our findings establish the first in-depth characterization of an SRS preclinical mouse model that identifies cellular processes that could be targeted for therapeutic outcomes. Current experiments focus on developing and evaluating gene therapy for SRS via a viral-mediated expression of WT *Sms* transgene in patients-derived fibroblasts and the G56S mice with the potential to rescue some of the abnormalities mentioned above. We anticipate that the successful completion of this study will open the door to a gene therapy approach for SRS and other polyamine-related genetic diseases.

1110. Alpha-Synuclein Artificial miRNA-Based AAV Gene Therapy for Synucleinopathies

Mei Zhu[1], Yian Khai Lau[1], Fares Bassil[2], Audrey Lee-Gosselin[2], Barbara Calamini[3], Ricardo Luis Sanz[3], Fiona Menzies[3], Benjamin Skykind[1], Anindya Sen[1], Mansuo Lu Shannon[1]

[1]Prevail Therapeutics, New York, NY,[2]Prevail Therapeutics, Indianapolis, IN,[3]Eli Lilly Neuroscience Research, Cambridge, MA

Synucleinopathies are neurodegenerative disorders characterized by neuronal or glial accumulation of aggregates of alpha-synuclein protein (α-Syn), encoded by the *SNCA* gene. α-Syn is primarily expressed in neuronal tissues, making up ~1% of total cytosolic protein of brain cells. In synucleinopathies, α-Syn aggregates may spread through a prion-like mechanism, with toxic aggregated forms being transmitted from cell-to-cell as the disease progresses. In this regard, facilitating the clearance of α-Syn aggregates may have therapeutic potential to reduce the spread of the pathology and to potentially slow or halt disease progression. Various approaches have been investigated to prevent and mitigate α-Syn toxicity, however, so far only some symptomatic therapies have been explored, and no disease modifying treatments are available for any of the synucleinopathies. Here we are developing an AAV-based gene therapy (PR014) to deliver an artificial miRNA (amiR) targeting the *SNCA* gene to reduce α-Syn mRNA and protein levels. We aim to knockdown ≥50% of α-Syn, which has been well-demonstrated to be neuroprotective in multiple preclinical models of synucleinopathies. We screened siRNA sequences targeting *SNCA* gene *in vitro* in human cell lines, and selected a lead α-Syn amiR candidate achieving robust knockdown efficacy in α-Syn transgenic mouse model and human Parkinson's disease patients' iPSC-derived neurons. Our lead vector, packaged in the AAV9 capsid, significantly decreased α-Syn aggregates in a human iPSC-derived neuron-based pre-formed fibril (PFF) seeding model. These results support the further development and the potential therapeutic value of PR014 gene therapy for the treatment of synucleinopathies.

1111. Advanced Therapeutic Intervention for GBA1-Associated Parkinson's Disease: Preclinical Evaluation of Efficacy and Safety of LY-N001

Yingying Cai, Guofang Yan, Xiaojing Sheng, Yixiong Chen, Qing Lin

Dept. of Discovery, Lingyi Biotech Co., Ltd., Shanghai, China

Parkinson's Disease (PD) represents a prevalent neurodegenerative disorder, predominantly characterized by static tremor, rigidity, bradykinesia, and postural instability. Notably, mutations in the GBA1 gene, responsible for encoding lysosomal enzyme glucocerebrosidase (GCase), have been implicated in enhancing susceptibility and exacerbating the progression of PD. This study delineates the development and preclinical assessment of LY-N001, an innovative adeno-associated virus serotype 9 (AAV9)-mediated gene therapy. LY-N001 is engineered to constitutively express a codon-optimized $GBA1^{LY}$ gene, aiming to rectify the intrinsic genetic defect leading to lysosomal malfunction, thereby altering the disease trajectory. The efficacy of LY-N001 was rigorously evaluated in a murine model, employing a chemically induced paradigm via conduritol-β-epoxide (CBE) to inhibit GCase activity, subsequently inducing accumulation of GluCer and GluSph, akin to the neuropathological phenotype observed in GBA1-PD heterozygotes. Administration of LY-N001 via intracerebroventricular (ICV) injection in neonatal mice facilitated extensive viral distribution within the central nervous system (CNS), with subsequent RNA-based in situ hybridization (RNAscope) affirming the vector's presence in critical cerebral regions including cortex, hippocampus, striatum, substantia nigra pars compacta (SNc), and cerebellum. Immunohistochemical analyses corroborated the pervasive distribution of GCase enzymes throughout the neuronal architecture. In CBE-administered cohorts, LY-N001 significantly augmented GCase activity, evidenced by a 40-fold amplification in cerebral tissue and a 300-fold enhancement in cerebrospinal fluid (CSF). Additionally, a marked decrement in glucosylsphingosine concentrations (approximately 90%) was noted in cortical structures, paralleled by observable ameliorations in motor functionality and behavioral indices. Notably, LY-N001 efficaciously attenuated CBE-induced reactive astrogliosis and microgliosis in a dose-responsive manner. In summation, the extensive preclinical dataset underscores the profound therapeutic potential of LY-N001 for GBA1-PD, potentially inaugurating a novel epoch in the therapeutic paradigm for this intricate neurodegenerative ailment.

1112. Proof-of-Concept Efficacy of BGT-PD, a Novel AAV-Based Gene Therapy for the Treatment of Levodopa-Induced Dyskinesia (LID) in Parkinson's Disease

Giulia Leoni, Simon Eaglestone, Leigh Shaw, Adrien Lemoine

Bloomsbury Genetic Therapies, London, United Kingdom

Levodopa-induced dyskinesia (LID) is a prevalent and debilitating side effect of chronic levodopa (L-Dopa) treatment, the current gold standard for the control of motor symptoms in Parkinson's Disease (PD). LID is characterised by abnormal, involuntary movements that can appear a few months after initiating L-Dopa treatment, with approximately 90% of PD patients developing LID in the advanced stages of the disease. LID can have a significant impact on the quality of life of PD patients, remaining a major challenge in PD treatment and only limited therapeutic options are currently available. While the pathophysiology of LID is complex, a key factor is the severe loss of dopaminergic terminals and in consequence loss of dopamine transporter (DAT) activity, which is critical for the physiological regulation of extracellular dopamine levels and dopaminergic neurotransmission. As the disease advances, most of the administered L-Dopa is instead converted to dopamine and released in an uncontrolled manner by serotonergic neurons, resulting in a sudden rise in extracellular dopamine levels and overstimulation of dopamine receptors. Here, we tested the hypothesis that reinstating DAT activity in the striatum by single administration of BGT-PD, an adeno-associated virus serotype-2 vector expressing the human DAT gene, could ameliorate or completely reverse LID in a PD model of severe LID. To test this hypothesis, 6-hydroxydopamine (6-OHDA) hemiparkinsonian rats, rendered dyskinetic by daily administrations of L-Dopa/Benserazide, were treated with a single unilateral intrastriatal injection of BGT-PD. LID severity was assessed by evaluating axial, limb and orolingual abnormal involuntary movements (ALO-AIMs) at 2-, 4- and 6- weeks post gene therapy. The data indicated a profound and sustained anti-dyskinetic effect of BGT-PD, with complete suppression of LID observed at 4- and 6- weeks post-treatment compared to vehicle-treated animals. Non-motor PD symptoms were also assessed at the end of the study indicating a potential effect of BGT-PD treatment on anxiety-like behaviours. Moreover, the treatment was well tolerated, with no overt negative side effects observed. In conclusion, this study provides initial evidence of the therapeutic potential of our gene therapy approach to completely reverse LID by reinstating DAT activity. Additional studies will be required to evaluate the long-term efficacy and safety of our treatment candidate and support its future clinical translation.

1113. AAV-Mediated Gene Therapy for GBA-PD

Swathi Ayloo[1], Jae Ryu[1], Shih-Ching Chou[1], Charles Miller[1], Tracy Lacson[2], Mariana Gonclaves[2], Lilu Guo[2], Shelley Naas[1], Bradford Elmer[1], Catherine O'Riordan[1], Martin Goulet[1], Christian Mueller[1], Shyam Ramachandran[1]

[1]Genomic Medicine Unit, Sanofi, Waltham, MA,[2]Precision Medicine and Computational Biology, Sanofi, Cambridge, MA

Mutations in *GBA1*, the gene encoding glucocerebrosidase (GCase) are one of the most common risk factors for Parkinson's Disease (PD). GBA-PD patients are a genetically well-defined subpopulation of PD that are carriers of heterozygous mutations in their *GBA1* gene. GCase is a lysosomal enzyme that catalyzes the hydrolysis of glycolipids glucosylceramide (GL1) and glucosylsphingosphine (Lyso-GL1). Reduction or loss of GCase activity leads to the accumulation of substrates, disrupting lipid homeostasis. In GBA-PD, this further cascades into accumulation of Lewy bodies containing α-synuclein, promoting neuronal cell death. Here, we propose one-time intra-CSF administration of AAV-mediated expression of engineered *GBA1* for treatment of both GBA-PD and demonstrate efficacy data in both rodents and non-human primates (NHPs). To enable broad distribution of *GBA1* throughout the brain, we engineered the WT *GBA1* to make it readily secretable to facilitate cross-correction. We assessed subcellular localization and GCase activity of these variants *in vitro* and observed that both localization to lysosomes as well as activity for all variants was comparable to WT *GBA1*. Subsequently we introduced the variants packaged in AAV.GMU1 into mice through intra cerebroventricular (ICV) injections. Consistent with our *in silico* analyses, histology assays revealed robust secretion of our *GBA1* variants throughout the brain four weeks post AAV dosing. We also performed functional efficacy studies by treating mice and NHPs with CBE, a covalent inhibitor of GCase. Mice that received *GBA1* variants effectively reduced substrate accumulation induced by CBE. Based on our efficacy data in both rodents and NHPs with intra-CSF dosing, we nominated SS3-GBA1 as our lead *GBA1* variant. Our future studies include dose-range finding studies in mice and NHPs and establishing minimally efficacious dose in the clinic. Collectively, our data establish AAV-based treatment modality for GBA-PD patients.

1114. Development of Conduritol-β-Epoxide Induced Lipid Flux Model in Non-Human Primates

Swathi Ayloo[1], Jae Ryu[1], Shih-Ching Chou[1], Jie Bu[1], Bill McCarty[2], Lilu Guo[3], Mariana Gonclaves[3], Bradford Elmer[1], Martin Goulet[1], Christian Mueller[1], Shyam Ramachandran[1] , Emily Crosier[1]

[1]Genomic Medicine Unit, Sanofi, Waltham, MA,[2]DMPK, Sanofi, Cambridge, MA,[3]Precision Medicine and Computational Biology, Sanofi, Cambridge, MA

Mutations in *GBA1*, the gene encoding glucocerebrosidase (GCase) is one of the most common risk factors for Parkinson's disease (PD) with 7-10% of PD patients carrying a mutation in GBA1. GCase is a lysosomal enzyme that catalyzes the hydrolysis of glucosylceramide (GL1) and glucosylsphingosphine (Lyso-GL1). Reduction or loss of GCase enzyme activity leads to the accumulation of these glycolipids, disrupting lipid homeostasis. This further cascades into the accumulation of Lewy bodies promoting neuronal cell death. In addition, bi-allelic mutations in *GBA1* are causative for a rare lysosomal storage disorder, Gaucher Disease (GD), wherein macrophages in multiple tissues have lipids built up that cause enlarged liver, spleen, and muscle weakness. Thus, lipid accumulation is a hallmark feature of mutations in *GBA1*. Owing to the lack of good rodent models for GBA-PD as well as GD, researchers have previously established conduritol-β-epoxide (CBE) induced lipid flux model to mimic lipid accumulation

seen in disease. CBE is an irreversible covalent inhibitor of GCase activity. Extensive research has now demonstrated that administration of CBE induces a dose-dependent lipid accumulation both *in vitro* in various cell lines as well in as rodents. In order to evaluate efficacy and rank order our engineered *GBA1* gene therapy constructs in non-human primates (NHP), we set out to develop a CBE-induced lipid flux model in NHPs. Here, we designed and implemented a pilot study to investigate changes in lipid substrates upon CBE administration in NHPs. First, we determined the doses of CBE using allometric dose-scaling from rodents to NHPs. We administered three different doses of CBE to NHPs and examined tissues and fluids post CBE dosing. At all three doses tested, we observed a robust increase in Lyso-GL1 in plasma indicating efficient target engagement by CBE. In addition, we also observed a dose-dependent increase in Lyso-GL1 in peripheral tissues such as liver and DRG as well as in the central nervous system including brain (64 brain punches encompassing representative grey matter and white matter regions) and spinal cord. Consistent with CBE testing in other model organisms, we also observed a concomitant dose-dependent decrease in GCase activity in all tissues tested. Importantly, the majority of the deep brain regions such as caudate, putamen, globus pallidus, thalamus, and subthalamus demonstrated robust CBE dose-dependent lipid accumulation and corresponding decrease in GCase activity. Collectively, our results are the first to establish a CBE-induced lipid flux model in NHPs. Our work provides a platform for efficacy studies in not only our gene therapy programs but also approaches with other modalities targeting *GBA1*.

1115. SNCA Reduction for the Treatment of Synucleinopathies

Bradford Elmer[1], Erik Wischhof[1], Tiffany Chan[1], John Bladon[1], Ye He[1], Thanga Aishwarya Mahendran[1], Brenda Richards[1], Robert Jackson[1], Catherine O'Riordan[1], Martin Goulet[1], Christian Mueller[2], Shyam Ramachandran[3]

[1]Sanofi, Waltham, MA,[2]Sanofi Genzyme, Framingham, MA,[3]Sanofi, Winchester, MA

Long-term neuroprotective therapy is of considerable interest for the treatment of neurodegenerative synucleinopathies like Parkinson's disease or multiple system atrophy (MSA). These diseases are characterized by the accumulation of alpha-synuclein protein in the brain with associated neurodegeneration. Multiple lines of evidence strongly implicate alpha-synuclein as a causal factor in neurodegeneration, and reduction of alpha-synuclein has been well studied in preclinical models of disease. RNA interference (RNAi) mediated by artificial miRNAs has shown increasing promise as a highly specific therapeutic modality to reduce levels of target mRNA and protein. Adeno-associated viruses (AAV) are well-validated and constantly evolving gene delivery vectors with the ability to express therapeutic constructs for years in the brain. Therefore AAV-mediated RNAi represents a promising approach for the long-term reduction of *SNCA* and treatment of synucleinopathy. Artificial miRNAs (amiRNA) were designed to target *SNCA* mRNA. In vitro screening demonstrated robust target knockdown in human cells. Partial reduction of *SNCA* in differentiated human dopaminergic cells was neuroprotective against rotenone-induced mitochondrial dysfunction. *SNCA* reduction in vivo was evaluated via AAV-mediated delivery of a tool sequence (amiR-SNCA) to the brains of wild type mice, with target engagement maintained for up to 6 months without behavioral alteration. To assess the potential for partial reduction of *SNCA* to prevent the spread of pathologic forms of synuclein protein, proof-of-mechanism studies in the pre-formed fibril (PFF)-model of neurodegeneration were run in wild-type mice treated with AAV vectors expressing amiR-SNCA or control miRNA. Partial, 25-60%, reduction of endogenous *SNCA* mRNA resulted in near complete mitigation of the spread of pS129 alpha-synuclein pathology to the substantia nigra. Importantly, reduction of SNCA also prevented the loss of TH+ neurons in this region, even in those animals with modest *SNCA* reduction. To support clinical translation additional, human-specific, sequences were screened in vitro and in vivo via multiple expression formats to optimize target engagement. Several candidates exhibited desirable in vitro and in vivo performance, supporting the continued development of *SNCA* lowering therapeutics as a safe and efficacious approach for treating patients with synucleinopathies.

1116. Successful Targeted Delivery of an AAV Reporter via MRI-Guided Surgery to CNS Tissue; Feasibility, Tolerability, and Challenges

Erin L. Slosarek, Rick Haas, James R. Nelson, Michael Taschwer, Jay K. Herman, Brian E. McIntosh

Labcorp, Madison, WI

Recent advances in clinical approaches to delivering targeted gene and cell therapies to the brain have necessitated *in vivo* safety studies applying the same procedures used in the clinical studies. Neurodegeneration in the putamen as indicated in Parkinson's and Huntington's disease, or in the hippocampus, as indicated in Alzheimer's disease, requires precise treatment for gene replacement or disease reversibility. As an alternative to achieving central nervous system (CNS) exposure, administration into the cerebral spinal fluid results in a broader distribution of these therapies, but often includes systemic exposure. By targeting current surgical approaches to disease-specific parenchymal structures, one can minimize broader distribution and focus the therapy to the intended area. In this work, we demonstrated the feasibility, tolerability, and challenges of direct targeting of parenchymal structures using magnetic resonance imaging (MRI)-guided Clearpoint catheter-based infusion in nonhuman Primates (NHPs). A 1.5T MRI scanner in conjunction with Brainsight software® was used to scan the brain and plan the bilateral trajectories to the putamen and hippocampus. Post dose MRI confirmation using 2% Gadoteridol allowed for target confirmation. In addition, 2.6×10^{12} GC/dose site AAV-9-mCherry was used for biodistribution analysis at necropsy, 28 days post-dose. MRI scanning after infusion confirmed the correct dosing of the targeted structure. After surgery, animals were monitored for signs of neurological impairment, clinical abnormalities, and alterations in body weight. The surgical procedures were well tolerated with no neurological or clinical impairments. Histological and biodistribution analyses were used to determine tissue response to the dosing procedure and indicated successful expression of mCherry transgene in the target tissue. In general, mCherry expression was significantly greater in the target CNS tissue compared to the liver or dorsal root ganglia, which are typically locations of AAV-9 expression using alternative methods of CNS dosing. Together, these data offer a path forward when testing the delivery of cells or cell specific gene

therapies directly to the putamen or hippocampus and can provide a clinically relevant method for targeted brain delivery with accuracy in NHPs.

1117. GBA1-Linked Parkinson's Disease AAV Gene Therapy

Raquel Nunez Toldra, Alex Dimokov, Eliza Bujor, Silvia Podda, Parisa Rahimnashat, Tihomir Dodev, Su Kit Chew, Mario Buono, Nisha Nair Dastidar, Eileen McNeill, Henning Stennicke, Rose Sheridan

Freeline Therapeutics, Stevenage, United Kingdom

Parkinson's disease (PD) is a chronic, progressive, neurodegenerative disorder characterised by α-synuclein accumulation, Lewy Body formation and loss of dopaminergic neurones within the substantia nigra pars compacta (SNpc) which controls movement and coordination. Non-motor symptoms include cognitive decline, sleep disturbance and psychiatric symptoms. Mutations in *GBA1* are linked to Gaucher disease (GD), one of the most common lysosomal storage diseases. In this population, approximately 9.1% of patients are likely to develop PD before the age of 80, compared to 3-4% for the wider population[1]. Heterozygous *GBA1* GD mutation carriers and a number of non-Gaucher PD associated *GBA1* mutations share a similar level of risk of developing PD. A proportion (5-15%) of people with PD carry mutations in *GBA1* which encodes the lysosomal enzyme glucocerebrosidase (GCase), resulting in dysfunctional enzyme and lysosomes[1]. AAV-mediated gene therapy providing sustained endogenous levels of fully functional GCase may reduce the early and accelerated rate of disease progression observed for *GBA1*-linked PD. Our GCase variant 85 ($GCase_{var85}$), with two amino acid substitutions to the mature human GCase ($GCase_{WT}$), has been established as a more stable enzyme[2] with clinical benefit in GD and offers the potential for effective delivery to and improved distribution across the brain in comparison to $GCase_{WT}$. *In vitro* transduction of brain derived cell lines, including SH-SY5Y (neuroblastoma), demonstrated up to 10-fold or more GCase activity in cell supernatants with AAV9-$GCase_{var85}$ compared to AAV9-$GCase_{WT}$ across all cell types, reflecting the improved stability. Expression and distribution were evaluated in C57BL/6J male mice of 9 weeks of age, injected unilaterally into the right-hand caudate putamen with vehicle or AAV9-GFP, AAV9-$GCase_{WT}$ or AAV9-$GCase_{var85}$ at a dose of 1.3×10^{10} vg per mouse and analysed four weeks post dose. Whole brains were coronally cryosectioned at the striatal site of injection and the substantia nigra and sections were immunofluorescently labelled for GCase or GFP. The AAV9-GFP reporter demonstrated effective retrograde transport from the caudate putamen, with GFP widely distributed in axons of the substantia nigra. Qualitative immunofluorescent staining for GCase gave a more intense signal in numerous somata and neuropil of the injected right hemisphere and signal in the left hemisphere for AAV9-$GCase_{var85}$ compared to AAV9-$GCase_{WT}$, with a clear GCase signal in tyrosine hydrolase-positive somata in the substantia nigra pars compacta of animals from both groups. Biochemical analysis of GCase activity extracted from the right hemisphere striatum or substantia nigra of treated animals demonstrated approximately 10-fold higher activity for AAV9-$GCase_{var85}$ compared to AAV9-$GCase_{WT}$ in agreement with *in vitro* observations. In conclusion, direct brain injection of AAV9 constructs to the caudate putamen is effectively distributed to the target cells of the substantia nigra. The more stable $GCase_{var85}$ results in a 10-fold higher GCase exposure with broader distribution across the murine brain. [1] Smith, L.; Schapira, A.H.V. GBA Variants and Parkinson Disease: Mechanisms and Treatments. Cells 2022, 11, 1261. https://doi.org/10.3390/cells11081261; [2] Comper, F et al., Poster #41 Generation of β-Glucocerebrosidase variants with increased half-life in human plasma for liver directed AAV gene therapy aimed at the treatment of Gaucher disease type 1. 1118. Transcriptomic Analysis of GDNF Treatment in MPTP Rhesus Monkeys

Kaya Ekin Ceyhan[1], Alessandro La Ferlita[2], Krystof Bankiewicz[1], Lluis Samaranch[1]

[1]Neurological Surgery, The Ohio State University, Columbus, OH,[2]Cancer Biology and Genetics, The Ohio State University, Columbus, OH

Parkinson's disease (PD) is a debilitating neurological disorder affecting millions globally. Characterized by the loss of dopaminergic neurons in the brain, particularly in the substantia nigra, PD leads to significant motor and cognitive impairments. Currently, there are no disease-modifying therapies approved that halt this disease's progression. Hence, multiple efforts to develop ultimate treatments for PD are currently ongoing. Today, certain therapeutic advancements in gene therapy exhibit significant promise in mitigating the manifestations of nigrostriatal degeneration by addressing and rescuing dopamine levels. Notably, the administration of glial cell-line-derived neurotrophic factor (GDNF) holds particular significance in these efforts, by which this potent neurotrophic factor demonstrates a selective enhancement of the survival of neurons in the dopaminergic nigrostriatal pathway. However, the molecular characterization of this treatment is poorly understood. To better characterize this treatment, seven young *Rhesus monkeys* were MPTP over-lesioned and divided into two groups according to their survival time. Group 1 received a striatal Convection Enhanced Delivery (CED) of either AAV2-GDNF (n=2) or PBS (n=1) and was followed for one month. Group 2 received a striatal CED infusion of either AAV2-GDNF (n=2) or PBS (n=2) and was followed for six months. Agilent Microarrays were performed on snap-frozen putamen tissue samples from all the animals. Transcriptomic analysis demonstrated that GDNF treatment resulted in several differentially expressed genes across each time point involving cell-to-cell signaling, cell proliferation, or cell growth. Bioinformatics analysis using Ingenuity Pathway Analysis demonstrated several significant pathways among the common shared upregulated differentially expressed genes based on MPTP doses and the different observational time points. In summary, this study provides clearer insight into the biological mechanisms behind GDNF's therapeutic effects in an MPTP-based PD animal model and highlights further areas of research.

1119. Neuronal-Type Specific *SNCA*-Targeted Epigenome Therapy for Precision Medicine in Synucleinopathies

Bernadette O'Donovan[1], Zhiguo Sun[2], Boris Kantor[3], Ornit Chiba-Falek[1]

[1]Neurology, Duke University, Durham, NC,[2]CLAIRIgene, Durham, NC,[3]Neurobiology, Duke University, Durham, NC

Synucleinopathies are neurodegenerative disorders that share a pathological lesion of intracellular protein aggregates largely composed of α-synuclein protein, known as Lewy Bodies (LB) and Lewy-neurites. Elevated SNCA levels are causative in synucleinopathy pathogenesis, particularly Parkinson's disease (PD) and dementia with Lewy bodies (DLBs), while normal physiological SNCA levels are essential to maintain neuronal function. While PD and DLB share some clinical and pathological similarities, each disease presents distinct characteristics including the primary affected brain region and neuronal type, *i.e.* dopaminergic vs cholinergic, respectively. We developed neuronal-type specific *SNCA*-targeted epigenome therapies precisely for PD and DLB. The system is based on *an all-in-one* lentiviral (LV) vector comprises of CRISPR/d*Sa*Cas9 and gRNA targeted at *SNCA*-intron1 fused with a synthetic repressor molecule of KRAB/MeCp2(TRD). To achieve neuronal-type specificity for dopaminergic and cholinergic neurons, the system was driven by TH and ChAT promoters, respectively. Transduction into human induced pluripotent stem cells (hiPSC)-derived dopaminergic and cholinergic neurons from a patient with the *SNCA*-triplication resulted in efficient and neuronal-type specific downregulation of *SNCA*-mRNA and protein. Furthermore, the reduction in *SNCA* levels mediated by the LV/d*Sa*Cas9-repressor vector rescued disease-related cellular-phenotypes including, Ser129-phophorylated α-synuclein, neuronal viability, and mitochondrial dysfunction. Next, we conducted *in vivo* validation studies using a PD-mouse model induced by an AAV/A53T-human (h)SNCA vector that contains the mutated human-SNCA coding sequence fused with its native promoter/intron1 region. We performed bilateral stereotactic injection of the AAV/A53T-hSNCA vector into the mouse substantia nigra (SN), the right SN was co-injected with the therapeutic LV/dCas9-repressor and the left SN was co-injected with the control vector (LV/dCas9 no repressor). Analysis of 8 mice demonstrated a significant reduction (33%) in hSNCA protein in the right SN. Pathological examinations showed a robust reduction in Ser129-phosphorylated SNCA (53%), the surrogate of α-synuclein aggregates. In addition, we observed significantly higher expression of tyrosine hydroxylase in the right SN and striatum (1.24- and 1.73- fold higher, respectively), suggesting a greater retention of dopaminergic neurons. We also collected safety measures. Monitoring daily behaviors showed no abnormalities in well-being criterions and no weight loss. Additionally, safety measures demonstrated no issues for blood counts, serum chemistry and liver histology. Biodistribution evaluation following unilateral injection of low and high viral-vector doses showed no distribution of the viral DNA in cortex, liver, or the uninjected side of the SN. In conclusion, we established a novel neuronal-type specific *SNCA*-targeted epigenome therapy and provided *in vitro* and *in vivo proof-of-concept* using human based and animal disease models. Our unprecedented therapeutics strategy effectively fine-tunes the reduction of SNCA expression in neuronal-type precision, sufficient for reversing disease-associated perturbations. Our results demonstrate the therapeutic potential of our technology for PD and DLB and provide the foundation to advance towards IND-enablement and clinical trials.

1120. SNCA Gene Repression Mediated by Zinc Finger Repressors (ZFRs) as a Therapeutic Approach for Parkinson's Disease

Andrew Young, Kenneth Kim, Jill Cifrese, Asa Hatami, Hoang-Oanh Nguyen, Qi Yu, Kimberly Marlen, David Paschon, Annemarie Ledeboer, Stephen Lam, Sarah Hinkley, Alicia Goodwin, Alex M. Ward, Kathleen Meyer, Bryan Zeitler, Amy M. Pooler

Sangamo Therapeutics, Inc., Richmond, CA

Molecular and genetic evidence implicate alpha-synuclein (*SNCA*) as a key mediator of Parkinson's disease (PD) pathogenesis; directly contributing to neuron loss. Given this, reducing alpha-synuclein expression in neurons has the potential to halt or slow PD progression. Zinc finger proteins (ZFs) are DNA-binding proteins that can be engineered to specifically bind any genomic sequence. When fused to transcriptional regulatory domain repressors (ZFRs), they can reduce the expression level of a targeted gene. We engineered ZFRs with human alpha-synuclein repression activity for use as potential therapeutics for PD. In a proof-of-concept study, we designed a library containing 100s of ZFRs targeting human sequences near the *SNCA* transcriptional start site. The library was initially screened in human and rodent neuronal cells lines. ZFRs were then packaged into AAV and screened in human iPSC-derived GABAergic and mouse primary cortical neurons *in vitro*. We identified ZFRs that repressed *SNCA* mRNA by more than 50% over a wide dose range with minimal detectable off-target activity as measured by global transcriptomics analyses. ZFR AAVs were identified *in vivo*, demonstrating successful repression of mutant *SNCA* in key brain regions of a humanized PAC SNCA disease mouse model. ZFR AAV repressed human *SNCA* transcript expression *in vivo* as detected in both bulk tissue from the thalamus and midbrain, as well as within individual, tyrosine hydroxylase+ neurons in the midbrain. The data presented here support continued development of *SNCA*-targeting ZFRs as a therapeutic approach for the potential treatment of Parkinson's disease.

1121. UBE3A Gene Activation Mediated by Zinc Finger Activators (ZFAs) as a Therapeutic Approach for Angelman Syndrome

Andrew Young, Julie Qiao, Daniel Chung, Siavash Fazel Darbandi, Esmeralda Ponce, Jason Eshleman, Patrick Dunn, Bob Radeke, Jisoo Lee, Sarah Hinkley, Gregory Davis, Bryan Zeitler, Amy M. Pooler

Sangamo Therapeutics, Inc., Richmond, CA

Angelman syndrome (AS) is a complex neurodevelopmental disorder often diagnosed in early childhood that primarily affects the central nervous system (CNS). Hallmark symptoms of AS include intellectual disability, severe speech impairment, developmental delays, movement issues and seizures. Although AS patients have a normal life expectancy, they require lifelong care and currently lack any disease-modifying treatment options. The genetic cause of AS is complex and involves the pathological loss of expression from a single allele of the *UBE3A* gene, coupled with the typical epigenetic silencing of the second *UBE3A* allele specifically in neurons, leading to a complete loss of *UBE3A* expression in neurons of the CNS. In addition, there are multiple UBE3A protein isoforms encoded by the human *UBE3A* gene, which are believed to have

distinct intracellular localization and functionality. Given this, there is a significant challenge with restoring physiological levels of UBE3A to neurons through standard gene therapy overexpression strategies. One approach that has the potential to restore UBE3A in neurons is targeting the healthy, but epigenetically silenced, *UBE3A* allele in order to "unsilence" its expression and restore physiological levels of UBE3A. Indeed, recent clinical trials using antisense oligonucleotides designed for this purpose have shown positive signs of therapeutic benefit in AS patients. To develop a one-time, neuron specific, disease-modifying approach we utilized our proprietary platform to design zinc finger proteins targeted to the endogenous *UBE3A* promoter and fused them with a novel transcriptional activator domain (ZFAs) to drive transcriptional upregulation of the healthy *UBE3A* allele. In a proof-of-concept study, we designed a library containing 100s of ZFAs targeting human sequences near the *UBE3A* transcriptional start site and selected those showing the highest fold change in neuronal *UBE3A* expression for packaging into AAV vector. Given that our approach is not designed to be allele specific, we demonstrated the utility of AAV ZFAs using human neurons derived from AS patients containing a pathological deletion in the active *UBE3A* allele. Under these conditions, any UBE3A expression would necessarily be from the healthy, epigenetically silenced allele. In patient-derived neurons selected AAV ZFAs increased both *UBE3A* transcript and UBE3A protein levels to meet or exceed those seen in WT neurons. Using surrogate reagents designed to target the endogenous Ube3a promoter regions in mice, we saw similar levels of AAV ZFA mediated *Ube3A* upregulation in primary neurons sourced from a disease mouse model of AS. Taken together these findings support continued development of ZFAs for the treatment of Angelman syndrome.

1122. AAV-Mediated APOE4 Gene Silencing to Treat Homozygous APOE4-Associated Alzheimer's Disease

Kalpita R. Karan, Mara R. Kebret, Neil R. Hackett, Ronald G. Crystal

Genetic Medicine, Weill Cornell Medical College, New York, NY

The homozygous APOE4 genotype is the major risk factor for the development of early Alzheimer's disease. Genetic studies in mouse models of human APOE4 dependent pathology have established that reduction of APOE4 expression can rescue the phenotype. There have been attempts to therapeutically suppress central nervous system (CNS) APOE4 in murine models using anti-sense oligomers or small interfering RNAs, but these approaches require repetitive CNS administration due to the short half-life of these drugs. We hypothesized that APOE4 could be persistently suppressed in the CNS of APOE4 homozygotes using adeno-associated virus (AAV) expression of microRNAs (miRNA) designed to hybridize to and suppress human APOE mRNA. To accomplish this, we conducted an initial screening of human APOE suppression by 9 different miRNAs following transfection in 293 and Huh7 cells. Optimal suppression in both cell types was obtained with miRNA2A (targeting coding region nt330-351, 66% suppression in 293 cells, 69% suppression in Huh cells) and miRNA N4 (3' untranslated region nt1142-1162, 57% suppression in 293, 82% suppression in HuH). miRNA expression cassettes were designed for delivery by AAV gene transfer vectors with two copies each of two different miRNAs (mir2A and mirN4) co-expressed from the CAG promoter with a mCherry reporter transgene. A neurotropic AAVrh.10 variant with an engineered capsid (AAV.S2) was used to deliver the suppression cassette to the hippocampus of TRE4 mice (murine ApoE knockout, human APOE4 knockin at the murine apoE locus). Two weeks after intra-hippocampus injection into TRE4 mice, 3 mm coronal tissue slices were collected. Regional expression of miRNA at the injection site was demonstrated both by direct assessment of miRNA level relative to an endogenous reference and by assessing mCherry level as a proxy. The AAV.S2 engineered capsid provided 2.31 ± 0.37-fold higher expression of miRNA over that provided by wildtype rh.10 ($p<0.05$). In the targeted region, a single intra-hippocampus administration suppressed hippocampal APOE4 mRNA levels by 76.5 ± 3.9% compared to 41.3 ± 3.3% with the same cassette delivered by the wildtype rh.10 capsid ($p<0.0001$). We conclude that an expression cassette with 2 different miRNAs targeting APOE4 and delivered by engineered AAV capsid will generate highly significant suppression of CNS APOE4. Since APOE4 heterozygote humans have lower risk of Alzheimer's disease than APOE4 homozygotes, this level of APOE4 suppression is potentially therapeutic.

1123. Enhancing Accessibility to Cell and Gene Therapy for Rare Diseases

Cecilia Marinova[1], Miriam Kolnikova[2], Eva Vlkova[3], Veronika Sladkova[4], Martina Losova[1], Sandra Skvarlova[4], Monika Horackova[5], Magdalena Netukova[6], Pavlina Skalicka[7]

[1]Medasol sro, Praha, Czech Republic,[2]Department of Pediatric Neurology, Comenius University in Bratislva, Faculty of Medicine, NUDCH, Bratislava, Slovakia,[3]Department of Ophthalmology, 3Faculty Hospital Brno, Brno, Czech Republic,[4]Medasol sro, Prague, Czech Republic,[5]Faculty Hospital Brno, Brno, Czech Republic,[6]Faculty Hospital of Královské Vinohrady, Praha, Czech Republic,[7]General University Hospital in Prague, Praha, Czech Republic

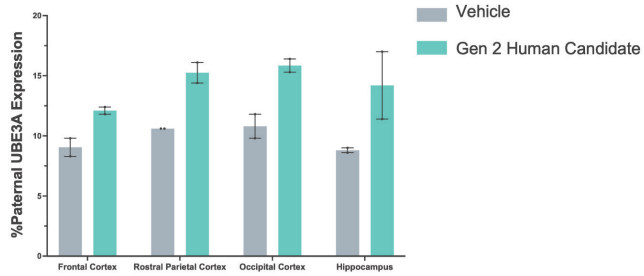
Introduction: In rare diseases for which cell or gene (C&G) therapy is approved, according to available data, only 30% of patients are diagnosed, and only half of them receive treatment. While the awareness of many rare disorders is usually high, the awareness about the approved treatments and their accessibility is low, with few diagnosed patients spread around the country. Another limitation of innovative therapies as a standard treatment is the administrative and logistical burden associated with the evaluation and management of each patient for whom C&G therapy (CGT) is indicated. Since a significant number of CGT is being developed in the neuro-muscular area, we wanted to assess whether we can learn from previous implementations of CGT and evaluate the role of processes in accelerating the access. Methods: The administrative processes for 6 different gene therapies in 20 diagnostic and treatment centers in Europe, from diagnosis to treatment, were mapped and evaluated. A total of 52 different processes were required from diagnosis to local treatment or cross-border treatment. Results: 133 patients were evaluated, and 29 patients received approved C&G therapy, since it has strict eligibility criteria. Between 6 and 18 months elapsed between diagnosis and initiation of therapy. A total of 52 different processes were required from diagnosis to initiation of therapy including management of cross-border treatment; 29 logistic processes were specific to CGT. 21 processes (40%) required more than 100 additional hours to establish a treatment center, 31 processes

(60%) related to the cross-border treatment (diagnosis assessment, treatment proposal, review, and implementation). Conclusions: A specific aspect to be recognized in the case of CGT is the additional procedures and administration that all stakeholders have to take care of, which limits scaling up if it is not effective.The process is complex and requires significant planning and resources. CGT is realized only in qualified centers and requires medical and treatment coordination patient transfer, often across borders. We observed that it significantly increases already high administrative and procedure demands on treatment centers as well as on diagnostic centers mostly medical expert team.Preparing documentation, and arranging additional tests and logistics require considerable time and a dedicated coordination team to contact stakeholders, from patients to payers. In cases where a diagnostic or referral center does not have its own CGT team, an experienced external team, like Medasol, can handle the coordination. The only way to successfully treat patients with CGT is by managing the CGT processes and administrative burden associated with it. Once a patient is diagnosed and eligible for CGT, the effective management of processes permits a higher number of patients that can access CGT.

1124. Patient Stratification Using iPSC-Derived Organoids as a Pre-Clinical Drug Testing Platform in Alzheimer's Disease

Cristina Zivko, Ram Sagar, Ariadni Xydia, Constantine G. Lyketsos, Vasiliki Machairaki

Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD



By 2050 the number of Alzheimer's Disease (AD) patients is projected to exceed 150 million worldwide. AD is an incurable, insufficiently understood, and devastating neurodegenerative disease, with high patient heterogeneity in terms of progression, clinical manifestation (including neuropsychiatric symptoms, NPS) and, importantly, responsiveness to treatment options.[1] In the last 20 years, 98% of clinical trials for AD have failed, highlighting the urgent need to drastically change pre-clinical research to develop better predictors of drug safety and effectiveness.[2] This is where our precision medicine approach of organoid in vitro models can be a game changer. Human peripheral blood mononuclear cells from healthy volunteers (n=6) and AD patient with (n=12) and without NPS (n=12) were reprogrammed into induced pluripotent stem cells (iPSCs)[3] and subsequently differentiated into hindbrain organoids, containing serotonin (5-HT) producing neurons. Extensive characterization and validation experiments were conducted to assess the quality of the iPSCs and of the 5-HT-organoids. These include karyotyping, fluorescent microscopy and flow cytometry to reveal the presence of pluripotency (OCT4, NANOG, TRA-1-60) and neuronal markers (TUJ1, TPH2, 5-HT), real time qPCR, ELISA measurement of 5-HT levels, size and circularity over 6 weeks of differentiation, for which we developed an in-house algorithm in Python. The 5-HT-organoids were treated with a selective serotonin reuptake inhibitor acutely (1 h) and for 1 week, upon which we could stratify the 30 individuals according to drug responsiveness. Shotgun proteomics analysis was performed on the treated and non-treated 5-HT-organoids from all 30 individuals by LC/MS to reveal distinctive relative abundance profiles. Experiments were run in biologically independent triplicates for 6 cell lines (3 healthy, 3 AD). The results from that training set were used to classify analytical results from the other 24 lines for AD biomarker discovery, as well as for drug responsiveness and effect. Highly reproducible, people-specific 5-HT-organoids were thus used to study inter-patient phenotypical variability and drug response diversity in a powerful, novel pre-clinical tool. Alzheimers Assoc. 2011; 7(5):532-539. doi: 10.1016/j.jalz.2011.05.2410 [3] Cells. 2023; 12(15):1990. doi: 10.3390/cells12151990.

1125. A Vectorized miRNA-Based Approach to Unsilence UBE3A in Angelman Syndrome

Sirika Pillay, Veda Tatavarty, Winnie Lin, Peter Neumann, Pingping Jia, Charles Cao, Sawyer Randles, Maria Abbasi, Szu-Ying Chen, Aurora Horta-Martinez, Cody McDermott, Ron Chen, Greg Lucey, Liz Hallam, Nathan Moerke, Sheila Sears, Serena Liu, Alex Weber, David Rodriguez, Amy Kim, Xiang Zhu, Adam Miller, John McLaughlin, Raghu Hosur, Archana Belle, Suresh Poda, Stephanie Tagliatela

Encoded Therapeutics, South San Francisco, CA

Rationale and Methods: Angelman syndrome (AS) is a neurodevelopmental disorder caused by the loss of function of the maternally inherited allele of ubiquitin-protein ligase E3A (*UBE3A*). Current treatment approaches are symptomatic as no approved disease-modifying therapies exist. Targeted knockdown of the long non-coding RNA, UBE3A-ATS, has the potential to upregulate paternal UBE3A expression in neurons and provide therapeutic benefit. We investigated an AAV-based vectorized miRNA approach targeting UBE3A-ATS to determine the therapeutic value of a microRNA (miRNA) knockdown strategy. **Results:** A miRNA tool candidate targeting the mouse UBE3A-ATS was capable of upregulating Ube3a RNA (11%) and protein (17%) in the brain within the null CNS background of AS mice. This candidate also rescued multiple phenotypes including body weight, hypoactivity and seizure sensitivity. Demonstrating further proof-of-concept, a human miRNA candidate targeting UBE3A-ATS knockdown was tested in non-human primates (NHPs), and showed UBE3A RNA and protein upregulation following intraparenchymal dosing. Subsequent optimization yielded multiple human candidates with more than a 100-fold increase in potency in human iPSC-derived neurons and showed promising off-target profiles *in vitro*. Finally, the top optimized human candidate resulted in paternal UBE3A RNA upregulation in the disease relevant cortex and hippocampus of NHPs following intracerebroventricular (ICV) dosing, a clinically relevant route of administration. **Conclusion:** These data establish the first *in vivo* proof-of-concept for miRNA-based UBE3A upregulation, identify promising human therapeutic candidates, and support the potential of a one-time, AAV-based approach for disease modification in the treatment of AS. **Figure 1.** Paternal UBE3A RNA upregulation in the cortex and hippocampus of wild-type non-human primates 60 days following ICV-dosing of miRNA treatment.

1126. Whole CNS Human Tau Knockdown for the Potential Treatment of Alzheimer's Disease and Other Tauopathies

Bryan J. Zeitler[1], Kimberly Marlen[1], David Ojala[1], Annemarie Ledeboer[1], Qi Yu[1], Yonghua Pan[1], Giulia Cisbani[2], Finn Peters[2], Chiara Melis[2], Matthew R. Tiffany[1], Sarah Mueller[1], Kenneth Kennard[1], Patrick Dunn[1], Hoang-Oanh Nguyen[1], Hung Tran[1], Kathleen Meyer[1], Amy Pooler[1]

[1]Sangamo Therapeutics, Inc., Richmond, CA,[2]Evotec SE, Hamburg, Germany

Alzheimer's disease (AD) affects millions of people and is currently the seventh leading cause of death in the United States. The neuronal accumulation of misfolded, neurotoxic species of Microtubule Associated Protein Tau (MAPT) closely tracks with neurodegeneration, disease progression, and clinical symptoms in AD. Reducing *MAPT* expression is well-tolerated and efficacious in tauopathy animal models, and a recent Phase 1/2 study in early AD evaluating repeated intrathecal injections of an *MAPT*-targeted ASO reported potential reversal of tau tangles in the brain and improvements in clinical symptoms. We are developing an IV-administered, epigenetic regulation approach to reduce tau expression using an engineered zinc finger transcriptional repressor (ZFR). Potential advantages include a single, non-invasive administration, the ability to selectively target and lower tau in neurons, and the use of an engineered BBB-penetrant AAV capsid that affords access to the whole brain, which could enable a potential universal therapy for all tauopathies, including AD. In early proof of concept studies, we previously demonstrated that ZFRs targeting mouse *Mapt* stably reduced tau in the brain. Here, we report the development of a lead ZFR that targets the human *MAPT* locus and achieves >95% knockdown of tau mRNA and protein in human iPSC-derived neurons with no detectable off-targets. The ZFR represses human and nonhuman primate *MAPT* equally due to full conservation of its target sequence, but is inactive in mouse neurons due to a single mismatch between the primate and mouse sequences. We tested the lead ZFR under the control of the Synapsin1 promoter in humanized htau mice using multiple routes of administration. Stereotaxic intrahippocampal AAV9 ZFR injections resulted in stable, dose-dependent mRNA and protein repression of up to 90% at 3 and 6 months after delivery. Single-cell analysis using multiplexed ISH and IHC revealed potent tau repression in neurons was achieved over >100x range of ZFR expression levels. In addition, htau mice dosed with IV AAV.PHP.B ZF-R at 10 months of age showed stable knockdown of tau mRNA and protein across the brain when examined at 18 months. Tau mRNA was reduced >90% in ZFR positive cells. Phosphorylated tau (ptau) at S199 and S202 was also reduced at the bulk and single-cell level, indicating ZFRs can remove a key pathogenic tau species from the brain. Evaluation of the lead ZFR in nonhuman primates using an IV-administered AAV capsid with the ability to cross the BBB is currently ongoing, with results expected shortly. Collectively these data support the development of a ZFR-based genomic medicine for the treatment of AD and other tauopathies.

1127. Focused Ultrasound-Mediated Blood Brain Barrier Opening for Targeted Delivery of Adeno-Associated Virus to the Mouse Striatum

Colleen Curley[1], Sambuddha Basu[1], Brittany Wicks[1], Tiffany Smith[1], Eric Kostuk[1], Brian Kelly[1], Andrew Nelson[1], Drew Peterson[1], Graciela Rivera-Pena[1], Charlie Li[1], Ashley Carter[1], Mohamad Nayal[1], Renee Gentzel[1], Joan Wicks[1], Lihua Shi[1], Matthew Wier[1], Junhua Wu[1], Alec Batts[2], Elisa Konofagou[2], Esteban A. Engel[1], Elizabeth Ramsburg[1]

[1]Spark Therapeutics, Philadelphia, PA,[2]Columbia University, New York, NY

Introduction: Focused ultrasound applied in the presence of intravenously administered microbubbles (FUS + MB) is a method for noninvasive and reversible blood brain barrier opening (BBBO) in targeted brain regions. Here we utilize FUS + MB BBBO applied to the mouse striatum to evaluate safety and efficacy of AAV9 delivery with this technique. **Methods:** AAV9 ($1e^{11}$ or $5e^{11}$ vgs/mouse) and microbubbles ($8e^{8}$ MBs/mL) were injected into mouse tail veins and focused ultrasound was applied bilaterally to striata at either a low 450 kPa or high 650 kPa peak-negative pressure (PNP) over a sonication duration of 2 min. BBBO was confirmed using contrast-enhanced T_1-weighted MR imaging following treatment. T_2-weighted MR imaging was performed on a subset of animals to assess safety. After two months, brain and peripheral organs were collected to assess vector biodistribution. Histopathological analysis was performed on a portion of brain samples from FUS-treated groups. We also plan to assess efficacy of this approach in a Huntington's disease animal model. **Results:** FUS+ MB BBBO yielded gadolinium extravasation into targeted brain tissue, confirmed via quantification of contrast enhancement on T_1-weighted MRI. Additionally, this approach resulted in increased biodistribution of AAV9 in targeted brain tissue compared to animals receiving vector without FUS treatment. AAV9 also exhibited biodistribution in peripheral organs due to systemic administration of the vector. Assessment of additional safety and efficacy readouts are currently in progress. **Conclusion:** Consistent with previous reports, focused ultrasound and microbubble treatment can open the blood brain barrier and enhance AAV9 delivery into the targeted brain region. Here we investigate the effect of vector dose and FUS pressure on AAV9 biodistribution in the brain and peripheral organs. These results inform ongoing work assessing therapeutic potential of focused ultrasound-mediated AAV delivery in neurodegenerative disease models.

1128. AAV-RNAi Mediated Reduction of *MAPT* for the Treatment of Alzheimer's Disease

Jessica Hogestyn[1], Yao Chen[2], Jie Bu[1], Erik Wischhof[1], Jordan Bresse[1], Tiffany Chan[1], Robert Jackson[1], Brenda Richards[1], Catherine O'Riordan[1], Martin Goulet[1], Christian Mueller[1], Shyam Ramachandran[1], Bradford Elmer[1]

[1]Genomic Medicine Unit, Sanofi, Waltham, MA,[2]Precision Medicine and Computational Biology, Sanofi, Cambridge, MA

The microtubule-associated protein tau (*MAPT*) plays a pathogenic role in a spectrum of devastating and incurable neurodegenerative diseases known as tauopathies. Of these, Alzheimer's disease (AD) is the most prevalent, with 6.7 million patients in the United States alone. AD is characterized by neuronal inclusions of phosphorylated tau, extracellular amyloid beta (Aβ) plaques, cortical atrophy, and progressive cognitive and executive dysfunction. Although recent advancements have been made to reduce Aβ pathology, the efficacy of these treatments are limited. Given that tau aggregates correlate more strongly with AD symptoms, targeting tau pathology can address a significant unmet need in these patients. RNA interference (RNAi) has shown increasing promise as a therapeutic modality to reduce levels of target mRNA and protein. Adeno-associated viruses (AAVs) are well-validated gene delivery vectors with the ability to express therapeutic constructs for years in the brain. Here, we describe the use of an AAV-RNAi vector for total *MAPT* lowering for the treatment of AD. *In silico* design tools and *in vitro* screening were used to identify artificial miRNA (amiRNA) sequences with low off-targeting potential that reduce expression of human *MAPT*. Candidates were cloned into AAV vectors to evaluate *MAPT* knockdown in the Tau22 mouse model, which overexpresses aggregate-prone mutant human *MAPT*. Not only did the lead amiRNA candidate Tau01 significantly reduce human *MAPT* mRNA and tau protein expression, but it also reduced pathological forms of phosphorylated tau in the cortex, hindbrain, and spinal cord. Levels of the axonal damage biomarker neurofilament light were also significantly reduced in cerebrospinal fluid and plasma, suggesting that total tau reduction by RNAi can significantly impact neurodegeneration. We further evaluated off-target mRNA reduction in human cells using paired RNA and CLIP sequencing to identify mRNA sequences that were significantly downregulated in Tau01-treated cells with evidence of physical Tau01 targeting within the RNA-induced silencing complex. In a dose-response validation experiment, we identified doses that maintained clinically-relevant *MAPT* reduction without significantly impacting off-target genes. We also conducted a pharmacology study in nonhuman primates (NHPs), using novel capsid AAV.GMU1 and an intrathecal lumbar catheter threaded to cisterna magna to deliver Tau01. While significant *MAPT* reduction was not achieved in bulk tissue RT-dPCR, we did demonstrate proof-of-concept for *MAPT* lowering in transduced neurons by dual RNAscope/Tau01 miRscope. Given the low number of transduced cells observed in this assay, we are now evaluating novel AAV capsids for improved biodistribution in the NHP brain. Improved AAV delivery, combined with the robust performance of the Tau01 amiRNA observed in the Tau22 mouse model, may support AAV-RNAi as a transformative treatment for patients with devastating neurodegenerative tauopathies.

1129. Preclinical Studies in Canines and Nonhuman Primates for IND- and IDE-Enabling Projects

Zhiming Zhang[1], Francois Pomerleau[1], Pete Huettl[1], Jorge E. Quintero[2], Richard Grondin[1], Greg Gerhardt[1]

[1]Neuroscience, University of Kentucky, Lexington, KY,[2]Neurosurgery, University of Kentucky, Lexington, KY

We have established a university-based research organization to facilitate a broad range of studies related to neurology and neurosurgery, from initial discovery to GLP-compliant studies. Our research group has gained considerable experience in the use of canine and non-human primate models for IND- and IDE-enabling studies using protocol-driven procedures. Both non-human primates and canines are excellent large animal models for drug and device development. Canines have been found to be a cost-effective alternative to non-human primates in preclinical research. Our laboratory has developed protocols that use MRI-guided stereotactic procedures to precisely implant devices into the CNS to deliver investigational biologics and drugs directly to the brain parenchyma or lateral ventricles and to investigate the safety and tolerability of intracranial ports and catheters. Both non-human primates and canines exhibit complex behaviors that allow for precise neurological examinations to determine the safety and tolerability of biologics, drugs and devices. In this presentation, we will discuss several examples of IND- and IDE-enabling studies related to Parkinson's disease, epilepsy, Huntington's disease, neuro-oncology and stroke that we have carried out through numerous sponsors at the academic and industrial level.

1130. Ependyma-Derived ApoE2 Protects Against Alzheimer's Disease Phenotypes in the Presence of ApoE4

Dementia and more specifically Alzheimer's Disease (AD) currently pose a global health crisis with more than 3 million cases of AD in

the US alone. Inheritance of the ε4 allele of apolipoprotein E (ApoE) is the strongest genetic risk factor associated with the sporadic form of AD, whereas the rare ApoE ε2 allele has the opposite effect. However, the mechanisms whereby ApoE confers risk and protection remain uncertain. ApoEε4 genotype has been associated with worsening plaque deposition, increased speed of cognitive decline and neurodegeneration as well as increased neuroinflammatory phenotype in microglia. We have previously shown that the introduction of ApoE4 or ApoE2 into the ependymal lining via AAV in amyloid plaque-bearing transgenic mice (expressing wild type murine apoE) exacerbated or reduced amyloid plaque burden, respectively (Hudry, et al. 2013 Sci Trans Med). Here a novel, capsid-modified AAV with restricted ependyma expression was used to evaluate ApoE2 replacement in plaque-bearing mice expressing human ApoE4 (mouse *apoe* negative; APP/PS1/ApoE4). Following intracerebroventricular (ICV) delivery, ependyma-derived ApoE2 expression accounted for ~20-30% of total ApoE protein in the CSF, a level sufficient to reduce the size and density of cortical amyloid plaques, the concentration of oligomeric Aβ in brains and notably, levels of activated microglia near plaques. Finally, we found that ApoE2 can prevent or lessen synapse loss near Aβ plaques. Together these data support the therapeutic efficacy of ependyma-derived ApoE2 in ApoE4 carriers by improving the classical lesions of AD (eg plaque deposition and neurodegeneration) as well as the increased neuroinflammation and synapse loss observed in sporadic AD. Studies to address translatability of our approach in non-human primates are ongoing.

1131. Enhancement of a Vectorized Tau Reduction Therapy with Low Intensity Focused Ultrasound Delivery

Irvin T. Garza[1], Sydni K. Holmes[1], Ibrahim Youssef[2], Krishanna Knight[1], Rajiv Chopra[2], Bhavya R. Shah[2], Rachel M. Bailey[3]

[1]UT Southwestern Medical Center, Dallas, TX,[2]Department of Radiology, UT Southwestern Medical Center, Dallas, TX,[3]Center for Alzheimers' and Neurodegenerative Diseases, UT Southwestern Medical Center, Dallas, TX

Microtubule associated protein tau is a protein that can misfold and accumulates in the brain driving neurodegeneration, e.g. Alzheimers' Disease. There are no approved treatments to reduce tau aggregation, but an antisense oligonucleotide therapy targeting tau in AD is currently in clinical trials suggesting that reducing pathological tau is well tolerated. To improve on this approach, we developed a recombinant adeno-associated virus (rAAV) encoding an artificial microRNA (hTaui) that selectively targets tau mRNA transcripts for degradation. Previously, we showed the therapeutic benefits of our vectorized tau gene therapy in a mouse model of tauopathy (PS19). PS19 mice express P301S mutant human tau, which results in tau aggregation, neurodegeneration, and early death. We found that intracisterna magna (ICM) administration of our AAV9/hTaui gene therapy significantly extended survival, improved quality of life, reduced human tau mRNA and protein levels, and reduced pathogenic tau formation. In agreement with the reported distribution of ICM injected AAV9, we found that vector distribution and tau reduction was highest in the hindbrain and low in the hippocampus and frontal cortex. To improve delivery of our gene therapy, we propose to use transcranial low-intensity focused ultrasound (FUS) to enhance delivery of AAV9/hTaui to the brain. Use of FUS to temporarily open the BBB can significantly reduce systemic vector doses and target rAAV vectors to select brain regions. We first tested the safety of hippocampal FUS BBB opening in PS19 mice by using either FUS alone, FUS and microbubbles to open the BBB, or FUS+BBB opening and intravenous (IV) injected AVV9/GFP. Three weeks post injection, immunohistochemical analysis of brains showed equivalent levels of staining for reactive astrocytes (GFAP), activated microglia (Iba1), and phosphorylated tau (AT8) in the treated and untreated hemispheres. These results support that AAV delivery with FUS was well tolerated short-term within PS19 mice. We then performed proof-of-concept studies where FUS was used to target IV injected AAV9/hTaui vector that also expressed a GFP reporter protein to the hippocampus of 6-month-old PS19 mice. Three points in the hippocampus of the right hemisphere were targeted, and BBB opening was confirmed using gadolinium-enhanced MRI. One-month post-treatment, brains were collected for IHC and biochemical analysis. GFP staining showed that AAV9/hTaui was robustly delivered to the hippocampus of the FUS treated side. qPCR analysis of hippocampal human tau showed that tau was significantly reduced in the treated hemisphere versus the untreated hemisphere. While FUS efficiently targeted IV injected AAV9/hTaui to the hippocampus, as expected following IV delivery in a middle-aged adult mouse, transduction efficiency of the remaining brain was quite low. To further improve FUS-mediated delivery of AAV9/hTaui, we propose to use FUS BBB opening in combination with intrathecal (IT) injection of AAV9. Studies by our group have demonstrated that combination IT and FUS delivery of AAV9 vectors results in greater hind brain and hippocampal transduction as compared to combination IV and FUS delivery. To test this, adult PS19 mice were treated with AAV9/hTaui or AAV9/scrambled control that was delivered via IT alone, combination IT and bilateral FUS targeting of hippocampi, or bilateral direct hippocampal injections. IT+FUS delivery of AAV9/hTaui improved survival over IT alone or direct hippocampal injections. Tissue analysis is ongoing and will be reported. Overall, our results support the use of FUS-mediated BBB opening to improve delivery of AAV9/hTaui in adult tauopathy mice.

1132. Endovascular Transdural Cerebello-Pontine Cistern Access Enables Intracisternal Microcatheter Navigation for Selective Intrathecal CNS Drug Delivery

Adel M. Malek[1,2], Aaron J. Levangie[2], Carl B. Heilman[1,2], Brandon M. Beneduce[2]

[1]Tufts Medical Center, Boston, MA,[2]CereVasc Inc., Charlestown, MA

Introduction: Intrathecal administration of cell-based, large molecular/gene therapy viral vectors represents an effective strategy to circumvent the blood-brain barrier and target central nervous system (CNS) tissue. Conventional intrathecal routes of administration are invasive or achieve inconsistent biodistribution to the brain. We previously described a minimally invasive, percutaneous, endovascular transdural catheter approach to access the lateral edge of the cerebrospinal fluid (CSF)-filled cerebellopontine angle (CPA) cistern for intrathecal administration. Here we describe a second-generation transdural access system serving as a platform for co-axial transdural microcatheter delivery and cisternal navigation to contralateral, cranial and caudal adjacent subarachnoid space for superselective

localized intrathecal administration. **Methods:** A 3D-printed model, derived from patient-based MRI segmentation of human anatomy including the CPA cistern and adjacent basilar subarachnoid space surrounding the anterior brainstem was filled with a low-density fibrillar mesh to simulate arachnoid fibers (**Figure 1**). Fluorographic cone-beam CT imaging of the anatomy model was performed to acquire baseline imaging (**Figure 1**) and navigate under roadmap guidance, the second-generation endovascular Polaris™ Cisternal Access System (CereVasc Inc., Boston, MA, USA) through the inferior petrosal sinus in a transdural fashion to serve as a CNS access platform. A neurovascular microcatheter (Echelon™ 10, Medtronic Inc.) was successfully navigated through the lumen of the Polaris catheter in selective fashion in all quadrants of the pontine, basilar and medullary cisterns at distances of >4 cm with the assistance of a laser-cut shapeable 0.014" microwire (Synchro Microwire, Stryker Inc.). **Results:** The neurovascular microcatheter was successfully navigated into the CPA cistern and adjacent subarachnoid spaces (**Figure 2**), directed towards the midline and into the contralateral CPA, as well as superiorly into the upper basilar cistern and inferiorly in front of the medulla. The 0.017" neurovascular microcatheter had a deadspace of 0.22 cc, through which a therapy could be administered. Use of a 0.014" or 0.010" microwire to assist navigation decreased the deadspace to 0.14 cc or 0.07 cc, respectively, to mitigate therapeutic volume-loss during administration. **Conclusions:** Endovascular CPA cistern access facilitates navigation to adjacent subarachnoid spaces via low-profile neurovascular microcatheter, through which AAV or other CNS-bound therapeutics could be administered. This approach enables close proximity to brain tissue and other locations near the base of the brain and upper brainstem that may be difficult to reach using other CNS routes of administration. These data warrant further investigation of the resulting transduction into target brain tissue from AAV administration into various subarachnoid spaces accessible through this technique.

1133. Metabolic and Neuropathological Profiling of SLC13A5 Epilepsy Gene Therapy

Raegan Adams, Morgan Schackmuth, Lauren E. Bailey, Krishanna Knight, Irvin T. Garza, Meghan Eller, Rachel M. Bailey

Center for Alzheimer's and Neurodegenerative Diseases, UT Southwestern Medical Center, Dallas, TX

SLC13A5 Epilepsy is a rare form of epileptic encephalopathy. This disorder is caused by loss of function variants in the SLC13A5 gene, which encodes for the plasma membrane sodium citrate co-transporter (NaCT) that is highly expressed in the brain and liver. These variants cause a decrease or complete loss of citrate transport, which consistently causes increased extracellular citrate. Studies in a small number of patients and from KO mice also show variable metabolic perturbations in blood, CSF, and brain tissues (mice only). Currently, while most patients are on several anti-seizure medications with varying amounts of control, there are no therapeutic options that target the underlying cause of the disorder. Gene therapy offers a promising therapeutic option for SLC13A5 Epilepsy patients. Our group has developed a recombinant adeno-associated virus (AAV) vector encoding a codon optimized human SLC13A5 gene (scAAV9/SLC13A5). In previous studies, we showed scAAV9/SLC13A5 is efficacious in Slc13a5 KO mice. While KO mice don't have an overt phenotype, like patients, they do have increased epileptic activity and increases in plasma citrate concentrations, which were ameliorated with gene therapy. In this study, we investigated the effects of scAAV9/SLC13A5 on metabolic and neuropathological phenotypes in KO mice. Slc13a5 KO mice were treated with scAAV9/SLC13A5 at post-natal day 10 via intrathecal lumbar puncture along with vehicle treated WT and KO littermate control mice. At ~6 months post-injection, cerebral spinal fluid (CSF) was withdrawn via the cisterna magna and brains were harvested for histological analysis. CSF was submitted for LC-MS analysis for a targeted panel of 17 metabolites, including citrate, aspartate, glutamate, malonate, and lactate, which were previously reported to be altered in patients and/or KO mice. Compared to WT mice, vehicle treated Slc13a5 KO mice had elevated citrate levels in the CSF, while scAAV9/SLC13A5 treated KO mice had levels similar to WT mice. Treatment effects of CSF citrate levels corresponded with changes in plasma citrate levels that were previously assessed. This suggests that the SLC13A5

transgene restored NaCT citrate transport function in the central nervous system and peripheral tissues. In contrast to other reports, at baseline we did not detect significant differences in the other tested metabolites in CSF of WT and KO mice. Interestingly, in treated KO mice, malonate was significantly increased as compared to KO and WT vehicle treated mice, which could indicate increased intracellular citrate. White matter abnormalities have been shown in some patient MRIs, and more generally, seizures are thought to induce reactive astrogliosis and interneuron loss. Histological changes in SLC13A5 patients and KO mice, however, have not been reported. To determine if loss of Slc13a5 function results in brain pathology, WT, KO and KO treated mice were stained for markers likely to be associated with the disease phenotype: parvalbumin (interneurons), myelin basic protein (myelination), and GFAP (astrocytes). At baseline, there were no overt differences in staining between groups, but quantification is ongoing and will be presented. These studies suggest that in addition to being effective in alleviating behavioral disease symptoms in KO mice, scAAV9/SLC13A5 treatment is effective in correcting citrate concentrations, a putative disease biomarker, in both plasma and CSF of KO mice.

1134. Optimization of AAV Vectors Packaged hfCas13Y or hfCas12Max to Treat Angelman Syndrome

Jinhui Li[1], Dong Yang[1], Shaoran Wang[1], Tong Li[1], Xuan Yao[1], Alvin Luk[1], Hui Yang[1,2], Linyu Shi[1]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Institute of Neuroscience, Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Angelman Syndrome (AS) is a rare neurodevelopmental disorder caused by mutation or deletion of the maternally-inherited ubiquitin protein ligase E3A (*UBE3A*) allele, which mediates the targeted degradation of several protein substrates. In neurons, only the maternally-inherited *UBE3A* allele is actively expressed because paternally-inherited *UBE3A* is selectively silenced in *cis* by its antisense transcript, *UBE3A-ATS*. In our previous study, AAV-hfCas13X has shown to restore the expression of paternal *Ube3a* in a mouse model of AS. The treated mice showed improvements in body weight and motor function, but not in the marble burying test or brain weight. Therefore, we optimized our gene-editing tools for the treatment of AS. **Methods:** To enhance the efficiency of AAV vector packaged high-fidelity Cas13Y (hfCas13Y) or Cas12Max (hfCas12Max) to facilitate the expression of *Ube3a*, we constructed a series of AAV transfer plasmids by changing the promoters, engineering gRNA, and adding the *cis*-regulatory motifs. The optimized AAV vectors were then administered to the AS mice on postnatal day 1 via intracerebroventricular (ICV) injection to assess the efficiency of *Ube3a-ATS* silencing *in vivo*. The RNA and protein of reinstated Ube3a in the dissected brain regions was evaluated by RT-qPCR or western blot (WB). **Results:** We delivered four versions of optimized AAV-hfCas13Y (V1, V2, V3, and V4) into the neonatal AS mice and observed that the paternal Ube3a protein expression in the cortex and hippocampus of AS mice surpassed 50% of that found in wild-type (WT) mice at 4 weeks post-infection with AAV-hfCas13Y V4 (Fig. 1A, C). The RNA level of *Ube3a-ATS* was also dramatically decreased by AAV-hfCas13Y V4 (Fig. 1B, D). In addition, we optimized the AAV-hfCas12Max system and assessed the efficacy of four AAV transfer plasmids. RT-qPCR results showed that AS mice injected with AAV-hfCas12Max V2 exhibited the highest *Ube3a* expression in the cortex and hippocampus, with restoration of the *Ube3a* mRNA expression to a level almost similar to that found in WT mice (Fig. 1E, G). WB results showed that AAV-hfCas12Max V2 significantly increased the UBE3A expression (Fig. 1I). **Conclusions:** The optimized AAV vectors, which encapsulated both the hfCas13Y and the hfCas12Max systems, were capable of significantly enhancing the expression of UBE3A, with AAV-hfCas12Max showing particularly robust results. Additional studies, including body weight and behavior tests, are currently being performed. Consequently, the knockdown of *Ube3a-ATS* RNA mediated by AAV-hfCas13Y or hfCas12Max may represent a more favorable approach for AS treatment.

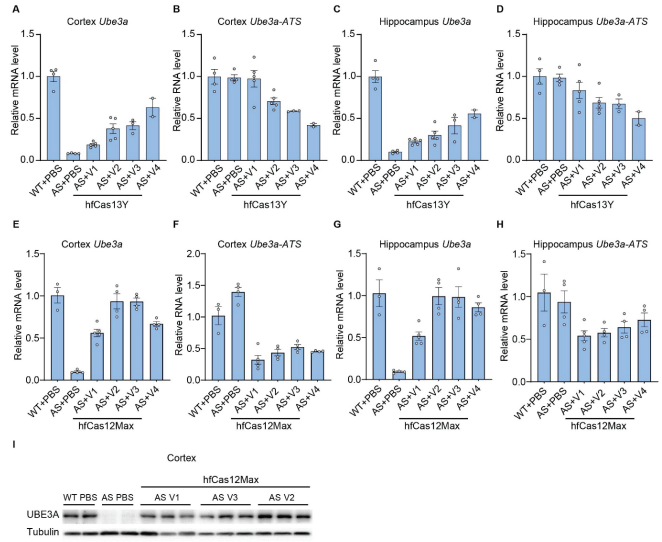

Figure 1. Optimization of AAV vectors encapsulating hfCas13Y or hfCas12Max for the treatment of AS. A-D, The mRNA expression levels of *Ube3a* and *Ube3a-ATS* in the cerebral cortex and hippocampus were analyzed using RT-qPCR with the indicated treatments of AAV-hfCas13Y or AAV-hfCas12Max. **I**, Western blot analysis of protein expression in the cortex was performed with the indicated treatments of AAV-hfCas12Max.

1135. RNA Targeting of *Bace1* by CRISPR-Cas13 Improves Memory Deficits in Alzheimer's Diseases

Yinan Yao[1], Hanbo Ma[2], Dong Yang[3], Yuanhua Liu[1], Hui Yang[1,3]

[1]Institute of Neuroscience, Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China,[2]International Peace Maternity and Child Health Hospital, Shanghai, China,[3]HuidaGene Therapeutics Co., Ltd., Shanghai, China

Background: Alzheimer's disease(AD) is a progressive neurological disease and the most common form of neurodegenerative dementia with no specific disease-modifying treatment, which brings great burden to the family and society. The approved drugs for AD could alleviate the symptoms of AD, but cannot reverse the progression of AD. β-secretase BACE1 (β-site amyloid precursor protein cleaving enzyme) is considered the potential and rationale target because it is involved in the rate-limiting step, which produces toxic amyloid β (Aβ) peptides that leads to deposits in the form of amyloid plaques extracellularly, resulting in AD. Here, we developed CRISPR/high-fidelity Cas13Y (hfCas13Y) RAN-targeting therapy for AD. **Methods:** In this study, we used hfCas13Y system which could specifically and efficiently target the

mRNA of *BACE1* without causing permanent changes at the genomic level. First, we screened the gRNAs targeting *BACE1* (g*BACE1*) by fluorescence-activated cell sorting(FACS) in 293, N2a, and Cos7 cells. Then, we administrated doses of AAV-hfCas13Y-g*BACE1* into the hippocampus of wild-type C57/B6 mice through stereotactic injection and assessed the knock down efficiency through qPCR, Western Blot (WB), and immunostaining at 2- and 8-week post-injection. To evaluate the therapeutic efficacy, we administrated the AAV-hfCas13Y-g*BACE1* into both hippocampal regions of 4-month-old 5xFAD mice, a mouse model of AD, via stereotactic injection. Following a period of 3 months and 6 months post-injection, behavioral assessments, including fear conditioning, Barnes maze, and water maze tests were conducted to evaluate the learning and memory capabilities of the mice. qPCR, WB, immunofluorescence (IF) staining, and enzyme-linked immunosorbent assay (ELISA) analysis were performed to measure Bace1 and Abeta levels. Electron microscopy (EM) was utilized to analyze the synapse number. Moreover, we systematically delivered AAV-hfCas13Y-g*BACE1* to 5xFAD mice via retro-orbital injection and evaluated the treatment's efficacy through the aforementioned behavior tests, qPCR, WB, IF staining, ELISA analysis, Golgi staining, and EM. **Results:** For CRISPR/hfCas13Y systems, we identified two gRNAs that could efficiently target the *Bace1* mRNA in human (reduced 99% for 293 cells, P<0.001), monkey (reduced 98% for Cos7 cells,P<0.001), and mouse (reduced 92% for N2a cells, P <0.01) cells. In C57 mice, we tested the *in-vivo* knockdown efficiency of the two AAV-hfCas13Y-*BACE1*-gRNAs at varying doses and observed that AAV-hfCas13Y-*BACE1*-gRNA2 demonstrated superior performance, reducing *Bace1* mRNA levels by 50% (P<0.01). Upon injection of AAV-hfCas13Y-*BACE1*-gRNA2 into the hippocampus of 5xFAD mice, we observed a reduction in Bace1 expression(Fig. 1A). Furthermore, the results from fear conditioning (Fig. 1B-C) and water maze (Fig. 1D-E) tests indicated that AAV-hfCas13Y-*BACE1*-gRNA2 treated 5xFAD mice via retro-oral injection enhanced the learning and memory capabilities when compared to AAV-hfCas13Y treated 5xFAD mice. **Conclusions:** In summary, we proved the feasibility of RNA-targeting CRISPR/hfCas13Y system as a therapeutic approach for AD, which efficiently reduced the mRNA of *Bace1*, alleviated Abeta pathologies, improved neuronal functions and refined the learning and memory abilities in the mouse model of AD.

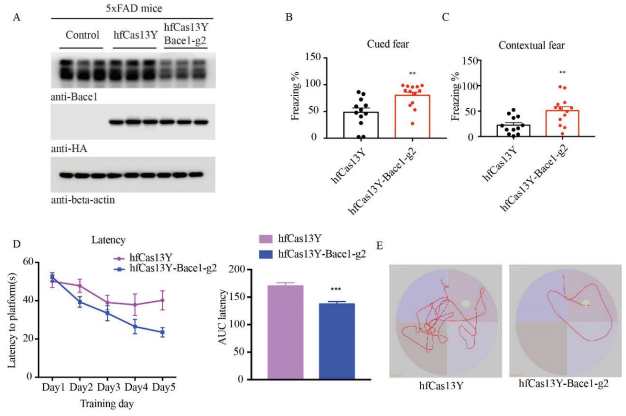

Figure 1. AAV- hfCas13Y-BACE1-gRNA 2 treatment alleviates behavior deficits in 5xFAD mice

1136. Development of an *Ex Vivo* Hematopoietic Stem Cell Gene Therapy for Frontotemporal Dementia (FTD)

Yuri Ciervo[1], Pietro Rigoni[1], Nadia Bologna[1], Massimo Accardo[1], Giulia Santinon[1], Chiara Recchi[2], Rita Milazzo[1], Alessandra Biffi[1]

[1]University of Padua, Padova, Italy,[2]Orchard Therapeutics, London, United Kingdom

Frontotemporal Dementia (FTD, OMIM:607485) is the second most common dementia in people under the age of 65 after Alzheimer Disease and is devoid of any cure or specific approved treatment. The incidence of pathogenic loss-of-function mutations in the progranulin gene (GRN) accounts for approximately 5% of all FTD cases. GRN is a secreted lysosomal protein that functions as neurotrophic factor and regulator of neuroinflammation. Raising GRN levels in the brain of FTD patients, and in particular in microglia, may result in therapeutic benefit. Hematopoietic Stem/Progenitor Cell (HSPC) Gene Therapy (GT) based on the use of lentiviral vectors (LVs) for gene transfer could thus represent a valuable treatment option for GRN-FTD patients as it could generate a long-lasting source of GRN in their brains through its myeloid, microglia-like CNS progeny. To explore this novel treatment option and generate proof of concept preclinical data, we developed and tested two therapeutic LVs with a strong constitutive (human PGK) *versus* a novel inducible synthetic promoter (derived from HLA-DRA) able to safely deliver multiple copies of the human *GRN* cDNA in GRN knock-out (ko) cell models, inducing over-expression of the therapeutic protein which is then correctly secreted and taken up by target GRN knock-out cells. Following *in vivo* and *in vitro* validation, the two vectors were employed in the setting of a proof of concept of efficacy study of HSC-GT for FTD in $Grn^{-/-}$ mice where the gene corrected cells were administered intravenously or in the brain lateral ventricles (ICV) in optimized transplant conditions enabling CNS-specific and selective engraftment of the transplanted cells. Independently from the promoter or delivery route, we showed that this approach efficiently delivers human GRN to the brain of transplanted GRN-ko mice, and that overall, the strategy is feasible, well tolerated, and capable of correcting disease associated phenotypic abnormalities at biochemical, clinical/behavioral and histopathological levels. In our settings, restoration of GRN at the 25-to-40% of wild-type levels in the brain is sufficient for long term phenotypic correction as demonstrated by normalization of well-known soluble disease biomarkers (BMP and GluSph) in plasma and brain, resolution of brain lipofuscinosis and reduction of both microgliosis and astrogliosis at 12 months after transplant. On-going analysis will provide additional conclusion related to the delivery route and/or promoter.

1137. Multi-Targeting Zinc Finger Nucleases as a Gene Therapy Vector for Angelman Syndrome

Hannah O. Bazick, Lucas M. James, Bonnie Taylor-Blake, Mark J. Zylka

UNC Chapel Hill, Chapel Hill, NC

Angelman syndrome (AS) is a severe neurodevelopmental disorder characterized by sleep dysfunction, seizure disorders, impaired cognition and speech, motor deficits, and microcephaly. Due to

epigenetic silencing of the paternally inherited allele of *UBE3A* (*patUBE3A*) by a long non-coding antisense RNA (*UBE3A-ATS*) in neurons, mutation or deletion of maternal *UBE3A* results in near complete loss of *UBE3A* in the brain. However, the intact patUBE3A can be unsilenced with genome editing nucleases, such as zinc finger nucleases (ZFNs), by prematurely truncating *Ube3a-ATS*, rescuing some AS-associated phenotypes. In our present work, we screened 8 ZFNs multi-targeted to repetitive *Snord115* snoRNAs located within *Ube3a-ATS* and evaluated their ability to unsilence *patUbe3a* after transfection onto *Ube3a*$^{mat+patYFP}$ mouse neurons. ZFN 17/18 yielded 1.9-times higher *patYFP* intensity than a multi-target Cas9-guide RNA (gRNA) targeted to a similar region within *Ube3a-ATS*. We then packaged ZFN 17/18 and NmCas9 gRNA9 into AAV2 and transduced *Ube3a*$^{mat+patYFP}$ mouse neuron cultures. At the highest titer tested (50,000 viral particles per cell), NmCas9 gRNA9 and ZFN 17/18 similarly reduced expression of *Ube3a-ATS* (25% and 34% to that of untreated levels, respectively), downregulated *Snord115* snoRNAs (26%, 35%), and upregulated *patUbe3a* (711%, 737% upregulation from baseline). Neither treatment affected expression of *Snord116*, downregulation of which can lead to Prader-Willi syndrome. Bilateral intracerebroventricular (i.c.v.) injection of 1-day-old Angelman syndrome model mice led to widespread unsilencing of UBE3A in the cortex by 90-days-old (34% to that of wild-type untreated), with UBE3A levels in some individual neurons reaching that of untreated wild-type levels. Overall, our study demonstrates a novel potential gene therapy for Angelman syndrome.

1138. Multifunctional Antibody Engineering for Tauopathy Immunotherapeutics

Lianna D'Brant[1], Michael Miller[1], Su Kyoung Na[1], Natasha Rugenstein[1], Anne Messer[1], Sally Temple[2], David C. Butler[1]

[1]Neural Stem Cell Institute, Rensselaer, NY,[2]New York Neural Stem Cell Institute, Rensselaer, NY

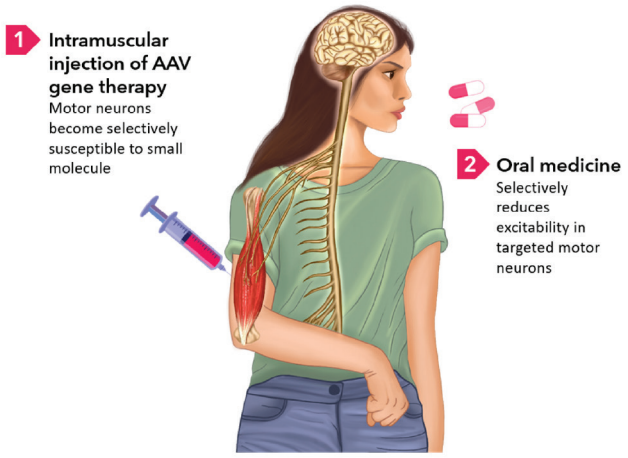
Tauopathies, encompassing conditions like Frontotemporal Dementia and Alzheimer's Disease (AD), manifest through the accumulation of insoluble tau proteins in neurons and glia, with the presence of ubiquitin-positive tau in neurofibrillary tangles correlating with the severity of AD-related dementia. We hypothesize that reducing monomeric tau through normal protein clearance pathways will mitigate abnormal tau accumulation, thus alleviating cell toxicity and neurodegeneration. Our approach utilizes bifunctional intrabodies that bind tau and prevent tau aggregation (a chaperone-like function) and target soluble monomer directly to the proteasome for degradation. Fusion with the ornithine decarboxylase (ODC) PEST degron enables ubiquitin-independent proteolysis of intrabody-bound tau by directly interacting with the proteasome. By leveraging this direct molecular interaction with the proteasome, we control the degradation process through programmable target antigen proteolysis technology (PTAP). We engineered 17 human anti-tau-PEST bifunctional intrabodies, selecting candidates based on their efficacy in reducing GFP-labeled 0N4R-tau in an immortalized rat neuronal progenitor cell line (ST14A). Ten intrabodies demonstrated a minimum 25% reduction in eGFP-tau (0N4R) levels compared to the empty-vector control, with three achieving reductions (** $p < 0.01$) of approximately 78%, 70%, and 74% after 72 hours of treatment. When the proteasome was inhibited using epoxomicin or MG132, tau levels significantly increased compared to vehicle-treated controls across all groups. Treatment of iPSC-derived 2-month-old cortical organoids over 21 days showed significant reductions in endogenous tau, with V-PEST, N-PEST, and F-PEST exhibiting reductions of 55.3% (** $p < 0.01$), 57.9% (** $p < 0.01$), and 38.82% (** $p < 0.05$), respectively. These findings underscore the potent efficacy of anti-tau-PEST intrabodies in reducing tau levels in cell lines and 3D organoid models. Excitingly, in 2D cortical cultures, these intrabodies were able to alleviate proteasomal impairment in V337M and N279K mutant cells. Furthermore, partial reduction of tau by PTAP is as effective as high reduction of tau to counteract cell death in the V337M cultures. In vivo efficacy of anti-tau PTAP intrabodies is being evaluated using the hTau.P301S transgenic mouse model, building on our demonstrated success with bifunctional anti-synuclein-PEST intrabodies.

1139. Transcriptomic Profiling of Glutamatergic Neurons Derived from Human Induced Pluripotent Stem Cells of Healthy Controls and Alzheimer's Patients

Ram Sagar[1,2], Ioannis Azoidis[1,2], Cristina Zivko[1,2], Ariadni Xydia[1,2], Esther S. Oh[2,3,4], Paul B. Rosenberg[2,4], Constantine G. Lyketsos[2,4], Vasiliki Mahairaki[1,2], Dimitrios Avramopoulos[1,2]

[1]Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD,[2]The Richman Family Precision Medicine Center of Excellence in Alzheimer's Disease, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD,[4]Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD

Alzheimer's disease (AD) is a gradually progressive, irreversible form of dementia with millions positive cases worldwide and the mechanisms of disease progression are not yet fully elucidated, to date there are no reliable biomarkers for early detection of pathogenic components of AD. Recent advances in the generation of induced pluripotent stem cells (iPSCs) from peripheral blood mononuclear cells (PBMCs) and differentiating them into a variety of cell types is allowing us to study them without the caveats associated with disease-related changes. We generated induced Pluripotent Stem Cells (iPSCs) from Alzheimer's disease (n=8) patients and healthy controls (n=6) and used lentiviral delivery mechanism to differentiate the iPSCs into glutamatergic neurons. The aim of this study was to generate a comparative transcriptomic profile between the diseased and controls to study the gene expression differences. A total of 621 genes were seen to be differentially expressed at adjusted $p<0.05$ between the case and control derived neurons. These genes show significant overlap and directional concordance with genes reported from a single-cell transcriptome study of AD patients; including five genes implicated in AD from genome-wide association studies and they appear to be part of a larger functional network as indicated by an excess of interactions between them observed in the protein-protein interaction database STRING. Exploratory analysis with Uniform Manifold Approximation and Projection (UMAP) suggests distinct clusters of patients, based on gene expression, who may be clinically different. Our research outcomes will



enable the precise identification of distinct biological subtypes among individuals with Alzheimer's disease, facilitating the implementation of tailored precision medicine strategies.

1140. A Low Dose, Targeted, and Controllable Gene Therapy for the Treatment of Spasticity

Miranda A. Mathews, Alba Guijarro Belmar, Calvin Chad Smith, Sylvain Gigout, Panayiota Demosthenous, Riccardo Privolizzi, Hanna Luniak, Brandon Roberts, Marta Zinicola, Devan Parmar, Raj S. Dattani, Robert M. Brownstone, Andrew J. Murray

Sania Therapeutics, London, United Kingdom

Gene therapies could potentially change healthcare by making previously intractable disorders amenable to treatment. These new treatments could improve and/or extend the lives of patients, and thus open substantial new healthcare markets. However, in order for gene therapies to reach widespread adoption, several challenges must be overcome. Many of these challenges relate to the delivery mechanism for genetic material which should achieve sufficient transduction of target cell types whilst minimising vector distribution to non-target tissues and limiting toxicity and immune response. Ideally these goals would be achieved with a low-dose viral vector to further increase safety and reduce overall treatment costs. We are aiming to overcome these challenges by developing low dose, highly targeted gene therapies that have been developed using our human-centric approach. Our lead therapeutic program is a gene therapy for spasticity - a prevalent and debilitating condition associated with several neurological diseases. Spasticity results from hyperexcitability of motor neurons in the spinal cord and is characterised by severe, involuntary muscle spasms, joint stiffness, and pain. Although approximately 2.5 million people in the US and Europe suffer from severe spasticity, they often receive a poor standard of care as current treatments are largely ineffective, invasive, and have non-specific mechanisms of action which leads to significant side effects. Sania's gene therapy for spasticity (SRx-T001) combines an engineered AAV vector and peripheral delivery to target gene delivery only to hyperactive motor neurons. Using our human-centric AAV evolution platform, R-Scan, we have identified multiple novel AAV capsids that show superior transduction of motor neurons. We demonstrate this superior transduction in human motor neurons in culture, human neuromuscular organoids and mouse motor neurons in vivo following intramuscular injection. We have also shown that the intramuscular route of injection prevents biodistribution to non-target cell and tissue types. This precision delivery system enables a targeted form of genetic neuromodulation (chemogenetics) to alleviate spasticity symptoms. Sania uses this novel AAV vector to drive overexpression of a human ion channel selectively in spastic motor neurons. This overexpression means that these motor neurons are selectively susceptible to low doses of a small molecule, taken orally. Binding of this small molecule to this ion channel reduces neuronal excitability. We have demonstrated that expression of our ion channel (SRx-490) in human motor neurons has little effect on the excitability of these neurons alone. However, application of low doses of the small molecule activator significantly reduces the electrical activity of these neurons. This chemogenetic system will allow patients and clinicians titratable control over motor neuron excitability and potentially allow the restoration of muscle function. By combining our unique vectors engineered in human motor neurons, targeted administration, and a novel chemogenetic system, we are developing a gene therapy with a high safety profile, high specificity, that can be delivered at relatively low cost. This combination will facilitate adoption for this prevalent movement disorder and provide a blueprint for future therapeutic approaches.

1141. BIUXX

Meysam Ganjibakhsh[1], Julieth A. Sierra Delgado[1], Babatunde Ogunlade[1], Yanina Tkachenko[1], Abuzar Kaleem[1], Kyle Faulconer[1], Pipasha Biswas[1,2], Krizelle Alcantara[1], Xiaojin Zhang[1], Shibi Likhite[1], Kathrin Meyer[1,2]

[1]The Research Institute at Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics, The Ohio State University, College of Medicine Columbus, Columbus, OH

Objective: GMPPA-Congenital Disorder of Glycosylation is a rare genetic disease characterized by alacrima, achalasia, and intellectual disability. This study aims to develop novel patient specific *in vitro* disease model systems to investigate and screen potential therapeutic avenues including gene therapy for patients with GMPPA. **Methods:** Patient-derived fibroblasts were directly converted into induced neurons (iNs) using a specialized neuronal induction medium with specific small molecules, generating disease-specific neuronal cell models. The iNs underwent characterization through comprehensive cell biology assays to assess disease-specific pathological contributions, including evaluations of cellular morphology and functional properties. In addition, Neural Progenitor Cells (iNPCs) were generated from GMPPA patient fibroblasts using a well-established direct reprogramming method developed by the Meyer lab and differentiated into induced astrocytes (iAs). iA function was evaluated via multiple assays including mitochondrial stress test using the Seahorse Bioscience Extracellular Flux Analyzer and co-culture assays with healthy mouse GFP+ neurons. These assays are currently used to evaluate the efficacy of small molecule drugs as well as an AAV gene therapy construct we recently developed. **Results:** Neurons derived from patients with GMPPA mutations displayed distinct disease phenotypes, such as reduced conversion rates and altered neuronal morphology. Moreover, we found significant changes in basal and ATP-linked respiration compared with healthy controls. In the co-culture system, iAs derived

from patients caused death of the co-cultured neurons, indicating that astrocytes might play a crucial role in the disease manifestation. We applied functionalized nanoparticles to iAs, and the results demonstrated the rescue of neuronal support and improvement of the metabolic phenotype. **Conclusion:** We developed novel *in vitro* model systems to study GMPPA disease mechanisms and test novel therapeutics in a rapid and patient-specific manner. Several therapeutic avenues are currently under evaluation including a AAV based gene therapy approach.

1142. How to Develop Treatments for Ultra Rare Disease + Applications for SCA3

Richard Horgan
Cure Rare Disease, Woodbridge, CT

There are currently over 7,000+ rare diseases, and 50% of patients affected are children. And while 1 in 10 people suffer from a rare or ultra rare disease, tragically only 5% of these diseases have effective treatments or a cure. There is a bias of traditional drug development towards diseases with large populations, leaving ultra rare disease patients with no traditional path forward for identifying new treatments or cures. However, new frameworks are allowing for the development of treatments on a smaller scale, offering hope for these patients. CRD-002 is an ASO drug being developed for the treatment of spinocerebellar ataxia type 3 (SCA3) also known as Machado-Joseph Disease. SCA3 is an ultra-rare genetic disease triggered by triplet expansion in the *ATXN3* gene. It is a debilitating and life-threatening disease, with low prevalence and with no available treatments. There are currently no therapeutic interventions and very few interventional clinical trials for this disease. CRD-002 targets exon 10 of the unprocessed, or pre-mRNA. This exon 10 contains the expanded CAG repeat. Through steric blocking, the ASO binds with the pre-mRNA such that the cellular machinery involved in processing does not recognize exon 10 and doesn't include it in the final transcript. The resulting protein will be slightly shorter, does not contain the toxic mutation but still contains most of its essential functional domains. Preclinical in vitro and in vivo experiments have demonstrated production of a functional ATXN3 protein and reduces disease phenotype in the brain. All SCA3 patients have an expansion of CAG repeats in the ATXN3 gene. Therefore, this treatment is applicable to all SCA3 patients because it targets the ataxin-3 RNA. As clinical research on genetic diseases advances, more traditional pharma companies will have the ability to follow this emerging pathway and explore future applications for advanced modalities, including in rare and ultra rare diseases. Before embarking on this journey, it's important that they learn from those who have established a framework - both in terms of "how to" steps but also lessons learned throughout the process. Moreover, it's important to understand the perspective of regulators and how clinical trials can be designed in light of lower prevalence numbers. This presentation will cover: - How to apply the ultra-rare drug development framework - Identifying disease targets and patients for treatment - The importance of focusing on mutation-specific therapies - How to collaborate with the FDA - Alternative funding pathways - How this approach is currently being taken to develop a therapy for SCA3

Thursday Posters: Musculo-Skeletal Diseases

1143. AAV-Mediated Exon51 Skipping Results in Durable Dystrophin Protein Restoration and Correction of Histopathology in a Mouse Model for Duchenne Muscular Dystrophy

Lan Jin, Randolph Qian, Steven Foltz, Ting Chen, Kirk W. Elliott, Jason Yang, Olivier F. Danos, Ye Liu
REGENXBIO Inc. - Rockville, Rockville, MD

Duchenne muscular dystrophy is caused by loss of function mutations in the *DMD* gene that encodes Dystrophin. Around 80% of these mutations disrupt the translation reading frame but can be reversed by excluding a specific exon of the *DMD* mRNA, which results in a slightly shorter but functional protein. Exon skipping using synthetic antisense oligonucleotides is an approved therapy for eligible DMD patients. Using a self-complementary (sc) AAV vector expressing antisense sequences fused to a modified U7 small-nuclear RNA (AS.snRNA), we have previously reported effective dystrophin exon 53 skipping in the *hDMDdel52/mdx* (Del52) mouse model which harbors a defective human *DMD* gene rescuable by skipping either exon 53 (Ex53) or exon 51 (Ex51). Dystrophin restoration, correction of histopathology, and muscle function improvement were demonstrated at 3 months after AAV.Ex53 treatment in mice. To expand the AAV-mediated exon skipping platform and potentially reach additional DMD patients, we have designed a similar approach for Ex51 skipping. Three antisense sequences were designed to target Ex51, the Ex51/Intron50 junction, and the Ex51/Intron51 junction. Each antisense sequence was fused to the 5' end of a modified U7 snRNA driven by a mouse U7 promoter. Three such U7 expression cassettes were cloned into a scAAV expression plasmid in tandem (AAV.Ex51.3AS), packaged into either AAVhu32 or AAV8 capsids, and tested in immortalized human myoblasts harboring the Del52 mutation. Up to 90% Ex51 skipping and 70% Dystrophin protein restoration were achieved in this system. The skipping efficiency was positively correlated with both AAV multiplicity of infection and the level of each AS.snRNA, indicating that the altered mRNA splicing is a specific result of the treatment. Both AAVhu32 and AAV8 vectors performed similarly in the Del52 human myoblast.Next, we treated Del52 mice with AAVhu32. Ex51.3AS vector at three doses of 5E13, 1E14, and 2E14 gc/kg, delivered intravenously. Necropsies were performed at 2- or 6-months post-dosing. At 2 months, Ex51 skipping efficiency reached up to 80% across skeletal muscles and the heart. This led to 17%, 25%, and 60% of wild-type level dystrophin protein restoration in the diaphragm, gastrocnemius, and heart, respectively. Dose-dependent AS.snRNA expression, *DMD* mRNA Ex.51 skipping, and Dystrophin protein restoration were observed in the diaphragm and gastrocnemius. At the low dose of 5E13 gc/kg, a notable 60% of Dystrophin protein was restored in the heart and did not further increase with a higher dose. In gastrocnemius, immunohistochemical analysis demonstrated up to 80% Dystrophin-positive fiber with proper sarcolemma localization, while Sirius Red staining demonstrated a reduction of fibrosis. At 6 months post-dosing, the Ex51 skipping efficiency remained stable, while Dystrophin protein levels increased further to 42% and 35% in the diaphragm and gastrocnemius, respectively. Dystrophin levels in

the heart remained at nearly 60%, regardless of dose levels, indicating highly efficient AAV transduction and exon skipping in the Del52 mouse heart. These findings collectively highlight the therapeutic and translational potential of the AAV.Ex51.3AS vector, which has the potential to treat up to 13% of all eligible DMD patients.

1144. Development of hfCas12Max-Based Single-Cut Gene Editing Therapy for Duchenne Muscular Dystrophy

Guoling Li[1], Jiajia Lin[2], Ming Jin[2], Zhifang Li[3], Tong Li[1], Shaoran Wang[1], Xuan Yao[1], Alvin Luk[1], Hui Yang[1,4], Linyu Shi[1]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Department of Neurology, First Affiliated Hospital, Fujian Medical University, Fuzhou, China,[3]Lingang Laboratory, Shanghai, China,[4]Institute of Neuroscience, Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Duchenne muscular dystrophy (DMD) is a rare, fatal, X-linked neuromuscular disease caused by mutations in the *DMD* gene, disrupting the translation of the dystrophin protein which leads to muscle degeneration, progressive muscle weakness, and premature death. Among thousands of *DMD*-causing mutations, the skipping and reframing of exon 45 and exon 51 is estimated to therapeutically benefit at least 8% and 14% of all DMD cases worldwide, respectively. Thus far, the antisense oligonucleotide (ASO) medicine, known as eteplirsen or casimersen, has been approved to treat DMD patients with particular mutations in the exon 45-55 hotspot regions. However, it has been shown that ASO medicines just restore dystrophin protein expression to less than 1% of the normal level after one year of continuous weekly intravenous administration. Therefore, exploring innovative and efficient therapeutic approaches to correct genetic mutations and restore dystrophin expression and muscle functions in DMD individuals is urgently necessary. **Methods:** Two humanized DMD mouse models were generated, one replacing mouse exon 51 with human exon 51 and deleting mouse exon 52 (DMD$^{\Delta mE51E52,hE51KI}$) while the other replacing mouse exon 45 with human exon 45 and deleting mouse exon 46, thereby disrupting the open reading frame of the dystrophin protein. We explored the efficiency of high-fidelity Cas12Max (hfCas12Max)-mediated single-cut genome editing in human *DMD* exon 51 splice donor (SD) site (Figure 1B) and exon 45 *in vitro*. An all-in-one AAV vector system was chosen for *in vivo* delivery of hfCas12Max and a guide RNA (gRNA) targeting the SD site of human exon 51 or exon 45 to manifest the *in-vivo* single-cut efficiency in DMD mice (Figure 1A) and wild-type non-human primates (NHPs) (Figure 1G). **Results:** Both humanized DMD mouse models exhibited phenotypes highly similar to those individuals with DMD, making them suitable for analyzing potential intervention strategies. We subsequently showed that hfCas12Max-mediated single-cut genome editing efficiently targeted the splice donor (SD) sites of human *DMD* exons 51 and 45 *in vitro*. Additionally, systemic delivery of AAV-hfCas12Max effectively restored dystrophin protein expression in both humanized DMD mouse models, and it improved the pathological features of DMD, including the histopathology and grip strength of these mouse models (Figure 1C-F). Moreover, the all-in-one single AAV vector induced therapeutically acceptable editing efficiency in exon 51 SD in healthy wild-type NHP with low dosage, and no hfCas12max-related toxicity was observed, indicating that the AAV-hfCas12Max therapy is relatively safe (Figure 1H,I). **Conclusions:** Our innovative CRISPR-based therapeutic, utilizing hfCas12Max for a precise single-cut modification of genomic DNA, presents a captivating new treatment paradigm, which offers a promising, long-lasting, and "one-and-done" new treatment modality that targets the underlying cause of DMD.

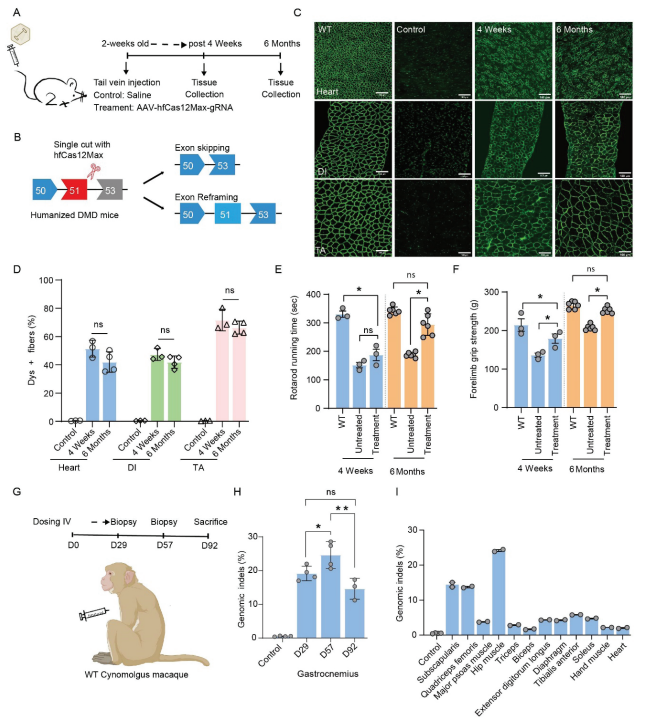


Figure 1. Intravenous delivery of hfCas12Max system efficiently rescues dystrophin expression and muscle function in humanized DMD mice. 1145. Adenine Base Editing Mediated Exon Skipping Restores Dystrophin Expression in a Humanized Mouse Model of Duchenne Muscular Dystrophy

Guoling Li[1], Jiajia Lin[2], Ming Jin[2], Zhifang Li[3], Qingquan Xiao[1], Tong Li[1], Shaoran Wang[1], Xuan Yao[1], Alvin Luk[1], Ning Wang[2], Wanjin Chen[2], Chunlong Xu[3], Hui Yang[1,4], Linyu Shi[1]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Department of Neurology, First Affiliated Hospital, Fujian Medical University, Fuzhou, China,[3]Lingang Laboratory, Shanghai, China,[4]Institute of Neuroscience, Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Duchenne muscular dystrophy (DMD) is the most common X-linked neuromuscular disease, caused by mutations in the *DMD* gene. Despite the existence of a multitude of clinically documented mutations, the majority of those responsible for DMD are concentrated within a "hotspot" region, which spans from exons 43 to 55 of the DMD gene. This specific genomic segment encodes the central rod domain of the dystrophin protein. Correction of the *DMD*

exon 51 deletion mutation by skipping exon 50 can therapeutically benefit ~3.8% of DMD patients. Here, we developed CRISPR adenine base-editing therapy for the treatment of DMD. **Methods:** We generated a humanized DMD mouse model by replacing mouse exon 50 with human exon 50, followed by the deletion of mouse exon 51 ($DMD^{\Delta mE50,51,\ hE50KI}$), which disrupted the dystrophin open reading frames (Figure 1A). Then, we explored the potential of a single adeno-associated virus (AAV) vector packaged with CRISPR adenine base editor (ABE) named NG-ABE in modifying splice donor sites of the *DMD* gene by intramuscular injection and systemic delivery, causing skipping of a common *DMD* deletion mutation of exon 51. The outcomes were analyzed at 6 weeks and 10 months post-treatment to evaluate the extent of exon skipping, dystrophin restoration, and phenotypic improvements of cardiac and skeletal muscles (Figure 1B). **Results:** Humanized DMD mice models exhibited numerous features characteristic of DMD pathology, such as the lack of dystrophin, inflammation infiltration, reduced muscle strength, and elevated creatine kinase (CK) levels. Intramuscular administration of AAV vectors encoding ABE components, utilizing a split-intein trans-splicing system, led to more than 90% targeted exon skipping in *DMD* mRNA and restoration of up to 60% dystrophin protein in the affected tissues. Systemic delivery of these AAV-ABE vectors effectively restored dystrophin expression and mitigated the pathologic hallmarks of DMD, encompassing histological changes, serum CK levels, and grip strength (Figure 1C-F). The therapeutic benefits were maintained for over 10 months. **Conclusions:** This distinctive DMD mouse model, which harbors the human genomic sequence, enables the *in vivo* evaluation of clinically relevant ABE gene editing strategies and other therapeutic interventions, signifying a substantial advancement towards the clinical application of adenine base editing for the correction of DMD in patients.

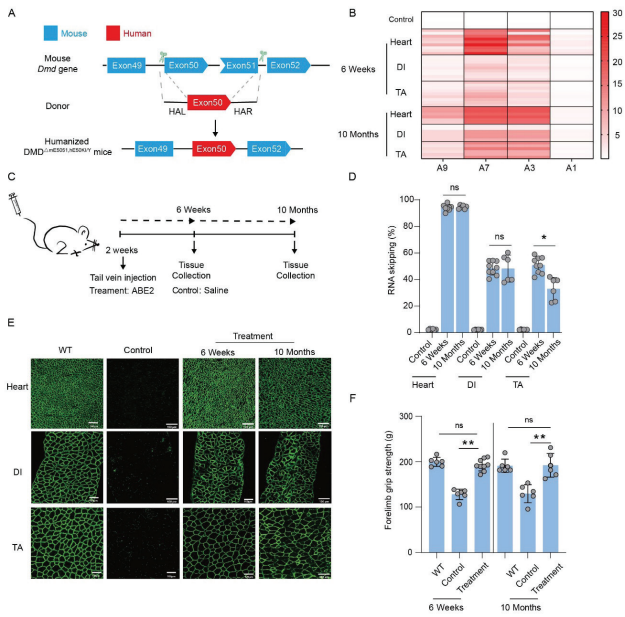

Figure 1. Intravenous delivery of the NG-ABE system efficiently rescues dystrophin expression and muscle function in humanized DMD mice. (A) Strategy for generating humanized DMD mouse model ($DMD^{\Delta mE50,51,\ hE50KI}$ mice). (B) Schematic of intravenous administration of NG-ABE particles. (E) Immunohistochemistry analysis shows restoration of dystrophin expression in multiple muscle groups of $DMD^{\Delta mE50,51,\ hE50KI}$ mice 6 weeks and 10 months after injection of NG-ABE. Dystrophin was shown in green. (F) Forelimb grip strength was measured in WT, $DMD^{\Delta mE50,51,\ hE50KI}$ mice, and $DMD^{\Delta mE50,51,\ hE50KI}$ mice treated with NG-ABE particles (n=6-9).

1146. Precise Correction of Duchenne Muscular Dystrophy by Compact Cytosine Base Editor-Induced Exon Skipping

Guoling Li[1], Qingquan Xiao[1,2], Dingyi Han[2], Haoqiang Wang[1], Tingting Ma[1], Jingxing Zhou[1], Yu Zhang[1], Xiumei Zhang[1], Tong Li[1], Shaoran Wang[1], Yuan Yuan[1], Xuan Yao[1], Linyu Shi[1], Yingsi Zhou[1], Hainan Zhang[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Institute of Neuroscience, Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Duchenne muscular dystrophy (DMD) is a fatal, X-linked recessive neuromuscular disorder, with an incidence rate of approximately 1:3500-5000 in live male births. Although the CRISPR base-editor-mediated exon skipping is highly effective for most DMD cases, the length of the coding sequence is more than 4.7 kb, rendering its ability to be packaged into a single adeno-associated viral (AAV) vector. The use of dual AAV vectors to deliver the CRISPR/Cas9 system not only necessitates the increased clinical dosages, poising greater AAV-related safety risks but also faces the drawback of low *in-vivo* recombination efficiency of the split CRISPR system, thus compromising editing efficiency and limiting its clinical application. As an evolutionary ancestor of the Cas9 nuclease, the IscB protein serves as a compact RNA-guided DNA endonuclease, positioning it as a potent candidate for DMD treatment. **Methods:** We employed a computational pipeline to annotate IscB orthologs,CRISPR array, ωRNA, and target adjacent motif (TAM) preferences by data mining assembled bacterial genomes (Figure 1A). An EGFP-activation reporter system was designed and used to screen functional CRISPR-IscB systems in human cells. Protein engineering combined with ωRNA optimization was used to generate enhanced IscB variants with high editing efficiency and broad TAMs. Subsequently, we explored the potential of a compact cytosine base editor (CBE) derived from IscB variants to modify the splice acceptor (SA) sites of the *DMD* gene, to induce skipping of a common *DMD* deletion mutation of exon 51 via intramuscular injection of AAV-CBE (Figure 1D). This evaluation aimed to assess the extent of compact CBE-mediated exon skipping, dystrophin restoration, and phenotypic improvements of cardiac and skeletal muscles in a humanized DMD mouse model, in which the exon 50 and 51 of mouse *Dmd* gene were replaced with human exon 50 sequence (Figure 1E). **Results:** We have identified 10 out of 19 uncharacterized IscB proteins from uncultured microorganisms, which are active in mammalian cells (Figure A). Through protein and ωRNA engineering, we have further enhanced the activity of the IscB ortholog IscB.m16 and expanded its TAM range from MRNRAA to NNNGNA, producing a variant known as IscB.m16*. By fusing the deaminase domain with the IscB.m16* nickase, we have created a derived compact CBE termed IscB.m16*-CBE (Figure 1B,C). Subsequent delivery of the IscB.m16*-CBE via a single AAV vector to the humanized DMD mice demonstrated effective exon 50 skipping by modifying the SA site of the targeted exon and restoration of dystrophin protein expression in the humanized DMD mice (Figure 1F-H). **Conclusions:** The engineered compact IscB-derived base editors have demonstrated to be a platform capable of highly efficient, specific, and broad-TAM-scope DNA base

editing in mammalian cells and in mouse models of diseases, such as DMD, which facilitates the subsequent drug development of single AAV-delivered base editor for gene therapy.

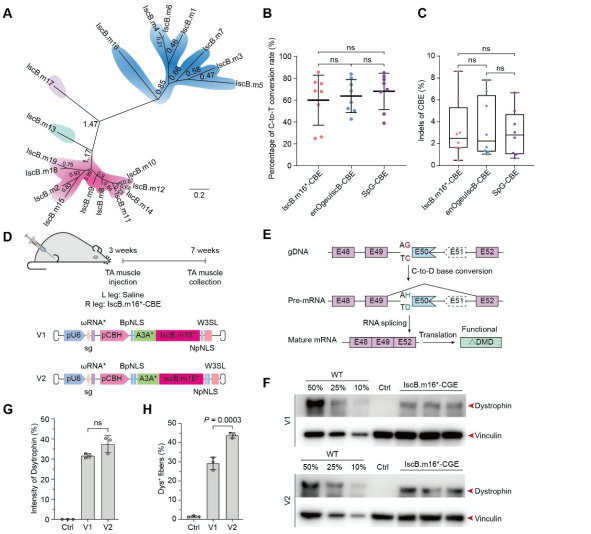

Figure 1. IscB.m16*-based cytosine base editor (CBE) mediates effective base editing and restores dystrophin expression in humanized DMD mice. (A) Phylogenetic tree of 19 uncharacterized IscB orthologs. (B) Comparison of the C-to-T conversion efficiency of IscB.m16-CBE, IscB.m16*-CBE, enOgueIscB-CBE and SpG-CBE at 8 target sites. (C) Indel efficiency of IscB- and SpG-derived CBEs at 8 endogenous loci. (D) Schematics of a single AAV carrying two different versions of IscB.m16*-CBE delivered to the muscles in mice via TA muscle injection. (E) Schematics of the strategy of IscB.m16*-CBE treating DMD. IscB.m16*-CBE disrupts the conserved guanine within the splice acceptor site for programmable exon 50 skipping, leading to the restoration of dystrophin expression. (F) Western blot analysis of dystrophin and vinculin expression in TA muscles 4 weeks after injection with AAV-IscB.m16*-CBE or saline. Quantification of dystrophin expression (G) and Dys+ fibers (H) in TA muscles.

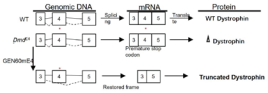
1147. Therapeutic Exon Skipping Through Cytidine Base Editing *In Vivo*

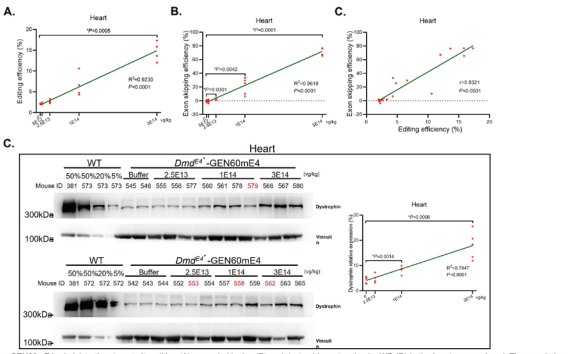
Chunyan He, Xiao Li, Kaixuan Qiao, Pei Tao, Jinting Zhang, Kai Jiang, Qiuyu Cao, Guangyuan Xiao, Li Chen, Fengpeng Li

SuZhou GenAssist Therapeutics Co., Ltd, Suzhou, China

Background Loss of dystrophin protein causes Duchenne muscular dystrophy (DMD), characterized by progressive degeneration of cardiac and skeletal muscles. GEN60mE4 is a mouse DMD exon 4 skipping base editing product containing two AAV9 vectors, ss.AAV9.oTAM (optimized Targeted AID-mediated Mutagenesis) and ss.AAV9.mE4-sgRNA. GEN60mE4 target the IVS4 5'SS in the mouse Dmd gene, leading to interruption of the recognition of exon 4 during splicing process, resulted in exon 4 skipping. *Dmd*^{E4*} is a DMD mouse model has 4-bp deletion leading to dystrophin protein disruption. GEN60mE4 induced exon 4 skipping resulted in truncated yet in-framed dystrophin protein (**Fig.1**). **Method** PND21 *Dmd*^{E4*} /BL10 mice received a single IV administration of formulation buffer or different dose of GEN60mE4. Age-matched WT mice were included as controls. Interim and terminal sacrifices occurred at the end of 4-, 8-, and 28-weeks post-dose, respectively. **Results** The transcripts of oTAM were highly distributed in heart and skeletal muscles confirmed strong muscle specificity of SYN promoter. The sgRNA has been reported to be stabilized by forming a complex with Cas9 protein, similar expression pattern of mE4-sgRNA as oTAM was observed. Dose-dependent exon 4 skipping was observed in both heart and other tested muscular tissues. Especially in heart of 3E14 vg/kg GEN60mE4 group, exon skipping efficiency is close to 80%, the edited Dmd mRNA level was comparable to that of WT controls. The dystrophin protein reached approximately 20% or 7 % of the WT level in the heart or TA of the animals in 3E14 vg/kg group, respectively (**Fig.2**). Serum CK-MB exhibited a 2-fold decrease in 3E14 vg/kg group compared to untreated *Dmd*^{E4*} mice (P=0.0181). Deep RNA sequencing of heart tissue was performed to analyze the gene expression after treatment. The results showed that the genes that were differentially expressed in WT versus *Dmd*^{E4*} groups were highly rescued with GEN60mE4 treatment. Most importantly, TAM-based cytosine base editor induced non-detectable RNA off-target at the transcriptome level (**Fig.3**). Vector copies of oTAM and sgRNA gradually decreased over time over 28-week observation. Interestingly, the restored dystrophin protein dramatically decreased at 8-week and further catching up over 28-week in heart. The Dystrophin protein restored to 25.58% and 35.59% of WT level in 5E13 and 1E14vg/kg group at 28-week, respectively. Consistently, the editing efficiency decreased at 8-week in the heart of treated mice. In comparison, no decreased editing was observed in TA. The minimal editing efficiency in TA was observed (3%) at 4-week. At week 28, the editing efficiency accumulated to 12.4% in 5E13 or 11.28% in 1E14vg/kg treated mice (**Fig.4**). Immune response against transgene or AAV was evaluated at 8- and 28-week. Strong humoral and cellular immune response against AAV9 or cas9 but not dystrophin protein was observed (**Fig.5**), which might be a reason for the rapid reduction of editing efficiency at week 8 since the successfully transduced cells were easy to be attacked by immune cells. **Conclusion** These studies demonstrate that TAM BE can restore the dystrophin protein and provide some therapeutic potential with long term observation. Immune response against AAV and transgene should be considered before human therapeutic application of base editors.

Figure1. Schematic of GEN60mE4 induced exon 4 skipping in *Dmd*^{E4*} mice model





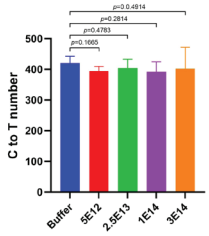


Figure2. GEN60mE4 induced target site editing, exon 4 skipping and dystrophin protein restoration in *Dmd*^{E4*} mice model

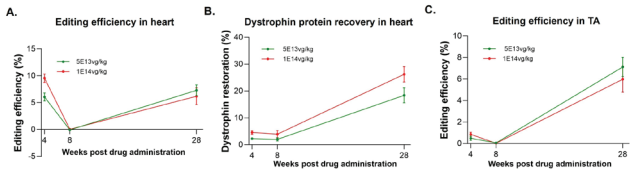
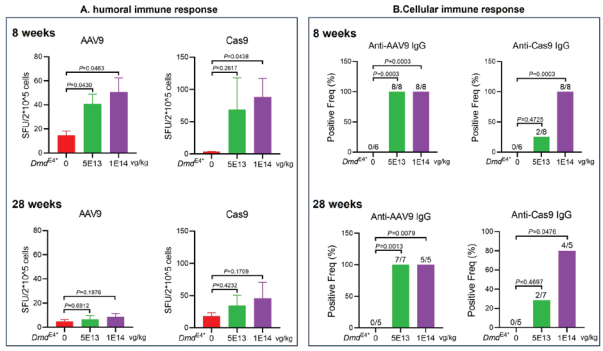


Four weeks after GEN60mE4 administration, target site editing (A), exon 4 skipping (B) and dystrophin restoration by WB (D) in the heart was analyzed. The correlation of target site editing and exon 4 skipping was analyzed (C). Statistical analysis was performed using simple linear regression model, two-tailed t-test was used for two groups comparison, *P*<0.05 was considered as statistically significant. N>=5 mice in each group.

Figure3. Non overall RNA off-target was observed



Four weeks after GEN60mE4 administration, RNAseq was performed in heart tissues, C to T conversion was calculated. Two-tailed t- test was used for two groups comparison, N=3 mice were included in each group.

1148. Assessing the Burden of Duchenne Muscular Dystrophy and Willingness to Take Gene Therapy in China

Chunyan He[1], Guangyuan Xiao[1], Yi Dai[2]

[1]SuZhou GenAssist Therapeutics Co., Ltd, Suzhou, China,[2]Peking Union Medical Hospital, Beijing, China

Introduction: Duchenne muscular dystrophy (DMD) is a devastating genetic disorder characterized by progressive muscle weakness. Individuals with DMD experience muscle weakness, which often leads to the use of wheelchairs during adolescence and finally resulting in cardiac and respiratory failure in their 20-30s. While the natural history of the disease is relatively well understood, knowledge about the overall costs of managing DMD patients in China remains largely unknown. **Objective:** The aim of this study was to assess the comprehensive cost of illness and economic impact associated with Duchenne muscular dystrophy (DMD) in China. In addition, the willingness to gene therapy were evaluated. **Methods**: The questionnaire was designed, distributed, and collected utilizing the online survey function of WeChat app, which is shared within patient organization groups from October 17, 2023, to November 3, 2023. Identification of patients with DMD is through their WeChat ID, telephone number, date of birth, and self-reported mutation type. Information on healthcare utilization, quality of life, employment status, and household expenses is gathered to calculate the costs associated with DMD from both the societal perspective and the perspective of caregiver households. Additionally, the willingness of patients to participate in clinical trials and how much they are willing to pay for gene therapy were collected. **Results:** The questionnaire was completed by a total of 2287 patient-caregiver pairs from 31 provinces in China. Among those patients, 13.55% were under 3 years old, 39.92% were in the early ambulatory stage, 34.85% were in the late ambulatory, and the remaining 11.67% were in the non-ambulatory stage (**table 1**). The total mean per-Patient annual cost of illness was estimated 128629 ￥. Mean per-Patient annual direct cost of illness was estimated 67749 ￥, the median is 42500￥(**table 2**). Indirect costs were substantial, constituting 34% of total costs (**Figure 1A**). There is an increasing trend in hospital expenses, travel for medical, rehabilitation, and wheelchair costs as the disease progresses to the early non-ambulatory stage, but a decrease is observed in the late non-ambulatory stage (**Figure 1B**). Most of patients express a strong willingness to participate in gene therapy clinical trials, with 52.92% patients preferring for enrollment in Phase III clinical trial (**Figure 2A**). Although with substantial economic burden of DMD patients, most of the patients are willing to pay for gene therapy. Notably, 80% of patients choose 30% down payment (**Figure 2B**) and more than 40% patients are willing to pay above 1million￥as down payment for gene therapy(**Figure 2C**). **Conclusion**: We show that DMD is associated with a substantial economic burden. Most of the DMD patients are willing to participate in gene therapy, with more than 40% are willing to pay around three million￥. We first described the economic context of a rare disease DMD, serves as important intelligence input to health policy evaluations of intervention programs and novel therapies, financial support schemes for patients and their families, and the design of future cost studies. **Limitation**: The questionnaire is exclusively obtained from WeChat app, in which the patients' identity cannot be fully confirmed. Most questionnaire providers are in the ambulatory stage (88.33%), which has a strong bias to underestimate the annual cost for all stage of DMD patients.

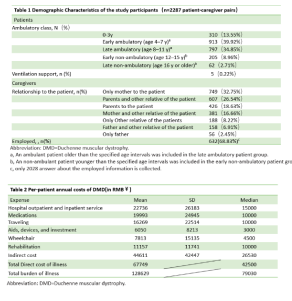

Table 1 Demographic Characteristics of the study participants (n=2287 patient-caregiver pairs)

Patients			
Ambulatory class, N (%)			
	0-3y	310	(13.55%)
	Early ambulatory (age 4-7 y)[a]	913	(39.92%)
	Late ambulatory (age 8-13 y)[a]	797	(34.85%)
	Early non-ambulatory (age 12- 15 y)[b]	205	(8.96%)
	Late non-ambulatory (age 16 y or older)[b]	62	(2.71%)
Ventilation support, n (%)		5	(0.22%)
Caregivers			
Relationship to the patient, n(%)	Only mother to the patient	749	(32.75%)
	Parents and other relative of the patient	607	(26.54%)
	Parents to the patient	426	(18.64%)
	Mother and other relative of the patient	381	(16.66%)
	Only Other relative of the patients	188	(8.22%)
	Father and other relative of the patient	158	(6.91%)
	Only father	56	(2.45%)
Employed, , n(%)		69268	8.97%

Abbreviation: DMD=Duchenne muscular dystrophy.
a, An ambulant patient older than the specified age intervals was included in the late ambulatory patient group.
b, An non-ambulant patient younger than the specified age intervals was included in the early non-ambulatory patient group.
c, only 2036 answer about the employed information is collected.

Table 2 Per-patient annual costs of DMD(in RMB￥)

Expense	Mean	SD	Median
Hospital outpatient and inpatient service	22756	26183	15000
Medications	19960	24845	10000
Traveling	16269	22514	10000
Aids, devices, and investment	6030	8213	3000
Wheelchair	7813	15155	4500
Rehabilitation	11157	13743	10000
Indirect cost	44611	42441	26540
Total Direct cost of illness	67749		42500
Total burden of illness	128629		79030

Abbreviation: DMD=Duchenne muscular dystrophy.

Figure 1. Components of annual cost of Duchenne muscular dystrophy and Mean per-patient annual cost of illness in different ambulatory stages. A) Percentage of each components of annual cost for DMD. Traveling including fees for transportation and hotels. Aids, devices, and investments include investments to and reconstructions of the home (e.g., fees for using stair board, corrective shoes.) B) The annual cost for each components in different ambulatory stage of DMD patients.

Figure 2. A) The distribution of patients willingness to participate into Phase I, Phase II, Phase III clinical trials. B) The percentage of patients' willingness to make various down payments, including 30%, 50%, 70%, and full payment. C) The percentage for the maximum down payment for patients can afford for gene editing therapy, including 1million,1.5 million, 2million, 3million, 4million and less than 1 million(all in RMB￥)

1149. Single Cell Analysis of Duchenne Muscular Dystrophy Skeletal Muscle Post Micro-Dystrophin Gene Therapy

Stanley Nelson[1], Kevin Chesmore[1], Deirdre Scripture-Adams[2], Florian Barthelemy[2], Richard Wang[1], Emilie Douine[1], Isaiah Little[2], Shirley Nieves-Rodriguez[1], Artemis Yip[2], Nicole Steady[2], Rosario Corona[1], M Carrie Miceli[3]

[1]Human Genetics, UCLA, Los Angeles, CA,[2]MIMG, UCLA, Los Angeles, CA,[3]CDMD, UCLA, Los Angeles, CA

Skeletal muscle is a cellularly complex and plastic tissue that responds to injury throughout life by recruiting and expanding immune cells and fibroblasts to guide muscle stem cell mediated repair of damaged multinucleated myofibers. Duchenne muscular dystrophy (DMD) is the most common form of muscular dystrophy accounting for 80% of deaths from muscular dystrophy before the age of 30 years. The lack of dystrophin, caused by mutations in *DMD*, leads to chronic and synchronous myofiber damage, inflammation, immune infiltration, dysregulation of repair, fibro-fatty replacement, and progressive loss of muscle function. Recently, micro-dystrophin gene therapy (GT) and mRNA exon skipping demonstrate replacement/repair of the missing dystrophin protein in myofibers helps to slow the disease progression. We have created a dataset of single nuclei/cell data from dozens of DMD individuals throughout the disease course and from some individuals post gene therapy from an amalgamated dataset of over 400,000 transcriptomes to reveal changes in the multi-cellular environment and cell-cell communications within dystrophic muscle using single cell and nuclei transcriptomics and infer muscle stem cell defects, mechanisms of fibroblast-mediated inflammation/fibrosis, and immune activation to reveal novel disease biomarkers and therapeutic targets.

1150. Fibrosis Restricts rAAV Gene Transfer and Can be Relieved by FAP-Specific CAR T Cells in a Murine Model of Duchenne Muscular Dystrophy

Maxime Ferrand[1], Sonia Albini[1], Céline Rocca[1], Valentina Buffa[1], Isabelle Richard[1], Anne Galy[1,2]

[1]UMR_S951 Integrare Research Unit, Genethon, Evry-Courcouronnes, France,[2]Art-tg, Inserm, Corbeil-Essonnes, France

Duchenne muscular dystrophy (DMD) is a muscle disorder that progressively weakens skeletal and cardiac muscles and causes fibrosis in muscle tissues. In the DBA2mdx mouse model of severe DMD, rapid and intense fibrosis was observed, characterized by dense collagen deposits in skeletal muscles, with over-expression of the FAP and Col3 genes in the TA, GA, EDL muscles at 2, 3, and 4 months of age compared to their aged-matched DBA2 littermates. It is hypothesized that fibrosis may limit the effectiveness of gene transfer therapy in DMD but direct evidence is lacking and strategies to reduce skeletal muscle fibrosis are limited. Because FAP-specific CAR-T cells were shown to reduce drug-induced cardiac fibrosis in mice, we tested whether FAP-specific CAR-T cells could also reduce the broad and spontaneously occurring skeletal muscle fibrosis in DBA2mdx mice. A FAP-CAR lentiviral vector (LV) encoding a third-generation CAR with an mFAP-specific ScFv was generated and validated on FAP-overexpressing 3T3 cells. The FAP-CAR LV was used to generate FAP-specific cytotoxic T cells from DBA2 spleen cells. Two consecutive administrations of FAP-CAR T cells to DBA2mdx mice reduced the histological and molecular biomarkers of fibrosis, as measured 2 weeks post-cell injection. When FAP-CAR T cells were injected into DBA2mdx mice before the intravenous administration of rAAV9 encoding a microdystrophin (5xE12 vg/Kg), there was an increased gene transfer efficacy as demonstrated by higher viral genome and transgene expression in TA and EDL muscles compared to controls. These results demonstrate for the first time that fibrosis acts as a restriction to rAAV gene transfer and provide a novel therapeutic option to treat muscular dystrophies by combining gene therapy and immunotherapy. *MF and SA contributed equally. IR and AG are co-senior authors of this study.*

1151. Utilizing Gene Therapy in Duchenne Muscular Dystrophy - Impact of Continuing Medical Education on Participant Knowledge and Behavior

Vandana Gupta[1], Carole Drexel[1], Crystal Proud[2]

[1]PlatformQ Health Educaton, Needham, MA,[2]Children's Hospital of The King's Daughters, Norfolk, VA

Background: In June 2023, the US Food and Drug Administration (FDA) approved the first gene therapy (GT) for the treatment of patients with Duchenne muscular dystrophy (DMD). We sought to characterize the impact of continuing medical education (CME) on healthcare professionals' (HCPs') awareness of the rationale for and data related to GT for DMD, as well as their ability to recognize and counsel patients who are candidates for GT. **Methods:** On September 15, 2023, we collaborated with the American Society of Gene & Cell Therapy (ASGCT) to launch a live, online, 1-hour, CME-certified activity featuring key opinion leaders experienced with newly available GT for DMD. The activity will remain on-demand for 1 year. Topics included: 1) rationale for GT in DMD, 2) clinical trial findings, and 3) pre-, peri-, and post-GT practical considerations, such as patient preparation, adverse-event management, and multidisciplinary care delivery. Session components included downloadable resources, live polling, and an audience real-time question-and-answer session. Educational impact was evaluated with knowledge and competence questions administered pre- and immediately post-activity (pre vs post). Chi-squared tests were used for statistical analysis. **Results:** As of January 2023, 1,003 HCPs from a variety of specialties (79% neurologists) had participated in the activity. 46% self-identified as prescribers seeing an average of 7 DMD patients per month. At baseline, only 30% of neurologists and 19% of all other learners were confident in their ability to counsel patients with DMD and their caregivers about GT. After the CME activity, there were marked improvements in knowledge and competence in each of the topics covered. Overall scores demonstrated learning gains on pre- vs post-education assessments (neurologists 72% pre vs 83% post; other learners 43% pre vs 58% post). Post activity, 42% of learners indicated that they intended to implement a practice change related to treatment, such as referral to specialty care. Learners also reported a need for greater understanding of the role of genetic testing in treatment decision-making (28%), and for strategies to address diagnostic challenges (16%). **Conclusions:** CME was successful in improving HCPs' ability to discuss the topic of GT with their patients by enhancing their knowledge and competence in critical areas related to the implementation of GT. Data also highlight a continued need for education related to DMD diagnosis, including genetic testing, which is an important issue based on the number of GTs on the horizon for DMD and other neuromuscular diseases.

1152. Immunomodulatory Effects of Amnion-Derived Mesenchymal Stromal Cells Preserve Muscle Function in a Mouse Model of Duchenne Muscular Dystrophy

Yuko N. Kasahara[1], Soya Nakayama[2], Koichi Kimura[1], Sho Yamaguchi[2], Yuko Kakiuchi[1], Chikako Nito[3], Masahiro Hayashi[2], Tomoyuki Nakaishi[2], Yasuyoshi Ueda[2], Takashi Okada[1]

[1]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan,[2]Kaneka Corporation, Kobe, Japan,[3]Nippon Medical School, Tokyo, Japan

[Background] Duchenne muscular dystrophy (DMD) is an incurable genetic disease characterized by degeneration and necrosis of myofibers, chronic inflammation, and progressive muscle weakness resulting in premature mortality. Immunosuppressive multipotent mesenchymal stromal cell (MSC) therapy could be an option for DMD patients. We focused on human amnion-derived mesenchymal stromal cells (hAMSCs), a clinically viable cell source owing to their unique characteristics, such as non-invasive isolation, mitotic stability, ethical acceptability, and minimal risk of immune reaction and cancer. We aimed to identify novel immunomodulatory effects of AMSCs on macrophage polarization and their transplantation strategies for the functional recovery of skeletal and cardiac muscles. **[Methods]** We used flow cytometry to analyze the expression of anti-inflammatory M2 macrophage markers on human peripheral blood mononuclear cells (hPBMCs) co-cultured with hAMSCs. hAMSCs were intravenously injected into DMD model mice (*mdx* mice) to assess the safety and efficacy of therapeutic interventions. hAMSC-treated *mdx* mice were monitored using blood tests, histological examinations, spontaneous wheel-running activities, grip strength, and echocardiography. **[Results]** hAMSCs induced M2 macrophage polarization in hPBMCs via prostaglandin E_2 production. After repeated systemic hAMSC injections, *mdx* mice exhibited a transient downregulation of serum creatin kinase. Limited mononuclear cell infiltration and a decreased number of centrally nucleated fibers were indicative of regenerated myofibers following degeneration, suggesting an improved histological appearance of the skeletal muscle of hAMSC-treated *mdx* mice. Upregulated M2 macrophages and altered cytokine/chemokine expressions were observed in the muscles of hAMSC-treated *mdx* mice. During long-term experiments, a significant decrease in the grip strength in untreated *mdx* mice significantly improved in the hAMSC-treated *mdx* mice. hAMSC-treated *mdx* mice maintained running activity and enhanced daily running distance. Notably, the treated mice could run longer distances per minute, indicating high running endurance. Left ventricular function in DMD mice improved in hAMSC-treated *mdx* mice. **[Conclusions]** Early systemic hAMSCs administration in *mdx* mice ameliorated progressive phenotypes, including pathological inflammation and motor dysfunction, resulting in the long-term improvement of the skeletal and cardiac muscle function. The therapeutic effects might be associated with the immunosuppressive properties of hAMSCs via M2 macrophage polarization. Although gene therapy and exon skipping are already approved for DMD drugs, hAMSCs treatment strategy could provide therapeutic benefits to DMD patients in the cases where these therapies are not indicated.

1153. Characterization of rAAV Genomic Integrity by Long-Read Sequencing of AAV9-MyoDys$^{45\text{-}55}$, a Gene Editing Therapy for Duchenne Muscular Dystrophy

Elizabeth Gibbs[1], William Dorst[1], Michael R. Emami[1], Laura Hagerty[1], Niclas E. Bengtsson[2], April D. Pyle[3], Melissa J. Spencer[3], Courtney Young[1]

[1]MyoGene Bio, San Diego, CA,[2]University of Washington, Seattle, WA,[3]UCLA, Los Angeles, CA

Duchenne muscular dystrophy is a fatal muscle wasting disease typically caused by out-of-frame mutations in the *DMD* gene resulting in a loss of the dystrophin protein. Thus, restoration of the reading frame offers a therapeutic approach which would turn Duchenne into a mild form of the allelic disease, Becker muscular dystrophy. Gene editing offers a reframing approach that would permanently change the patient's own DNA and retain more of the protein coding sequence than AAV-based gene replacement therapies. We have developed a gene editing therapy, MyoDys$^{45\text{-}55}$, that generates an in-frame deletion of exons 45-55, mimicking one of the mildest versions of Becker where some patients have been asymptomatic into their 60s. Importantly, deletion of this hotspot region would be applicable for 50% of Duchenne patients. We are currently developing a dual vector adeno-associated virus (AAV) delivery approach for MyoDys$^{45\text{-}55}$ where one vector carries Cas9 and one carries the guide RNAs. Here we describe long-read PacBio sequencing of the AAV cargos. Long-read sequencing is useful for understanding the packaging of AAV by sequencing the cargo in a single read. Since our Cas9 vector is slightly oversized and the guide RNA vector contains secondary structures, fully understanding the packaged genomes is critically important. For each vector, we sequenced AAV produced by three different commercial vendors and compared genomic integrity and contamination. These data demonstrate we do observe complete packaging of both vectors although some preps of the Cas9 vector show higher levels of truncation. This work supports the comprehensive assessment of AAV9-MyoDys$^{45\text{-}55}$ for Duchenne, which aims to permanently restore the reading frame for a large proportion of patients.

1154. MyoAAV-Mediated Systematic Delivery of Full-Length Dystrophin Improved Histopathology and Function in DMD Mice

Chen Zhang, Yuan Zhou, Renzhi Han

Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN

Recently, the US Food and Drug Administration (FDA) granted accelerated approval to Sarepta's Elevidys for Duchenne muscular dystrophy (DMD) patients at 4 to 5 years of age. Elevidys and other similar gene therapy approaches for DMD utilize adeno-associated virus (AAV) to deliver miniaturized dystrophin, also known as micro-dystrophin (μDys). However, due to the lack of 2/3 of the dystrophin coding sequence containing critical rod and hinge domains of dystrophin needed to connect with other proteins in the dystrophin complex, these μDys gene therapies are unable to provide full protection of skeletal and heart muscle integrity and function. Here we developed a novel triple vector system to address this limitation, aiming

to deliver full-length dystrophin (FL-dystrophin) into striated muscles. The FL-dystrophin is strategically split into three fragments (N, M, and C), fused with two orthogonal pairs of split intein. This design enabled the efficient and unidirectional assembly of FL-dystrophin. These three fragments were packaged into a recently engineered myotropic AAV capsid (MyoAAV4A). Systemic delivery of MyoAAV4A leads to the restoration of FL-dystrophin and the dystrophin-glycoprotein complex components at the sarcolemma of both skeletal and cardiac muscles in a mouse model of DMD. Notably, muscle histopathology, contractility, and overall strength were significantly improved following MyoAAV4A delivery. In summary, the FL-dystrophin gene therapy promises to offer maximum protection for DMD, addressing the limitations of the current μDys-based gene therapy.

1155. Targeting Muscle Stem Cells for Permanent Correction of Dystrophin Expression in Duchenne Muscular Dystrophy

Stephen D. Hauschka, Jeffrey S. Chamberlain, Niclas E. Bengtsson

University of Washington, Seattle, WA

Our longtime research efforts have been focused on correcting dystrophin expression and pathophysiology in Duchenne muscular dystrophy (DMD). An integral part of these efforts has involved development of miniaturized muscle-specific gene regulatory cassettes (RCs) to express high levels of therapeutic proteins in striated muscle following Adeno-associated viral (AAV) vector-mediated delivery. To date, these have been used to restore expression of dystrophin in cardiac and post-mitotic skeletal muscles via AAV-mediated gene transfer of ectopically expressed dystrophins, or via editing of the endogenous dystrophin gene using CRISPR/Cas9. However, the lifelong workloads of skeletal muscles may cause therapeutic efficacy to decrease over time due to muscle remodeling in response to growth, maintenance, exercise, or trauma. Thus, sustained therapeutic outcomes could benefit greatly from co-treatment of muscle stem cells (satellite cells, or SCs), in which successful gene editing of dystrophin mutations could provide newly regenerated myofibers with a lifelong supply of myonuclei that express functional dystrophins. Studies have suggested that at least some SCs and/or their replicating progeny can be transduced by AAV vectors to express delivered cargo genes using constitutively active promoters. However, non-specific Cas9 expression raises potential safety issues due to elevated immunogenicity and unintended editing effects in non-muscle cells. We are thus developing AAV packaging size-compatible RCs derived from highly conserved gene regulatory regions of *PAX7* and *MYOD1* (genes expressed in SCs, and myoblasts). SC RCs containing single as well as multiple *PAX7* and *MYOD1* regulatory regions or mosaic combinations (400 to 1800 base pairs), exhibit a range of activities in primary SC-derived myoblasts *in vitro* as well as in FACS-isolated SCs from wildtype versus dystrophic mice following AAV transduction. Promising RC candidates are currently being used to optimize dystrophin gene editing in SCs of DMD mice. Further tests also involve screening for AAV capsids that allow for the most efficient SC transduction, as well as exploring SC RC design enhancements via miniaturization and multimerization of the most active sequences to boost activities. Safe and effective correction of dystrophin mutations in SCs using promising RC candidates from this study in conjunction with dystrophin replacement or gene editing of postmitotic myonuclei, constitutes an instrumental element for addressing current limitations of skeletal muscle gene therapies aiming to treat DMD and potentially many other genetic muscle diseases.

Thursday Posters: Genetic Disorders of the Blood and Immune System

1156. Efficient rAAV6-Mediated HDR with Low Toxicity as a Therapy for GATA2 Deficiency Through Allele-Specific Gene Correction in Hematopoietic Stem Cells

Thomas W. Skov[1], Jonas H. Wolff[1], Didde Haslund[2], Anne L. S. Revenfeld[2], Bjarne K. Møller[2], Trine H. Mogensen[1], Rasmus O. Bak[1], Jacob G. Mikkelsen[1]

[1]Department of Biomedicine, Aarhus University, Aarhus C, Denmark,[2]Department of Clinical Immunology, Aarhus University Hospital, Aarhus N, Denmark

GATA2 deficiency is an autosomal dominant disorder caused by mutations in the gene encoding the transcription factor GATA2, leading to hematopoietic stem cell (HSC) dysfunction. This condition is associated with a reduction in immune cells, known as cytopenia, and a substantially increased risk of developing malignant blood diseases. Our study focuses on developing a novel therapy for GATA2 deficiency through ex vivo allele-specific correction of the *GATA2* variant c.956_962delGTGGCCT based on Cas9/sgRNA RNP delivery via nucleofection, coupled with DNA donor delivery for homology-directed repair (HDR) using rAAV6. Through the screening of multiple sgRNAs, we identified a sgRNA that exhibited no activity against the WT *GATA2* sequence and efficiently facilitated indel formation in the c.956_962delGTGGCCT allele in K562 cells, peripheral blood mononuclear cells (PBMCs), and hematopoietic stem and progenitor cells (HSPCs). In K562 cells engineered to carry c.956_962delGTGGCCT, co-delivery of Cas9/sgRNA RNPs and a rAAV6 vector carrying a DNA donor designed to correct the variant resulted in complete correction (>99% HDR) and fully restored GATA2 protein levels. Off-target analyses using DISCOVER-seq and subsequent high-throughput amplicon sequencing revealed a single bona fide off-target site in the lncRNA gene *AATBC*, which was targeted by HiFi Cas9 RNPs with 5.25% indel frequency in patient-derived PBMCs. Initially, editing of HSPCs using RNP nucleofection and rAAV6 donor delivery at an MOI of 2500, yielding an HDR rate of 71%, resulted in high toxicity and a severe reduction in colony-forming units (CFUs). Modification of medium composition, codelivery of multiple different mRNA transcripts to mitigate toxicity and increase HDR (GSE56, Ad5-E4orf6/7, and i53), and a 10-fold reduction in rAAV6 MOI alleviated toxicity while maintaining an HDR efficiency of 35% with no reduction in viability and CFUs. We evaluated the impact of *GATA2* editing in HSPCs by examining their differentiation through CFU assays, comparing normal HSPCs to those with a *GATA2* knockout (KO). *GATA2* KO increased the proportion of macrophage colony-forming units (CFU-M) at the expense of granulocyte-macrophage (CFU-GM) and erythroid colonies, along with a marked reduction in cell proliferation. Rescue of the KO through HDR partially

recovered differentiation and proliferation in the HSPCs to a level corresponding to the HDR rate. To investigate the potential selective advantage of *GATA2*-corrected HSCs *in vivo*, immunodeficient mice were engrafted with mixed populations of HSPCs containing cells engineered to carry either (i) the GATA2 c.956_962delGTGGCCT variant or (ii) silent mutations in *GATA2*. We found a significant enrichment of non-disruptive mutations after engraftment, suggesting that HSCs with functional *GATA2* outcompeted HSCs carrying defective *GATA2* alleles. Notably, using the optimized editing protocol in patient-derived HSPCs, we achieved 82% and 73% correction of the c.956_962delGTGGCCT allele at MOIs of 500 and 250, respectively. Ongoing studies focus on engraftment of corrected patient-derived HSPCs in immune-deficient mice, exploration of potential unintended large on-target modifications, and further investigation of potential off-target sites in patient-derived HSPCs using DISCOVER-seq.

1157. Expansion of CD33/HBG-Promoter Edited HSPCs with Mylotarg for *In Vivo* HSC Gene Therapy of Hemoglobinopathies

Aphrodite Georgakopoulou[1], Chang Li[1], Hans-Peter Kiem[2], Andre Lieber[1]

[1]University of Washington, Seattle, WA,[2]Fred Hutch, Seattle, WA

We developed an *in vivo* HSC gene therapy approach that consists of HSC mobilization and intravenous injection of HSC-tropic HDAd vectors. To achieve therapeutically relevant numbers of corrected cells, we incorporated *in vivo* expansion of transduced cells. We used an HDAd vector for a multiplex adenine base editing approach to *i)* remove the region within CD33 that is recognized by gemtuzumab ozogamicin (GO) (Mylotarg™), and *ii*) create therapeutic edits within the HBG1/2 promoters to reactivate γ-globin/HbF. *In vitro* studies with HDAd-transduced human CD34$^+$ cells showed editing of both targeted sites and a 2- to 3-fold GO-mediated expansion of edited erythroid/myeloid progenitors. After erythroid *in vitro* differentiation, up to 40% of erythrocytes were HbF positive. For *in vivo* studies, mice were transplanted with human CD34$^+$ cells. After engraftment, HSCs were mobilized with G-CSF/AMD3100 followed by an intravenous HDAd injection and GO-mediated *in vivo* selection. Two months later, editing in human cells within the bone marrow was significantly higher in GO-treated mice. The percentage of HbF$^+$ human erythroid cells was 2.5-fold greater compared to untreated mice. These data indicate that *in vivo* GO selection can increase edited erythroid cells to levels that are clinically relevant for treatment of hemoglobinopathies. These findings should also have important implications beyond hemoglobinopathies since the ability to use nongenotoxic in vivo selection / enrichment approaches of genetically modified cells can also be applied to other genetic diseases.

1158. A Comparison of Red Blood Cell (RBC) Functional Biomarkers in Successful Hematopoietic Stem Cell Transplantation (HSCT) versus Graft Failure

Aliya U. Zaidi[1], Rasa Borhan[1], Robert Goodrich[1], Marta Ferranti[1], Xiufeng Gao[1], Cynthia Joseph[2], Emily Limerick[2], Courtney D. Fitzhugh[2], Patrick C. Hines[1,3,4]

[1]Functional Fluidics Inc., Detroit, MI,[2]NHLBI/NIH, Bethesda, MD,[3]Division of Pediatric Critical Care Medicine, Wayne State University, Detroit, MI,[4]Division of Pediatric Critical Care Medicine, Wayne Pediatrics, Detroit, MI

Introduction: Sickle cell disease (SCD) is characterized by a mutation in the hemoglobin subunit β (HBB). Allogeneic HSCT is the most widely available cure, and the use of haploidentical donors has expanded the donor pool. Successful HSCT (S-HSCT) is associated with absence of SCD manifestations, including pain, normalized hemoglobin (Hb), and reversal of hemolysis. Critical aspects of red blood cell health (RBCH), such as adhesion and Hb polymerization, can predict future SCD severity and may provide earlier and more precise insight into HSCT efficacy. We assessed changes in flow adhesion of whole blood to vascular cell adhesion molecule (FA-WB-VCAM) and P-selectin (FA-WB-Psel), and RBC sickling with the dynamic sickling assay (DSA) before and after HSCT. Graft failure (GF), pain, opioid use, and clinical labs were captured. **Methods:** Samples were collected from 4 SCD subjects and 4 donors enrolled in NHLBI HSCT protocol 17-H-0069 or 000539-H. FA-WB-VCAM and FA-WB-Psel utilized a microfluidic well-plate system and were reported as cells/mm^2. DSA samples were exposed to a proprietary enzymatically-induced hypoxic environment, time-lapse photomicroscopy and AI-based SICKLE image analysis software quantifying RBC sickling. Parameters measured include: time to 5% and 50% morphological point of sickling (mPoS@5%, mPoS@50%), maximum rate of sickling (% /min), maximum sickling (%), and AUC10 (%*min). All values presented are mean ± standard error; $p<0.05$ considered statistically significant. **Results:** 3 subjects had S-HSCT, 1 experienced GF. In S-HSCT, Hb increased from 9.2±0.3 to 11±2 g/dL, bilirubin was reduced significantly from 1.7±0.3 at BL to 0.4±0.06 mg/dL at 6M ($p<0.01$). FA-WB-VCAM and FA-WB-Psel BLs in S-HSCT were 369±63 and 36±18 cells/mm^2, respectively. FA-WB-VCAM decreased significantly (26±9 cells/mm^2, $p<0.01$) by 3M and sustained at 6M (59±8 cells/mm^2, $p<0.01$). Although FA-WB-Psel decreased p-HSCT, it was not statistically significant. In GF, FA-WB-VCAM increased p-HSCT and FA-WB-Psel adhesion doubled from BL to 6M. Max rate of sickling in S-HSCT significantly decreased from 38±7 to 1.1±0.7 %/min ($p<0.01$) at 3M, and further to 0.4±0.4 %/min ($p<0.01$) at 6M. In GF, an initial reduction in sickling rate from BL to 3M was followed by an increase at 6M p-HSCT. Max sickling in S-HSCT significantly decreased from 0.68±0.16 at BL to 0.1±0.01 ($p=0.02$) and 0.06±0.01 ($p=0.02$) at 3M and 6M, respectively. In contrast, max sickling increased in GF from a BL of 0.50 to 0.75 at 6M (Fig.1). **Conclusions:** RBC health normalizes following S-HSCT as evidenced by statistically significant reductions in adhesive properties, reduced sickling rate and amplitude within 3 months. The subject experiencing GF demonstrated a worsening of adhesive and sickling parameters of RBC health consistent with sickle RBCs. A longer post HSCT follow-up period is needed to establish clinical improvement following S-HSCT, but reduced pain and lower

opioid usage in patients is encouraging. These findings suggest that FA-WB-VCAM, FA-WB-Psel and DSA could serve as objective indicators of RBC health normalization p-HSCT. Future studies will determine if these biomarkers could be surrogates for long-term clinical efficacy.

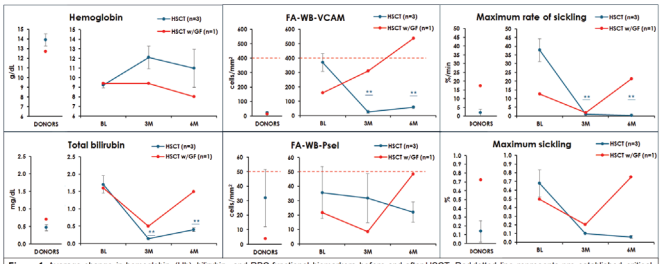

Figure 1. Average change in hemoglobin (Hb), bilirubin, and RBC functional biomarkers before and after HSCT. Red dotted line represents pre-established critical threshold. * *p*-values <0.05 ** *p*-value<0.01

1159. Comparative Interrater Analysis of Regulatory Challenges in Recently Approves Gene Therapies for Sickle Cell Disease: Towards a Semi-Quantitative Method for Assessing Gene Therapy Regulatory Development Complexity

Angela N. Johnson[1,2], Limin Wang[3], Johanna Nurbo[1], Arthur Fulgoni[4], Andreia Domingues[5], Sandra Racordon-Pape[5]

[1]Global Regulatory, Cytiva, Boston, MA,[2]School of Professional Studies, Regulatory Sciences, Northeastern University, Boston, MA,[3]Regulatory Sciences, Cytiva, Marlborough, MA,[4]Biopharma Product Regulatory Compliance, Cytiva, Boston, MA,[5]Regulatory Sciences, Cytiva, Boston, MA

Background: Standardized methods are needed in regulatory science to enable objective evaluation of regulatory complexities for gene therapies. In December 2023, two landmark gene therapies came to market with United States Food and Drug Administration (FDA) approval for treating sickle cell disease (SCD), using a lentiviral vector platform (*lovotibeglogene autotemcel*, LYFGENIA®, Bluebird Bio) and first-in-class CRISPR (*exagamglogene autotemce*l, CASGEVY®, Vertex). The CRISPR product functions by editing (or "cutting") a specific gene that enables reactivation of fetal hemoglobin production to dilute faulty red blood cells, while the lentiviral therapy employs a viral envelope to deliver a healthy hemoglobin-producing gene *in vivo*. This research aims to develop and employ a standard multi-rater instrument to examine relative complexity of regulatory domains of these products. **Methods:** US FDA approved labeling and summary basis for approval documents (FDA.gov) for *lovotibeglogene autotemcel* (Bluebird Bio) and *exagamglogene autotemce*l (Vertex) were analyzed by 3 independent expert regulatory science raters with 5Y+ experience. Domain areas of regulatory complexity were agreed prospectively between raters, and the resultant instrument was used by each rater independently to record differences in regulatory development effort/complexity level between the 2 products on a 5-point Likert scale (1 = no significant difference, 5 = highly differentiated). Interrater reliability (IRR) was assessed, and results were summarized with descriptive statistics using SAS® 9.4 TS1M8. **Results:** Regulatory expert raters assessed that the most substantive developmental differences in the two commercial products were severe reaction warnings (mean 4.7±0.6), limitations of use (3.7±1.2), and labelled adverse reactions with the potential to trigger need long-term follow-up (4.3±0.6). All other differences were ranked <2.7, with minor differences in mobilization and apheresis in product manufacture (2.0±1.0), cryopreservation manufacturing practices (2.0±0), and long-term follow-up study design and complexity (2.3±0.6) observed, along with notes on variations in product positioning domains. IRR was high (>0.6), except in rater evaluation of cryopreservation complexity (i.e. suspension methods, use of bags vs vials), importance of hypersensitivity reactions and relative importance of addressing differences in preparation for infusion (centrally specificity around number of days prep, differing between the two products), which may reflect variable manufacturing vs clinical experience between raters. **Conclusions:** Modern regulatory science has often been critiqued for deploying subjective, anecdotal methods with variable and non-replicable outcomes. Using this proof of concept data, we propose that standard assessment tools help us move the needle towards highly replicable regulatory assessments, potentially useful in policy making, drug development strategy, assessing efficacy of regulatory programs, and fostering drug developer-supplier-regulatory discourse on regulatory outcomes.

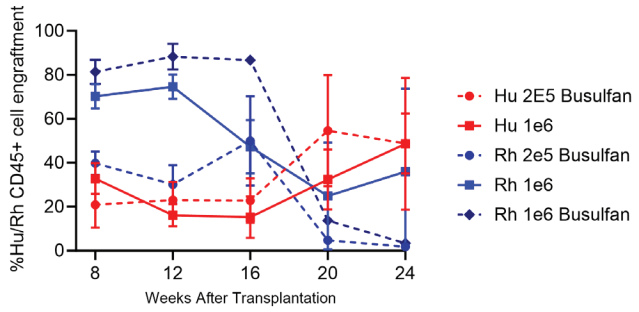
1160. The Novel Animal Models to Evaluate Preclinical Studies of Thalassemia



Tingting Gu, Shiying Guo, Jianming Xu, Hongyu Wang, Jing Zhao, Xiang Gao
GemPharmatech Co. Ltd, Nanjing, China

Thalassemia is a diverse group of genetic disorders with a worldwide distribution affecting globin chain synthesis the pathogenesis lies in the unbalanced globin chain production, leading to ineffective erythropoiesis, increased hemolysis, and deranged iron homeostasis. α thalassemia and β thalassemia are the main types of thalassemia, while α thalassemia is caused by reduced or absent synthesis of alpha globin chains, and β thalassemia is caused by reduced or absent synthesis of beta-globin chains. Traditional clinical therapy, requiring lifelong transfusion support and iron chelation is mainly used with a prolonged life expectancy, however, this therapy results in co-morbidities and substantial disease burden. Curative therapy with edited hematopoietic stem cell (HSC) transplantation, a kind of cell gene therapy, is developed for thalassemia patients, which has shown bright efficacy in improving anemia and transfusion burden, making it a promising approach. However, we lack animal models to evaluate the ability of edited HSC in thalassemia-relative preclinical studies. GemPharmatech developed 2 types of mouse models to assist CGT therapy of thalassemia in preclinical studies. One type is NCG-X mouse, a novel mouse model with W41 mutation in proto-oncogene c-KIT in NCG immunodeficient mice. The mutated mice have spontaneous anemia and are the only immunodeficient mice that can support the erythroid reconstitution in bone marrow, which could help to evaluate erythroid relative indicators. The other type is β-Thalassemia mouse with the knockout of Hbb-bs and Hbb-bt and α-Thalassemia mouse with the knockout of Hba-x, Hba-a1, and Hba-a2 in C57BL/6JGpt mice. The knockout mice have the thalassemia-like phenotype, including homozygous lethal, lower hemoglobin level (~105 g/L), and so on. Benefiting from the advantage of being immunodeficient, NCG-X mice are widely used to evaluate the human-origin HSC, while the α and β-Thalassemia mice are usually applied to evaluate the mouse-origin HSC. For CGT preclinical studies, the edited HSCs are injected into the mice. Body weight, survival, and clinical signs were used to evaluate the health status. Blood routine and FACS analysis of blood and bone marrow are used to evaluate the reconstitution level. DNA sequencing, qPCR of mRNA, and protein HPLC are used to evaluate the hemoglobin repair ability. All in all, NCG-X, β-Thalassemia, and α-Thalassemia mice are ideal mouse models for thalassemia preclinical studies.

1161. Establishment of a Rhesusized Mouse Model for Predictive Rhesus Hematopoietic Studies

Selami Demirci[1], Henna Butt[1], Evan London[1], Naoya Uchida[1], Matthew M. Hsieh[1], Chuanfeng Wu[2], Taha B. Hayal[2], N. Seth Linde[2], Aylin C. Bonifacino[2], Cynthia E. Dunbar[2], Robert E. Donahue[1], John F. Tisdale[1]
[1]CMTB, NHLBI/NIH, Bethesda, MD,[2]TSCB, NHLBI/NIH, Bethesda, MD

While mouse models are common for *in vivo* investigations for gene therapies, their physiological and immunological differences limit their predictability in humans (HU). Conversely, large animal models such as rhesus macaques (RM) offer greater fidelity due to phylogenetic proximity, similar hematopoietic system, longer lifespan, and immunological relevance. However, RM models are constrained by high costs, limited availability, slower breeding and life cycle, and the need for specialized facilities and expertise. As such, we have long sought to develop a "rhesusized" xenograft mouse model to allow parallel studies in the RM that would permit comparisons with results obtained *in vivo*. Prior work spanning many years in a series of xenograft mouse models were unsuccessful. Further improvements in the xenograft model have led to the availability of the highly immunodeficient NBSGW model which carries a *c-Kit* mutation allowing engraftment without conditioning. Thus, the NBSGW may provide a novel platform for evaluating gene therapy approaches if the results match those in the RM. The humanized NBSGW mouse model requires 1 - 2 × 10e6 HU CD34+ HSPCs per mouse. We previously showed that busulfan (BU) conditioning significantly reduces the cell doses required (Leonard et al., 2019). Accordingly, we infused HU or RM peripheral blood CD34+ HSPCs after one-day pre-stimulation into unconditioned or BU-conditioned (10 mg/kg) NBSGW mice at cell doses of 2 × 10e5 or 1 × 10e6 per mouse (n=5/group). Peripheral blood (PB) analysis at 16 weeks revealed a range of 47 - 86% RM and 15 - 22% HU CD45+ cells. Strikingly, BU conditioning facilitated superior engraftment in mice receiving RM cells (Figure). However, RM cell frequency gradually declined (3.4 - 36.0%) by week 24, in contrast to HU cell frequency of 46.8 - 48.8%. Examination of PB cell lineage demonstrated CD20+ B-cell dominance at 12 - 16 weeks, followed by a reduction in CD20+ B and CD33+ myeloid cells and an increase in CD3+ T-cell frequency (74.1 - 95.7%) at 24 weeks across all groups. Notably, in the mice receiving RM cells, 80% of high-cell dose BU-conditioned mice and 60% of high-cell dose non-conditioned mice in whom high levels of engraftment were obtained expired by week 16 (presumably from GVHD), accounting for the drop in engraftment for the groups as a whole. Analysis of bone marrow (BM) from deceased animals revealed robust engraftment in both HU and RM groups (84.8% to 98.8%). Pathology results indicated lymphocytic and/or histiocytic infiltration in the lungs, liver, BM, and spleen. However, BM engraftment in the surviving mice from the RM groups diminished to 0.92% - 6.5% at week 24, aligning with the observed reduction in PB cell frequency. In contrast, HU cell engraftment remained consistently high at 92.8% - 94.0%. The prevalence of BM CD3+ T-cells was notably elevated in RM groups (47.2% - 92.5%), contrasting with the relatively lower frequency observed in HU groups (8.7% - 12.4%). Additionally, the frequency of Band3+ red blood cells ranged from 46.1% to 50.4% in HU groups, while remaining low in RM groups (0.2% - 0.45%). In summary, our "rhesusized" mouse model efficiently supports RM cell engraftment, providing a valuable platform for assessing HSPC gene therapy approaches. These findings hold the potential for further advancements in preclinical animal models.

1162. Alpha-Globin Lentiviral Vectors for Hematopoietic Stem Cell Gene Therapy of Alpha Thalassemia

Eva Segura Gensler[1], Kevin Tam[1], Beatriz Campo Fernandez[1], Karen Li[1], Carol Mulumba[1], Andrea Gutierrez[1], Roger Hollis[1], Tippi MacKenzie[2], Donald Kohn[1]

[1]Microbiology, Immunology, & Molecular Genetics, University of California, Los Angeles (UCLA), Los Angeles, CA,[2]School of Medicine, University of California, San Francisco (UCSF), San Francisco, CA

INTRODUCTION Alpha thalassemia is an inherited blood disorder caused by mutations in α-globin genes (*HBA1* and *HBA2*) resulting in the reduction of the α-globin subunit, which together with β-globin chain, compose adult hemoglobin (HbA). Severe cases of alpha thalassemia appear when α-globin expression drops to 30% or less, which is often caused by the absence of three or all four α-globin genes (Hemoglobin H or Alpha Thalassemia Major (ATM), respectively). Because most patients suffering from severe anemia do not have a suitable donor, they depend on blood transfusions every 2-5 weeks and daily iron chelation therapy. While enabling patients to live into mid- to late-adulthood, these frequently required therapies drastically lower patients' quality of life and can cause serious clinical manifestations. **METHODS** Our laboratory has developed a stem cell gene addition therapy in which functional copies of α-globin genes integrate into the genome of patient's hematopoietic and progenitor stem cells (HSPCs) by lentiviral vectors (LVs) to normalize the globin chain imbalance and restore hemoglobin function. A series of α-globin LVs have been developed and are originally based on *GLOBE* β-globin LV utilized in a clinical trial for β-thalassemia (NCT02453477), which successfully led to transfusion independence in patients with transfusion-dependent β-thalassemia major. To target infective erythropoiesis and hemoglobin dysregulation, we have constructed a series of vectors optimized for titer production, high CD34+ HSPC infectivity, and high levels of α-globin expression. Vectors were first characterized in bone marrow HSPCs from healthy donors (HD) following transduction and differentiation into red blood cells (RBCs). The top two candidate vectors, A2-UV and A2-Globe, were then assessed in differentiated RBCs derived from HSPCs from bone marrow, fetal liver, and cord-blood of three ATM donors. **RESULTS** A2-UV and A2-Globe are two highly efficient vectors resulting in similar total α-globin chains and complete hemoglobin restoration, which they achieved through different modes: A2-UV is a small-proviral length vector that transduces in a higher percentage of CD34+, and yields a higher average vector copy number (VCN) when compared to A2-Globe, which in turns possesses a larger β-globin enhancer and higher α-globin gene expression per VCN. A2-Globe yielded up to 88% transduction efficiency in HD CD34+ HSPCs while maintaining a steady and well-distributed VCN ranging from 1 - 3 in 81% of transduced HSPCs and averaging 46% α-globin gene expression per VCN. At half a log lower concentration, A2-UV similarly transduced up to 88% HD CD34+ HSPCs, with a VCN ranging from 1 - 4 in 66% of transduced HSPCs and averaged 33% α-globin gene expression per VCN. (These studies are now being conducted in ATM HSPCs). Both vectors led to ~92% of endogenous α-globin chain production and successfully achieved a complete restoration of HbA levels in bone marrow-derived ATM patient RBCs while retaining a VCN of 5 or below. Similar results have been observed in two other ATM donors. **FUTURE DIRECTIONS** *In vivo* studies, conducted in NSG mice, are underway to assess engraftment, gene transfer distribution, and vector integration site analysis. Furthermore, single cell RNA-sequencing on transduced and erythroid differentiated bone marrow HSPCs from ATM patient cells is ongoing to assess the upregulation of genes involved in oxygen, iron transport and hemostasis, as well as hydrogen peroxide processes that are downregulated in patient RBCs. **CONCLUSION** Overall, this project describes successful pre-clinical data and offers a promising one-time autologous stem cell gene therapy for alpha thalassemia.

1163. Sickle Cell Mouse Diet (59M3) Strengthens Animals for *In Vivo* HSC Gene Therapy with HDAd5/35++ Vectors

Sucheol Gil, Theo Koob, Chang Li, Andre Lieber

University of Washington, Seattle, WA

Townes mice are an adequate mouse model for Sickle Cell Disease (SCD). In this mouse model, the murine α-globin genes were replaced with the human α-globin and the murine adult β-globin genes were replaced with human sickle β^S and fetal γ-globin genes linked together. To make the Townes model suitable for HDAd5/35++ transduction, which requires human CD46 as a receptor, we bred Townes mice with human CD46 transgenic mice (CD46/Townes). After three rounds of backcrossing, mice homozygous for human CD46 and the two human (α, β^S/γ) globin genes were used for experiments. Triple homozygous CD46/Townes mice displayed sickle-like erythrocytes, severe anemia, ~40% reticulocytes in the peripheral blood as well as leukocytosis and thrombocytosis. This pathological phenotype of SCD caused high mortality, both before and during in vivo studies, which involve HSC mobilization with G-CSF/AMD3100, intravenous injection of HDAd5/35++ vectors and in vivo selection with O^6BG/BCNU. We therefore used an individual diet (59M3 from TestDiet, St. Louis, MO) with higher amounts of protein, fat, carbohydrates, specific amino acids, and vitamins. While the mortality rate of triple homozygous mice before initiation of the diet was greater than 50%, only ~25% of mice on 59M3-diet died over an 8-month period. The effect of the 59M3-diet was visible in a ~20% body weight gain within one month after initiation. Long-term, body weight of animals on diet were comparable with those of control CD46-transgenic mice. These improvements in the animal model allowed us to perform *in vivo* HSC prime editing studies with the goal of correcting the SCD mutation in CD46/Townes mice. The treated mice demonstrated phenotypic correction, reflected by normalized blood parameters and spleen size.

1164. *In Vivo* HSC Base Editing to Install the Hemoglobin G-Makassar Variant for Sickle Cell Disease Gene Therapy in a Mouse Model

Chang Li[1], Aphrodite Georgakopoulou[1], Sucheol Gil[1], Kiriaki Paschoudi[2], Evangelia Yannaki[2], Hans-Peter Kiem[3], Andre Lieber[1]

[1]University of Washington, Seattle, WA,[2]G. Papanicolaou Hospital, Thessaloniki, Greece,[3]Fred Hutch, Seattle, WA

Sickle Cell Disease (SCD) results from a single nucleotide transversion (A to T) in the sixth codon of the β-globin gene. Precise genome engineering in hematopoietic stem cells (HSCs) represents a potential curative option for SCD patients. We aimed to correct the SCD phenotype by converting the sickle mutation (GTG) into a benign G-Makassar variant (GCG) using in vivo base editing in HSCs. We have developed a next-generation gene therapy approach involving *in vivo* transduction of mobilized hematopoietic stem cells. The central idea of this *in vivo* approach is to mobilize HSCs from the bone marrow, and while they circulate at high numbers in the periphery, transduce them with an intravenously injected HSC-tropic, helper-dependent adenovirus (HDAd) gene transfer vector system. Transduced cells return to the bone marrow where they persist long-term. For efficient HDAd vector production, we utilized miRNA-regulated gene expression, virus associated RNA (vaRNA), and anti-CRISPR inhibitors to suppress transgene expression in HDAd producer cells. HDAd vectors expressing the latest version of an adenine base editor (ABE8e) linked with a Cas9 variant (NRCH) under a human PGK or EF1α promoter were successfully produced. *Ex vivo* transduction of lineage-minus (Lin^-) cells from SCD mice (Townes/CD46) with HDAd-PGK-Maka or HDAd-EF1α-Maka followed by transplantation into irradiated recipient mice led to 55.2% to 88.2% stable correction of the sickle cell mutation (GTG>GCG; V6>A) in peripheral blood cells. The HDAd-EF1α-Maka was chosen for downstream experiments due to its higher activity. In an *in vivo* HSC transduction setting, involving HSC mobilization by G-CSF/AMD3100, intravenous injection with HDAd-EF1α-Maka, and short-term selection with low doses of O^6BG/BCNU, an average of 25.4% correction of the sickle mutation was achieved. Deep sequencing of week 16 bone marrow samples revealed that most of the edited alleles contained the expected GTG>GCG conversion. Less than 1.5% byproducts (mostly short deletions) around the predicted nicking site were found, consistent with the property of base editors to function independently of double-stranded DNA breaks. Phenotypic correction was observed in treated Townes/CD46 mice, including reticulocyte counts, spleen sizes, hematological and histological parameters. We did not observe significant adverse effects related to *in vivo* transduction/selection. Lin^- cells were isolated from *in vivo* transduced animals and plated for colony-forming unit (CFU) assay as well as transplanted into irradiated C57BL6 recipient mice. The CFU assay showed that 19.2% and 12.5% of colony-forming stem cell progenitors had monoallelic and biallelic correction, respectively. The editing levels remained stable in the secondary recipients. In $CD34^+$ cells from a SCD patient, transduction with HDAd-EF1α-Maka led to 11% GTG>GCG conversion at the sickle mutation site. This is significantly higher than the 4.5% correction level with a prime editing strategy (HDAd-PE5max) reported previously. SCD $CD34^+$ cells from additional donors are being investigated. We are currently evaluating the fidelity of in vivo base editing by measuring off-target events at top-ranked genomic sites. Our *in vivo* approach requires only one non-integrating vector, only intravenous/subcutaneous injections, and minimal *in vivo* selection. This technically simple approach has the potential for application in resource-poor countries where SCD is prevalent.

1165. Further Investigation of HBB Gene Editing with CRISPR/Cas9/rAAV6 in Human HSPCs to Treat Sickle Cell Disease

Liwen Xu[1], Sridhar Selvaraj[2], Matthew H. Porteus[3]

[1]Pediatrics, Stanford Univ. School of Medicine, Stanford, CA,[2]Pediatrics, Stanford University, Stanford, CA,[3]Pediatrics, Stanford University School of Medicine, Stanford, CA

Sickle cell disease (SCD) is the most common serious monogenic disease with 500,000 births annually worldwide. It is an autosomal recessive disease resulting from a single nucleotide variant in codon six of the β-globin (HBB) gene. The current curative treatment of SCD is allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, HLA-matched donors are limited and graft-vs-host disease (GVHD) may occur after allo-HSCT. *Ex vivo* gene correction in autologous hematopoietic stem/progenitor cells (HSPCs) by editing the disease-causing mutation in HBB gene with CRISPR/Cas9 and a recombinant adeno-associated virus serotype 6 (rAAV6) as the correct DNA donor template to treat SCD has now entered early-phase clinical investigation (NCT04819841). Finding the optimal *ex vivo* gene editing (GE) condition in human HSPCs and understating molecular status of some key gene editing reagents are important to ensure the progress and success of this technology. In this work, we demonstrated that multiplicity of infection (MOI) 600 with 12pmol p53-siRNA and 0.5uM AZD7648 (DNA-PKcs inhibitor) results in better cell proliferation, higher HDR% and lower p53 pathway activation. Furthermore, we showed no detectable rAAV6 virus remaining on cell surface or existing in cells at 48-hour post GE, the endpoint of drug manufacture. We also detected approximately 170,000-280,000 Cas9 protein molecules inside each cell at 6-hour post GE, the peak period of Cas9 protein inside the cells. Our results will provide important insights into the development and application of CRISPR/Cas9/rAAV6 genome editing and highlight some of the current safety and efficacy properties of the process.

1166. Development of Adenoviral Vectors Targeted to Human Hematopoietic Stem Cells, Expressing Mutated CXCR4 Variants, for the Sequential Mobilization and Transduction of HSC-Enriched Populations *In Vivo*

Jia Yao[1], Svetlana Atasheva[2], Dmitry M. Shayakhmetov[1]

[1]Emory University, Atlanta, GA,[2]Pedaitrics, Emory University, Atlanta, GA

Safe and efficient gene correction in human hematopoietic stem cells (HSCs) in vivo may provide curative therapeutic options to millions of patients with inherited diseases of blood and immune system. One limitation of current gene editing approaches in HSCs is the necessity to mobilize HSCs from the bone marrow into peripheral blood. Following in vivo or ex vivo editing, corrected HSCs must re-home to their bone marrow niche in sufficient numbers for polyclonal reconstitution of all blood cell lineages throughout the patient's life. Previous studies

have shown that the re-homing of mobilized hematopoietic stem and progenitor cells (HSPCs) to the bone marrow is inefficient. However, the efficacy of HSPC re-homing can be increased through transient ectopic expression of CXCR4, which plays a critical role in guiding and retaining HSPCs within their bone marrow niches. In this study, we explored how primitive human HSPC populations respond to ectopic expression of two CXCR4 splice variants, CXCR4-V1 and CXCR4-V2, both carrying the D262N mutation that abrogates binding to the HSC-mobilizer AMD3100, while preserving functional receptor interaction with the CXCL12 ligand. To deliver CXCR4 variants to human HSPCs, we employed the recently developed AVID-388 adenovirus vector-based platform, which preferentially transduces primitive human HSPC populations in vitro and in vivo after intravenous vector administration. The AVID-CXCR4 vectors expressed CXCR4 under the control of the EF1a promoter, along with a GFP reporter for analyzing CXCR4 expression and function in vector transduced cells. Flow cytometry and single cell RNA-seq analyses revealed that cells of the CD34+CD45RA-CD38+ phenotype expressed the highest levels of CXCR4 among other HSPC populations. In contrast, CD34+CD45RA-CD38- HSPCs expressing CD90, which are highly enriched for LT-HSCs, expressed medium to low CXCR4 levels. Analysis of primary human CD34+ cells infected with CXCR4-expressing and control vectors showed that up to 70% of LT-HSCs expressed GFP 24h post virus infection. Migration analysis of LT-HSCs toward CXCL12 gradient showed that the proportion of GFP-negative LT-HSCs migrating toward CXCL12, was not different between cells infected with all three vectors. However, we observed a 100% increase in the number of GFP+ LT-HSCs migrating toward CXCL12 after cell transduction with the AVID-CXCR4-V1 variant, whereas migration of GFP+ LT-HSCs increased only marginally compared to control after cell infection with the AVID-CXCR4-V2 vector. Next, we will explore whether a strategy of repeated mobilization and intravenous administration of the AVID-CXCR4-V1 vector to humanized huCD34+ NSG mice may increase the efficacy of gene transfer to the LT-HSC compartment in vivo by promoting the re-homing and retention of in vivo transduced LT-HSCs in their bone marrow niche. Because AVID vectors can accommodate all currently available gene editing technologies, the HSC-targeted CXCR4-expressing AVID platform may enable safe and effective therapeutic gene editing of human hematopoietic stem cells in vivo.

1167. Social Media Engagement Post Announcement of the FDA Approval of Two Gene Therapies for Sickle Cell Disease

Christineil Thompson

Mayo Clinic, Rochester, MN

Introduction On December 8th 2023, the United States Food and Drug Association (FDA) approved two gene therapies for the treatment of sickle cell disease. Social media sites have been the preferred news source for most US adults with previous surveys demonstrating that 86% get their news from a digital device often or sometimes and 58% preferring a digital method of news dissemination. X (formerly known as Twitter) has in 2023 been surveyed as the site where the highest percentage of users (53%) regularly receive their news. The ability to share critical medical advances to a large audience in real time can be harnessed by health care providers who can capitalize this social impetus to increase advocacy and patient counselling. Objective To analyze the most followed and popular news accounts on X (formerly known as Twitter) to determine the social media impact of the news of the U.S. FDA approval of two gene therapies for sickle cell disease. Methods: The top 30 most followed news accounts were identified through Intelligence Fusion statistical report. The top 10 accounts were selected then were individually searched for the terms "FDA" "sickle cell" and "gene therapy". The accounts which posted on the FDA approval on December 8th 2023 were selected and the key interactions, likes, comments, retweets and views were recorded. Popular US news media sites Bloomberg, NBC, Fox News and ABC News were also included. Results Of the 13 accounts selected there were 2, 751 likes, 1, 443 retweets, 511 comments and 1, 438,000 views. CNN Breaking News, The U.S. FDA, the Washington Post (WP), CNN and the New York Times were the accounts with the highest interactions generating over a 1.11 million views. Conclusion With nearly 1.5 million individuals viewing the announcement of the U.S. FDA approval of two gene therapies for sickle cell disease there is vast potential for launching this social capital to further conversations with patients and families with sickle cell disease.

X (Twitter) Interaction	U.S. FDA	The New York Times	CNN Breaking News	CNN	Fox News	NBC	Bloomberg	Reuters	WSJ	WP	Time	ABC News	Huff Post	Total

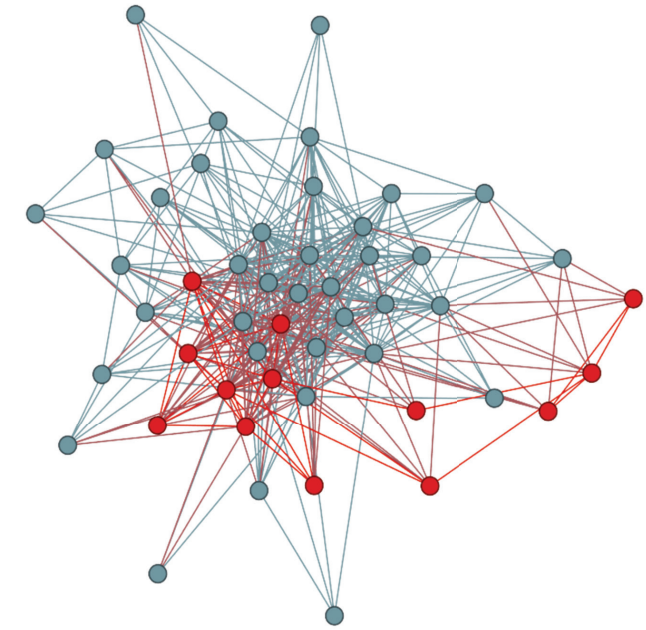
1168. The Impact of Social Networks on Participant Engagement in Gene Therapy Community-Based Research



Diba Seddighi, Laura M. Koehly, Vence L. Bonham

Social and Behavioral Research Branch, National Human Genome Research Institute, Bethesda, MD

Background: Community-based participatory research (CBPR) serves as a bridge directly connecting researchers with the communities impacted by their work. Collaboration among diverse contributors from relevant research, industry, academia, patient, and advocacy communities fosters a more inclusive approach for the development and implementation of gene therapies. Given the recent milestone FDA approvals of two gene therapies for the treatment of sickle cell disease (SCD), it is increasingly important to understand the factors that shape the successful integration of research with community partnerships as gene therapy becomes more accessible to the public. Social networks, or the web of interpersonal relationships within a group, are crucial influencers in community engagement. Within collaborative processes, interpersonal networks impact engagement dynamics, communication patterns, decision-making, and collaborative outcomes. *Methods*: Data were acquired from a four-day virtual SCD CBPR meeting, conducted as part of the Democratizing Education for Sickle Cell Disease Gene Therapy project between January and March 2022. After day three, participants completed a social network survey detailing their pre-existing connections with other participants. Survey responses were input into Gephi software (v0.10) for diagram production and

network analyses. Transcripts of the virtual meetings will be analyzed using R (v4.3.1) to assess engagement dynamics through measures of speaking frequency, speaking duration, and statement valence. *Results*: This study utilized a mixed methods approach including social network analysis (SNA) and engagement analytics to assess the interactions among 52 SCD partners across the research community (representatives of industry, research, government, healthcare, and academia) and the patient and advocacy community (individuals with SCD, community based SCD advocacy groups, and parents of children with SCD). The network analysis produced a diagram containing 52 nodes, or participants, and 588 ties, or connections between a pair of participants, out of 1,326 total possible ties (Figure 1). Participants affiliated with the research community exhibited a significantly higher number of connections to other participants and were better situated to act as bridges or intermediates between other nodes, compared to the patient and advocacy community. These network centrality measures emphasize the significant contribution of the research community to enhancing network connectivity, implying a heightened influence of these participants on the dynamics of information flow and interactions within the network. Engagement data from eight break-out group sessions and four whole-group sessions will be analyzed within the framework of each meeting's social network diagram to further evaluate the influence of network structure on participation. *Conclusions*: The findings of this research offer insights into how social networks play a significant role in shaping the active participation and meaningful inclusion of community partners in development of education resources related to gene therapies. As we strive to advance the dynamic field of gene therapy, intentionally considering established network ties when forming community partnerships will promote more equitable engagement, enabling the incorporation of a broader range of voices and perspectives.

Thursday Posters: Epigenetic Editing and RNA Editing

1169. Characterization and Repair of Sodium Channel Models for Autism Spectrum Disorders

Ahmad Al Saneh[1], Lionel Gissot[1], Aislinn Williams[2], Christopher Ahern[1], Karina Kruth[2], Katelin Scott[2], Hsiang Wen[2], Olivia Klein[2]

[1]Molecular Physiology and Biophysics, University of Iowa, Iowa City, IA,[2]Neuroscience, University of Iowa, Iowa City, IA

Autism spectrum disorder (ASD) is estimated to occur in one out of every 36 children. The understanding of the mechanism behind ASD remains limited largely due to the disorder's remarkably complex etiology. Hundreds of genes have been implicated in autism risk, in addition to factors such as parental age, environmental conditions, and even some medications. Nevertheless, a small percentage of ASD cases are monogenic in origin and can be traced to a single causal genetic variation. These ASD examples provide an invaluable, simplified model of ASD that can be used to better correlate molecular dysfunction to phenotype. One such monogenic form of autism is caused by variations in the *Scn2a* gene which lead to premature truncation of the encoded protein, the sodium channel NaV1.2. Nonsense mutations leading to the abortive translation of the *Scn2a* gene result in reduced social interactions and repetitive behaviors, as well as ataxia and cerebellar atrophy, highlighting the important role of *Scn2a* in the cerebellar cortex as well.We have developed two *Scn2a* PTC mice (p.Tyr84X and p.Arg1626X), the first PTC autism rodent models to date. These mice are specific genetic models for ASD-linked *Scn2a* mutations that provide an opportunity to investigate the effects of *Scn2a* haploinsufficiency. In parallel, we have developed an approach using anticodon-edited transfer RNA (tRNA) to repair in-frame termination codons. This strategy is generally agnostic to the position of the variation and has the potential to be disease-modifying, that is, of the primary defect of the disease, not just symptomatic treatment. We have previously developed a platform of anti-codon modified human tRNAs to identify multiple tRNA types for every known human PTC disease variant. Using ribosomal profiling and mass spectrometry we have found that expressed suppressor tRNAs have minimal contact with native stop codons. Additionally, qRT PCR proved no significant upregulation of ER stress and UPR pathway proteins *in vitro*. Further, through quantitative RNA methods, we showed that SCN2a PTC mRNAs display modest nonsense mediated decay. Those suppressor-tRNAs have been packaged into Adenovirus as well as Adeno-Associated virus and transduced into cerebellar granular neurons that have been obtained from *Scn2a* p.Y84X and p.R1626X mice, as well as induced pluripotent stem cells (iPSCs) from patients with *Scn2a* PTC variants. This enables the investigation of human neurons derived from *Scn2a* syndrome patients. Additionally, we will also present data on a new mouse model that stably expresses a suppressor-tRNA targeted to the "safe harbor" *Hipp11* mouse locus. This resource will allow us to investigate, *in vivo,* the possible interactions between suppressor tRNA and native stops, and ER stress/UPR pathway activation, thereby further validating our codon-edited tRNA as a viable therapeutic strategy.The project provides valuable new resources for therapy as we investigate

the engineered tRNA's fidelity, interactions with native stop codons and its potential to activate the ER and UPR stress pathways. Such developments have significant implications for all diseases resulting from PTCs, beyond monogenic autism.

1170. Modeling of a Rare X-Linked Disorder for a CRISPR/dCas9 Based Epigenetic Rescue

Casiana E. Gonzalez, Julian A. N. M. Halmai, Isaac J. Villegas, Nicole B. Halmai, Kyle D. Fink

UC Davis, Sacramento, CA

CASK-related microcephaly with pontine and cerebellar hypoplasia (MICPCH) is a rare X-linked neurodevelopmental disorder caused by mutations in calcium/calmodulin-dependent serine protein kinase (CASK). We aim to create iPSC-based CASK relevant *in vitro* model systems and to rescue CASK expression via an CRISPR/dCas9 based epigenetic therapeutic. As females have two X-chromosomes, disease causing mutations present with a 50/50 expression of mutant and wildtype, due to the mosaicism caused by random X-chromosome inactivation (XCI). To this point, we will utilize a fibroblast cell line with nonpathogenic single nucleotide polymorphisms within *CASK,* which have been clonally selected to express from only one allele. This allows for analysis of expression changes from either allele via RT-qPCR. Additionally, we created a disease relevant model via prime editing on a healthy iPSC background to recapitulate clinically described disease-causing point mutations that result in a loss of function of CASK protein. Reduction of *CASK* expression and CASK protein was confirmed by next-generation sequencing and western blot and these iPSCs will be differentiated into neurons for future therapeutic analysis. Further, this project will adapt an established CRISPR/dCas9 epigenetic approach to rescue expression from the silenced, wild-type CASK allele. We aim to accomplish this through testing different dCas9 orthologues and a guide RNA screen targeting the *CASK* promoter. Constructs will be tested for optimal targeting efficacy *in vitro* and assessed via RT-qPCR. Additionally, epigenetic modifications from our approach will be analyzed through bisulfite sequencing, as we anticipate that following an increase of *CASK* expression, there would be a decrease in region specific promoter methylation. Ultimately, this project aims to show the potential of an epigenetic therapeutic for CASK-related MICPCH, as well as create a disease relevant iPSC-derived neuronal model for measurement a functional rescue. Currently, our results show the ability to target *CASK* and assess gene expression changes with CRISPR/dCas9 paired with an epigenetic modifier and transcriptional activator. This project will demonstrate the first therapeutic avenue for CASK-related MICPCH, as well as demonstrate the potential to utilize targeted X-reactivation as a platform approach for X-linked disorders. Further, investigation of smaller dCas9 orthologues prepares our approach for future translational applications such as packaging into AAV for delivery.

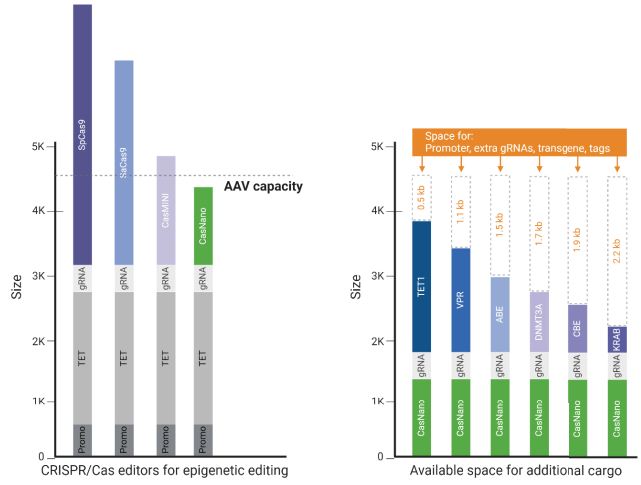
1171. Rescue of Haploinsufficient Expression of *ADNP* in Human Cell Lines Using CRISPR Activation and Gene Replacement Therapy

Katherine L. Lucot[1], Renee E. Napoliello[2], Julian A. N. M. Halmai[3], David J. Segal[4], Jill Silverman[5], Kyle D. Fink[5]

[1]Neurology, UC Davis School of Medicine, Sacramento, CA,[2]Neurology, UC Davis, Davis, CA,[3]Neurology, UC Davis, Sacramento, CA,[4]UC Davis Genome Center, Davis, CA,[5]UC Davis, Sacramento, CA

Introduction: *Activity-dependent neuroprotective protein* (*ADNP*) Syndrome, is a rare neurological disorder caused by a pathogenic mutation in one copy of the *ADNP* gene. These mutations are *de novo* and result in a loss of function of the mutated copy of the gene causing haploinsufficency; with the p.Y719X mutation being the most prevalent. Clinically, patients with *ADNP* Syndrome present with autism, mild to severe intellectual disability, brain abnormalities (e.g., sleep disorders and seizures), organ system complications (e.g., gastrointestial and cardiovascular defects), skeletal abnormalities, and dysmorphic features. *ADNP* plays a critical role in brain development, cognition, and motor function; and while CP201 (NAP) and ketamine have been tested for off-label use and/or are currently in clincial trials, they have not been able to fully restore a healthy phenotype in these children. Herein, we investigate the utility of a CRISPR activation (CRISPRa) system in an AAV-ready construct, paired with a single guide RNA (gRNA), to target and increase expression of endogenous *ADNP* and gene replacement therapy with an AAV- codon optimized *ADNP* casette. Methods: A human gRNA, targeting the promoter of *ADNP*, was triple transfected with intein-containing vectors, each containing one terminus of dCas9 fused to either the activating domains mini-VPR (VP64-p65-Rta) or MS2-P65-HSF1 (MPH) into a neural stem cell (NSC) line harboring the p.Y719X mutation (Y719X) and an isogenic control; or with the same gRNA paired with the same vectors containing GFP or dsRed instead of activating domains as a control. The potency of the gRNA to increase *ADNP* transcription was measured using RT-qPCR. Concurrently, both cell lines were transfected with the gene replacement therapy and the codon optimized transcript was measured using RT-qPCR. Results: When treated with the CRISPRa system, the Y719X line showed a 1.3- fold ($p = 0.0625$) increase in *ADNP* transcripts, and the isogenic line showed a 2.5-fold ($p = 0.1386$) increase, respectively. When treated with the gene replacement therapy, the Y719X line showed 1×10^7-fold ($p = 0.0012$) increase in codon optimized *ADNP* expression compared to endogenous expression, while the isogenic line showed a 7.6×10^6-fold increase, respectively. Conclusion and Future Directions: Both the split dCas9 system with activation domains and the *ADNP* gene replacement therapy are promising tools for altering the epigenetic state and increasing endogenous *ADNP* expression and codon optimized *ADNP* expression, respectively. Experiments using highly sensitive ELISAs are being done to evaluate if ADNP protein levels increase, post treatment, with the therapeutic constructs. Additionally, these therapies are currently being evaluated in NSC lines containing other common patient mutations, to further evaluate rescue of cellular function.

1172. CRISPR Activation of *SYNGAP1* Haploinsufficiency



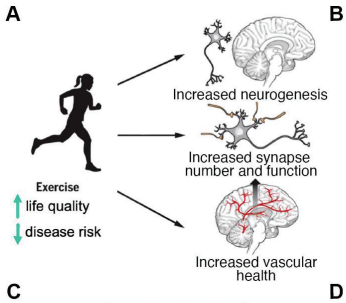
Paula Vij, Jasmine L. Carter, Julian Halmai, Peter Deng, David Cameron, Jill Silverman, Kyle D. Fink
University of California, Davis, Sacramento, CA

SYNGAP1-related intellectual disability (ID) is a genetic disorder that affects brain development and causes intellectual disability, seizures, and other neurological symptoms. *SYNGAP1* encodes for the SynGAP protein which has been shown to play an important role in the modification of synaptic strength by altering membrane trafficking of AMPARs through GTPase regulation. De novo mutations in the *SYNGAP1* gene lead to genetic haploinsufficiency causing a severe to mild ID. A concept of possible therapeutic relevance is the 'reversal of haploinsufficiency,' which is the increase of expression levels of the normal gene copy by targeting the regulatory elements that control the expression of the gene. Therefore, the purpose of our study is to use a genome-modifying mechanism, CRISPR-mediated activation (CRISPRa), which targets a transcriptional activator to the gene's promoter as a viable approach that could potentially correct *SYNGAP1* expression and rescue haploinsufficiency. Preliminary data from our lab has demonstrated increased expression of SYNGAP1 mRNA *in vitro*, specifically using mouse Neuro 2A (N2a) cells and patient-derived Neuronal Stem Cells (NSCs). Furthermore, our *in vivo* testing has demonstrated a significant upregulation in *SYNGAP1* mRNA expression within our experimental system. Given the pivotal role of *SYNGAP1* in neurodevelopment, our study also seeks to investigate its neurobiology deeper, aiming to bridge existing gaps and enhance our comprehension of normal and abnormal development. Thus, we aim to establish a disease model by characterizing a patient-derived iPSC neuronal model and conducting rescue experiments to gain insight into the *SYNGAP1* haploinsufficiency phenotype. Preliminary data underscores significant developmental and morphological differences in neurons derived from patients' cell lines harboring mutations in the *SYNGAP1* gene in comparison to those from control subjects. Our future directions involve the validation of our system in patient-derived neurons, along with comprehensive functional characterizations and rescue experiments with CRISPRa using patient-derived iPSC neurons.

1173. CasNano, an Ultracompact CRISPR/Cas for AAV-Based Therapeutic Applications

Woofung (Yi-Ting) Tsai, Dongkyeong Kim
Epitor Therapeutics, NYC, NY

The development of compact CRISPR-Cas systems is important for therapeutic delivery applications with size constraints such as adeno-associated viruses (AAVs). We report the engineering of a novel class 2 type V Cas nuclease named CasNano for efficient mammalian genome editing. CasNano was identified from a commensal bacterium species and constitutes the smallest known Cas effector to date at only 399 amino acids (1.2kb). Importantly, CasNano recognizes a GC-rich PAM sequence rather than the T-rich PAMs typical of other popular compact effectors such as CasMINI and Cas12a (Cpf1). Wildtype CasNano shows moderate DNA cutting or gene regulation activity in human cells. We therefore developed an iterative protein engineering strategy to optimize CasNano functionality in the context of the human genome. Beginning with bioinformative prediction guided by ESM and AlphaFold, we identified key residues involved in DNA binding for further engineering. After several rounds of directed evolution and screening, the optimized CasNano variants demonstrated robust activation capability when fused to transcriptional activators, greatly improved over wildtype levels. In addition, the gRNA size was reduced via scaffold optimization to improve performance. Importantly, CasNano showed ability to epigenetically regulate gene expression when fused to a TET 5-methylcytosine dioxygenase, a DNA methyltransferase (DNMT), VPR or KRAB. Furthermore, when fused with base editor domain, CasNano mediated efficient C-to-G editing of target DNA sites in human cells. Finally, we show that nuclease-active CasNano induces cuts and frameshift mutations for gene knockout. With its reduced size and non-pathogenic bacterial source, CasNano is well-suited for therapeutic delivery and gene editing applications via AAVs, lipid nanoparticles, or other modalities. Overall, CasNano expands and diversifies the toolkit of programmable Cas effectors available for developing next generation CRISPR-based genetic medicines.



1174. CRISPR Epigenetic Reprogramming of Myokines as Therapy for Alzheimer's Disease

Thyago Leal Calvo[1,2], Viviana Salinas-Rios[1], Ilana Burg[1], Fernanda G. De Felice[3], Fyodor D. Urnov[1]
[1]Innovative Genomics Institute, University of California Berkeley, Berkeley, CA,[2]Pioneer Science Initiative, D'Or Institute for Research and Education, Rio de Janeiro, Brazil,[3]Department of Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada

Background. Alzheimer's disease (AD) is a neurodegenerative condition imposing a significant burden on healthcare systems globally. Despite extensive efforts, it remains incurable, with only moderately effective treatments available for some patients. Gene therapy, particularly using CRISPR-Cas, holds promise as an advanced alternative. The ability to reprogram cell phenotypes by regulating gene expression via epigenetic reprogramming using the CRISPR-dCas9 variant has widened our options for complex disease therapies, like AD. It's known that exercising modulates genes encoding for myokines that regulate other factors in the brain, leading to neurogenesis, reduced neuropathology, and fewer cognitive deficits in AD. e hypothesized that using CRISPR-dCas epigenetic reprogramming to upregulate

exercise-responsive genes could mimic the beneficial effects of exercise in the brain, potentially slowing AD progression. As CRISPR delivery methods advance, there's optimism that this strategy could not only delay the onset of AD and its progression but also reduce cognitive decline in patients. ***Experiments.*** We used the CRISPR-dCas9-VPR-WPRE/BGH containing both viral (VP64, Rta) and human transactivation domains (RELA, p65), known to recruit epigenetic effector proteins. We tested six single-guide RNAs (sgRNAs) designed around 200 bases upstream of our top myokine gene transcription start site (Fig. 1A). We also tested two 3' untranslated sequences (WPRE or BGH) to see if they affect mRNA stability and modulation efficiency. The cells used were iPS-derived neural progenitors. sgRNAs and mRNAs were transfected with cationic lipids. Our in vitro transcriptions incorporated pseudouridine instead of uridine into the mRNAs. Experiments have as readout the mRNA expression measured by TaqMan RT-qPCR (Fig. 1B). ***Results.*** For the six tested sgRNAs and 3'-UTRs, we obtained at least a 3-fold increase in mRNA expression of the target gene. Two-way ANOVA showed no interaction between sgRNA and 3'-UTR, but a slightly higher upregulation with the WPRE ($F = 7.37_{df = 39}$, P = 0.011, Fig. 1C). The fold-change among the six sgRNAs for the WPRE construct ranged from 3.3× up to 31× over the non-targeting control (Fig.1D). As a result, the top three sgRNAs with the largest fold-changes were W0-CB3 (31.2×), C1 (19.1×), and WE3 (10.8×). In summary, the sgRNAs located around -292 bases upstream of the transcription start site showed improved upregulation of the target transcript. ***Conclusions.*** We have shown that all sgRNAs can effectively upregulate the target gene mRNA up to 30-fold. Next experiments will evaluate if protein levels correlate with the mRNA's. We will also try the transcriptional activation of selected sgRNAs on cortical neurons. In the future, in vivo experiments on Alzheimer's disease mouse models will measure the effect of this approach on disease progression, memory, and neuropathology.

1175. Chemical Design of Oligonucleotides That Support Targeted RNA Editing in the CNS of Non-Human Primates

Chikdu Shivalila[1], Genliang Lu[1], Christopher Acker[1], Ian Harding[1], Jigar Desai[1], Jack Godfrey[1], Naoki Iwamoto[1], Pachamuthu Kandasamy[2], Hui Yu[1], Tomomi Kawamoto[1], Jake Metterville[1], Megan Cannon[1], Purcell-Estabrook Erin[1], Faraone Alyse[1], Prashant Monian[1], Stephany Standley[1], Jesse Turner[1], Ryan Yordanoff[1], Fangjun Liu[1], Hailin Yang[1], Michael Byrne[1], Chandra Vargeese[1]

[1]Wave Life Sciences, Cambridge, MA,[2]Wave Life Sciecnes, Cambridge, MA

Using chemically modified oligonucleotides to harness endogenous adenosine deaminase acting on RNA (ADAR) enzymes is an emerging approach to targeted therapeutic RNA editing, and it has been shown to direct editing in the liver of non-human primates (NHPs). The central nervous system (CNS) is another attractive tissue for RNA editing via endogenous ADAR enzymes because ADAR1 and ADAR2 are highly expressed in the CNS, and there is a large unmet need for approaches that can repair causal mutations in CNS disorders. However, published reports of measurable directed RNA editing in the CNS *in vivo* have been limited to murine models and relied on expression of hyperactive ADAR enzymes. Here, we describe high efficiency A-to-I RNA editing in human neuronal cell models and in the CNS of NHPs *in vivo* using a novel chemical design of Wave's AIMers, which are short, chemically modified oligonucleotides that direct RNA editing via endogenous ADAR enzymes. We identify sugar, base, and backbone modifications across the ~30mer AIMer structure that enhance potency *in vitro* and *in vivo* compared to our benchmark AIMers and help mitigate ADAR's natural bias against adenosines positioned within certain sequence contexts. The optimized design resulted in >50% maximal editing in primary mouse hepatocytes for most sequences tested, including sequence combinations that have very low editing efficiencies reported due to ADAR's sequence preferences. A key feature of the design is the introduction of an N-3-uracil (N3U) modified base positioned across from the target adenosine, which is hypothesized to support enhanced editing efficiency by creating RNA-enzyme interactions that mimic a hyperactive ADAR mutant. These AIMer design developments support targeted editing in CNS cell types and tissues. In human iPSC-derived neuron and astrocyte cell models, AIMers direct up to 80% and 70% editing, respectively, against the ubiquitous housekeeping transcript *ACTB*. To assess the ability to edit a clinically relevant target in the CNS, we designed AIMers to edit the *MECP2* R168X mutation, the most frequent nonsense mutation that causes Rett Syndrome (RTT), a rare neurodevelopmental disorder. These AIMers are designed to convert the premature stop codon to tryptophan, promoting translation readthrough and protein restoration. In human and mouse neuronal lines, *MECP2* AIMers direct ~15% to 90% RNA editing, respectively. In a mouse neuronal cell model of RTT, we restore detectable expression of full-length MECP2 protein. To investigate whether AIMers can support editing in the CNS *in vivo*, we delivered AIMers directed against the housekeeping gene *Ugp2* via intracerebroventricular (ICV) administration to transgenic mice expressing wild-type human *ADAR1*. Single-dose injection resulted in 25% to 65% RNA editing of *Ugp2* across the entire CNS, which was durable up to 16 weeks. In NHPs, intrathecal injection of a single dose of AIMers directed

against *ACTB* resulted in around 50% RNA editing in the spinal cord and up to 30% in the brain one-week post-dosing. These preclinical investigations describe the development of an oligonucleotide design that supports directed *in vivo* RNA editing in the CNS of NHPs via harnessing the endogenous ADAR machinery and lay the foundation for the development of AIMers as potential RNA medicines to treat human neurological diseases.

1176. CRISPR-Activation of Syngap1 in Neurodevelopmental Disease Models

Molly Reilly, Elizabeth Heller
University of Pennsylvania, Philadelphia, PA

Almost 400,000 children born each year develop neurodevelopmental disorders whereby a *de novo* genetic mutation arises in one of the two alleles, leading to only one functional copy of the gene. Mutations in one such gene, Syngap1, results in SYNGAP1-related intellectual disability characterized by cognitive impairment, seizures and sleep disturbances. We hypothesize that upregulating the "good" copy of each gene using CRISPR-activation will rescue the disordered phenotypes in mouse disease models and patient cells, similar to therapeutic strategies for Spinal Muscular Atrophy. We have verified that our CRISPR activation strategy increases Syngap1 expression when injected into the hippocampus of adult mice and we are currently testing if this molecular rescue impacts cognitive behavior and sleep deficits. The results of these experiments will elucidate the efficacy of CRISPR activation in treating neurodevelopmental disorders that result from a lack of functional protein.

1177. A Modular CRISPR System for Molecular Therapy of Neurodevelopmental Disorders

Julian Halmai, Jennifer Waldo, Casiana Gonzalez, David Cameron, Isaac Joseph Villegas, Kyle D. Fink
UC Davis, Sacramento, CA

Out of the over 20 000 genes in the human genome, only a small fraction of genes can be currently targeted by the existing pharmacopeia. The advent of gene editing has vastly increased our ability to make the undruggable genome druggable. Here, we developed a novel, modular tool for transcriptional regulation of genes involved in neurodevelopmental disease in the absence of creating double-stranded breaks. Following an intein screen using transfection in HEK293T cells we identified *Rma*DnaE for efficient trans-splicing of amino- and carboxyl-terminal split, catalytically inactive, dCas9 both *in vitro* and *in vivo* following packaging into AAV9. Likewise, direct intracranial injection of two split constructs containing fluorescent proteins fused to dCas9 (N-terminal dsRed and C-terminal turboGFP) resulted in efficient distribution and co-transduction of neurons in the mouse brain. We utilized this novel platform technology to identify sgRNAs that efficiently regulate expression of two intellectual disability genes, *FOXG1* and *SYNGAP1*. Using a modular assembly of CRISPR trans-activators, including single and dual VP64 dCas9 fusion proteins, sgRNA-mediated MS2 p65 HSF (MPH) recruitment or the addition of the VPR tripartite effector (VP64, p65, Rta) can induce dynamic gene regulation. We can further increase mRNA levels of *FOXG1* and *SYNGAP1* using duplexed sgRNAs paired with a combination of N-terminal VPR-dCas9 and C-terminal dCas9-MPH. We demonstrate that *FOXG1* gene upregulation results in a significant increase in FoxG1 protein translation. Following treatment of mutant *FOXG1* neural stem cells with the CRISPR activators, we observed a significant increase in *FOXG1* expression with no-off targets as determined by *in silico* sgRNA binding prediction paired with RNA-sequencing. In addition to transcriptional modulation, we also demonstrated that the modular assembly allows for the fusion of DNA methylation editing effector proteins that when targeted to the X-linked *CDKL5* promoter can result in erasure of CpG island promoter methylation. We demonstrate the clinical utility of the editor in patient-derived organoids, demonstrating reactivation of methylation-silenced *CDKL5* and rescue of phosphorylation substrates of the kinase. In addition, we optimized promoter and polyA configurations to reduce construct size and improve AAV manufacturing to further increase capsid ratios and *in vivo* bioactivity. Ongoing studies are addressing molecular and behavioral rescue in multiple animal models of disease and patient-derived brain organoids. This approach holds great promise for those affected by rare genetic conditions.

1178. Adeno-Associated Viral Vector Resource for the RNA-Targeting Cas13d: A Comparison of High-Fidelity Variants, DjCas13d and hfCas13d

Frank Back[1], Alfredo Sandoval[2], Rachel Barkey[1], Sven Kroener[3], Benedict Kolber[3], Jonathan E. Ploski[1]
[1]Neural and Behavioral Sciences, Penn State College of Medicine, Hershey, PA,[2]University of Texas Medical Branch, Galveston, TX,[3]Neuroscience, UT Dallas, Richardson, TX

RNA-targeting CRISPR-Cas systems have emerged as alternatives to RNA interference technology to knock down specific RNA transcripts. In particular, Cas13d derived from Ruminococcus flavefaciens (CasRx, RfxCas13d) has generated sustained interest due to its superior knockdown efficiencies; however, accumulating evidence indicates that CasRx is prone to inducing significant transcriptome alterations due to its tendency to cleave bystander RNAs. High-fidelity Cas13d (hfCas13d) derived from CasRx and DjCas13d, an ortholog of Cas13d derived from Ruminococcus sp. UBA7013 (gut metagenome), are two recently identified variants that have both been shown to be superior to CasRx. They both show reduced tendency to cleave bystander RNAs. In this study, we created a resource of adeno-associated viral (AAV) vectors designed to deliver Cas13d, including hfCas13d and DjCas13d. We present data that CasRx is prone to causing transcriptome disturbances when targeting highly-expressed genes. Then, we directly compared hfCas13d and DjCas13d for their on- and off-target potential in 293FT cells. We report that while both of these enzymes exhibit generally similar levels of knockdown potential, hfCas13d caused significantly fewer transcriptome alterations when targeting highly-expressed genes compared to DjCas13d.

1180. The Ethics of Human Epigenetic Editing: Just a New Approach or Entirely New Problems?

Rami M. Major[1], R. Jean Cadigan[2]
[1]Curriculum in Genetics and Molecular Biology, The University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Department of Social Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Ethical concerns associated with classic gene editing (i.e., the cutting and subsequent repair of target DNA sequences) have been heavily described and debated in the literature. Some of the most pressing concerns invoke questions of how humanity might reckon with permanent changes to something as intrinsic as the human genome, in somatic cells and beyond to germline cells altering the very fabric of future generations. The permanence of these interventions seems to elevate the gravity of them in the eyes of many stakeholders. As gene editing technologies evolve, new approaches have been developed that may skirt this issue, challenging our assessment of the ethical concerns routinely associated with gene editing. One emerging use that raises the prospect of re-examination is epigenetic editing, which alters gene expression rather than genes themselves. Two technological features of epigenetic editing particularly warrant additional ethical analyses beyond those completed for classic gene editing because they potentially alter the risk/benefit ratio of the interventions: 1) epigenetic editing is not permanent, which may be desirable for reversibility attempts but may be undesirable if the goal is to deliver a long-lasting therapeutic, and 2) epigenetic editing has unique features beyond classic gene editing, including its potential to regulate many genes at once, which may be desirable for the treatment of polygenic disorders but undesirable for potentially more significant off-target risks. These two features of epigenetic editing will push the bounds of what the gene editing field has conventionally considered treatable conditions, creating new opportunities to impact humanity and warranting a frank discussion about how to eventually deploy this new technology in the clinic. Drawing on interviews we conducted with scientists who use gene editing technologies in their research, we will highlight conditions that our interviewees proposed for potential epigenetic editing, including neuropsychiatric disorders, pain, viral immunity, and obesity, and offer an ethical analysis of its use in these different contexts. We will also offer insight into how these scientists think about the future of epigenetic editing in comparison to gene editing. Before epigenetic editing extends beyond basic research, it will be important to consider the facets of epigenetic editing that set it apart from classic gene editing to inform a safe and ethical path forward to the clinic.

Thursday Posters: Gene Disruption and Excision

1181. Optimized Homogenization Matrix to Produce High Purity, Tag-Less, 160kDa Nuclease Using Ion Exchange and Size Exclusion Chromatography

Virginia L. Nash, Brittany A. M. Sangiovanni, Eva L. Geygan, Dylan J. Vasconcelles, Dennis O. Concepcion, Carson G. White, Mahajoub B. Bello Roufai
Research and Process Development, Akron Biotech, FL, Sarasota, FL

The discovery of the type II prokaryotic CRISPR "immune system" has allowed the development of an RNA-guided genome editing tool that is simple, easy, and quick to implement. Since then, several approaches to genome editing have emerged. The applications of such nucleases are ever-expanding and were recently validated with the US FDA approval of Casgevy, the first gene editing therapy for the treatment of sickle cell disease. The approval of Casgevy, coupled with the many gene editing programs necessitates versatile, cost-effective enzyme production and purification processes. A well-known strategy to facilitate protein purification is to engineer and express the protein with a Tag (e.g., Histidine Tag). This allows the use of affinity-based purification to achieve high purity. Cleavage of the Tag post-purification may be necessary, as its retention can cause interference with the protein's intended function. In this work, we describe a purification process using Akron's optimized homogenization matrix which allows isolation of the nuclease of interest at a relatively high purity after capture chromatography (Cation Exchange chromatography). A second chromatography step consisting of Size Exclusion Chromatography (SEC) resolves impurities (up to 100kDa) from the 160kDa nuclease using an enhanced buffer system. A 97.4% purity, measured by RP-HPLC, was achieved after two chromatography columns. A final chromatography step, designed solely for the reduction of endotoxin, achieved a reduction from ~69.8 EU/mg to levels as low as <1.0 EU/mg. The efficiency of the first CEX was shown to be scalable from a 10mL column volume (CV) to 5,000mL CV. This newly developed purification process using cGMP compatible resins, chemicals, and supplies is being assessed for scalability at Akron to establish a cost-effective nuclease purification process that does not require affinity chromatography.

1182. Chemically Modified AsCas12a Guide RNAs Improve Lipid Nanoparticle-Mediated *In Vivo* Gene Editing in Different Tissues

Paul J. Wrighton, Judith Newmark, Chrysa Latrick, Vikram Soman, Andrea Pinilla, Mark Jones, Eleanor Quenzer, Alison Miller, Steve Bottega, Alexis Benedis, Bryant Chica, Bridget Moffet, Meng Wu, Eugenio Marco, Swarali Lele, Ramya Viswanathan, He (Harry) Wang, Xiaoqi (Kevin) Sun, John A. Zuris, James Bochicchio, Kayla Delano, Georgia Giannoukos, Kai-Hsin Chang, Stephen Pietrasiewicz, Mariacarmela Allocca, Heather MacLeod, Steven Wolk

Editas Medicine, Cambridge, MA

CRISPR-Cas gene editing is a transformative technology with the potential to enable durable treatments for many diseases with unmet clinical need. Compared to the typically employed SpCas9 nuclease, our engineered AsCas12a nuclease has advantages in potency, specificity, and guide RNA (gRNA) chemical synthesis. To realize the potential of AsCas12a gene editing, methods must be developed to deliver AsCas12a nuclease and gRNA to the target cells *in vivo*. Lipid nanoparticles (LNPs) are capable of packaging AsCas12a mRNA with gRNA and delivering the cargo to various target organs *in vivo*. Yet, once the LNP delivers the payload into the cell, the RNA components can be rapidly degraded, reducing editing efficiency. Much effort has focused on protecting mRNA cargoes with chemical modifications to resist nuclease digestion and increase translation. However, less is known about protecting small AsCas12a gRNAs. Our goal was to develop a set of AsCas12a gRNA modifications that would universally enable high-potency gene editing regardless of target cell type. To this end, we performed three iterative rounds of chemical modification testing. The first round demonstrated several different chemically modified gRNAs increased editing potency compared to unmodified gRNA. The second round built upon the most efficacious initial designs and showed further improvements to editing potency. The third round of modifications consisted of combinations of modifications tested in the first two rounds and resulted in maximum editing potency. Our data showed that top modifications consistently improved gene editing potency across multiple immortalized cell lines and primary cell types *in vitro*, including HEK293T, Hep3B, primary trabecular meshwork (TM) cells, and primary human hepatocytes. Importantly, local administration of LNPs containing AsCas12a mRNA and modified gRNAs into the anterior chamber of the eye enabled *in vivo* editing in mouse TM cells. Furthermore, systemic delivery of LNPs via intravenous injection demonstrated similarly improved editing potency in the liver as a result of gRNA modification optimization. Notably, we demonstrated that improved binding affinity between engineered AsCas12a protein and gRNA correlates with improved gene editing potency following LNP delivery, providing a potential mechanistic explanation. These data demonstrate universal applicability of gRNA modifications to enhance gene editing outcome *in vitro* and *in vivo* and will enable the development of efficacious gene editing medicines.

1183. Improving HDR-Editing of the Sickle Cell Disease Mutation in Human CD34+ Cells via Electroporation

Anh Le[1], Julia Ball[1], Avery Bradley[1], Selami Demirci[1], Xiong Liu[1], Matthew M. Hsieh[1], Megan Embrey[2], Diwash Acharya[2], John F. Tisdale[1], Naoya Uchida[1]

[1]Cellular and Molecular Therapeutics Branch (CMTB), National Heart Lung and Blood Institutes (NHLBI), National Institutes of Health (NIH), Bethesda, MD,[2]MaxCyte®, Inc., Rockville, MD

Gene-editing technologies have advanced over time and applied to correct genetic disorders such as sickle cell disease (SCD). SCD is caused by the 20A>T mutation in the β-globin gene, and gene correction (HDR) of the SCD mutation in hematopoietic stem cells (HSCs) allows for phenotypic correction with adult hemoglobin production, eliminating sickle hemoglobin. In our SCD gene-correction model, CRISPR-edited CD34+ HSCs via electroporation (EP) were demonstrated to achieve ~30% HDR *in vitro* and engraftable post-transplant in xenograft mice and rhesus macaques (Cell Rep Med. 2021). HDR-edited cells were detectable on both DNA and protein levels long term; however, HDR-editing ratios were reduced to ~1% in rhesus. Therefore, here, we further optimized our system to increase editing efficiencies as well as cell recovery for HDR-edited CD34+ cells. Mobilized healthy-donor CD34+ cells were pre-stimulated for 2 days and electroporated by MaxCyte ATX® electroporator with normal β-globin-specific guide RNA, SpCas9 protein, and 100b donor single-strand DNA including the SCD mutation. We evaluated 1-week cell recovery by a semi-automated counter and gene-editing efficiency by reverse-phase HPLC after 2-week erythroid differentiation or digital-droplet PCR (ddPCR) after 1-week culture. At first, we evaluated 1-5x amounts of RNP (guide RNA and Cas9 protein), 0.5-10e7/mL cell densities in the EP cuvette, 1-40e5/mL of pre-stimulation cell culture densities, with HDR analysis by HPLC. The greatest amount of 5x RNP resulted in a lower level of 11% HDR as compared to 47-49% HDR at 1-2.5x RNP, likely due to cell toxicity with 2-fold lower cell recovery. All tested cell densities in the EP cuvette allowed for comparable levels of cell recovery, and HDR ratios were proportionate at 2-10e7/mL when we obtained sufficient amounts of HPLC samples. Up to 4-fold greater cell expansion was observed when CD34+ cells were seeded at lower cell densities, with 2.5e5/mL having the highest cell recovery post-EP ($p<0.05$, compared to 20-40e5/mL). HDR efficiencies gradually increased by reducing pre-stimulation cell density, from 15% HDR at 40e5/mL to 46% HDR at 1e5/mL. These data demonstrate that the low-amount RNP, a wide-range cell density in the EP cuvette at 0.5-10e7/mL, and low cell density in pre-stimulation culture allow for higher HDR editing in CD34+ cells. Next, we evaluated 100-300μg/mL donor DNA amounts, 2-40min resting times post-EP, and EP energy among preset programs HSC1-5, with HDR analysis by ddPCR. We found that a donor DNA addition reduced cell recovery ($p<0.01$), compared to no donor DNA and no cargo. 100μg/mL donor DNA resulted in up to 2-fold higher cell recovery and the highest 34% HDR editing among the tested donor DNA amounts. When resting CD34+ cells post-EP for 10-40min, 10min resting allowed for the highest 4-fold improvement of cell recovery, compared to no resting ($p<0.05$), along with similar 11-25% HDR editing efficiencies. A shorter resting at 2-10min increased cell recovery by 3 fold with similar HDR editing. We observed a trend of lower cell recovery up to a 5-fold range when

using higher energy of EP ($p<0.01$), while similar 19-21% HDR ratios resulted from HSC3-5, suggesting that HSC3 is optimal. These data demonstrate that a low-amount donor DNA, a short resting period post-EP, and program HSC3 improve HDR editing and cell recovery in CD34+ cells. In summary, we optimized HDR editing in human CD34+ cells *in vitro* to achieve higher HDR efficiencies and reduce cell toxicity. These findings should be useful to counter HDR toxicity and improve the engraftment of HDR-edited CD34+ cells.

1184. Designer Recombinase Mediated Reactivation of Fetal Hemoglobin for Treating β-Hemoglobinopathies

Manavi Jain[1], Nadja Schubert[2], Maciej Paszkowski-Rogacz[1,3], Lukas T. Schmitt[1,3], Duran Sürün[1], Frank Buchholz[1]

[1]UCC Medical Systems Biology, Medical Faculty, Technical University Dresden, Dresden, Germany,[2]DKMS Life Sciences Lab gGmbH, Dresden, Germany,[3]Present Address: Seamless Therapeutics GmbH, Dresden, Germany

Hemoglobinopathies are prevalent monogenic disorders with a profound global health impact affecting millions of individuals. Defects in the β-globin gene leads to abnormal structure or production of β-chains causing sickle cell disease (SCD) or β-thalassemia (β-thal), respectively. Allogenic hematopoietic stem cell transplantation (HSCT), the conventional curative option, is severely limited by donor availability and risk of immunological complications. Genetically modified autologous HSCT emerges as a promising alternative for patients lacking compatible donors. In contrast, hereditary persistence of fetal hemoglobin (HPFH) is a naturally occurring benign condition characterized by a substantial elevation of fetal hemoglobin (HbF) in adult red blood cells. Co-inheritance of HPFH with hemoglobinopathies results in milder clinical symptoms. Consequently, the reactivation of HbF has been extensively explored as a favorable approach to alleviate the clinical manifestations of both β-thal and SCD. Endogenous reactivation of HbF expression requires the development of efficient and safe genome editing tools. Tyrosine site-specific recombinases (Y-SSRs) present an attractive tool due to their exceptional ability to mediate DNA excision between two target sites with nucleotide precision. In our work, we leveraged this precise mechanism of Y-SSRs to reactivate HbF by seamlessly editing its transcriptional repressor, BCL11A (B-cell lymphoma 11A) gene. For reprogramming SSRs to predefined sequences in the BCL11A gene, we applied substrate linked directed evolution. High-throughput deep-sequencing-based screening of the resulting recombinase library was then used for rational selection of candidates displaying specific editing of the BCL11A target sites. Furthermore, expression of selected variants via mRNA electroporation resulted in the accurate DNA excision in reporter cell lines with an efficiency of up to 35%. Exact deletion at the endogenous BCL11A locus was confirmed through sequencing. Altogether, our findings highlight the therapeutic potential of designer recombinases as precision genome editing tool for treating β-hemoglobinopathies.

1185. Gene Editing Validation of Engineered Hypercompact OsCas12f Using LoxP-Targeted Reporter Assay in Mammalian Cells

Araba Abaidoo-Myles[1], Xinxu Yuan[1], Abdul Rasheed Baloch[1], Dabbu Jaijyan[1], Fang Li[1], Binhua Ling[2], Wenhui Hu[1]

[1]Virginia Commonwealth University School of Medicine, Richmond, VA,[2]Texas Biomedical Research Institute, San Antonio, TX

Due to size constraints for AAV gene therapy, efforts have been directed towards minimizing CRISPR/Cas editors, resulting in the identification of compact variants like Cas12f (Cas14a), Cas12j, and Cas13x. Compact editors offer advantages in viral packaging and targeting efficiency. Un1Cas12f (529 aa) from an Uncultured archaeon, initially recognized as Cas14a in 2018, originally demonstrated ssDNA cleavage. Subsequent studies revealed detectable nuclease activity (dsDNA) in prokaryotic cells, but not in eukaryotic cells. Recent findings highlighted the enhanced editing efficiency of Un1Cas12f in mammalian cells following protein engineering and sgRNA scaffold modification. AsCas12f, a newly discovered variant from Acidibacillus sulfuroxidans, with only 422 aa (1266 bp), exhibits high editing activity in mammalian cells in vitro and in vivo upon protein and scaffold engineering. Similarly, Oscillibacter sp. Cas12f (OsCas12f, 433 aa) demonstrates significant editing efficiency following protein and sgRNA engineering. This study aims to validate editing efficiency of the enhanced OsCas12f (enOsCas12f) in mammalian cells using LoxP-STOP-LoxP-tdTomato (LSL-tdT) reporter system. The LoxP-targeted sgRNA expression cassette was integrated into both constitutive (AAV-CBs-enOsCas12f and AAV-CBs-EGFP-enOsCas12f) and inducible vectors (AAV-CBs-ecDHFR-enOsCas12f and AAV-CBs-EGFP-ecDHFR-enOsCas12f). High editing efficiencies were observed in transiently transfected LSL-tdT reporter plasmids in HEK293T cells under both constitutive (85-90%) and inducible (50-60%) enOsCas12f expression. However, AAV-DJ8 delivery into neural stem cells from LSL-tdT mice (Ai14) yielded lower editing efficiencies (15-30%). In conclusion, the LoxP-targeted reporter assay validated the high editing efficiency of enOscas12f in mammalian cells, chromatin loci influence editing efficiency. Further evaluation of AAV-mediated in vivo delivery and gene editing with enOsCas12f is warranted.

1186. Targeting a Mutation Agnostic Regulator of *PKD1* Using CRISPRCas9 for Therapeutic Intervention in Autosomal Dominant Polycystic Kidney Disease

Poulami Chaudhuri[1], Neha Gaur[1], Rakesh Kappagantu[1], Yugantak Raj Gupta[1], Sadhana Mutalik[2], Harsha Rohira[1], Naveen Kumar D[2], Rohini Kalvakuntla[1], Anirudh Nishtala[1]

[1]Helex, Inc., New York, NY,[2]Unicas Biotech, Hyderabad, India

Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a hereditary condition caused by mutations in the *PKD1* (85% cases) or *PKD2* (13% cases) genes, which encode polycystin-1 and polycystin-2 proteins, respectively. This condition is characterized by the formation of fluid-filled cysts within the kidneys, which arise from renal tubules and can lead to end-stage renal disease (ESRD). *PKD1/PKD2* genes

are significantly repressed in ADPKD and lead to cytogenesis. In various pre-clinical models and humans with ADPKD, *PKD1/PKD2* gene re-expression has displayed attenuation as well as reversal of cyst formation proving this strategy to be of therapeutic potential. As 85% of ADPKD cases are contributed by *PKD1* mutations and there are more than 800 pathogenic mutations in *PKD1*, we are pursuing a mutation-agnostic approach than the conventional single-target therapies for ADPKD caused by *PKD1*. We employ Helex's proprietary Epic-Cure™ platform, which uses 3D genome architecture and epigenetics of ADPKD patients to design the gRNAs in conjunction with the molecular scissor CRISPR-cas9, to edit the mutation agnostic target that regulates *PKD1* gene in the most effective, precise and safe way. One of the most crucial challenges for developing a therapeutic for renal indications is the delivery to the kidney cells. We designed our own proprietary LNP that could facilitate kidney delivery of the gene editing cargo. We confirmed the knockout of the mutation agnostic target region by using the T7E1 assay and Sanger Sequencing in patient derived immortalised cell line, WT9-12 and patient derived cyst cells. Additionally, we observed a significant four-fold increase in *PKD1* mRNA levels, as evidenced by reverse transcription polymerase chain reaction (RT-PCR) post editing. This demonstrates our editing approach, facilitated by Helex's proprietary EPIC Cure platform, effectively eliminates the mutation agnostic target that regulates the *PKD1* gene. We were able to display significant kidney tropism for our proprietary LNP via tail vein injections in BALB/c mice using a DiR dye both in in vivo and ex vivo imaging. This precise intervention of the mutation agnostic target showing a significant increase in *PKD1* mRNA expression and the specificity of the proprietary kidney tropic LNP vector together showcases the potential as a therapeutic modality for ADPKD. Our mutation-agnostic strategy, harnessing Helex's proprietary Epic-Cure™ platform and genome editing (CRISPR-Cas9), holds promise in advancing therapeutic interventions to not just halting the disease but reversing the disease phenotype which goes way beyond current treatments, which focus on managing symptoms and slowing the progression of the disease.

1187. Investigating the Impact of CRISPR-Induced DSB Repair Mechanisms on *In Vivo* Recombinant AAV Integration

Martin Bilbao-Arribas[1,2], Julen Torrens-Baile[1], Laura Torella[1], Nerea Zabaleta[3], Gloria Gonzalez-Aseguinolaza[1]

[1]DNA & RNA Medicine Division, CIMA Universidad de Navarra, Pamplona, Spain,[2]IdISNA, Navarra Institute for Health Research, Pamplona, Spain,[3]Mass Eye and Ear/Harvard Medical School, Boston, MA

The use of paired Cas9 nickases has been proposed as a safer alternative to Cas9 nucleases for therapeutic gene disruption, but this strategy requires further characterization for in vivo applications. The choice of double strand break (DSB) repair pathway can be influenced by different factors such as the sequence context, cell type and cell cycle stage, or the nature of the free cut-ends. In a previous study we used adeno associated viruses (AAVs) to deliver CRISPR-Cas9 systems to hepatocytes for in vivo gene disruption of *Hao1* gene. We showed that paired Cas9 nickase-induced DSBs are mainly repaired through microhomology-dependent repair pathways and exhibit lower rates of vector sequence insertion compared to Cas9 nuclease-induced DSBs. Here, we shed light on the relationship between AAV integration frequency and the choice of DSB repair pathway by analysing the editing outcomes of several in vivo studies. The widely used tools for indel analysis of targeted amplicon sequencing data have not been optimised for the characterization of variants resulting from paired Cas9 nickase-induced DSBs, particularly concerning large insertions like AAV sequence insertions. Our study aimed to benchmark different tools to identify the best performing for paired Cas9 nickases in terms of total indel quantification and AAV insertion detection. Additionally, we conducted an alignment parameter optimisation to further improve AAV insertion quantification. Importantly, these optimised parameters can be applied to commonly used gene editing analysis tools, refining the efficiency of AAV insertion recovery. Seeking to understand the factors contributing to the observed reduction in AAV insertions with paired nicks, we delved into the DNA ends and repair systems involved in AAV integration. A reanalysis of a set of short-read amplicon sequencing data from various publications utilizing different CRISPR-Cas systems alongside AAVs for gene editing revealed a correlation between increased microhomology (MH) involvement and diminished AAV insertions. Interestingly, nucleases generating staggered ends, such as those created by the type V CRISPR family or paired Cas9 nickases, resulted in the highest MH scores and the lowest AAV insertion frequencies. Conversely, in the case of nucleases that create blunt ends, like those generated by Cas9 enzymes, indel outcomes - including AAV insertions - likely depended on the sequence context or other variables. Consequently, we are performing ad hoc experiments in vivo using selected guides having high or low predicted MH scores, as well as on-target long-read sequencing, to elucidate whether the frequency of AAV insertions depend on the staggered-end formation and/or the repair mechanisms involved. These results support the use of paired Cas9 nickases for in vivo gene disruption because on one side, it is known to minimise the risk of off-target modifications, and on the other, reduces the frequency of AAV insertions.

1188. CRISPR/CasX-Mediated Gene Editing as a Therapeutic Approach for HSV-1 Keratitis

Guoxiang Ruan[1], Nadia Amrani[1], Kevin Luk[1], Meltem Isik[1], Sarmistha Bhattacharya[2], Niles P. Donegan[3], Martina Donadoni[4], Anna Bellizzi[4], Ilker K. Sariyer[4], Matthew Hayden[2], Jennifer Gordon[1]

[1]Excision BioTherapeutics, Watertown, MA,[2]Dartmouth Health, Lebanon, NH,[3]White River Junction Veterans Affairs Medical Center, White River Junction, NH,[4]Temple University School of Medicine, Philadelphia, PA

Herpes simplex keratitis (HSK), caused by the infection of herpes simplex virus type 1 (HSV-1) of the cornea, is a major cause of blindness worldwide. After primary infection of the ocular surface, HSV-1 is transported to trigeminal ganglia (TG) and other ganglia and establishes lifelong latency. Periodically reactivated HSV-1 virus travels back to the cornea, causing recurrent HSK. Current anti-HSV-1 therapies, such as acyclovir, valacyclovir, and famiciclovir, interfere with viral DNA replication. However, these antiviral agents do not eliminate HSV-1 reservoirs or prevent recurrence. CRISPR/Cas-mediated gene editing can potentially address the underlying causes of the disease by eliminating the latent HSV-1 reservoirs directly. While efficient gene editing can be achieved by Cas9 nucleases, their large size has hindered delivery by a single adeno-associated virus (AAV)

vector. CasX (type V Cas12e) from *Planctomycetes* (hereafter CasX2) has gained significant attention due to its compact size (<1000 aa). Compared to Cas9, CasX2 is small enough to be delivered by a single AAV, with additional room for multiplexed guide RNAs. This study aims to identify CasX2 guide RNA pairs that effectively excise the DNA fragment between two vital HSV-1 genes, ICP27 and ICP0. We first designed 20 and 22 gRNAs targeting conserved sequences of the ICP27 and ICP0 genes, respectively. To identify the most effective gRNA pairs, we created a LentiCasX2-2xgRNA library comprised of the 440 CasX2 gRNA pairs formed from the gRNAs targeting the two genes. Lentiviral vectors prepared from the LentiCasX2-2xgRNA library were used to infect an HSV-1 gain-of-signal knock-in reporter HEK 293FT cell line containing the ICP27 and ICP0 consensus sequences. Cells with successful ICP27-ICP0 excision were enriched with blasticidin drug selection and harvested with FACS. The region containing the paired CasX2 gRNAs was PCR amplified and sequenced using Nanopore long-range sequencing. Out of the 440 gRNA pairs, 23 pairs showed more than two-fold enrichment with lentiviral screening. The top two CasX2 gRNA pairs from the screen were tested in Vero cells infected with the HSV-1 virus. To slow down the quick replication of the HSV-1 virus, the Vero cells were treated with valacyclovir for 24 hours post-infection, and then cultured for an additional four days to allow the HSV-1 to replicate. Compared to the empty vector control, the two CasX2 gRNA pairs reduced HSV-1 genome DNA and viral titer by over 96%. In conclusion, we successfully used a high-throughput lentiviral screening method to identify effective guide RNA pairs to disrupt the HSV-1 viral genome and inactivate the HSV-1 virus. Our findings suggest that CRISPR/CasX gene editing could be a potential cure, preventing HSV-1 recurrence in HSK and other HSV-1 related diseases.

1189. Allele-Specific CRISPR/Cas9 Editing Inactivates a Single Nucleotide Variant Associated with Collagen VI Muscular Dystrophy

Veronique Bolduc[1], Katherine Sizov[1], Astrid Brull[1], Eric Esposito[1], Grace S. Chen[1], Prech Uapinyoying[1], Apurva Sarathy[1], Kory Johnson[2], Carsten G. Bonnemann[1]

[1]Neuromuscular and Neurogenetic Disorders of Childhood Section, NINDS/NIH, Bethesda, MD,[2]Bioinformatics Core, NINDS, Bethesda, MD

The application of allele-specific gene editing tools can expand the therapeutic options for dominant genetic conditions, either via gene correction or via allelic gene inactivation in situations where haploinsufficiency is tolerated. Here, we used allele-targeted CRISPR/Cas9 guide RNAs (gRNAs) to introduce inactivating frameshifting indels at a single nucleotide variant in the *COL6A1* gene (c.868G>A; G290R), a variant that acts as dominant negative and that is associated with a severe form of congenital muscular dystrophy. We expressed spCas9 along with allele-targeted gRNAs, without providing a repair template, in primary fibroblasts derived from four patients and one control subject. Amplicon deep-sequencing for two gRNAs tested showed that single nucleotide deletions accounted for the majority of indels introduced. While activity of the two gRNAs was greater at the G290R allele, both gRNAs were also active at the wild-type allele. To enhance allele-selectivity, we introduced deliberate additional mismatches to one gRNA. One of these optimized gRNAs showed minimal activity at the WT allele, while generating productive edits and improving collagen VI matrix in cultured patient fibroblasts. This study strengthens the potential of gene editing to treat dominant-negative disorders, but also underscores the challenges in achieving allele selectivity with gRNAs.

1190. Optimization of Multiplex CRISPR-Cas9 Editing of Human Primary T Cells Using Lipid Nanoparticles (Lnp's) and Subsequent Off-Target Evaluation

Erica Warriner[1], Samuel Clarke[1], Meenakshi Swaminathan[1], Bernice Thommandru[2], Reka Geczy[1], Rita Zhao[1], Krystal Tan[1], Kevin Low[1], Aruna Balgi[1], Stella Park[1], Ethan Watt[1], Vaughn Thada[3], Garrett Rettig[2], Angela Zhang[1], Rolf Turk[2]

[1]Cytiva, Vancouver, BC, Canada,[2]Integrated DNA Technologies, Coralville, IA,[3]Integrated DNA Technologies, Coralville, ID

Background and Aims: CRISPR/Cas9 has emerged as a dynamic tool for gene editing of human primary T cells. Previously, we demonstrated a novel lipid nanoparticle (LNP) reagent for engineering of gene-edited CAR T cells with high cell viabilities and potency, even after multiple genetic manipulations. Here, we extend this work by optimizing multi-gene knockouts and assessing potential off-target editing effects in T cells, with RNAs delivered either by electroporation or LNPs. Further, through extensive T cell media evaluation, we show the critical nature of cell culture conditions for efficient LNP-mediated transfections. **Methods:** LNPs encapsulating wild type or high fidelity S.p. Cas9 mRNA and various TRAC and CD52 targeted guide RNAs (sgRNAs) were produced using the scalable NxGenTM mixing platform. Alongside, electroporation was performed to deliver equivalent cargoes. Primary T cells were cultured, activated, and expanded in different commercial media T cell media in static culture. Gene expression and cell viability were measured using flow cytometry. Multi-target performance of CRISPR-Cas9 editing was evaluated through rhAmpSeq-based targeted next-generation sequencing (NGS) and indels analyzed for with CRISPRAltRations. **Results:** TCR or CD52 targeted Cas9 mRNA-LNP addition or electroporation yielded high single and double knockout efficiencies. We tested a range of sgRNA targets, wild-type and high-fidelity Cas9 mRNAs, and determined off-target editing. We achieved 90% ±2.6% double edited T cells (TCR-/CD52-). Similar results were obtained when comparing different LNP batch sizes (micro to milligram RNA) and cell culture vessels (0.1 to 45 million cells), demonstrating scalability of both LNPs and cell treatment. Editing efficiency and potency was affected by the type of culture media. LNP delivery to T cells for gene editing was optimized in two commercially available T cell culture media yielding similar EC50 values (0.3 to 0.5 µg/million cells). **Conclusions:** The results from this study further support the utility RNA-LNPs for the genetic engineering of primary T cells. The simple and gentle nature of LNP cell treatment allows for multiple genetic engineering steps for simultaneous expression and deletion of proteins for future cell therapies. These LNPs can be easily manufactured from small-scale screening of RNA libraries to rapid scale-up for clinical translation.

Thursday Posters: Targeted Gene Insertion

1191. Tridimensional Scaffolds Preserve Hematopoietic Stem and Progenitor Cell Polarity and Restrains DNA Damage for Efficient Gene Therapy Applications

Federico Midena[1], Laura Alessandrini[2], Roberta Vacca[1], Matteo Barcella[1], Emanuela Jacchetti[3], Edoardo Carsana[1], Claudio Conci[3], Teresa Tavella[1], Ivan Merelli[1], Manuela Raimondi[3], Raffaella Di Micco[1]

Hematopoietic Stem and Progenitor Cells (HSPC) engineering, and particularly long-range gene correction, requires *ex vivo* activation to achieve a sizable fraction of edited cells. However, we recently discovered that *ex vivo* culture inadvertently leads to ROS-dependent proliferative stress and DNA damage, resulting in stem cell dysfunctions and potentially jeopardizing the efficacy of genetic engineering for HSPC-based clinical applications. We reasoned that these detrimental responses may arise from HSPC removal from the hypoxic bone marrow niche and be exacerbated by growth on bidimensional substrates. Thus, we employed a biocompatible tridimensional scaffold to counteract culture stress and reported mitigation of DNA damage accumulation, increased clonogenic potential, and enhanced multi-lineage repopulating capacity upon transplant into immunocompromised mice. Surprisingly, RNA-Seq analyses revealed massive transcriptional changes upon 3D culture, including upregulation of genes belonging to cytoskeleton organization and adhesion, and concomitant downregulation of oxidative phosphorylation and protein synthesis, which are associated with more primitive stem cells. Mechanistically, 3D scaffolds prevented HSPC deformation and squashing occurring in bidimensional culture, conserving nuclei morphology and tubulin polarity, potentially facilitating adaptation to *ex vivo* culture and preservation of stemness properties. Most importantly, pre-culture on 3D scaffolds ameliorated HSPC functionality upon Cas9/AAV6-mediated GE, endowing edited cells with increased multi-lineage output at single-cell resolution *in vitro* and superior engraftment into NSG mice. Similar results were obtained across different HSPC sources, such as cord blood and mobilized peripheral blood, as well as in multiple therapeutic settings, including lentiviral gene transfer and HSPC expansion, which is particularly relevant for certain diseases in which only a limited number of cells can be harvest from patients. Overall, our results highlight the importance of tridimensional interactions for the maintenance of HSPC biological properties, especially during *ex vivo* manipulation for gene therapy applications.

1192. Assessing the Best Strategy and Timeframe for *In Vivo* Genome Editing of Progressive Familiar Intrahepatic Cholestasis Type 2

Chiara Simoni[1,2], Elena Barbon[1], Francesco Starinieri[1], Martino Alfredo Cappelluti[1], Justine Nozi[3], Camilla Negri[1], Elisabetta Manta[1], Mauro Biffi[1], Matteo Mori[2], Rossana Norata[1], Martina Rocchi[4], Francesca Sanvito[4], Giuseppe Ronzitti[3], Angelo Lombardo[1,2], Alessio Cantore[1,2]

[1]SR-TIGET, Milan, Italy,[2]Vita Salute San Raffaele University, Milan, Italy,[3]Genethon, Evry-Courcouronnes, France,[4]IRCCS San Raffaele Scientific Institute, Milan, Italy

Progressive familiar intrahepatic cholestasis type 2 (PFIC-2) is a monogenic metabolic disorder caused by mutations in *ABCB11* gene encoding the Bile Salt Export Pump. Loss of function of this protein results in impaired secretion of bile from the liver leading to jaundice, pruritus, fibrosis and ultimately to liver failure. PFIC-2 treatment consists in alleviation of pruritus, external or internal biliary diversion or ileal transporter inhibitors. Since liver transplantation has shown to be beneficial but is associated to several possible complications, liver-directed *in vivo* genome editing may represent an alternative treatment, potentially allowing for stable and precise gene correction in paediatric patients. Here, we aim to compare different strategies based on the CRISPR-Cas9 platform, to select the most efficient to integrate *ABCB11* cDNA under the control of its endogenous promoter. We plan to deliver *in vivo* donor DNA with viral vectors and Cas9 mRNA and guide RNA (gRNA) with lipid nanoparticles (LNP). Firstly, we designed 12 gRNAs targeting the first intron of *Abcb11* to address most of the disease-causing mutations and maintain as much as possible physiological gene regulation. We screened the gRNAs based on their cutting efficiency in hepatocyte cell lines and selected the best performing one. Afterwards, we used mCherry as reporter gene, to compare different donor DNAs designed to exploit homology directed repair (HDR) or homology-independent targeted integration (HITI). *In vitro*, we observed the highest integration rate with the HDR-based donor DNA. *In vivo*, we systemically administered adeno-associated viral vectors (AAVs) delivering the different donor DNAs configurations to Cas9 transgenic mice. We observed slightly higher integration rate, mCherry expression and mCherry-positive liver area exploiting HDR-based donor DNA. We obtained the same results in 2-week- and 2-day-old Cas9 mice. Since patients affected by PFIC-2 develop liver fibrosis even before one year of age in the most severe forms, we set out to assess its impact on *in vivo* genome editing. Indeed, liver fibrosis may negatively affect the delivery efficiency of genome editing components, either by viral vectors or LNP, and therefore the efficacy of the treatment. Thus, we evaluate the impact of fibrosis on viral vector transduction, exploiting both chemically induced and genetic mouse models of liver fibrosis. We intravenously administered lentiviral vector (LV) or AAV encoding for a reporter gene to CCl_4 treated mice, which display intermediate to severe pericentral fibrosis. In this model we observed reduced LV transduction while AAV transduction was not affected. In mice treated with DDC diet, which display intermediate to severe periportal fibrosis, we observed reduced transduction efficiency by both LV and AAV. Moreover, we intravenously administered LV to 6-month-old PFIC-2 mice, displaying mild periportal fibrosis, and showed a slight

reduction of LV transduction. These findings highlight the need for early intervention in diseases like PFIC-2 which rapidly develop liver fibrosis. Overall, these data provide the basis to further develop *in vivo* genome editing approaches and to assess the best timeframe for the treatment of PFIC-2 patients.

1193. Dual AAV-Delivered, Meganuclease-Mediated Gene Insertion Approach for the Treatment of Phenylketonuria - Proof-of-Concept Study in Rhesus Macaques

Benedicte Rousseau[1], Celensia Tolson[1], Rucha Fadnavis[1], Taku Moriwaki[1], Katrina M. Ralph[2], Kathryn Shelton[2], Luke J. Segura[2], Rick A. Finch[2], R. Jason Lamontagne[1], Jenny A. Greig[1], James M. Wilson[1]

[1]Gene Therapy Program, University of Pennsylvania, Philadelphia, PA,[2]MD Anderson, Bastrop, TX

Phenylketonuria (PKU) is an autosomal recessive metabolic disorder caused by missense mutations in the gene encoding phenylalanine hydroxylase (*PAH*), a hepatic enzyme that catalyzes the conversion of phenylalanine to tyrosine. Although PKU does not directly shorten life expectancy, high phenylalanine concentrations in tissues and blood can result in symptoms ranging from a musty odor from the skin and urine to intellectual disability, epilepsy, and hyperactivity/behavioral problems. Most PKU cases are detected at birth via newborn screening; overall incidence is 1/15,000 in the United States, but this rate varies around the world. Dietary and pharmacological treatment options exist, but their life-long, inconvenient nature can raise compliance and efficacy issues. Our aim was to establish a long-lasting, single-administration treatment for PKU. Here, we developed a dual adeno-associated virus (AAV) vector-delivered, meganuclease-mediated gene insertion approach to insert the human PAH transgene into a previously identified safe harbor site for sustained expression. Our approach comprises two AAVrh79 vectors. The first vector encodes an engineered ARCUS meganuclease, M2PCSK9, that targets the human *PCSK9* gene. The second, a "donor" vector, encodes a codon-optimized version of the human PAH transgene flanked by 500 bp homology arms on either side of the meganuclease target site in the human genome (and ~95% homologous to rhesus macaques) to aid insertion at the meganuclease-induced double-strand break. We evaluated our approach in a proof-of-concept study in 6-9-month-old rhesus macaques following intravenous administration. The dual AAVs were administered at a total dose of 4 x 10^{13} GC/kg (n=2; high dose) and 1.33 x 10^{13} GC/kg (n=2; low dose) with a 3:1 donor-to-meganuclease vector ratio. Another cohort received a 1:1 ratio for a total dose of 2 x 10^{13} GC/kg (n=2; intermediate dose). Liver biopsies were performed at three months post dosing, and animals were followed with bi-monthly blood tests to monitor liver function. Transient, mild elevations of liver enzymes (alanine transaminase and aspartate transaminase) that resolved without intervention were observed and blood chemistry analyses showed no signs of decreased liver function. As the M2PCSK9 meganuclease specifically disrupts PCSK9 expression, we used total serum PCSK9 protein levels as a surrogate readout of target site editing. We observed a consistent decrease in PCSK9 levels in all three dual treatment cohorts, with the intermediate- and low-dose cohorts achieving a > 50% reduction compared with the donor-only group. We conducted amplicon sequencing to directly assess target site editing at the three-month biopsy timepoint. At the meganuclease target site, we detected an insertion/deletion frequency of 5% in the low-dose, 21.1% in the intermediate-dose, and 11% in the high-dose cohorts compared with 0.08% in the donor-only group. *In situ* hybridization from liver biopsy tissue analyses of the dual treatment cohorts showed expression of human PAH RNA in 4.5% of cells in the low-dose, 8.5% in the intermediate-dose, and 3.1% in the high-dose animals, and 4.5% in the donor-only group; we confirmed this expression pattern via RNA transcript levels. These results indicate that our dual AAV vector-delivered, meganuclease-mediated gene insertion approach can safely introduce a PAH transgene into the liver of nonhuman primates. This finding raises the possibility that our combination therapy may represent a single-administration treatment approach for PKU that is PAH-mutation-agnostic and that may provide a less restrictive, improved quality of lives for those affected by PKU.

1194. Dual AAV-Delivered, Meganuclease-Mediated Gene Insertion Approach for the Treatment of Citrullinemia Type 1

Mark Urban[1], Rucha Fadnavis[1], Celensia Tolson[1], Hongwei Yu[1], Katrina M. Ralph[2], Kathryn Shelton[2], Luke J. Segura[2], Rick A. Finch[2], Lili Wang[1], R. Jason Lamontagne[1], Jenny A. Greig[1], James M. Wilson[1]

[1]Gene Therapy Program, University of Pennsylvania, Philadelphia, PA,[2]MD Anderson, Bastrop, TX

Citrullinemia type 1 (CTLN1) is characterized by elevated blood citrulline levels caused by mutation of the argininosuccinate synthetase 1 (*ASS1*) gene. ASS1 converts citrulline and aspartate to argininosuccinate in the urea cycle. Loss of functional ASS1 results in a failure to clear ammonia through urea, which can lead to hyperammonemia, which, in turn, can cause lethargy, increased intracranial pressure, seizures, coma, and death. Liver transplantation currently represents the only effective curative treatment. Here, we developed a dual adeno-associated virus (AAV) vector-delivered, meganuclease-mediated gene insertion approach to insert the human ASS1 transgene into a previously identified safe harbor site for sustained expression. Our approach comprises two AAVrh79 vectors. The first vector encodes an engineered ARCUS meganuclease, M2PCSK9, that targets the human *PCSK9* gene. The second, a "donor" vector, encodes the native human ASS1 transgene flanked by 500 bp homology arms on either side of the meganuclease target site in the human genome (and ~95% homologous to rhesus macaques) to aid insertion at the meganuclease-induced double-strand break. We evaluated our approach in infant (2-3-month-old) rhesus macaques following intravenous administration at a total dose of 1.33 x 10^{13} genome copies (GC)/kg (n=2) or 4 x 10^{13} GC/kg (n=2). An additional animal was injected with 3 x 10^{13} GC/kg of the donor vector alone (n=1). Vector administration was well tolerated with normal serum biochemistry and liver function indices throughout the study, indicating that our approach posed a low risk to liver integrity and function. As the M2PCSK9 meganuclease specifically disrupts PCSK9 expression, we used total serum PCSK9 protein levels as a surrogate readout of target site editing. We found a dose-dependent reduction in PCSK9 serum levels compared with the donor-only control during the first year following treatment. Liver biopsies were taken at ~3 months and

one-year post-injection to determine ASS1 transgene expression and editing at the *PCSK9* locus. Amplicon sequencing of the meganuclease target site revealed an insertion/deletion frequency of 12.3% (low dose) and 30.7% (high dose) compared with 0.02% in the donor-only group, indicating efficient meganuclease-mediated target site editing. Levels of hepatic ASS1 RNA and protein expression were found to positively correlate with vector dose. *In situ* hybridization analyses at 3 months showed ASS1 RNA expression in 7.1% (low dose) and 20.8% (high dose) of cells in macaques dosed with the dual vector approach, but only in 1.6% of cells in the donor-only macaque. Human ASS1 protein expression, assessed by immunofluorescence, was present in 8.9% (low dose) and 14.5% (high dose) of cells at 3 months in macaques dosed with the dual vector approach, but only in 1.5% of cells in the donor-only animal. Follow-up analyses (currently ongoing) suggest that these expression levels were maintained for at least 12 months. Previous studies in multiple models of CTLN1 indicate that achieving 5%-10% of normal ASS1 activity confers a therapeutic effect, suggesting that our dual AAV vector approach can achieve clinically relevant, stable ASS1 expression in the liver of NHPs. These results add to a growing body of data that supports the use of our dual AAV vector-delivered, meganuclease-mediated gene insertion approach to treat various genetic metabolic conditions using disease-specific donor vectors in combination with our *PCSK9* safe harbor site-targeting meganuclease.

1195. Efficacy and Toxicology Studies of a Clinical Candidate Dual AAV-Delivered, Meganuclease-Mediated, Gene Insertion Approach for Ornithine Transcarbamylase Deficiency

Claude C. Warzecha[1], Lili Wang[1], Peter L. Bell[1], Yanqing Zhu[1], Cecilia D. Dyer[1], Elizabeth L. Buza[1], Rucha Fadnavis[1], Zhenning He[1], Hong Zhang[1], Celensia Tolson[1], Katrina M. Ralph[2], Carolyn L. Hodo[2], Kathryn Shelton[2], Luke J. Segura[2], Rick A. Finch[2], R. Jason Lamontagne[1], Jenny A. Greig[1], James M. Wilson[1]

[1]Gene Therapy Program, University of Pennsylvania, Philadelphia, PA,[2]MD Anderson, Bastrop, TX

Ornithine transcarbamylase deficiency (OTCD) is an X-linked urea cycle disorder that causes neurotoxic ammonia buildup, which can result in potentially fatal episodic hyperammonemia crises. Current medical management of OTCD includes a protein-restricted diet and ammonia-scavenging agents. Liver transplantation is the only available curative treatment option. However, these options may be insufficient or unavailable to alleviate hyperammonemia crises in infants; thus, there is an unmet clinical need for a long-term curative treatment. Here, we report two investigational studies with a dual adeno-associated virus (AAV) vector-delivered, meganuclease-mediated gene insertion approach to treat OTCD. Our approach comprises two AAVrh79 vectors that insert the OTC transgene into a previously identified safe harbor site for sustained expression. The first vector encodes an engineered ARCUS meganuclease, M2PCSK9, that targets the human *PCSK9* gene. The second "donor" vector encodes a codon-optimized human OTC transgene flanked by 500 bp homology arms on either side of the meganuclease target site in the human genome (~95% homologous in rhesus macaques) to aid insertion at the meganuclease-induced double-strand break. We conducted a minimal effective dose study in *spf^{ash}* mice, an OTCD model, to assess efficacy. Neonatal *spf^{ash}* mice received intravenous (IV) injections of one of three total vector doses ($4.4x10^{12}$ genome copies [GC]/kg, $1.3x10^{13}$ GC/kg, or $4.0x10^{13}$ GC/kg) of a murine surrogate (homology arms include mouse genomic sequences) or $3.0x10^{13}$ GC/kg of the donor vector alone for human OTC expression; additional *spf^{ash}* mice and wild-type mice received vehicle as controls. *spf^{ash}* mice injected with the intermediate or high doses of the dual vector survived 9.6 days or 8.6 days, respectively, during a 10-day high-protein diet challenge, whereas vehicle-treated mice survived an average of 7.6 days. We achieved OTC enzyme activity levels in the livers of high-dose-treated *spf^{ash}* mice up to 29% of wild-type levels, compared with 10% or 13% of wild-type levels in *spf^{ash}* mice injected with vehicle or OTC donor vector only, respectively. These increases in OTC enzyme activity and survival demonstrated the advantage of our approach over traditional gene therapy (as modeled by donor vector alone). We also performed a toxicology study in infant rhesus macaques whereby 6-12-week-old macaques received IV injections of $4.0x10^{13}$ GC/kg of our dual vector (n=4) or vehicle (n=2). Three animals (one vehicle and two vector-injected macaques) were necropsied on Day 91; the remaining three animals had a liver biopsy on Day 91 and were necropsied one-year post-injection. *In situ* hybridization and immunostaining assays revealed stable human OTC mRNA and protein expression, respectively, from Day 91 through one-year post-dosing, in which 25%-30% of hepatocytes were positive for human OTC. Vector administration was well tolerated, with no impact on clinical pathology parameters except for transient, mild liver enzyme elevations that resolved without intervention. Comprehensive histopathological examination at Day 91 and one year revealed vector-related, non-adverse mild mononuclear cell infiltrates in the portal area of the liver and minimal neuronal degeneration/necrosis in the trigeminal and dorsal root ganglia. In conclusion, these data suggest that our dual AAV vector-delivered, meganuclease-mediated gene insertion approach could safely and efficiently insert a human OTC transgene into the genome in a mutation-agnostic manner to treat OTCD.

1196. Leveraging Homology Directed Repair with the Use of an AAV Donor and CRISPR/Cas9 Nuclease to Accelerate Efficacy in Wilson Disease Mice

Amy M. Bastille[1], Jay Wang[1], Shreya Amarwani[1], Kirsten Lapoint[1], Don Foster[1], Neil Huang[1], Megan Ericson[1], Ogooluwa Ojelabi[2], Shiliang Hu[1], Bei Cheng[3], Matthew Chiocco[1], Mariana Nacht[1], Mathias Hebben[1]

[1]Alexion Genomic Medicine, Astra Zeneca Rare Disease, Lexington, MA,[2]LogicBio Therapeutics, Lexington, MA,[3]Astra Zeneca, Waltham, MA

Wilson Disease (WD) is a progressive, rare monogenetic disease resulting in excessive copper accumulation in tissues such as liver, brain and eye. This disease is caused by a mutation in the ATP7B gene and transmembrane protein, resulting in copper toxicity. We previously used GeneRide, our AAV insertion technology, to demonstrate that correction of hepatocytes in a mouse model of WD resulted in lowering of urinary copper and the level of plasma liver injury marker, ALT. To accelerate metabolic correction and reduce disease pathogenesis, we investigated the combination of GeneRide with a CRISPR/Cas9-based

nuclease delivered by lipid nanoparticles (LNPs). Our historical data with GeneRide demonstrated therapeutic benefit in this model, relying on the phenomenon of selective advantage that can be observed in diseases with severe liver damage such as methylmalonic acidemia (MMA) and hereditary tyrosinemia type I (HT-1). Selective advantage and hepatocyte expansion occurs because GeneRide-edited hepatocytes are healthier than mutant hepatocytes, and the repopulation of the liver by edited hepatocytes drives efficacy over time. However, due to the low initial editing rate with GeneRide alone, it can take many months to see benefits of the therapy in some models of metabolic disease. With the addition of a nuclease to GeneRide, in wild-type mice we observed an up to 1000-fold increase in the amount of ALB2A, a circulating technology-specific biomarker that correlates with the number of edited hepatocytes. To see if editing more cells initially, in conjunction with selective advantage, would accelerate time to efficacy, we evaluated this strategy in the WD mouse model. We observed an increase of 750-fold in ALB2A expression, compared to GeneRide alone, at one-week post-dose which suggests a higher editing efficiency. This level of ALB2A expression corresponded to a level achieved after 7-8 months with GeneRide alone. Furthermore, a longitudinal analysis of the surrogate biomarker ALB2A and ATP7B expression directly, along with key WD-associated biomarkers shows an acceleration of metabolic correction and therapeutic benefit. This suggests that combining a nuclease with GeneRide technology could be used to treat a variety of metabolic diseases.

1197. Endogenous Human TRIM Protein Expression Influences Potency of a Knock-In Human-Rhesus Chimeric Protein Expression Platform for CXCR4-Tropic HIV-1 Cure

Amanda M. Dudek[1,2], Elena J. Sasu[1,2], Matthew H. Porteus[1,2]

[1]Pediatrics, Stanford University School of Medicine, Stanford, CA,[2]Institute for Stem Cell Biology & Regenerative Medicine, Stanford University School of Medicine, Stanford, CA

Allogeneic hematopoietic stem and progenitor cell transplant (Allo-HSCT) of naturally *CCR5*-null cells has cured HIV-1 infection in some individuals, however these instances have been extremely rare due to several limitations, including high prevalence of dual co-receptor and CXCR4-co-receptor using viral strains. We have recently reported a Cas9/AAV based multi-target genome editing strategy which can be used in an autologous HSCT setting (therefore preventing the risk of graft verses host disease), and which shows greater than 2,000-fold reduction in viral load upon CXCR4-tropic challenge of primary human peripheral blood derived CD4+ T cells. During challenge of individual components of this multi-editing strategy, we identified that single knock-in of the inhibitory protein hRhTRIM5α (a humanized chimera of the species specific restriction factor TRIM5α) showed high donor-to-donor variability in efficacy for restricting CXCR4-tropic replication. While highly effective at restricting HIV replication in some T cell donors (>200- fold reduction in free virus concentration), this individual factor showed very little effect in other donors (~3-fold reduction), suggesting donor-specific or cell-biology-specific differences in restriction factor function. As a multi-meric and catalytically active protein, we hypothesized that endogenous human TRIM5 and TRIM5-interacting proteins may be influencing the efficacy of the therapeutic hRhTRIM5α protein after knock-in. Using peripheral blood CD4+ T cells from previously characterized donors, we have identified that knock-out of the endogenous human TRIM5 locus decreases the efficacy of hRhTRIM5α restriction, causing a roughly 20-fold reduction in restriction factor potency in multiple T cell donors. Reduction in restriction factor efficacy was observed not only by reduction in fold-change of free-virus concentration, but additionally in reduced inhibition of intracellular HIV DNA copy accumulation. These data highlight an interesting mechanistic result that human TRIM5 may facilitate a cooperative effect that augments the effective concentration of restrictive TRIM proteins in primary CD4+ T cells. Additionally, these results have significant implications for improving the efficacy of various gene editing and cell therapy strategies in development using this family of proteins, and highlights the importance of personalized medicine in development of effective therapies for HIV-1.

1198. *In Vivo* Transgene Expression from Hematopoietic Cells in Primatized Mouse Models Following Non-Viral Knock-In

Jack M. P. Castelli[1,2], Rachel Cunningham[1,2], Molly E. Cassidy[2], Youngseo Jwa[2], Matthew D. Gray[3], Mark R. Enstrom[2], Jonathan D. Linton[2], Anthony Rongvaux[2,4], Justin J. Taylor[5], Jennifer E. Adair[2,6]

[1]Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA,[2]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA,[3]Vaccine and Infectious Diseases Division, Fred Hutchinson Cancer Center, Seattle, WA,[4]Department of Immunology, University of Washington, Seattle, WA,[5]Beirne B. Carter Center for Immunology Research, University of Virginia, Charlottesville, VA,[6]Department of Medical Oncology, University of Washington, Seattle, WA

Broadly neutralizing antibodies (bnAb) against HIV are capable of providing immune protection in non-human primate (NHP) models and clinical trials but require repeated injections. Endogenous production of bnAbs could provide life-long treatment for controlling HIV, ideally as a single intervention. We previously presented editing of the immunoglobulin heavy chain locus in NHP hematopoietic stem and progenitor cells (HSPC) to achieve knock-in and expression of long transgenic sequences, without the use of viral vectors. Here, we show that edited HSPCs are capable of engrafting in primatized mouse models and differentiating into cells of the lymphoid lineage. Comparing 10 different CRISPR/Cas guides using 2 different nucleases, we show that the Cas12a ribonucleoprotein can achieve perfect homology-directed repair (HDR) events at a frequency of 2.4% (Fig.a). Cas9 guides displayed lower editing on average (27.4% ± 15.3%) and a higher frequency of imperfect HDR (96.2% ± 1.7% of total HDR events) than Cas12a guides (39.8% ± 12.1% and 68.3% ± 13.1% respectively). Electroporation assays in $CD34^+$ cells isolated from healthy donor pigtail macaques (*Macaca nemestrina*) showed that single-stranded oligodeoxynucleotide templates achieved 4-fold more HDR events than double-stranded DNA of the same length. Edited NHP HSPC (n=2 donors) were injected into a sub-lethally irradiated neonatal immunodeficient mouse model. Cell doses of 1.5×10^5 per

mouse achieved engraftment of up to 3.1% ± 0.5% NHP-derived cells in the blood (n=19 mice), allowing for study of lymphocytes (Fig.b). As previously observed, B cell populations start at a higher fraction and steadily decline over time until T cells become the dominant lineage at 12-14 weeks (Fig.c). A fluorescent eGFP reporter under the control of a B cell specific antibody heavy chain gene promoter shows expression patterns that match this shift, with 0.41%-0.77% of NHP-CD45$^+$ cells expressing eGFP in some mice before week 14 (Fig.d). Ongoing studies are focused on NHP HSPCs edited with a transgene encoding the bnAb 10-1074, an investigational drug for treatment and prevention of HIV. In addition, we show that edited NHP HSPC (n=1 donor) can engraft in a non-irradiated adult immunodeficient mouse model and result in higher than 73% B cell populations (n=8 mice). We anticipate that higher B cell populations with similar editing levels will enable us to track expression patterns and bnAb production in this model. These studies will pave the way for future validation of one-time gene therapy treatments in NHP models of HIV infection.

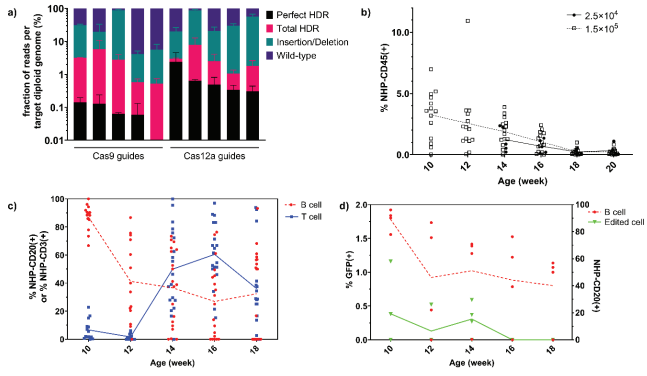

Figure. a) Cumulative frequency of editing outcomes at target locus in NHP lymphocyte cell line. b, c) Engraftment rate of mice at varying NHP-CD34$^+$ cell doses and lymphocyte populations as a fraction of NHP-derived cells in the blood. d) Transgene expression levels and corresponding B cell population in mice showing any level of eGFP out of 8 mice injected with edited HSPC.

1199. Innovative IDLV Design for Transgene Targeted Integration via Microhomology-Mediated End Joining Pathway

Giulia Scalisi[1,2], Aboud Sakkal[1,2], Lacombe Laurie[1,2], Alexandra Tachtsidi[1,2], Guillaume Corre[1,2], Giulia Pavani[3], Peter Lenting[4], Anne Galy[5], Mario Amendola[1,2,6]

Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France,[5]ART-TG, Accelerator of Technological Research in Genomic Therapy - Inserm US35, EVRY, France,[6]Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy

Ex vivo gene correction of hematopoietic stem and progenitor cells (HSPCs) is a promising therapeutic approach for numerous genetic disorders. While the combination of the CRISPR-Cas9 system with various DNA donors has enable gene correction and genomic integration, several pitfalls are still present, including the limited size of the DNA payload and low editing efficiency in HSCs. Integrase-defective lentiviral vectors (IDLV) offer a notable advantage in delivering large transgenes compared to AAV6. However, their integration still relies on homology direct repair (HDR) mediated integration with low efficiency in HSCs. Here we introduce a new class of IDLVs as DNA donor vector that leverages the microhomology end joining (MMEJ) DNA repair pathway. We designed an IDLV where the transgene expression cassette is flanked by a gRNA target site (23 bp), and a short (35 bp) sequence homologous to the intended genomic integration site (microhomology arm, MH). The underlying hypothesis is that the Cas9/gRNA cutting of IDLV will expose the MH for recombination with the genomic double strand brakes (DBS), to achieve a directional and precise target integration (TI). Compared to HDR, which requires cell cycle, MMEJ is active in all cell cycle phases and should be proficient in quiescent HSCs and the use of a small MH-arm will be an asset in terms of space for insertion of longer therapeutic cassettes. For linearizing the episomal IDLV, we used the same gRNA required to introduce DSB at the selected genomic locus, thus simplifying gRNA delivery and reducing potential off-targets associated with the use of two different gRNA.As proof of concept, a reporter gene was targeted to a safe harbor site (AAVS1) and a clinically relevant genomic locus (HBA) in K562 and T-cell lines. We showed that combining the MH-arm and the linearization of the IDLV we obtained efficient on-target, directional and seamless GFP TI (as measured by ddPCR, FACS and by Sanger sequencing of genome-IDLV junction PCR). In addition, using targeted nanopore long-read sequencing (LRS), we demonstrated the correct integration of the whole DNA expression cassette at the expected locus. To assess the contribution of the gRNA target and MH sequence alone, we generated IDLV with each one of these sequences and we demonstrated that both are required to achieve efficient and precise integration. All these data were further confirmed by molecular analysis of single cell clones. We then moved to clinically relevant human HSPC. After optimizing transduction and editing condition, we achieved and GFP integration efficiency in both genomic loci that was similar to the classical HDR based IDLV integration. Again, molecular analysis, LRS and single colony PCR confirmed the efficiency and precision of the strategy. We then challenged our IDLV to deliver and integrate a FVIII cDNA (5kb) and demonstrated once more efficient and precise integration and proficient protein expression. We are currently testing this strategy using additional therapeutic transgenes. We also have preliminary data that NHEJ inhibitors can increase IDLV integration, and we are exploring the use of different IDLV envelope to increase HSC transduction. In conclusion, we propose an MH-IDLV system as an effective platform for cell editing, alternative to the HDR-based TI, which may have important therapeutic implications in the treatment of genetic and tumour pathologies.

1200. Hematopoietic Stem and Progenitor Cell Gene Editing for Congenital Dyserythropoietic Anemia Type II

Mercedes Dessy Rodríguez[1], Sara Fañanas-Baquero[1], Carmen Contreras[1], Rolf Turk[2], Garret Rettig[3], Giandomenico Turchiano[4], Nathan White[4], Yi-Ting Hu[4], Michael Tadros[5], Jose-Carlos Segovia[1], Oscar Quintana-Bustamante[1]

[1]CIEMAT, Madrid, Spain,[2]Integrated DNA Technologies, Coralville, IA,[3]Integrated DNA Technologies (IDT), Coralville, IA,[4]University College London, London, United Kingdom,[5]Danaus GT, Madrid, Spain

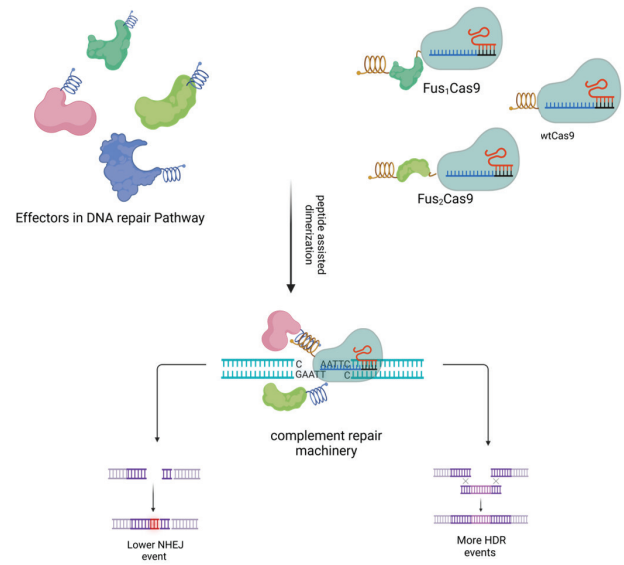
Congenital dyserythropoietic anemias (CDAs) are a group of inherited anemias that affect the development of the erythroid lineage. CDA type II (CDAII) accounts for around 60% of all CDA cases. CDAII patients suffer from ineffective erythropoiesis, morphologic abnormalities in erythroblast within the bone marrow, hemolysis, and iron overload. CDAII is caused by mutations in the *SEC23B* gene, with more than one hundred pathological variants described throughout the gene. Allogeneic hematopoietic stem cell transplant (HSCT) represents the only curative option for this disease, but it implies serious side effects. Autologous HSCT of genetically corrected cells would mean a definitive treatment for CDAII. To address the genetic correction of most CDAII patients, we have established a gene editing approach based on knock-in wild-type *SEC23B* cDNA at the endogenous locus in hematopoietic stem and progenitor cells (HSPCs). First, we designed and tested different sgRNAs targeting the initial sequence of the *SEC23B* locus in human HSPCs. We selected the most active sgRNAs and performed GUIDE-Seq analysis to assess their off-target potential. A sgRNA showed only 0.8% off-target events. Then, we performed CAST-Seq analysis for this sgRNA to reinforce its safety profile. A low chromosomal aberration frequency, with most of the translocation events in less than 0.01% of alleles, was detected with this sgRNA in human HSPCs. Based on the target sequence of this sgRNA we designed two rAAV-based knock-in donors to insert the wild-type SEC23B cDN or a turbo GFP (tGFP) cDNA, together with a splicing acceptor signal and the bovine growth hormone polyadenylation (bGH polyA), into the sgRNA genomic target sequence to express the exogenous cDNAs under the control of the *SEC23B* promoter. We nucleofected the sgRNA and transduced healthy HSPCs with the rAAV knock-in donors. We detected up to 70% edited cells with wild-type SEC23B cDNA and up to 80% HSPCs expressing tGFP. We confirmed the expression of wild-type SEC23B-bGH-polyA mRNA in HSPCs gene-edited with the wild-type SEC23B donor by RT-PCR assay. This result showed the correct expression of the exogenous *SEC23B* cDNA by the endogenous SEC23B promoter. Furthermore, to evaluate the erythroid potential of our gene editing strategy, we performed an *in vitro* erythroid differentiation in healthy donors HSPCs. We observed that the editing with SEC23B cDNA did not alter the erythroid differentiation phenotype of the healthy donor cells. However, the editing with the tGFP cDNA caused the reduction of SEC23B protein and hampered erythroid differentiation *in vitro*, indicating the disruption of the *SEC23B* gene. In summary, we have established a gene editing approach for SEC23B deficiency, which might be used as potential gene therapy for CDAII.

1201. Development of Evolutionarily Conserved Viral Integration Sites as Safe Harbors for Human Gene Therapy

Marco Antonio Quezada-Ramirez

Gene Therapy Center, UMASS Medical School, Worcester, MA

Gene transfer into CD34$^+$ hematopoietic stem and progenitor cells (HSPCs) involving integrating viral vectors has unpredictable outcomes including adverse events like leukemogenesis. Therefore, identifying and characterizing genome safe harbor (GSH) sites where exogenous gene material can be safely integrated is critically important for therapeutic gene addition in hematological diseases. To date, few GSHs have been characterized and applied in preclinical HSPCs-gene addition studies (*AAVS1*, *hROSA26*, and *CCR5* loci). Thus, to extend the options for gene knock-ins while reducing the risks of insertional mutagenesis, we use a novel approach to identify GSHs based on a proven system of stable transgene insertion: the evolutionarily conserved integration of parvovirus DNA into the genome of host species. From a dataset of 199 unique endogenous parvovirus (EPV) integration events bioinformatically identified in vertebrate species, 102 loci were mapped to the human genome, and 17 were experimentally evaluated as GSHs in primary CD34$^+$ HSPCs from the bone marrow of adult healthy donors. Targeting each candidate GSH was performed through electroporation with Cas9:gRNA complex and ssDNA templates to insert an eGFP expressing cassette, or by combining Cas9:gRNA nucleofection with rAAV6 transduction delivering the same expression transgene. Following this approach at least nine promising GSHs for blood disorder therapies were identified. Similar to the reference locus *AAVS1* (an EPV-derived site), little effect on cell viability was observed after gene addition while maintaining the multipotency and persistent transgene expression. Of the nine GSHs, six targeted loci displayed widespread expression in both erythroid and immune phenotypes while three clearly exhibited immune branch specific-regulation after the differentiation of edited cells. Remarkably, transcriptional disturbances were minimal when targeting intergenic located GSHs and no evidence of malignant transformation was observed through RNAseq. According to these results, additional GSHs are likely to emerge from the remaining mapped loci. Furthermore, since it is unlikely that the lineage restricted transgene expression from some GSHs is exclusive to hematopoietic cells, other tissue-specific GSH sites are likely to emerge. Thus, our approach extends the available locations for gene knock-ins while reducing the risks of insertional mutagenesis, unpredictable transgene expression profiles, effects on differentiation, and increasing the therapeutic effects. This approach is also intended to allow the multiplex editing of primary cells in order to increase the traits carried by edited cells aside the therapeutic transgene, such as selective resistance of modified cells or tracking phenotypes for animal studies.



Thursday Posters: Gene Targeting and Gene Correction New Technologies

1202. Peptide-Assisted Tethering of DNA Repair Effectors to Cas9 for Precise Genome Editing

Sibtain Haider[1], Ali Faiq[1], Toni Cathomen[2], Claudio Mussolino[2]

[1]Institute for Gene Therapy, Freiburg, Germany,[2]Medical Center - University of Freiburg, Freiburg, Germany

CRISPR-Cas9 has emerged as a versatile gene editing tool in the field of cell and gene therapy. Its ability to induce dsDNA breaks can be exploited to revert a disease-causing mutation via the homology-directed repair (HDR) pathway. However, such strategies suffer from the intrinsically low frequency of HDR compared to the alternative non-homologous end-joining (NHEJ) repair pathway at target site. Efforts to enhance HDR efficiency include the use of drugs, that inhibit NHEJ, or the development of Cas9 fusion proteins, that alter the normal resolution of the Cas9-induced DNA break to eventually favour HDR. While promising, the efficacy of these approaches varies greatly across cell types, possibly related to different expression profiles of DNA repair factors. To address cell type specificity, we introduce an innovative CRISPR Cas9 strategy designed to exploit the dimerization capability of synthetic peptides. The proposed CRISPR Peptide Assisted Localization (PAL) system comprises two essential elements: 1) a Cas9 nuclease fused to a small synthetic peptide and 2) a library of DNA repair effectors fused to a complementary peptide. Here, we demonstrate how CRISPR-PAL can be used to identify the most effective combination of effectors tailored to a particular cell type. Distinct nuclease and effector combinations resulted in up to a 2.5-fold increase in HDR events compared to unmodified Cas9 across diverse cell types. Furthermore, the dimerization capability of CRISPR-PAL system enabled the use of novel combinations that were unamenable through mere overexpression of effectors. Our findings highlight the versatility of this system that can be optimized to maximize precision editing across wide range of cell types. Ongoing experiments explore the efficacy of the CRISPR-PAL system in correcting Fanconi Anemia (FA) specific mutations by enriching the missing effectors at target site in patient-derived cells. We anticipate that the CRISPR-PAL approach will prove instrumental in the development of more effective, tailored genome editing solutions with broad therapeutic applications.

1203. Decoding Rhodopsin Gene Regulation to Build Innovative Retinal Gene Therapies

Rosa Maritato, Emanuela D'Andretta, Alessia Medugno, Enrico Maria Surace

Department of Translational Medical Sciences (DiSMeT), Univesity of Naples "Federico II", Napoli, Italy

Rhodopsin-Autosomal Dominant Retinitis Pigmentosa (RHO-ADRP) is a progressive photoreceptor degenerative condition leading to irreversible vision loss. In our efforts to develop a treatment for RHO-ADRP, we successfully established a robust proof of principle for gene therapy using Adeno-associated virus (AAV) vectors, combining gene silencing and gene replacement strategies. This innovative approach involves the incorporation of two expression cassettes in a single AAV vector. The silencing step employs an unconventional transcriptional repression system, by using DNA-binding domain (DBD) (ZF6) which operates without repressor domains. Through the sole binding of ZF6 to short and accessible DNA Cis Regulatory Element (CRE), which is unbound from endogenous transcriptional modulators, we achieved effective RHO gene silencing at low doses with minimal off-target effects and limited engagement with cellular systems. Building on this success, we conducted a comprehensive exploration of this CRE consisting of CRX and NRL DNA binding sites with a 22bp (linker) sequence interposed, bound by ZF6. We named this complex Rho regulatory unit RRU (CRE-RRU). Manipulation of factors such as orientation, order, spacing, and sequence composition of this RRU (CRE-RRU syntax) demonstrated a broad spectrum of modulation in transcriptional outputs. In conclusion, by deciphering the gene regulatory code inherent in these CREs, we achieved a controlled expression of silencing and replacement transgenes. Importantly, this control mechanism remained effective across a wide range of vector doses, ensuring a safer and more efficacious gene therapy for RHO-ADRP.

1204. Targeting the Sense and Antisense Pathogenic C9ORF72 Transcripts as Therapy for C9ORF72 ALS

Vanessa Zancanella[1], Kristel van Rooijen[2], Ines Lopes Pereira[2], Cynthia Brouwers[2], Noortje Heidinga[2], Soraya Smit[2], Warner Hoornenborg[2], Rhode Erbrink[2], Irena Bockaj[2], Greg Dobrynin[2], Jovana Kovacevic[2], Morgane Wartel[2], Stijn Waaijer[2], Tycho Hoogland[2], Mercedes Valls Seron[2], Melvin M. Evers[2], Ying Poi Liu[2]

[1]UniQure biopharma B.V., Amsterdam, Netherlands,[2]uniQure biopharma B.V., Amsterdam, Netherlands

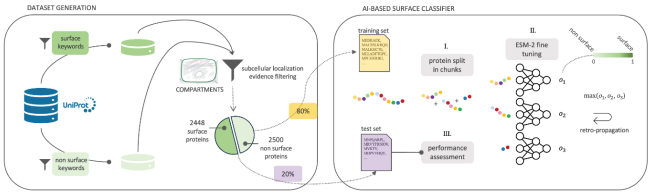
Amyotrophic lateral sclerosis (ALS) is a devastating and fatal neurodegenerative disorder affecting the upper and lower motor neurons in the brain and corticospinal tract leading to muscle atrophy, paralysis and eventually death. The most frequent genetic cause of familial ALS is a hexanucleotide GGGGCC repeat expansion in the C9orf72 gene. These expanded repeats are bidirectionally transcribed into repeat containing transcripts, which forms sense and antisense RNA foci. These repeat containing transcripts can also be translated in a non-ATG dependent manner into different dipeptide repeat proteins. Both the RNA foci and dipeptide repeats (DPRs) proteins contribute to disease by acquiring toxic properties. Using our novel linQURE™ technology, we developed an AAV gene silencing strategy based on concatenation of 2 miQURE®-based microRNAs to silence both the sense and antisense repeat containing transcripts (V1 and V3). This approach used our learnings from our previously reported sense C9ORF72-targeting miQURE® expression and target engagement in ALS mouse models where we demonstrated a sustained and dose-dependent effect. These second generation linQURE™ constructs are designed to specifically target the toxic transcripts to prevent the formation of RNA foci and DPRs, while preserving healthy C9ORF72 levels. After careful optimization of linQURE™ and characterization and selection of the most potent synthetic miQURE® combinations, we have shown expression of the novel linQURE™ miRNAs for targeting both sense and antisense repeat containing C9orf72 transcripts. Further investigation of AAV-linQURE™ is under way to show efficacy, tolerability, and safety in larger animals. miQURE is a registered trademark in the US and other jurisdictions. linQURE is a trademark pending in several jurisdictions.

1205. The Efficacy of AAV-Mediated Genome Editing, and Undesired Vector Integrations Are Influenced by R-Loops Formation

Francesco Puzzo[1], Madzia Crossley[2], Aranyak Goswami[1], Katja Pekrun[3], Feijie Zhang[1], Karlene Cimprich[2], Mark A. Kay[1]

[1]Pediatrics and Genetics, Stanford University School of Medicine, Stanford, CA,[2]Chemical and Systems Biology, Stanford University School of Medicine, Stanford, CA,[3]Pediatrics and Genetics, Stanford University, Stanford, CA

AAV vectors have been reported to stimulate homologous recombination (AAV-HR). Moreover, they can randomly integrate into numerous regions throughout the genome.Our lab previously demonstrated that the use of a promoterless AAV vector with host genomic homology arms, flanking a therapeutic coding sequence, could induce homologous recombination in mouse liver. While this approach achieved therapeutic efficacy in some animal models, the percentage of edited cells remains low (~ 1.0%). To enhance the efficiency of AAV-HR, we performed a genetic screen (deAlencastro et al., 2021) that led us to identify the Fanconi Anemia complementation group M (FANCM) as one of the major determinants influencing the AAV-HR. FANCM is among the helicases required to resolve DNA/RNA hybrids, also known as r-loops, that can occur when an RNA filament anneals to a single strand DNA. R-loops form primarily during DNA transcription, and if not tightly regulated may trigger the cellular DNA damage response and induce unscheduled DNA breakage. However, these hybrids are resolved by specific helicases or also enzymes belonging to the RNase H family which degrade the RNA strand of the DNA/RNA hybrid. Here, by inhibiting two enzymes, FANCM and SRSF1, involved in r-loop dissolution we demonstrated a significant improvement of AAV-HR in vitro. In addition, the use of a small molecule (topotecan) increased the formation of r-loop levels in a murine hepatoma cell line (HEPA1-6) and mouse liver. Interestingly, treatment with topotecan resulted in a significant improvement of AAV-HR, 8-fold and 2.5-fold in HEPA1-6 and liver respectively. We showed the mechanism underling the enhancement of AAV-HR efficiency was indeed due to r-loop formation as co-treatment with RNAseH1 resulted in a 1.5-fold decrease in AAV-HR. Furthermore, we mapped and quantified r-loops throughout the genome. To this end, we performed DNA/RNA immune precipitation sequencing (DRIP-seq) experiments in HEPA1-6 and mouse liver. To our knowledge, this is the first genome-wide r-loop map of an intact tissue. Particularly, we detected a remarkable r-loops levels in the region of the *Albumin* region (exons 12-14) where we designed homology targeting arms (Barzel et al. Nature 2015). Conversely, we did not observe any integration when targeting a different *Albumin* region with low r-loops levels. In addition to enhanced AAV-HR, our data suggest that genomic regions enriched for r-loops may represent hotspots for "random" AAV integration. Indeed, recent studies showed AAV vector integrated in genes with relatively high level of r-loops upon liver gene transfer. Bioinformatic analyses are ongoing in order to identify prospective genomic features that might further explain the interplay between vector integration and r-loops. These findings may shed light on processes that could improve the efficacy of genome editing and possibly enhance our ability to predict regions most susceptible to insertional mutagenesis with therapeutic viral vectors.



1206. An Adapted Protein Language Model for Cell Surface Protein Identification in Genomic Therapies

Chloé Canavate, Lélia Polit, Oscar de Felice, Dina Zielinski, Julien Cottineau, David Del Bourgo

WhiteLab Genomics, Paris, France

Genomic therapies hold great promise for providing a durable cure for untreatable diseases but require precise targeting of the affected tissue or cells. Advances in target specificity, for example by designing binders through rational or guided strategies [1] have led to improved efficacy. However, experimental validation is prohibitively expensive. Thus, identifying specific cell surface receptors is a crucial step to increase the transduction of target cells. It aims at enhancing efficacy, reducing immunogenicity, and avoiding the transduction of certain

tissues to reduce off-target effects. We aimed at accelerating research and development of vectors for gene therapies with a rationally guided approach by optimizing the identification of target-specific receptors to limit the number of potential candidates and reduce associated costs. To this end, we developed a deep learning method that predicts whether a protein is at the cell surface or not, based only on its amino acid sequence and can be applied to any protein, regardless of length. Numerous *surfaceomes*, databases of proteins located at the cell surface, have been documented in the literature, including experimental approaches [2], *in silico* methods [3] and combined. Current approaches are based on several pre-computed features [3] or predict other topological domains rather than surface proteins. However, a reliable gold standard is currently lacking, and each of these databases represents a finite set which is a strong limitation to scale these approaches. Here, we employ a comprehensive approach integrating biological context, a highly curated training dataset, and advanced deep learning methodologies without the need for feature selection, which can limit model generalizability.

To construct an appropriate dataset, we leveraged UniProt, by identifying keywords associated with either cell surface proteins or non-cell surface proteins which were then cross-checked in datasets with high confidence subcellular localization data from COMPARTMENTS. This resource integration enhances the reliability of our selection, limited to proteins with well-established surface or non-surface localization, which is the basis for developing a well-performing and generalizable model. The backbone of our deep learning approach consists of protein language models based on the amino acid sequence as input. These models have been adapted to accommodate proteins of variable length, enhancing their versatility in capturing intricate sequence patterns. Through fine-tuning, we adapted the models to our classification task of discerning between surface and non-surface proteins. This adaptation leverages the inherent features of protein sequences, enhancing the models' discriminatory capabilities for more specific applications in genomic therapies. The final ensemble model is composed of 100 ESM-2 learners, obtained via cross-validation and hyperparameter search. The model is able to discriminate between surface and non-surface proteins with an accuracy of 84% on the internal test set requiring only the protein sequence as input. This work contributes to the ongoing development of targeted therapies, by accelerating and de-risking their development, with potential implications in the discovery of candidate receptors for advanced therapeutics. [1] Pupo A et al, *Mol Ther*. 2022. [2] Bausch-Fluck D et al, *PLoS One*. 2015. [3] Bausch-Fluck D et al, 2018

1207. Isolation of AAV-Derived Inverted Repeats for Enhanced Gene Editing

Naveen Vridhachalam[1,2], Brian Golitz[3,4], Matthew L. Hirsch[1,2]

[1]Gene Therapy Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Department of Ophthalmology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]University of North Carolina School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC

Previous studies have shown that a DNA double strand break (DSB) at or near a chromosomal target site enhances homologous recombination (HR) mediated genome editing. As such, designer endonucleases that recognize specific DNA sequences and generate a DSB at a site of interest have rose in popularity, however, concerns exist for in vivo therapeutic applications including the immune response to foreign epitopes and off-target mutagenic activity. A reported alternative to site-specific endonucleases are proximal inverted repeats (IRs), structured DNA elements processed to DSBs via endogenous DNA repair. To date, the influence of IRs engrafted on the DNA repair molecule have not been well characterized in a gene editing context. The hypothesis of this work is that DSBs and/or inverted repeats on the repair template will enhance gene editing towards the objective of adeno-associated virus (AAV) recombinant genomes enhanced for homology directed repair. In this work, the effect of a nuclease-induced DSB or adeno-associated virus (AAV) derived inverted repeats located on a repair plasmid was investigated for chromosomal gene editing in human embryonic kidney cells. The results demonstrate that, in conjunction with a DSB at the chromosomal target site, inducing a DSB on the repair molecule significantly increased the gene editing frequency. Consistent with reports that IRs are processed to DSBs, the presence of the AAV serotype 2 ITR sequence on a repair plasmid significantly increased chromosomal gene editing compared to a no structure control. Deletion analysis of the AAV IR identified the viral origin of replication as necessary for optimal gene editing and putative stem length was directly correlated to HR. Next, a truncated AAV IR enhanced for editing was randomly mutated in a manner that conserved sequences necessary for vector production thereby generating a mutant ITR library of $>10^6$ diversity. High throughput screening of individual mutant ITRs in a gene editing selection identified AAV IR sequences decreased and enhanced for gene editing compared to the library parent and the wt AAV IR sequence. Consistent with the AAV ITR2 deletion analysis, the recovered mutant IR most enhanced for editing contained mutations in the AAV origin of replication. Currently, bioinformatic analyses correlating sequence/structure to chromosomal repair efficiencies and AAV vector production are in progress. Together, these results demonstrate that a DSB or viral IR sequences on the repair molecule stimulate gene editing and offer mechanistic insights into the generation of AAV viral vectors that mediate high efficiency genetic engineering in the absence of a site-specific endonuclease.

1208. Aldevron's Nanoplasmid™: Big Benefits in a Small Package

Jeremy Luke[1], Tyler Kozisek[1], Jason Devlin[1], Patrick Alfredo Paez[1], Denis Arutyunov[1], Aaron Carnes[2], James Williams[1], Seshidhar Reddy Police[3], Venkata Indurthi[1]

[1]Aldevron, Fargo, ND,[2]Aldevron, Lincoln, NE,[3]Aldevron, Boston, MA

Aldevron's Nanoplasmid™ vector backbone (<500 bp) is a replacement for a previous generation of *Escherichia coli* plasmid backbones that improves manufacturing workflows, safety, and performance of gene and cell therapeutics. Nanoplasmid vectors do not include antibiotic resistance markers, which improves safety compared to plasmids or minicircles that rely on antibiotic resistance for bacterial selection during the manufacturing process. Nanoplasmid vectors contain a 70 bp RNA-OUT antisense RNA cassette that confers sucrose resistance to the host cells by suppressing the mRNA translation of sucrose toxicity gene *sacB*. This allows antibiotic-free plasmid selection in sucrose-containing media. Nanoplasmid vectors also contain a small (300 bp) specialized bacterial R6K replication origin in place of the traditional pUC replication origin and can only replicate within the specialized *E. coli* host strains. The latter feature makes the risk of horizontal gene transfer by the Nanoplasmid vectors significantly lower than that of traditional systems. An alternative R6K replication origin-based Nanoplasmid vector backbone also dramatically improves fermentation yields of the clinically important vectors, namely adeno-associated virus (AAV) gene therapy vectors and mRNA vaccine vectors, which are known to have several challenges from a manufacturing standpoint. Namely, AAV transfer plasmids contain highly structured palindromic Inverted Terminal Repeats (ITRs), flanking the 'payload' transcription unit. These ITR repeats, which contain a viral replication origin and viral packaging signals, are unstable and difficult to replicate in *E. coli*, creating challenges for AAV transfer plasmid manufacture. On the other hand, mRNA vaccines are manufactured from poly (A) tail-repeat containing template plasmid vectors that contain an antigen gene upstream of a poly (A) tail repeat. Similarly to ITR repeats, the long (80-120 bp) polyA repeats are prone to deletions, and mRNA vaccine vectors are often low-yielding in *E. coli*. These challenges appear to be due to the traditional backbone pUC replication origin having difficulty replicating closely positioned structured DNA sequences. Nanoplasmid vector backbones can be easily retrofitted into the existing clinically proven AAV transfer vectors or mRNA vaccine vectors to replace the pUC origin with the R6K origin and an antibiotic resistance marker with an RNA-OUT cassette while not changing the sequence of the vector payload. In addition, the Nanoplasmid vector host strains were engineered to produce R6K replication protein, which initiates replication from the R6K origin, which drives high-yield fermentation (>1 g/L pDNA) of Nanoplasmid vectors in the Aldevron HyperGRO™ fermentation process. The next generation REVIVER™ host strain supports the propagation of R6K origin-based Nanoplasmid vector backbones while increasing the yield and replication stability of structured DNA sequences even further. REVIVER strain shows higher fermentation productivity compared to the standard recombination deficient hosts such as SURE, Stbl3™, or, Stbl4™ where multiple mutations characterizing these strains lead to very poor biomass and vector yields in the large-scale fermentation required for the production of vectors for clinical and commercial applications.

1209. Novel CRISPR Effectors and Reverse Transcriptases Discovered from Metagenomics Enable Extensive Remodeling of the Human Genome

Morayma M. Temoche-Diaz[1], Leanna R. Monteleone[1], Rebecca C. Lamothe[1], Sourab Kulkarni[1], Sarah M. Laperriere[1], Anu Thomas[1], Kaitlyn Tsai[1], Whitney Krey[1], Shailaja Chadha[1], Lisa M. Alexander[1], Hannah T. Engel[1], Keirstinne Turcios[1], Ketaki D. Belsare[1], Margaret Hackney[1], Jennifer S. Oki-O'Connell[1], Steve J. Flammer[1], Jerry Hung-Hao Lo[1], Chloe O. McCollum[1], Dominic T. Castanzo[1], Owen Perot Janson[1], Catalina Alonso-Martinez[1], Steffen Durinck[1], Cristina N. Butterfield[1], Cindy J. Castelle[1], Daniela S. A. Goltsman[1], Megan van Overbeek[1], Alan R. Brooks[1], Brian C. Thomas[1], Christopher T. Brown[2]

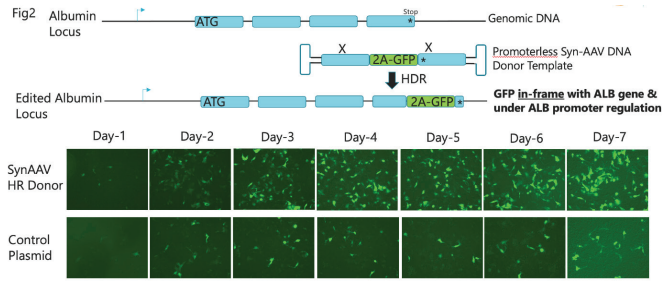
[1]Metagenomi, Inc., Emeryville, CA,[2]Metagenomi, Emeryville, CA

CRISPR is revolutionizing biotechnology and human therapeutic development. Multiple clinical trials have been conducted for therapeutics created using CRISPR nucleases, and recently the first approval has been granted by the United States Food and Drug Administration. Despite significant advances, many diseases are not yet treatable owing to a need for additional specific and efficient gene editing systems, including those that are capable of introducing complex edits. In vivo gene editing has the potential to cure patients by leveraging existing, safe RNA delivery technology. Such diseases include transthyretin amyloidosis, hemophilia, Wilson's disease and alpha-1 antitrypsin deficiency. Here, we demonstrate the ability of a novel gene editing platform for therapeutically-relevant knock-out, correction, and large gene insertion using all-RNA delivery. This was accomplished by mining the natural environment for novel programmable CRISPR systems as well as reverse transcriptases (RTs) for converting editing templates delivered as RNA into DNA. We identified a novel CRISPR nuclease capable of efficient genome editing and validated therapeutically-relevant guides in vivo in a mouse study using lipid nanoparticles (LNP) for delivery. No off-targets could be identified for top-performing guides based on an unbiased cell-based assay, further establishing the utility of this system for therapeutic applications. Given the in vivo translation, efficiency, and specificity of this CRISPR nuclease, we used the system in conjunction with novel RTs to accomplish prime editing as well as large, targeted integrations. Millions of RTs were characterized to identify candidates capable of accomplishing either small replacements or large integrations. Novel RTs showed improvements in prime editing efficiency and specificity, compared with industry-standard controls across diverse and therapeutically relevant edits and cell types. Furthermore, we believe we are the first to demonstrate programmable large integration of up to 1 kb into the genome of human cells using a system delivered entirely as RNA. Taken together, this flexible platform, which we refer to as RIGS (RNA-mediated integration systems), is compatible with readily available LNP delivery systems and has the potential to cure numerous diseases through in vivo genome editing.

1210. Synthetic AAV DNA Mediates High-Efficiency Homology-Directed Genome Editing

Christopher Luis Chavez
Visgenx, Santa Cruz, CA

AAV-based genome editing offers a promising alternative to CRISPR methods due to its enhanced safety profile and precision. Unlike CRISPR, AAV vectors integrate genetic material into the host genome in a more controlled manner, reducing the risk of off-target effects and unintended mutations. However, AAV-based genome editing is very inefficient, often reported below 0.1%. To overcome this limitation in efficiency, a synthetic AAV DNA system has been developed. Synthetic AAV DNA is a single-component, completely synthetic alternative to CRISPR/Cas9 or AAV-based genome editing tools that takes advantage of many of the inherent properties and versatility of AAV-based genome editing while bypassing its limitations (low editing efficiencies and manufacturing costs). In addition, synthetic AAV DNA is not bound to the payload size limitations of a standard AAV system, allowing for targeting of previously untreatable genetic diseases. Synthetic AAV DNA is produced utilizing enzymes in a cell-free system and results in a linear closed-ended double-stranded DNA molecule with full AAV ITRs at each end (Fig1). Genome editing with the synthetic AAV DNA does not require exogenous proteins or guide RNAs for editing and does not induce double strand breaks in genomic DNA. This eliminates on-target cutting of unedited alleles and off-target cutting effects resulting in unintended mutations. Genome editing is directed to the target sequence by homology arms matching the target sequence within the synthetic AAV DNA sequence. *In vitro* experiments utilizing a P2A-GFP synthetic AAV targeting the highly expressed ALB locus in HepG2 cells have consistently demonstrated GFP gene addition efficiencies between 40-50%. By placing GFP in-frame with the ALB gene, GFP expression is controlled by native ALB gene regulatory elements (Fig2). Gene addition in this manner demonstrates the potential applications for treating hemophilia for Factor VIII or Factor IX deficiencies. The synthetic AAV DNA system can also be used to repair point mutations and deletions. A synthetic AAV was designed to target and swap a TA pair to an AT pair at the AAVS1 locus. This substitution removes an NheI site and allows for editing efficiency to be visualized by restriction analysis. Editing rates at the AAVS1 locus in HeLa cells are currently ~30% for this two base-pair swap. Base substitutions of this manner have potential to repair point mutations like those responsible for sickle cell disease. Junctional analysis for both the GFP gene addition and the two-base substitution, reveal seamless editing with no inclusion of AAV ITR sequences detected. The synthetic AAV DNA system can also be used as a gene therapy vector to express genes over 4.7 kb in size. An example synthetic AAV ABCA4 (6.8 kb) expression vector was assembled to show this feature of the system. An ABCA4 synthetic AAV could be used to treat Stargardt's disease. Other oversized synthetic AAV DNA vectors have potential to treat diseases such as Usher's (16.6 kb) and DMD (11.1 kb). A suitable delivery system will be needed to deliver the synthetic AAV system to the appropriate target tissues.



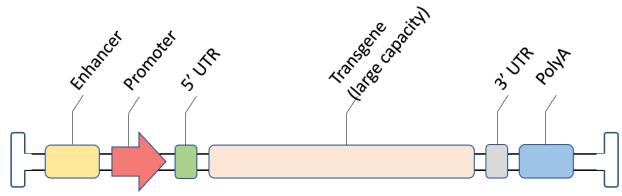


Figure 1

1211. Synthetic, Enzymatically Produced DNA and Non-Viral Delivery Systems for Gene Editing Applications

Amine Bouchareb, Samantha Mnkandla, Ana-Vanina Hangu, Anca-Paula Ristin, Tejaswini Mahadeva, Elena Dyankova, Amy Walker
4basebio, Cambridge, United Kingdom

The manufacture of high-quality, GMP grade DNA is a major bottleneck in the production of mRNA, and DNA templates used in gene editing applications. In addition to worldwide lack of capacity and long lead times, complex sequences or long polyA tails are difficult to propagate in bacteria. 4basebio has developed a proprietary, scalable, fast and fully enzymatic synthesis process for the production of linear DNA constructs. The process is size and sequence independent. Unlike plasmid DNA, 4basebio DNA eliminates contamination from endotoxins or host proteins. Hermes™, 4basebio's proprietary non-viral delivery system, is a nanoparticle vector that can encapsulate a range of payloads, including synthetic DNA, mRNA, RNP complexes, or a combination thereof, and can be customised to target cells or tissues of interest. The particles additionally offer long term stability at 4°C, overcoming cold chain requirements. Here, we present the combination of synthetic DNA and Hermes™ nanoparticles to integrate a GFP template. Furthermore, synthetic opDNA™ was used for the production of Cas9 mRNA. High template integration efficiencies and high cell viability were observed across a range of cell types. Importantly, a reduced DNA template size, owing to a lack of bacterial backbone, allows for a copy number advantage over plasmid DNA, facilitating reduced DNA doses and improved toxicity profiles. 4basebio's double-stranded and single-stranded DNA offerings enable superior editing efficiencies in cells. In combination with the Hermes™ nanoparticle delivery platform, 4basebio offers an alternative to viral vectors and a promise to advance non-viral gene editing therapies both *ex-vivo* and *in-vivo*.

1212. Comprehensive Genomic Profiling of Human CD19 CAR T-cells Engineered with a Mammalian Transposon

Alisa O. Vershinina[1], Geneva Young[1], Francisco Navarro[1], Joshua LaMora[1], Rebecca Panitch[2], Hugues Bernard[1], Argus Athanas[2], Shanfu Xie[1], Joseph J. Higgins[1], Oleg Iartchouk[1]

[1]SalioGen Therapeutics, Lexington, MA,[2]Watershed Informatics, Cambridge, MA

Introduction: Existing gene therapy modalities cause unintended off-target events (e.g. chromothripsis, random insertions, deletions, chromosomal rearrangements) that increase the risk for oncogenesis and mutagenesis. To overcome these safety concerns and limitations in payload size, we engineered the only active mammalian transposable element (TE) derived from bioengineered *Myotis lucifugus* (*bMLT*) with the ability to target specific octanucleotide sites in the human genome and deliver large payloads by a mechanism referred to as Gene Coding technology. **Methods:** Primary T-cells from three human donors were electroporated with an engineered *bMLT* mRNA and a *CD19 CAR* plasmid DNA element (modified group), the *CD19 CAR* DNA element alone (control group) or were left untreated (unmodified group). *CD19 CAR* expression and copy number were measured by FACS and ddPCR in all T-cell groups. Efficacy studies were conducted in Nalm6 xenografted NSG™ immunodeficient mice. To assess the genomic safety profile, we applied chromosomal analyses, targeted NGS (Illumina), and hybrid capture long-read third generation sequencing (PacBio) to compare the profiles of modified CD19 CAR-T cell lines (n=3) to the unmodified group (n=6). To investigate structural alterations, we conducted genomic hybridization screening (KromaTiD), optical genome mapping (Bionano), and G-banding of metaphase chromosomes. We tested CD19 CAR-T cells by in-solution hybridization capture utilizing 7,816 oligonucleotide probes. The probes spanned 800 kb across 127 genes, which are associated with 12 tumor tissue types (IDT). **Results:** Modified CD19 CAR-T cells showed expression levels up to 62%, an average of 5.62 vector copies/cell, and persistent tumor suppression in xenografted mice treated for up to 70 days. About 80% of integration sites were within intergenic and intronic regions on one allele with the majority (>98%) at specific octanucleotide motifs. Long read sequencing showed no detectable structural variants in the human genome within 3 kb of the integration sites. Further analysis showed normal 46, XX female karyotypes in modified and unmodified T-cells without evidence of chromosome loss, chromothripsis, rearrangements, or activation of oncogenes. Across the three donor cell populations, we identified 68 low-to-high frequency somatic variants of which 15 were small non-pathogenic indels not reported in ClinVar. Out of 53 single nucleotide polymorphisms (SNPs), we discovered 16 novel and 37 previously reported variants. The SNPs overlapped with 63 genes, 432 transcripts, and 15 regulatory features. Most of the SNPs were in regulatory regions with 39% downstream or upstream of genes, and 18% in 3' UTRs. The remainder resulted in transcriptional modifications with 70% of variants leading to synonymous and 30% to missense changes. We identified copy number variation (CN) in 25 genes. These SNP and CN genomic variations were present in unmodified and modified samples with no increase in mutational burden attributable to modifying T-cells by Gene Coding. **Conclusions:** We performed comprehensive genomic profiling of primary human T-cells modified by a *bMLT* TE using Gene Coding technology to generate *CD19 CAR*. These human T-cells delivered therapeutic levels of *CD19 CAR* expression without exacerbating the risk of oncogenic mutations, cancer-associated somatic mutations or increasing the mutational burden. These findings suggest that Gene Coding technology may provide an avenue for therapeutic DNA insertion that overcomes many common safety concerns with current gene therapies.

1213. Space Health Innovations: Using Gene Therapy to Induce Metabolic Torpor in Human Organoids

Jonathan Diaz[1], Ritu Ramamurthy[1], Caleb Heathershaw[1], Gemma Nomdedeu-Sancho[1], Olivia Latham[1], Jacolby Roddey[1], Frido Welker[2], Jorsua Bethencourt[2], Antonis Bartsiokas[3], Vijay Gorantla[1], Tom Shupe[1], Alan Jacobson[1], Paul F. Wilson[4], Joshua T. Maxwell[1], Anthony Atala[1], Graça Almeida-Porada[1], Christopher D. Porada[1]

[1]Wake Forest University School of Medicine, Wake Forest Institute for Regenerative Medicine, Winston Salem, NC,[2]Globe Institute, University of Copenhagen, Denmark,[3]Democritus University of Thrace, Komotini, Greece,[4]Pacific Northwest National Laboratory, Richland, WA

To ensure astronaut health on long-duration space missions, it is necessary to identify means of protecting astronauts from the unique environmental (microgravity, space radiation) and psychological (isolation, distance) stressors, which can profoundly impair multiple tissues/organs. Torpor induction could significantly mitigate these stressors and reduce resource consumption and waste production during extended space missions. The ability to induce metabolic depression/ torpor also has the potential to transform medicine on Earth. Our research adopts an innovative approach, utilizing gene therapy to induce metabolic torpor in human organoids. At the center of our approach are two key tools: 'omics data from the extinct S.H. hominins, who appear to have hibernated, and the FOXO1A gene, which plays a vital role in regulating metabolism, stress resistance, and cell longevity. We hypothesized that these 'omics data (when compared to closely related non-hibernating hominins, and the FOXO1A gene network could serve as blueprints of pathways that can be leveraged to induce metabolic torpor in modern humans. We developed a lentiviral vector system that integrates a cumate switch to precisely control expression of FOXO1A (and ultimately genes identified as unique to the S.H. hominins) linked to a GFP reporter for real-time tracking of gene expression. This system (with FOXO1A) is currently being tested in human liver, cardiac, and trabecular bone organoids to explore gene therapy's potential for modulating metabolic rate and inducing a state of torpor. Experiments to-date in liver organoids using a battery of viability, functionality, and metabolic assays have revealed that 5'-AMP plays a critical function in safely maintaining hypometabolic states, particularly under stress conditions. This parallels its role in hibernating animals, where it helps reduce metabolic rates and conserve energy - a mechanism we aim to exploit to induce torpor in modern human tissues. Cardiac organoids exposed to decreasing glucose exhibited a clear threshold of reduced contractility and altered calcium transients, providing valuable baselines for metabolic management in

space and terrestrial medical scenarios, using FOXO1A and/or gene pathways identified in S.H. hominins. The implications of our research are broad and multifaceted. In space medicine, the ability to induce hypometabolism in human tissues could revolutionize how astronauts' health is managed. Looking beyond space exploration, the potential terrestrial applications of this technology are equally groundbreaking. This includes the potential to revolutionize treatment paradigms for metabolic disorders, enhance strategies in critical care, and improve outcomes in scenarios such as organ transplantation and trauma care. Our studies thus mark an advancement in the fields of gene therapy, space health, and regenerative medicine. While our findings are currently in preliminary stages, they establish a robust foundation for future investigations, they underscore the pivotal connection between space exploration and advancements in global healthcare, and they may ultimately pave the way for a future where the boundaries of human resilience and medical innovation are continually expanded.

1214. L-PGI: A DNA Ligase Mediated Gene Editing System for Versatile and Precise Genomic Integration

Jenny Xie[1], Angela Nan[1], Chris Bartolome[1], Sandeep Kumar[1], Shakked Halperin[2], Michael Chickering[2], Parbir Grewal[2], Leonard Chavez[2], Jonathan D. Finn[1]

[1]Tome Biosciences, Inc., Watertown, MA,[2]Replace Therapeutics, LLC, a direct and wholly owned subsidiary of Tome Biosciences, Inc., Watertown, MA

The efficiency of genome modifications using CRISPR nucleases and reverse transcriptase (RT) is limited by RT processivity, template complexity, and intracellular dNTP levels, which can become rate limiting in non-dividing cells and tissues of therapeutic interest. To overcome these challenges, we present Ligase-mediated programmable genomic integration (L-PGI), a CRISPR-guided DNA ligase system for highly precise replacement/integration of a targeted sequence of pre-synthesized DNA containing desired edit. L-PGI uses 5 components: (1) Cas9 nickase, (2) DNA ligase, (3) pre-synthesized DNA donor template that contains the desired edit, (4) splint, and (5) ligase mediated guide RNA (lmgRNA). Once delivered to the cell, Cas9 nickase forms an RNP with the hybridized lmgRNA-splint-donor complex, binds to the genomic target, and nicks the DNA, which releases the genomic flap. The splint acts as a bridge between the lmgRNA, genomic target site, and donor DNA, precisely aligning all of the components in the correct spatial configuration, allowing the DNA ligase to ligate the genomic flap and donor. The ligated donor displaces the endogenous strand and results in incorporation of the edits encoded in the donor into the genome. L-PGI does not induce significant double stranded breaks, is not subject to RT limitations, and is efficient in both dividing and non-dividing cells. The single-step direct integration of pre-synthesized DNA can incorporate a variety of edits from small nucleotide conversions to deletions and insertions up to greater than a hundred base pairs, all with higher efficiency and lower incidence of unintended edits than existing gene editing platforms. Due to its versatility, L-PGI has the potential for broad therapeutics application in the treatment of a variety of genetic diseases, ranging from single mutation correction to whole gene replacement to exon displacement.

1215. Genetic Medicines Have Arrived. How Do We Afford Them?

Manar Zaghlula

UC Berkeley/Innovative Genomics Institute, Berkeley, CA

Eighteen genetic therapies have been approved by the U.S. Food and Drug Administration to date, a number that now includes the first CRISPR genome editing therapy for sickle cell disease, CASGEVY. This extraordinary milestone is widely celebrated because of the promise for future genome editing treatments of previously intractable genetic disorders and cancers. At the same time, such genetic therapies are the most expensive drugs on the market, with list prices exceeding $3 million per patient. Although all approved cell and gene therapies trace their origins to academic institutions, reliance on for-profit pharmaceutical companies for subsequent development and commercialization results in prices that prioritize recouping investments, paying for candidate product failures, and meeting investor and shareholder expectations. To increase affordability and access, sustainable discovery-to-market alternatives are needed that address system-wide deficiencies. Here, we present recommendations of a multi-disciplinary task force assembled to chart such a path. We describe a pricing structure that, once implemented, could reduce per-patient cost at least tenfold and propose a business model that distributes responsibilities while leveraging diverse funding sources. We also outline how academic licensing provisions, manufacturing innovation and supportive regulations can reduce cost and enable broader patient treatment.

Thursday Posters: Oligonucleotide Therapeutics

1216. miX^{on}, a System for Tunable Control of miRNA Expression by Drug-Induced Splicing

Ryan C. Giovenco[1], Alejandro Mas Monteys[2], Ellie Carrell[3], Beverly L. Davidson[3]

[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA,[3]Children's Hospital of Philadelphia, Philadelphia, PA

MicroRNAs (miRNAs) are small noncoding RNAs that modulate gene expression by blocking translation or inducing decay of target mRNAs through complementary base pairing. Mature miRNAs are processed from long primary miRNAs (pri-miRNAs) in a multi-step process in which the RNAseIII endonucleases, Drosha and Dicer, cleave a stable hairpin to generate functional 20-24 bp sequences. Ultimate strand-loading preference into the RNA-induced silencing complex (RISC) is determined by multiple factors, including the identity of the 5' base and low 5' thermodynamic stability within the RNA duplex. Endogenous pri-miRNA scaffolds have been successfully adapted to host artificial miRNAs that, when delivered using adeno-associated viruses (rAAVs), lead to sustained knockdown of disease-related transcripts and protein for therapeutic benefit. Although we previously demonstrated that artificial miRNAs mitigate the toxicity of short hairpin RNAs (shRNAs) (McBride et al. 2008), toxicity remains possible due to unintended silencing (Monteys et al. 2014). Thus, a system to fine-tune miRNA

expression following AAV delivery would be a beneficial addition to the RNA interference (RNAi) toolkit. Previously, we developed X^{on}, a drug-induced splicing switch that controls translation initiation in response to the small molecule LMI070 (Monteys et al. 2021). Here, we modified X^{on} to provide drug-inducible control over miRNA expression, which we present as miX^{on}. The miX^{on} cassette was designed to control the expression of miS1, our well-characterized RNAi sequence targeting human ATXN1. Following modifications to optimize strand biasing and sequence engineering to minimize background splicing, we developed a construct that showed 47% knockdown in a luciferase reporter system in response to LMI070, with no background knockdown in untreated, transfected cells. Moreover, this construct demonstrated reduced silencing efficiency in Drosha knockout cells, supporting miRNA processing by Drosha. Next, we engineered miX^{on} to target an endogenous mRNA, PCSK9. Transfection of a constitutively spliced miX^{on} cassette into HuH-7 cells led to a 22% knockdown of PCSK9. Interestingly, we observed a 12-fold increase in miRNA processing from a canonical miR-30 scaffold compared to our miX^{on} construct, with a 60% knockdown in PCSK9. This disparity between miRNA processing and knockdown could indicate an upper threshold for miRNA silencing by transfection and supports future efforts to optimize strand biasing and scaffold design for robust silencing. Overall, miX^{on} displays significant promise as a novel system for drug-inducible control over miRNA expression.

1217. Analytical Methods and Platforms for circRNA Vector Engineering to Improve Circularization Efficiency

Yali Sun, Anis Khimani, Yanhong Tong, Zhi-xiang Lu
Revvity, Waltham, MA

Background: Circular RNAs (circRNAs) have emerged as pivotal players in RNA medicine. Unlike linear counterparts, circRNAs possess a closed-loop structure, conferring them with enhanced stability and resistance to degradation. This resilience makes them promising candidates for diagnostic and therapeutic applications. The ribozyme-based strategy stands out as the predominant method for synthetic circRNA production. Optimizing the ribozyme backbones for enhanced RNA circularization is a critical aspect of upstream process development. This highlights the essential need for analytical solutions to precisely measure circularization efficiency. **Method:** T4 phage and Anabaena permuted intron-exon (PIE) were used as ribozyme backbones. Revvity RNA Pico reagent (Part#: CLS960012), and DNA 5K/RNA/CZE HT LabChip (Part#:760435) were used on LabChip® GX Touch™ (Part# CLS138160) for fragment analysis. Revvity Respiratory SARS-CoV-2 RT-PCR Panel 1 reagent kit (Part# SDX-56390) was used for reverse transcription and real-time PCR analysis (***Figure 1***). **Result and Conclusion:** We characterized peaks from circRNA processing samples in Labchip® electrophoresis (***Figure 2***). Our study illustrates the systematic analysis of circularization efficiency through the integration of the Labchip® electrophoresis fragment analysis and real-time PCR platforms (***Figure 1***). The analytical methods will capture the attention of industrial experts, particularly those focused on optimizing RNA circulation efficiency in upstream process development. Simultaneously, it will assist academic researchers accelerating studies and exploring key elements for ribozyme catalytic activity.

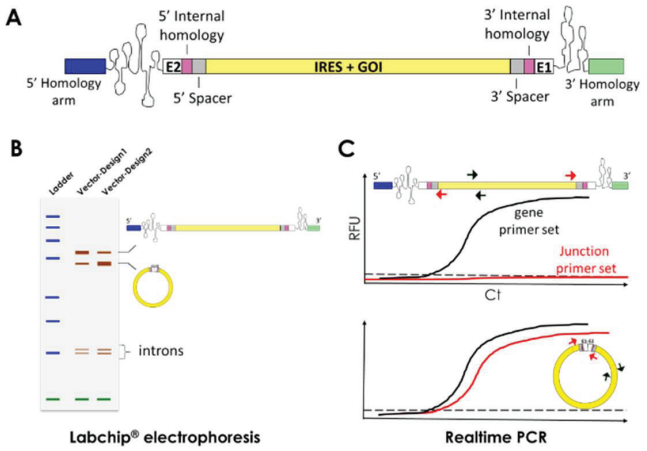

Figure 1: Analytical analysis workflow of synthetic RNA circularization. (A) A typical permuted intron-exon construct design for synthetic circRNA precursor. E1, E2: exon 1, exon2; IRES: internal Ribosome entry site; GOI: Gene-of-Interest; Catalytic intron as a preserve element critical for ribozyme folding is drawn as scribble lines and hairpin structures. **(B)** Schematic diagram showing fragment analysis of RNA species in RNA circularization on LabChip®. Construct variants by circRNA vector engineering are labeled as Vector-Design1 and Vector-Design2. **(C)** Real-time PCR primer design and amplification curve for measuring ribozyme circularization. Top diagram represents results from linear precursor or samples with no or low circulation yield; bottom diagram represents results from samples with success circularization. Red arrows represent junction primer sets; black arrows represent body primer set.

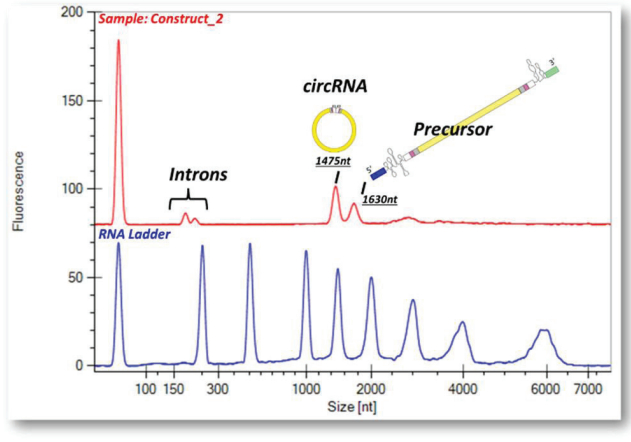

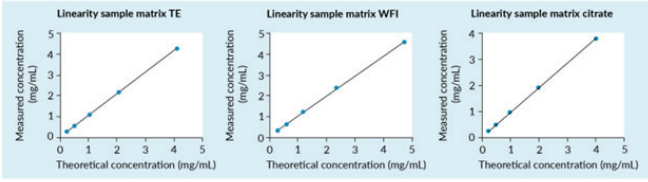

Figure 2: circRNA peak patterns using RNA pico reagents on LabChip®. *Top: one typical non purified RNA product by ribozyme-based circularization. Bottom: RNA Ladder from RNA Pico reagent. If size resolution of electrophoresis platform is optimal, assuming no 100% circularization efficiency, four bands are usually expected: small introns' peaks excised from 5' end and 3' end, one circRNA peak and one RNA precursor peak. The sizes labeled below RNA species are theoretical value based on sequence design.*

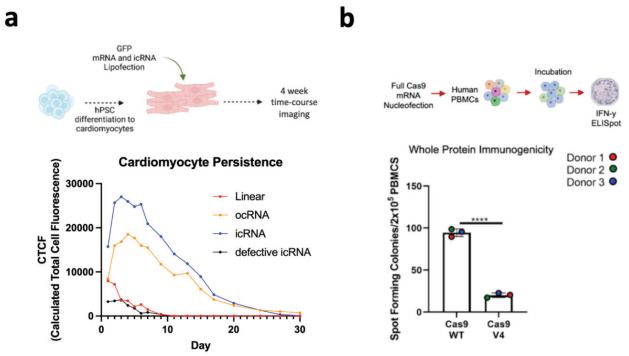
1218. mRNA Concentration Determination with the CTech™ SoloVPE® System

Paul Mania
Repligen, Jamison, PA

mRNA-based therapeutics differ from small molecules and other biologics and have significant analytical challenges. mRNA characterization for pre-clinical/clinical testing and lot-release are required to stay concurrent with regulatory standards, to be competitive in the marketplace. Traditional analytical methods used to quantify mRNA face challenges involving, dilution error, fixed-pathlength measurements and measuring among other UV-absorbing components in the matrix. These challenges can lead to variability making it difficult to transfer methods. There is an important demand in the industry to perform robust, repeatable mRNA concentration acquisitions in a single-test, utilizing low volumes and in a timely manner. The SoloVPE variable pathlength spectrophotometer is a preferable alternative to traditional UV spectrophotometry. Utilizing the versatility of the variable pathlength technology (VPT) allows measurements to be performed without dilution and without blanking with other matrices. The study shows how the SoloVPE can accurately and repeatably measure mRNA concentration among other matrices that would normally need to be blanked and diluted by traditional UV analytical methods. Validation results for linearity in different sample matrices are plotted in Figure 1, showing the SoloVPE can accurately measure concentration of different gradients in the presence of multiple different matrices. The SoloVPE technology is platform-able and allows for a single test method to be leveraged that can support multiple mRNA products without the need to redevelop and validate multiple methods. The versatility of the SoloVPE reduces the cycle time for product-specific work, helping to support streamlined products and allowing CDMOs to easily development and validate the platformed analytical method.

Data are reported as mean ± SEM).

1219. A Universal Assay Determination Method for Antisense Oligonucleotides - A New Approach Using Slope Spectroscopy



Kaitlin Alexander
Repligen, Oceanside, CA

Antisense oligonucleotides (ASO) are an important drug discovery platform for most major pharmaceutical companies. For drug safety and efficacy, an in-process control (IPC) assay of the active ingredient concentration is used to determine the quality of the ASO drug product. Standard HPLC-UV methods for IPC measurements are time consuming and have a relatively complex process. A novel method using the SoloVPE slope spectroscopy system was developed to have high repeatability, robustness, and significantly decreased the time to results. The following experiments were performed using multiple ASO samples with several chemistry modifications. One of the ASO samples was tested across several days and different analysts to assess intermediate precision of the method. This resulted in less than 1% RSD across test days and analysts. All samples were then tested within various buffer solutions and validated internally as well as at two different contract manufacturing organizations (CMO) to determine the method's repeatability, accuracy, and reproducibility. The method revealed to produce a 98%-102% recovery compared to the expected value and less than 1% RSD. The robustness of the method was also tested by adding several set-up adjustments, such as base, sugar, and linkage modifications. These experiments resulted in an overall difference of less than 2%, proving the SoloVPE method to be consistent and can be implemented universally. Using the SoloVPE method also saved approximately 4 hours of processing time and 67% cost/time reduction as compared to the former HPLC method. The SoloVPE method allows for the same accuracy and precision, compared to HPLC but with superior efficiency and a more universal IPC assay for ASO product measurement.

1220. Robust Protein Translation and Genome Targeting via HPLC-Free *In Situ* Circularizable and *In Vitro* Circularized RNA

Michael Tong[1], Hammza Khaliq[1], Aditya Kumar[1], Sangwoo Han[1], Nathan Palmer[1], Emma Finburgh[1], Madeleine K. Wing[1], Camilla Hong[1], Amir Dailamy[1], Joseph N. Rainaldi[2], Wei L. Chew[3], Ester J. Kwon[1], Prashant Mali[1]
[1]Bioengineering, University of California, San Diego, La Jolla, CA,[2]Biomedical Sciences, University of California, San Diego, La Jolla, CA,[3]Agency for Science, Technology and Research, Singapore, Singapore

RNAs are a powerful therapeutic class, but their inherent transience limits their activity. Circularization of RNA can improve their persistence, but simple and scalable approaches to achieve this are lacking. To facilitate the pursuit of circular RNAs, we developed two methods: "**o**utside developed" **c**ircular RNA (ocRNA) to enable robust in vitro circularization and in situ or "**i**nside developed" **c**ircular (icRNA) for in cell circularization. Importantly, we concurrently developed simple protocols to enable the successful purification of these circular RNAs without utilizing HPLC while retaining high yields (20-70%). These constructs enabled various applications (Figure A) demonstrating strong functional expression and persistence. We also further optimized protein translation from icRNAs and characterized significant expression differences from cap independent and cap dependent translation across cell lines, as well as relationships between immune response and protein expression. Leveraging this persistence, we enabled robust genome and epigenome targeting via both zinc finger proteins and CRISPR-Cas9 systems delivered as icRNAs. To enable compatibility between persistence of expression and immunogenicity of these delivered proteins, we next developed a novel **lo**ng **ra**nge multiple**x**ed (LORAX) protein engineering methodology to screen combinatorial variants, and demonstrated efficient genome targeting via deimmunized CRISPR-Cas9 (Figure B) delivered as icRNAs. We anticipate our highly simple, scalable, and versatile icRNA and ocRNA methodologies will have broad utility in basic science and therapeutic application.

1221. tRNA Therapeutics to Treat Stop Codon Disease

Stephen W. Eichhorn
Alltrna, Cambridge, MA

Nonsense mutations, which convert a sense codon within a protein-encoding mRNA into a stop codon and thus cause premature termination of protein synthesis, are the underlying cause of approximately 10% of all genetic diagnoses in humans. In recent years, transfer RNAs (tRNAs) engineered to read through premature termination codons (PTCs) and restore continued synthesis of the polypeptide chain have gained attention as an emerging novel therapeutic approach to potentially unify the treatment of thousands of rare and ultrarare stop codon diseases. To develop tRNAs with desired therapeutic features, such as high activity, specificity and durability, and low immunogenicity, Alltrna has built a unique platform based on *(i)* high-throughput screening of engineered tRNA oligonucleotides combining optimized sequence and chemical modification patterns and *(ii)* rational and machine learning-guided design principles. Preclinical data demonstrate productive PTC readthrough *in vitro* in a wide range of clinically relevant disease models spanning more than 15 different genes, and *in vivo* in PTC-containing mouse models across different stop codons. These preclinical proof-of-concept results are promising and provide an attractive programmable design framework for tRNAs as a novel class of medicines to restore disrupted protein production, regardless of target, for thousands of diseases with the same underlying genetic mutation. Recent preclinical data will be presented at the meeting.

1222. vMIX: Towards a "Plug-and-Play" Platform for Gene Silencing Therapy in Neurodegenerative Diseases

Catia Andreassi[1], Randa Elsayed[1], Agnieszka Ule[1], Alice Gennari[1], Deborah Ojutalayo[1], Lawrence Oliver[1], Joana Furtado[1], Zoe Walker[1], Yalem Bekele[2], Amrita Abhilash[2], Paniz Hosseini[2], Samantha Correia[2], Philip Coan[3], Olivier Brock[4], Carlos J. Miranda[3], Romain Joubert[1], John Isaac[1], Chris E. Shaw[1,4]
[1]Discovery, AviadoBio Ltd., London, United Kingdom,[2]Vector Sciences, AviadoBio Ltd., London, United Kingdom,[3]PreClinical, AviadoBio Ltd., London, United Kingdom,[4]UK DRI, King's College London, London, United Kingdom

Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal Dementia (FTD) are devastating neurodegenerative diseases that may present with distinctive clinical manifestations while sharing common underlying genetics and pathology. To date there are no therapies able to make a major impact on survival. Presence of abnormal protein aggregates is an hallmark of many neurodegenerative diseases. In 95% of ALS and tau-negative FTD cases, widespread dysregulation in mRNA splicing due to cytoplasmic aggregates of the RNA binding protein TDP-43 is observed. Aggregation of TDP-43 is facilitated by another RNA binding protein, Ataxin-2 and reduction of *ATXN2* mRNA has been protective against TDP-43 toxicity in cellular and animal models. Aggregates of mutant superoxide dismutase 1 (SOD1) protein are causative in a substantial proportion of familiar cases of ALS and reduction in mutant *SOD1* mRNA has also proved beneficial *in vitro* and *in vivo* studies. Therefore, we have developed an adeno-virus associated (AAV) vectorised gene silencing platform, vMIX, that expresses proprietary microRNAs (miRNAs) capable of down-regulating target mRNA levels as a potential therapy for ALS and FTD. MicroRNAs are able to recognise specific mRNA sequences and engage the RISC complex leading to mRNA degradation or stalling in the translation, and decreased protein expression. The miRNA biogenesis is a complex, multi-step process that starts with the synthesis of a longer pri-miRNA precursor sequence and continues with its maturation to pre-miRNA by sequential cleavage reactions in the nucleus , and then in the cytoplasm to generate a mature miRNA duplex. Because of the rule of complementarity between target mRNA and miRNA, only one (called guide) of the 2 sequences in the mature miRNA duplex will be able to pair with the target mRNA. When loaded in the RISC effector complex, this sequence will be stabilized and by binding to the target mRNA, it allows the execution of the silencing activity. The complementary sequence (passenger) will be degraded. Therefore, an efficient RNAi based silencing approach relies on precisely processed miRNA precursors. However, the maturation of the miRNA precursors is a complicated process and not all the variables that control it are well understood. The sequences of the miRNA itself, of the flanking stems and of the loop that connects the miRNA duplex do have a major impact on the maturation process and affect the precision with which the miRNA is generated. In order to generate precise miRNAs able to accurately target the mRNAs of interest, we have developed a battery of miRNA candidates targeting *SOD1* or *ATXN2* mRNAs, and studied the impact of sequence variations on the maturation process. Using Next Generation Sequencing (NGS) technologies, we have assessed the effectiveness of alternative sequences on: - the cleavage precision,

guide sequence, and guide to passenger ratio of the candidate miRNAs; - the silencing efficiency of the candidate miRNAs; - the expression of endogenous miRNA repertoire. In addition, we investigated the species-specificity of the miRNA processing by conducting parallel experiments in cell lines originating from different species, and further compared the results of in *in vitro* and *in vivo* studies. By combining these analyses with a rational candidate design, we are endowing the vMIX platform with nucleotide-precise targeting abilities, developing a versatile, ready-to use miRNA-based gene therapy approach.

1223. Divalent siRNA Therapy for Huntington's Disease Demonstrates Robust Safety and Efficacy in Pre-Clinical Assessment in an Ovine Model

Hector Ribeiro Benatti[1], Rachael Miller[1], Toloo Taghian[1], Dimas E Moreno[1], Jillian Gallagher[1], Erin F. Hall[1], Abby McElroy[1], Nathan K. Yingling[1], Vania Anagnostakou[1], Ellen Sapp[2], Marian DiFiglia[2], Anastasia Khvorova[1], Heather L. Gray-Edwards[1], Neil Aronin[1]

[1]UMass Chan Medical School, Worcester, MA,[2]MassGeneral Institute for Neurodegenerative Disease, Charlestown, MA

Background: Huntington's Disease (HD) poses a significant challenge as an autosomal dominant neurodegenerative disorder, resulting from the expansion of CAG repeats on chromosome 4. This expansion triggers the translation of a mutant huntingtin (mHTT) protein. Its chronic expression leads to protein aggregation in the central nervous system (CNS), and subsequent cell death. The severity and onset of HD correlate with the size of the CAG repeat, manifesting in various symptoms like choreiform movements, behavioral disturbances and dementia. Despite the absence of therapies capable of altering the onset or progression of the disease, there remains an urgent demand for safe and effective interventions. A prevailing hypothesis suggests that diminishing mHTT expression within the CNS could alleviate the pathological features of the disease and improve the overall clinical condition. **Methods:** Our study addresses the therapeutic potential of a non-allele selective divalent small-interfering RNA (di-siRNA) scaffold designed to reduce normal huntingtin (HTT) and mHTT expression in the CNS. Utilizing this di-siRNA, notable efficacy was achieved in mice. However, acute seizures were noted, likely due to siRNA's negative charge. To address this issue we optimized the formulation to include calcium and magnesium cations and corrected the seizure phenotype. Advancing to a pre-clinical stage, safety and efficacy assessments were conducted in wild type sheep (n=28 divided in 7 cohorts) through intracranial ventricular (ICV) and intrathecal injections. Cohorts included a low ICV dose (25mg) and dose escalation groups (50, 75, and 100mg). Lumbar intrathecal injections offer an alternative less invasive route; therefore we tested a moderate 50mg dose. Safety and HTT knockdown (mRNA and protein) were analyzed 2-months and 6-months post-injection. Safety monitoring included real-time holter electroencephalography (EEG), histopathology and pre/post-MRI analysis. **Results:** EEG revealed a dose-response toxicity: 25 and 50mg doses demonstrated safety, while 100mg resulted in seizures. Tissue analysis revealed efficacy in the striatum of sheep, one of the regions of the brain most severely affected by HD, demonstrated by HTT mRNA and protein reduction. The 50mg dose demonstrated superior efficacy compared to the baseline dose, revealing a notable reduction of approximately 50% in mRNA and an approximate 75% decrease in HTT expression. Intriguingly, doses >50mg did not increase knockdown further. After 6 months silencing in the cortex and hippocampus was evident, but not in the striatum. **Conclusion:** Here we demonstrated the potential of a di-siRNA as a therapeutic approach for HD. The observed dose-dependent seizure phenotype emphasizes the necessity for meticulous safety EEG assessments. The long-term durability findings suggest a need for repetitive dosing <6 months to sustain the therapeutic efficacy in the striatum. Next, we will test the impact of repetitive dosing using the most effective and safe dose (50mg). Looking toward future clinical trials, we will also test magnesium-only formulation, addressing the unavailability of USP-grade calcium and magnesium buffers. These findings not only advance our understanding of HD treatment but also pave the way for future clinical trials.

Thursday Posters: Nonviral Therapeutic Gene Delivery and Synthetic/Molecular Conjugates

1224. Silicon Nanoneedle Microarray-Based Delivery of Cell Gene Therapies

Salma Sami

Mekonos, Inc., Alameda, CA

The field of cell and gene therapies is quickly revolutionizing modern medicine by redefining treatment modalities. Genetic disorders previously deemed incurable are now open to newly developed treatment options. At its core, cell gene therapy involves the delivery of genetic material into the cell for the purpose of correcting or improving an underlying genetic problem. Over the years, multiple vehicles of gene delivery have been developed, with varying degrees of success. Among these, viral vectors, electroporation and transfection are most common. Unfortunately, these methods are inefficient, cumbersome, stressful to the cells and, in case of viral vectors, may lead to downstream genomic instability and potential adverse effects like secondary cancer. To address these bottlenecks, Mekonos has capitalized on the nanoneedle cell delivery technology and developed a high throughput gene delivery system based on solid silicon nanoneedle microarray chips. Mekonos' novel cell engineering platform side-steps the problematic use of canonical modes of gene delivery by utilizing an array of solid silicon nanoneedles to enable delivery of biomolecular payloads of various compositions and sizes. Our method of silicon nanoneedle fabrication utilizes semiconductor technology to produce needles of consistent height and width. Cells of interest are first "trapped" (temporarily immobilized) on the system membrane using microfluidics, then the payload-coated chip is placed on the cell array, thereby ensuring one needle-one cell interaction and delivery. The workflow is scalable, efficient and causes minimal cell damage. Additionally, our method has been demonstrated to be independent of cell or cargo type and has been utilized to deliver a plethora of cargo (CRISPR-Cas reagents, nucleic acids) into a variety of cells (immortalized, primary, stem). The

advantage of Mekonos' silicon nanoneedle-based delivery platform is that it allows for scaled up workflows, efficient and controlled payload delivery to various cell types, as well as the ability to deliver multiple cargo modalities, singly or in multiplexed arrays. Moreover, unlike other gene delivery vehicles in use today, our platform enables the delivery of very large cargo, for example >100kb plasmids, in a dose-controlled manner to various cell types of interest, with minimal stress and loss in viability. A unique advantage of our platform is the ability to multiplex heterogenic cargo for one-time or sequential delivery into multiple cell types with no additional steps. This allows for the delivery of both plasmids and RNPs on the same needle, at the same time, in any iteration controlled by the end-user, allowing for multiple gene edits while minimizing risk of genomic instability. Perhaps the most unique aspect of our technology is its cross-platform functionality since it can be used to manipulate a wide variety of cell types, including mammalian, plant and yeast, among others. We envision that the combination of our semiconductor, microfluidic, and surface chemistry technologies will redefine cell therapies, facilitating the precise and scalable engineering of all cell types.

1225. DELiveri: A Novel High-Throughput Screening Platform for the Discovery of Molecules That Promote Extra-Hepatic Nucleic Acid Delivery

Omer Ziv[1], Adrej Alendar[1], Shoval Tirman[2], James Murphy[1], Liv Austenaa[1], Chiara Barberio[1], Omer Weissbrod[2], Yaniv Erlich[1], Paloma H. Giangrande[3]

[1]Eleven Therapeutics, Cambridge, United Kingdom,[2]Eleven Therapeutics, Tel-Aviv, Israel,[3]Eleven Therapeutics, Cambridge, MA

Cell-specific delivery is the holy grail of RNA therapeutics. Currently, small chemical conjugates such as GalNAc have been successful in achieving liver-specific delivery. However, delivery to other tissues/organs remains a major hurdle. DNA-encoded chemical libraries (DELs) have the potential to provide hypothesis-free screening methods to discover new RNA conjugates that can enable extra-hepatic delivery. Here, we present DELiveri, a groundbreaking DEL-based screening platform for identifying nucleic acid conjugates for productive cytoplasmic delivery in a massive parallel fashion. DELiveri harnesses a synthetic biology genetic circuit that converts cells into molecular radars. This circuit creates a strong and unique signal when the DEL barcodes are bioavailable in the cytoplasm. After extensively validating our circuit in small-scale experiments, we utilized our technology to simultaneously screen over 35,000 delivery molecules in human cells. Our results showed high consistency among biological replicates (R >0.9), strong separation between negative and positive controls, agreement with the expected chemoinformatic trends (i.e., molecular structure, hydrophobicity content), and strong chemical similarly between the hits. Importantly, we identified molecules with cell-specific signatures that are currently being evaluated as cell-specific delivery ligands for various RNA therapeutic modalities. In summary, our strategy quantitatively decodes the structure-activity relationship (SAR) of cell-specific delivery molecules and opens an avenue for the use of generative AI tools in designing new molecules that enable extra-hepatic nucleic acid delivery.

1226. Skeletal Muscle *liveGT* Enhances Therapeutic Expression Levels over Several Months

Michael Francis[1], Jacob Hensley[2], Alex Otten[2], Anna A. Bulysheva[2]

[1]University of South Florida, Tampa, FL,[2]Medical Engineering, University of South Florida, Tampa, FL

Gene electrotransfer is an established physical method for delivery to various tissue and organs *in vivo* including melanoma tumors, skin, cardiac muscle, and skeletal muscle. GET advantages include nonimmunogenic and nonintegrative gene delivery to targeted tissues. Disadvantages include low expression levels, short-lived/transient expression, and muscle stimulation. Skeletal muscle, localize in vivo electro gene therapy (*liveGT*) as a next generation GET, was utilized with a monopolar electrode and optimized pulse sequences to determine longevity of expression and feasibility of reaching therapeutic blood levels of expression. *LiveGT* was administered directly to the skeletal muscle of Sprague Dawley rats, with plasmid DNA encoding luciferase or human insulin and glucokinase co-delivery. Expression levels were monitored with bioluminescence imaging as well as directly from serum samples via ELISA over nine months post initial *liveGT*. Additionally, to evaluate therapeutic potential blood glucose measurements were also monitored. Two-way ANOVA and Tukey multiple comparison tests were used to determine statistically significant differences, with $p<0.05$ considered significant. Control groups received vehicle, or no delivery at all. Reporter expression was observed to be maintained for over six months with significantly higher (over 100-fold) than respective controls. Exogenous human insulin expression and blood glucose modulation were maintained over three months, with significant reduction in mean circulating glucose compared untreated animals. Therefore, our preliminary findings implicate *liveGT* skeletal muscle reprogramming as a viable target for secretory protein therapies as therapeutic levels of expression can be achieved and maintained for several months without risks of integration and immunogenicity.

1227. Gene Electrotransfer Increases Mammalian Cell Glucose Consumption in an Insulin-Dependent Manner

Jacob W. Hensley[1], Michael Francis[2,3], Alex Otten[1], Tina Gagliardo[1], Anna Bulysheva[1]

[1]Department of Medical Engineering, University of South Florida, Tampa, FL,[2]Department of Orthopaedics, University of South Florida Morsani College of Medicine, Tampa, FL,[3]Asante Bio, Tampa, FL

More than 9 million adults are diagnosed with Type 1 Diabetes worldwide. Traditional therapies utilize insulin protein injections and continuous blood glucose monitoring. Research advancements for alternative treatment include Beta cell encapsulation, artificial pancreas systems, FDA approved pancreatic islet cellular therapy, Lantindra, and delivery of insulin and glucokinase via AAV, however, immunomodulation is required. The goal of this study is to deliver exogenous insulin and glucokinase via gene electrotransfer (GET) for glucose modulation. Transient transfection of C2C12 myoblasts with Nanoplasmid ® DNA encoding human insulin and glucokinase utilizing gene electrotransfer as the delivery vehicle was examined to overcome the need for immunomodulation. Following transfection of

myoblasts, media glucose levels were measured daily for seven days. Two-way ANOVA comparison and Tukey multiple comparison tests were used for quantitative statistical analysis. Immunofluorescence analysis measured transfection efficiency and percent co-localization. Exogenous co-expression of both insulin and glucokinase significantly increased media glucose depletion compared to respective controls, indicating that GET delivery of insulin and glucokinase is a viable therapeutic pathway. Of the myoblasts expressing either exogenous protein in the group transfected with both insulin and glucokinase on the same plasmid, there was 70% co-expression of both insulin and glucokinase. These findings are consistent with our hypothesis that cells can be reprogrammed to modulate blood glucose levels in an insulin-dependent manner, resulting in a potential treatment for Type 1 Diabetes without the use of immunomodulatory drugs.

1228. Targeted Non-Viral Gene Delivery through Transcutaneous Ultrasound Enables Rapid, Robust, Redosable, Titratable, and Durable Gene Expression in the Liver in Murine and NHP Models

Surabhi Rao, Victor Foster, Bert Frederich, Barry Campbell, Adel Alonso, Glenda Arauz, Celia Ortiz, Oliver Chen, Charlotte He, Elizabeth Del Greco, David Satyadi, Anagha Rao, Dhruv Bole, David Kim, Katie Benthall, Margarita Krivega, Julia Poniatowski, Ivan Krivega, Zoya Gluzman-Poltorak, Steve Feinstein, Kenneth Greenberg

SonoThera,Inc, South San Francisco, CA

Introduction: Robust delivery of DNA payloads to the liver remains a significant challenge for the development of safe and effective nonviral genetic medicines. Current limitations include the ability to 1) achieve durable episomal gene expression in a safe, titratable, and redosable manner, 2) deliver large DNA payloads (>5kb), 3) bypass endosomal and cytoplasmic immune recognition and effectively transit the nuclear envelope, and 4) achieve targeted transgene expression in clinically relevant hepatic cell types. Transcutaneous ultrasound-mediated gene delivery (UMGD) is a noninvasive *in vivo* gene delivery approach that may overcome the key delivery challenges facing genetic medicines. SonoThera is developing a novel ultrasound-guided nonviral gene therapy platform based on UMGD that allows selective targeting of specific organs and tissues within the body in a safe, redosable, durable, and titratable manner. Methods: To evaluate the potential of UMGD for safe and efficient DNA delivery to the liver, we developed a technology platform that utilizes novel acoustic profiles and next-generation genetic payloads with FDA-approved ultrasound components. The delivery process involves intravenous co-administration of DNA payloads and ultrasound contrast agents (a.k.a microbubbles), coupled with targeted application of externally applied ultrasound energy to guide the DNA into specific tissues via UMGD. *In vivo* bioluminescence imaging of firefly luciferase reporter gene expression was evaluated using an IVIS imaging system at multiple timepoints in the mouse liver following UMGD. Mouse and monkey liver tissues were analyzed for reporter gene presence and expression. Multiple clinical and molecular safety assessments were evaluated using established methods. Results: Rapid and robust transgene expression was detected in the mouse liver within 3 hours following DNA sonoporation, which persisted for at least 6 months after a single treatment. Furthermore, repeated administrations resulted in significant increases in gene expression levels relative to single administrations. Gene expression levels were titrated effectively in a dose responsive manner. Reporter gene presence and expression were efficiently detected in the analyzed mouse and NHP liver tissues. Safety assessments including clinical observations, ALT, AST, and a proinflammatory cytokine panel indicate an excellent tolerability and safety profile following single and repeat treatments in both murine and NHP models. Conclusion: These results position a novel UMGD platform as a promising technology for *in vivo* noninvasive transgene delivery using next-generation non-viral DNA payloads, thereby laying the foundation for the development of future redosable and titratable genetic medicines targeting the liver.

1229. Development of a Next-Generation Non-Viral Human FVIII Therapeutic Administered through Targeted Transcutaneous Ultrasound Enables Normal Physiological Levels of FVIII Transgene Expression in a Redosable and Titratable Manner

Margarita Krivega, Julia Poniatowski, David Kim, Elizabeth Del Greco, Ivan Krivega, Surabhi Rao, Victor Foster, Bert Frederich, Barry Campbell, Adel Alonso, Glenda Arauz, Celia Ortiz, Oliver Chen, Dhruv Bole, Katie Benthall, Charlotte He, Anagha Rao, David Satyadi, Zoya Gluzman-Poltorak, Steven B. Feinstein, Kenneth P. Greenberg

SonoThera, South San Francisco, CA

Introduction: Hemophilia A (HemA) is caused by the absence or deficiency of Factor VIII (FVIII) protein resulting in uncontrolled bleeding. The current primary standard of care for HemA consists of lifelong infusions of recombinant FVIII protein on a frequent basis. The recent approval of viral gene therapy for HemA provides an alternative, potentially once-a-lifetime treatment option. However, several limitations including high product cost, preexisting immunity to viral vectors, lack of durable FVIII expression, and lack of redosing capabilities suggest the need to develop alternative non-viral HemA gene therapy treatments to overcome these major limitations. Transcutaneous ultrasound-mediated gene delivery (UMGD) is a noninvasive *in vivo* gene delivery approach that may overcome the key delivery challenges facing HemA genetic medicines. SonoThera is developing a novel ultrasound-guided nonviral gene therapy platform based on UMGD that allows selective targeting of specific organs and tissues within the body in a safe, redosable, durable, and titratable manner. **Methods**: Using genetic engineering and screening of next generation DNA payload formats, we developed an optimized episomal DNA payload expressing a clinically validated human FVIII transgene. Transgenic FVIII expression was measured *in vitro* in human and mouse cells and *in vivo in mouse plasma*. To evaluate the potential of UMGD as a nonviral HemA treatment option, we delivered an optimized HemA payload using novel acoustic profiles, developed by SonoThera, and FDA-approved ultrasound components. The delivery process involves intravenous co-administration of DNA payloads and ultrasound contrast agents (a.k.a microbubbles), coupled with targeted

application of externally applied ultrasound energy to guide DNA into specific tissues via sonoporation. **Results**: The next-generation optimized DNA payload was determined to yield high human FVIII expression levels and secretion in human and mouse cells *in vitro* in a dose responsive manner. Additionally, the protein was determined to be functionally active via an established coagulation assay. By optimizing the UMGD *in vivo* delivery acoustic profiles, we have been able to efficiently deliver the optimized FVIII payload to the liver and reach sustainable therapeutic levels of FVIII in mouse plasma without triggering liver toxicity. Repeated UMGD treatments led to a significant increase in transgenic FVIII levels in plasma suggesting a redosing treatment regimen for elevating or maintaining a normal physiological level of circulating transgenic FVIII. **Conclusion**: These favorable efficacy and safety results achieved using a novel UMGD platform suggest further translation of the optimized non-viral human FVIII payload and delivery method into clinical development for the treatment of Hemophilia A.

1230. Safe and Redosable Non-Viral Gene Therapy in Hemophilia A: Transcutaneous Ultrasound-Mediated FVIII Delivery as a Promising Therapeutic Approach

Ting-Yen Chao, Meng-Ni Fan, Yuanyi Xu, Xiaohe Cai, Carol H. Miao

Seattle Children's Research Institute, Seattle, WA

Hemophilia A (HemA) is an X-linked clotting disorder characterized by a deficiency of functional factor VIII (FVIII) protein. Gene therapy is promising for treating hemophilia but the safety concerns and challenges brough by the pre-existing antibodies against viral vectors when using such vectors. Ultrasound-mediated gene delivery (UMGD) has emerged as a promising non-viral method that utilizes therapeutic ultrasound (US) and microbubbles (MBs) to facilitate gene transfer. This study aims to develop a noninvasive intravenous non-viral gene delivery protocol in combination with transcutaneous UMGD (tUMGD) in Hemophilia A mouse models to achieve efficient transfection of FVIII plasmids in the liver. To achieve sustained FVIII expression, FVIII plasmid was mixed with RC2K cationic MBs for 5 minutes, and subsequently injected intravenously into groups of mice via retro-orbital injection with tUMGD to induce cavitation in the liver for 60 seconds. The US parameters used in our experiments include: a center frequency of 1.1 MHz, a pulse repetition frequency of 14 Hz, and peak negative pressure (PNP) between 1.2 and 1.5 MPa, with a pulse duration of 150 μs in a 1-second ON and 2-seconds OFF pulse train for a total treatment time of 60 seconds. Blood samples were collected weekly for detecting human FVIII activity and alanine aminotransferase levels. Initially, HemA mouse models were subjected to treatment with various human FVIII plasmid candidates to enhance FVIII activity following hydrodynamic injection. The HemA mice treated the selected high-expressing FVIII plasmid achieved an impressive FVIII activity ($1.3x10^4$ %), representing a 10-fold increase compared to the mice treated with the other FVIII plasmid (1200%). Subsequently, we assessed US conditions using the high-expressing FVIII plasmid in HemA mice. Administering a total of 50 μg DNA with repeated US treatments using a PNP of 1.2 MPa resulted in significantly higher FVIII activity (19.5%), mirroring the outcomes observed in mice treated with a total of 75 μg DNA under the same US conditions. It was noted that a plateau in expression level was achieved with 50 μg plasmid DNA. Variant US conditions, ranging PNP between 0.5 and 1.5 MPa, were explored, and the optimal condition was identified as PNP 1.5 MPa. To evaluate the feasibility of redosable tUMGD using the FVIII plasmid, we utilized immunodeficient NSG HemA mice to perform tUMGD experiments with optimized US conditions and DNA doses for plasmid transfection in the absence of antibody formation. Mice treated with 50μg high-expressing FVIII plasmid under repeat tUMGD, initially achieved approximately 40% activity, sustaining around 10% for a month. A subsequent treatment aimed to enhance FVIII activity in these mice, resulting in an initial 35% activity, which gradually stabilized at 18% for two months. A third treatment was administered for redosing purposes, a similar trend in FVIII activity was observed. Slightly elevated ALT levels post-treatment normalized within a week, affirming the safety of tUMGD. In conclusion, these results demonstrated that tUMGD is a highly efficient, stable, and redosable nonviral delivery method. This minimally invasive, non-viral, and effective method holds promise for translating into future treatments for hemophilia A patients.

1231. A Scalable Insect Cell-Dual Baculovirus System for Non-Viral Gene Therapy (NVGT) Production

Adhvait Shah, Swetha Kumar, Hyun-Woo Kim, Darrick Yu, Jeong Lee

Cell Culture Process Development, GMU CMC, Sanofi, Waltham, MA

Sf9 cells have been employed successfully as a viable alternative to produce AAV. Recombinant AAV can elicit immune responses, thereby preventing drug redosing, and have limited payload capacity, thereby limiting the number of disorders addressed. NVGT allows re-dosing with larger payloads. In addition, NVGT methods such as using lipid nanoparticles, polymers, etc. are alternative approaches that pose low cytotoxic and immunogenic risks. Moreover, the Sf9-baculovirus platform has a favorable safety profile due to lack of pathogenicity of baculovirus in humans, thus offering an excellent platform to manufacture NVGT products. We developed and optimized an Sf9-baculovirus upstream process for manufacturing NVGT products such as closed-ended DNA or ceDNA. Although the Sf9-baculovirus system has previously been used for AAV manufacturing, the restricted coding capacity of AAV prevents its use as a vector for a number of diseases. We showed better process performance controlling for several parameters, which are typically not controlled in Sf9 culture. The optimized process resulted in 5-fold improvement in ceDNA titers, significantly reducing the number of batches needed to meet the clinical demand while maintaining product quality and thereby reducing the cost of goods. This allows shorter timelines for the therapy to reach patients. In this work, we have compared two approaches to infection of Sf9: one-baculovirus and two-baculovirus systems. The two-baculovirus system have rep and transgene on two different baculoviruses while the one-baculovirus system has the transgene stably integrated in the Sf9 genome, with the rep gene encoded by a baculovirus. The two-Baculovirus system was found to be more robust and superior in performance compared to the one-baculovirus system. Various parameters including, but not limited to, viable cell density at infection, relative MOI, MOI ratio, medium composition, pH, and temperature were optimized for the two-bac system. This optimization

resulted in 5-fold improvement in ceDNA titers. This optimized process was scaled-up for evaluation and validation including Ambr ® 250 systems, bench top bioreactors and pilot scale reactors up to 500 L. We demonstrated robust performance of this process both regarding the growth of Sf9 and ceDNA manufacture while maintaining product quality and productivity. We developed a harvest process using a continuous centrifugation strategy to process pilot-scale volumes of cell culture, up to 500 L. We identified a combination of centrifugation parameters using a single-use continuous centrifugation strategy that enabled quick and efficient generation of concentrated cell suspension, with minimal loss to cell viability and product quality. In conclusion, two-Baculovirus Sf9- baculovirus system for ceDNA production offers greater flexibility with an ability to deliver large transgenes. Since the two-baculovirus system allows for easily swapping to new transgenes by substituting a different transgene-baculovirus construct, as opposed to transfection/isolation of a new Sf9 clone, time-to-clinic for new indications is drastically reduced. Our novel seven-day two-baculovirus process includes growth of insect cells, NVGT product manufacture, and concluding with single-use continuous centrifugation to harvest a concentrated cell suspension for faster purification. The improved process requires fewer batches to meet the clinical demand, thereby making NVGT more accessible to patients.

1232. Rapid Enzymatic Synthesis and Scaling of DNA Gene Therapy Molecules

Daniel Blackstock, John Durant, Joris Cipi, David Turkington, Adam Villa, Russell Monds, Matthew Stanton

Generation Bio, Cambridge, MA

Non-viral gene therapy technologies offer many manufacturing advantages over viral-based therapies. Since virus production is not required, the costly, complex, and hard to control cell-based viral vector productions can be eliminated. Additionally, because intracellular encapsidation is abolished, the synthesis of the payload nucleic acids can be separated from the production of the delivery vehicle allowing for enhanced quality control of the drug produced. Without the necessity for the viral vector, the potential to introduce a completely cell-free method for simplified and accelerated nucleic acid manufacturing becomes a possibility. As demonstrated with mRNA vaccines, enzymatic *in-vitro* transcription (IVT) technologies have resulted in platform synthesis methods which can enable extremely flexible, rapid, and scalable production of RNA pharmaceuticals. While DNA production has traditionally relied on plasmid cloning and *E. coli* fermentation for scaling, we have developed a platform analogous to IVT, facilitating synthetic DNA production. Our rapid enzymatic synthesis (RES) method enables the production of kilobase length DNA transgenes at cutting edge speed, with flexible-end compositions for desired functionality, and gram / liter scalability. Our RES process consists of (1) DNA template amplification, (2) selective digestion and ligation driven assembly of ITR oligonucleotides onto the ends of the transgene cassette, (3) residual DNA clean up using a nuclease. The RES process eliminates any extraneous DNA typically present with plasmid backbone and reduces sequence specific biases that are often observed with *E. coli* scaling. RES generates synthetic transgenes up to at least 7kbp in size with tunable end structures and composition that allows for incorporation of additional functionality (*e.g.* modified nucleotides, aptamers). The yields achieved are >1000x template input, enabling gram / liter outputs for reduced scale requirements and enhanced ease of production. RES produces DNA transgenes with >99% purity when processed using chromatographic methods and products have been expression validated *in vivo* with performance comparable to plasmid-based transgenes.

1233. *In Vivo* High-Throughput Pooled Screening of Transcriptional Regulatory Elements for Gene Therapy

Jessica Keenan, Jicong Cao, Anais Sidonia, Russell Monds

Molecular Biology, Generation Bio, Cambridge, MA

Identification of genetic elements that drive therapeutic levels of gene expression often requires testing candidates in a series of model systems of increasing relevance (e.g., cells lines, mice, non-human primates). Arrayed construct screening (individual testing of each candidate) limits the number of designs that can be tested in a single experiment, particularly in the most relevant models. As a result, the design space than can be interrogated is limited and evaluation of performance is heavily weighted on experiments in less relevant models. In this work, we utilize a pooled screening approach to simultaneously characterize thousands of transcriptional regulatory elements in a single mouse and directly compare our results to an *in vitro* model. We designed a library of 6,000 transcriptional regulatory element candidates ("enhancers") intended to increase expression when inserted upstream of the transthyretin (TTR) liver promoter. Each enhancer candidate was composed of a combination of 8 binding sites for 12 transcription factors that regulate liver gene expression. Candidates were each assigned a unique 10 nt barcode to facilitate enhancer-specific quantification of mRNA expression. The enhancer/barcode pairs were synthesized as an oligo pool and used to generate a plasmid pool with the transgene cassette structure: enhancer candidate|TTR promoter|luciferase gene|barcode|3' UTR|polyA signal. The plasmid library was delivered to CD-1 mice (n = 3) via hydrodynamic tail vein injection and liver mRNA expression was measured by amplicon sequencing of the barcode regions. Replicates were highly correlated ($r > 0.96$) and >10 barcode counts were recovered for 99.8% of candidates. Enhancers spanned a broad range of activity levels, with the top 1% of candidates showing >5-fold increase in expression compared to the median expression of 50 random size-matched sequences and >2.5-fold increase compared to a benchmark enhancer. To compare enhancer performance between *in vitro* and *in vivo* models, the same plasmid library was transfected into HepG2 human hepatocellular carcinoma cells and mRNA expression was measured by amplicon sequencing. Replicate HepG2 experiments were highly correlated ($r = 0.97$) and >10 barcode counts were recovered for 99.9% of candidates. Comparing between *in vivo* and *in vitro* pooled experiments, expression values were moderately correlated ($r = 0.54$), suggesting that translation between models in pooled experiments is enhancer dependent. Notably, many enhancer variants with high expression *in vivo* would not have been chosen for additional characterization based on *in vitro* data, highlighting the value of expanding the design space screened in the most relevant models. Increasing screening throughput also enables learning design rules. Our library included a subset of variants to assess the impact of number of transcription factor binding site repeats

and spacing between repeats, which we discuss here. We also briefly discuss a separate *in vitro* pooled screening experiment in which we assess all single nucleotide variants of a genomic liver enhancer and identify a conserved single nucleotide change that increases expression, highlighting the value of pooled screening for construct design and optimization. To better understand the potential and limitations of pooled construct screening, future studies will focus on assessing the translation between pooled and arrayed experiments, both *in vivo* and *in vitro*. Successful validation of pooled screening *in vitro* and in murine models would suggest translation of the strategy to non-human primates as a future direction, a potentially transformative approach for developing the most effective constructs for new therapeutics.

1234. Ultrasound Mediated Gene Delivery of Cas9 Plasmids in Hemophilia A Mice Display Therapeutic Levels of Endogenous FVIII

Savannah M. Lawton, Meng-Ni Fan, Ting-Yen Chao, Chun-Yu Chen, Yuanyi Xu, Xiaohe Cai, Carol H. Miao
Seattle Children's Research Institute, Seattle, WA

Hemophilia A (HA) is a bleeding disorder in which an individual cannot produce functional clotting factor VIII (FVIII). Correction of the disease-causing mutation through gene editing is an attractive option for HA because there are currently no robust, long-term, non-repeat treatments available. Ultrasound mediated gene delivery (UMGD) has been shown to be a safe and effective non-viral method of gene delivery, that has the capability to predominately transfect a specific cell type, depending on the plasmid and ultrasound condition used. In this study, we investigated the capability of UMGD to successfully target liver sinusoidal endothelial cells (LSECs)- the native production site of FVIII, using CRISPR/Cas9 plasmids to restore endogenous FVIII production. Previous UMGD experiments in mice have shown a pulsed, therapeutic, ultrasound (US) treatment at 1.1 MHz frequency, 14 Hz PRF, with 50W power, and 150 μs PD, results in primarily LSEC transection in the liver. We utilized these ultrasound conditions, in combination with RN18 microbubbles (MBs) to enhance gene transfer of a Cas9 plasmid via cavitation. A mixture of MBs and Cas9 plasmid are injected into the portal vein of mice for 30s, while simultaneously the US transducer is placed on the surface of the liver and treated for 60s. For our gene editing animal model, we used immunodeficient mice with a 5 base pair deletion in exon 1 in the FVIII gene (NSG HA mice). The sgRNA is designed to target this deletion location in exon 1 (mF8sgRNA) and included in the Cas9 plasmid. Blood was collected from the mice at various timepoints over 90 days and the FVIII activity was determined via the aPTT assay. The livers were perfused with a digestion buffer prior to collection, and the hepatocyte and LSEC cell populations were separated. DNA was isolated from each cell population and sent for sequencing to evaluate editing efficiency. Sanger sequencing of treated mice liver DNA (n=4) showed LSEC's had an average in-frame editing efficiency of 1.6% and hepatocytes had an average in-frame editing efficiency of 0.68%. Additionally, mice had an average FVIII expression of 5% over the 90 days followed. While this editing efficiency remains relatively low, it is noteworthy that LSECs exhibit a higher efficiency compared to hepatocytes. This observation aligns with the indication that the US condition employed predominantly facilitates the transfection of LSECs. These results indicate that UMGD successfully delivered a CRISPR/Cas9 plasmid into LSEC's of HA mice, facilitating effective gene editing and leading to therapeutic levels of FVIII

1235. Circularization of Non-Viral Single-Strand DNA Template for Gene Correction and Gene Insertion Improves Editing Outcomes in HSPCs

Alex Boyne[1], Arianna Moiani[2], Gil Letort[2], Diane Le Clerre[2], Cosimo Ducani[3], Roger Salvatori[3], Alexandre Juillerat[1], Aymeric Duclert[2], Philippe Duchateau[2], Julien Valton[2]
[1]Cellectis, Inc., New York, NY,[2]Cellectis, Paris, France,[3]Moligo Technologies, Solna, Sweden

Leveraging the TALEN® technology, we developed a gene editing process leading to highly efficient gene correction and gene insertion via homology directed repair, in hematopoietic stem and progenitor cells (HSPCs). We first assessed the potential of non-viral linear single-stranded DNA (LssDNA) donor template delivery strategies versus the more commonly used viral (AAV) delivery. Both strategies led to high and comparable efficiencies of gene correction in HSPCs *in vitro*. We then compared the use of LssDNA versus circularized single-stranded DNA (CssDNA). We found that circularization markedly increased the knock-in (KI) efficiency with respect to its linear counterparts. Interestingly, this increase of KI was correlated to higher viability and a lower knock-out (KO) in circular versus linear ssDNA edited cells, respectively. In-depth characterization of edited HSPCs by scRNAseq unraveled different transcriptomic profiles associated to different donor template formats when using LssDNA or CssDNA, compared to AAV. Overall, we showed that non-viral ssDNA delivery associated to TALEN® gene editing reduces the toxicity usually observed with viral DNA delivery and allows high levels of gene correction in long-term repopulating hematopoietic stem cells. Circularization of the ssDNA has the potential to further increase the rates of KI without impacting cellular viability and fitness, facilitating the development of next generation cell therapies.

1236. Nano-Enhanced Optical Delivery of Optogenes in the Central Nervous System for Pain Modulation

Darryl Narcisse[1], Bob Benkowski[1,2], Matthew Dwyer[3], Samarendra K. Mohanty[4,5]
[1]Opsin Biotherapeutics, Fort Worth, TX,[2]DesignPlex Biomedical, Fort Worth, TX,[3]Texas Christian University, Fort Worth, TX,[4]Nanoscope Therapeutics Inc, Bedford, TX,[5]Opsin Biotherapeutics, Bedford, TX

Purpose: Pain is a major health issue that causes serious deficits in the psychological and physiological state of patients worldwide. Earlier, we have demonstrated pain inhibition by optogenetic modulation of specific neurons in the Anterior Cingulate cortex (ACC) and spinal cord using AAV-based gene delivery. Localized expression of genes in targeted cells is valuable for achieving efficacy without the potential for off-target expression and deleterious effects. Here, we describe the use of far-red laser-based spatially targeted nano-enhanced delivery (NOD) of genes encoding for multi-characteristic opsin (MCO).

Method: MCO is a highly sensitive optogenetic actuator that can be activated by red light, which can penetrate deeper tissue with less absorption and scattering loss. NOD is a non-viral delivery technique that uses nano-enhancers that amplify the light intensity that creates hot spots in the vicinity of targeted cells to perforate the membrane leading to the uptake of the genes. We utilized Gold Nanorods (GNRs) as nano-enhancers along with a 650 nm laser to deliver GAD-MCO genes into dorsal regions of the ACC and lumbar spine. The mixture of GNRs and GAD-MCO plasmids was injected into the target tissue (intracranial for ACC and intrathecal for the spinal cord at the L5-L6 junction) before laser irradiation. The laser beam was delivered via an optical fiber to result in ~ 35 mW power at the surface. Optogenetic stimulation of MCO-sensitized ACC and spinal cord was achieved via a low-power (<1 mW) red LED. Both acute inflammatory (via formalin injection) and chronic neuropathic hyperalgesia (by sciatic nerve constriction) pain models were used to evaluate the therapeutic efficacy of laser-delivered and optically-stimulated MCO in ACC and spinal cord. Results: The qPCR-based evaluation of MCO-transgene biodistribution showed localized presence in the targeted tissues. Immunohistochemistry of targeted tissue shows robust expression of mCherry (reporter for MCO) in the inhibitory GABAergic neurons of the ACC and spinal cord regions targeted by laser irradiation. Red light stimulation (via LED) of MCO-expressing GABAergic neurons of localized regions in ACC and spinal cord led to inhibition of inflammatory pain (measured by formalin test of licking/lifting) as well as reduction of chronic pain (assessed via paw withdrawal threshold using Von Frey assay). Conclusion: Non-viral laser delivery of MCO to neurons in the ascending /descending pain pathway has the potential to improve the efficacy of optogenetic modulation by localizing the gene expression at the site(s) of interest. The NOD method will also enable control on duration of gene expression and redosing while avoiding immune rejection and adverse events typical of virally delivered gene therapies.

Thursday Posters: Other Nonviral Delivery

1237. Lipid Nanoparticles Encapsulating FVIII Transgene as Re-Dosable and Durable Non-Viral Gene Therapy in Hemophilia A

Meng-Ni Fan, Xiaohe Cai, Ting-Yen Chao, Yuanyi Xu, Carol H. Miao

Seattle Children's Research Institute, Seattle, WA

Background: Current viral vector-based gene therapy has demonstrated success in achieving therapeutic coagulation factor levels in both hemophilia A and B. However, the application is restrained by potential risks and challenges arising from pre-existing neutralizing antibodies against these vectors. Additionally, post-therapy development of neutralizing antibodies poses hurdles for vector re-administration, crucial for maintaining adequate coagulation factor levels over time. Non-viral gene therapy utilizing lipid nanoparticles (LNPs) emerges as a promising strategy for treating hemophilia without the concerns of vector-neutralizing antibody formation hindering the therapeutic effects. **Goal:** Our goal is to establish non-viral gene therapy by using lipid nanoparticles to deliver FVIII plasmid with re-dosable capability to achieve stable and therapeutic levels of FVIII expression. **Method:** LNPs were composed of either a biodegradable cationic lipid (LipidA) or the FDA-approved lipid, MC3 as control for formula evaluation. These LNPs encapsulated plasmids comprising a CAG promoter and either secreted luciferase (LNP-scLuc) or FVIII-X10 variant (LNP-FVIII). Expression of scLuc and FVIII were evaluated in LNP injected C57BL/6 mice and HA immunodeficient mice (HA-NSG), respectively. Alanine transaminase (ALT) level in plasma was measured to evaluate hepatotoxicity. **Result:** Significantly higher scLuc expression was observed in mice receiving LipidA-LNP-scLuc compared to MC3-LNP-scLuc at days 1 and 7, showing transfection in 84.4% of hepatocytes in the liver. HA-NSG mice injected with LipidA-LNP-FVIII at doses of 0.5 μg/g (low dose) and 1 μg/g (high dose) exhibited approximately 11.8% and 23.0% FVIII activity at week 1, respectively. Re-administration of LipidA-LNP-FVIII resulted in peak FVIII expression around 39.1% two weeks after the second injection in the high-dose group. Sustained and detectable levels of FVIII expression were observed for more than 3 months in both high and low dose groups. Importantly, no significant elevation in plasma ALT levels was detected in LipidA-LNP-FVIII treated HA-NSG mice during the initial 2 weeks, suggesting the absence of apparent hepatotoxicity. **Conclusion:** Our results highlight the potential of LNPs as a non-viral approach for hemophilia A gene therapy, mitigating the risks linked with viral gene therapy. Moreover, the LNP platform allows re-administration strategies to sustain the therapeutic benefits.

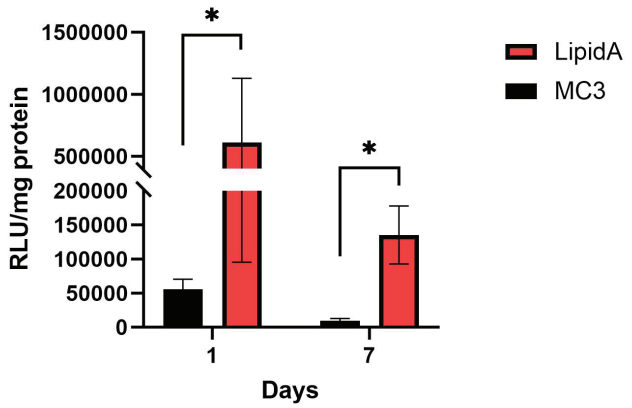


Figure 1. LNP formula comparison

C57BL/6 mice injected with LipidA-LNP-scLuc (shown in red) exhibited significantly elevated levels of scLuc expression in comparison to MC3-LNP-scLuc (shown in black) at both day 1 and day 7. Statistical difference was analyzed using Mann-Whitney test (*$p < 0.05$).

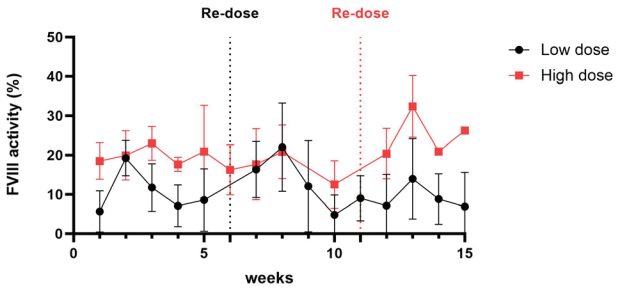

Figure 2. Plasma FVIII activity in HA-NSG mice administered with varied dosages of LipidA-LNP-FVIII

Plasma FVIII activity in HA-NSG mice receiving LipidA-LNP-FVIII at low dosage (0.5 μg/g, shown in black) or high dosage (1 μg/g, shown in red) was monitored over time. LipidA-LNP-FVIII was administered at week 0 and 6 for the low dosage group and at week 0 and 11 for the high dosage group.

1238. ARMMs as Non-Viral Vehicles for the Delivery of Therapeutic Payloads to Liver Sinusoidal Endothelial Cells

Ryan von Kleeck, Shu-Lin Liu, Carson Semple, Lucy Sun, Pearl Moharil, Wendy Zhao, Jennifer Badji, Emmanuel Appiah, Kevin Le, Steven Greenway, Qin Yu, Joseph Nabhan

Vesigen Therapeutics, Cambridge, MA

Viral and non-viral approaches including AAVs and LNPs have been used to deliver therapeutics to the liver. However, selective delivery of payloads to specific cell types, such as Liver Sinusoidal Endothelial Cells (LSEC), remains a challenge. We engineered a class of extracellular vesicles called ARMMs (ARRDC1 Mediated Microvesicles) to enable non-viral delivery of a wide range of payloads including RNA, proteins and gene editing protein/RNA complexes (Cas9/gRNA). To evaluate functional delivery of ARMMs to various liver cell populations *in vivo*, we intravenously administered ARMMs loaded with Cre recombinase protein to Ai14 reporter mice and evaluated downstream tdTomato reporter gene activation. We observed a high level of biodistribution of ARMMs to Kupffer Cells and LSECs with no Hepatocyte uptake. Furthermore, *in vivo* administration of ARMMs loaded with Cas9/gRNA showed notable gene editing efficiency in the LSEC population. These results suggest that delivering therapeutically-relevant payloads using ARMMs may be an effective approach to treat liver diseases involving the LSEC population, such as Hemophilia A.

1239. Optimizing Lipid Nanoparticle Formulations for Enhanced Non-Viral Gene Therapy: Overcoming DNA Delivery Challenges and Achieving High-Efficiency Transgene Integration

Hua Wang, Nicholas Cam, Alicia Davis, Khalid Hajj, Gopi Vemuri, Minghao Xu, Lijun Huang, Brian Truong, Sang Jun Lee, Johnnatan Tamayo, Eliana Estrada, Fernando Lopez Espinoza, Cindy Negron, Matt Nitzahn, Arturo Barcenas, James Clancy, Johannes Schwerk, Mu Li, Michael Bennett, Joshua Rychak

Poseida Therapeutics, San Diego, CA

Non-viral gene therapy technologies face significant challenges in achieving efficient gene correction or gene delivery. Despite recent advances with lipid nanoparticle technologies, safe and effective DNA delivery has proven very difficult. DNA is particularly challenging due to its unique physicochemical properties, its potent immunogenicity, its susceptibility to nuclease-mediated degradation in the cytosol, and the requirement of nuclear translocation. These challenges have been tackled through our focused optimization of DNA delivery to hepatocytes, in vivo, and genomic integration using the piggyBac® DNA insertion system and the super piggyBac transposase (SPB). We developed purpose-built lipid nanoparticle (LNP) formulations for efficient DNA encapsulation and delivery, using a design-of-experiment (DoE) approach. High-performing LNPs showed consistent physicochemical properties, but plasmid DNA (pDNA) required unique lipid-to-payload ratios, indicating a need for custom formulation. Exploring the role of ionizable lipids further, we created a library of 28 lipidoids combining common amine cores and novel terpene-based hydrophobes. While many lipids efficiently delivered mRNA, fewer were effective for pDNA. Further lipid design identified additional unique ionizable lipids with enhanced pDNA encapsulation and delivery capabilities. For hepatocyte targeting and immune cell avoidance, LNPs were modified with a GalNAc moiety, yielding dramatic decreases of IFN-gamma, liver transaminases (AST and ALT), and markers of biliary atresia (GGT). To address challenges unique to pDNA delivery and cellular trafficking, we evaluated the performance of LNPs in conjunction with a novel class of amphipathic compounds, with the hypothesis that such compounds would improve endosomal escape. We identified multiple compounds that provided a pronounced effect on LNPs encapsulating DNA plasmid reporters in HepG2 cells. An evaluation of one such compound yielded a nearly 2-log enhanced expression of a luciferase reporter, as measured by *in vivo* bioluminescence imaging. These LNP platform improvements were combined and applied to liver-directed gene therapies using the SPB transposase for transgene cargo integration. In a mouse model of Hemophilia A, characterized by a deficiency of FVIII, our optimized LNP-DNA formulations achieved FVIII levels much higher than conventional LNPs, reaching nearly 800% of normal. In another disease model, Arginase-1 deficiency, a urea cycle disorder that affects ammonia processing, the LNP platform yielded Arg1 expression in 20% of hepatocytes in juvenile mice, nearing the efficiency level of an AAV vector. In conclusion, DNA delivery requires unique LNP formulation parameters and optimized excipients for maximizing

cellular trafficking. Such optimization realizes the full potential of our non-viral DNA platform technology and piggyBac DNA insertion system for treating serious genetic disorders.

1240. Optimization of Ionizable Lipid Structure to Modulate ApoE Binding and Enable Stealth Lipid Nanoparticles

Daniele Vinciguerra, Douglas Rose, Sandy Serizier, Andrew Milstead, Nolan Gallagher, Viktoriya Syrovatkina, Ryan Delaney, Prudence Li, Di Bush, Matthew Stanton, Randall Toy

Generation Bio, Cambridge, MA

Lipid nanoparticles (LNPs) are the primary means of non-viral delivery of nucleic acid gene therapies. With the current generation of clinically validated LNP delivery systems, their efficacy is dependent on the activity of the serum apolipoprotein E (ApoE) (1). As an important fat transporter, ApoE binding may have a substantial impact on LNP circulation time and hepatic uptake. Therefore, modulating ApoE binding could be an important method by which hepatic LNP uptake can be circumvented, which is an important characteristic toward the development of stealthy, long-circulating LNPs. We hypothesized that ApoE binding is dependent on the LNP lipid composition and more specifically, on specific structural elements of the ionizable lipid. Starting from a parental ionizable lipid, we modified different chemical regions of the lipid and assessed the impact of these structural changes. To determine biologically-relevant ApoE binding, we leveraged the ApoE-HSPG-LDLR pathway, which enables liver-specific LNPs accumulation in hepatocytes (2) and developed a heparin affinity chromatographic method that allows for rank ordering of LNPs based on their ability to productively bind ApoE. Following serum incubation, LNPs with higher ApoE binding interact more effectively with the column, allowing for selection of ionizable lipids that do not effectively recruit ApoE. Specifically, we demonstrate that correct positioning of a degradable ester along the lipid tail can significantly change binding as compared to the parent ionizable lipid, whereas lengthening the ionizable lipid tails leads to a decrease in binding. Interestingly, rank ordering of lipid binding to the column changed when sera from different species was used, indicating that certain ionizable lipid structures may preferentially harvest species-specific ApoE isoforms. To directly assess the impact of modulating ApoE binding on uptake and expression in hepatocytes, we leveraged hepatocyte cell lines and measured uptake and expression using DiD-positive, GFP mRNA-containing LNPs. We found that following serum incubation, decreased ApoE binding is correlated to decreased hepatocyte uptake and expression. The properties of reduced ApoE binding and hepatocyte uptake, while maintaining endosomal escape are ideal for applications outside of the liver. Our stealth compositions that have been retargeted to other cell types such as T cells take advantage of ionizable lipid designs aimed at minimization of lipoprotein binding. (1) Akinc A. et al. Targeted Delivery of RNAi Therapeutics With Endogenous and Exogenous Ligand-Based Mechanisms. Mol. Ther. 2010, 18 (7), 1357 - 1364. (2) Sato Y. et al. Different kinetics for the hepatic uptake of lipid nanoparticles between the apolipoprotein E/low density lipoprotein receptor and the N-acetyl-Dgalactosamine/asialoglycoprotein receptor pathway. 1241. Development of Cell-Targeted Lipid Nanoparticles Using Antibody Derived Ligands for Targeted Delivery to Hepatocytes and Immune Cells

Douglas Rose, Lalita Oonthonpan, Ryan Delaney, Nolan Gallagher, Andrew Milstead, Anthony Perniciaro, Luke Hamm, Matt Manganiello, Brandon Johnston, Di Bush, Anthony Brouillard, Pei-Ni Tsai, Nathaniel Silver, Connie Martin, Tiffany Tate, Raphael Gagne, Dan Garafola, Yao Xin, Thamara Desilva, Christian Slubowski, Matthew Stanton, Phillip Samayoa

Generation Bio, Cambridge, MA

The field of gene therapy has long sought a non-viral redosable delivery strategy that can reach both the liver and extra-hepatic cell populations. To that end, Generation Bio has developed a cell-targeted lipid nanoparticle (ctLNP) capable of delivering nucleic cargo to targeted cell populations. Our ctLNP comprises three primary components: a stealth LNP carrying a nucleic acid cargo, an optimized bioconjugation linker, and a modular targeting ligand that directs receptor-selective biodistribution of the ctLNP to the intended cell population. The stealth LNP is a key component of this technology and exhibits minimal protein corona formation and extended residence time in the blood, avoiding off-target clearance by liver and spleen and allowing for efficient, highly selective redirection to cells of interest. This profile may enable ctLNPs to target tissues and cell types that have been previously out of reach for genetic medicines. Our demonstration of cell-type-specific targeting began in the liver with the asialoglycoprotein receptor (ASGPR), which has been clinically validated as a target for delivery of small interfering RNA and anti-sense oligonucleotides to the liver. Most commonly, ASGPR is targeted using multivalent GalNAc ligands which have a high affinity for the multimeric ASGPR complex. Initial work with GalNAc targeting ligands on a ctLNP demonstrated delivery to hepatocytes. However, increasing levels of GalNAc led to increased delivery to Kupfer cells, a cell type that expresses CLEC10A (CD301), which contains a conserved carbohydrate recognition domain shared with ASGPR. To reduce off target delivery, we took a protein-based ligand approach and identified an antibody fragment that shows higher binding affinity towards ASGPR over CLEC10A, which were conjugated onto stealth LNPs. To maximize ctLNP performance, we optimized the ligand identity, bioconjugation linker chemistry, linker length, and ligand density and assessed their impact on the physicochemical properties and functional activity of the ctLNPs. We also evaluated conjugation process steps that influence reaction completion, avoid formation of degradation products, preserve LNP characteristics after conjugation, and remove unreacted materials. Interestingly, while high ligand densities typically lead to lower ctLNP stability, ligand density can be tuned to find the optimal amount of stability and functional activity. Additionally, the spatial orientation and local accessibility of the targeting ligands play vital roles in the functional activity of the ctLNP. We compared the performance of ctLNPs with multivalent GalNAc ligands against those conjugated to antibody-derived targeting ligands and observed enhanced delivery to hepatocytes both *in vivo* and *in vitro* when using our antibody-derived ligands. From this initial demonstration, we have built upon our ctLNP technology and demonstrated successful extrahepatic targeting of immune cells. Starting from the previously optimized conjugation conditions, we

further refined ligand conjugation for T-cell targeting and attached the most highly specific and high affinity T-cell receptor-targeted ligands to our stealth LNPs. The resulting ctLNPs were evaluated based on their ability to deliver a GFP-expressing mRNA cargo into T-cells. We demonstrated that ctLNPs targeting CD3 led to significant amounts of T-cell depletion while targeted delivery to other T-cell receptors of interest led to a dose-responsive level of GFP expression with minimal off target delivery to myeloid & B-cell populations.

1242. Development of AAV No-End DNA-Containing Lipid Nanoparticles for Improved Delivery and Transgene Expression

Porkizhi Arjunan[1,2], Jakob Shoti[1], Yamika Ramesh[1], Keyun Qing[1], Srujan Kumar Marepally[2], Arun Srivastava[1]

[1]University of Florida, Gainesville, FL,[2]Centre for Stem Cell Research, Vellore, India

We have described the development of an AAV DNA-based synthetic vector, termed no-end DNA (NE-DNA), which is devoid of AAV capsid proteins, and mediates sustained expression following transfection into human hepatic cells (*Frontiers in Microbiology*, 13: 1033615, 2022). However, since NE-DNA is unlikely to be efficacious *in vivo*, in the current studies, we synthesized a number of lipid nanoparticles (LNPs) - Lipo 1-Lipo 12, based on our previous observation that galactosylated lipids mediate delivery of nucleic acids to liver with higher precision (*Biomaterials*, 2009 30: 2369-2384, 2009). These LNPs were used to encapsulate linear and NE-DNAs containing firefly luciferase (FLuc) and enhanced green fluorescence protein (EGFP) reporter gene expression cassettes. The encapsulation productivity was characterized by gel-retardation and heparin-displacement assays, and the stability of encapsulated DNA was corroborated by DNase 1-sensitivity assay. Each of the LNPs was used to transduce a human endothelial cell line, SK-Hep-1 and a human hepatic cell line, Huh7. These results for FLuc expression are shown in the two cell lines in **Figure 1A** and **Figure 1B**, respectively. As can be seen, in both cell lines, the extent of transgene exprpression was significantly higher with most of the LNPs containing the NE-DNA than those containing the linear DNA, and Lipo 1 was found to be the most efficient. Cyotoxicity assays revealed >90% viability in both cell lines transduced with Lipo-1, and was used in all subsequent experiments. Similar results were obtained with Lipo 1-EGFP LNPs in both cell lines, which were similar to that with the commercially available cationic liposomes, Lipofectamine (LF) (**Figure 1C** and **Figure 1D**). The efficacy of Lipo 1-FLuc LNPs, containing linear and NE-DNAs is curently being evaluated in a mouse model *in vivo*. Experiments are also currently underway to encapsulate linear and NE-DNA containing human clotting factors (hFVIII and hFIX) under the control of a liver-specific promoter. The development of Lipo 1-NE-DNA presents a promising strategy for repeat administration of hFVIII and hFIX genes, for the potential gene therapy for hemophilia A and hemophilia B, respectively, in humans.

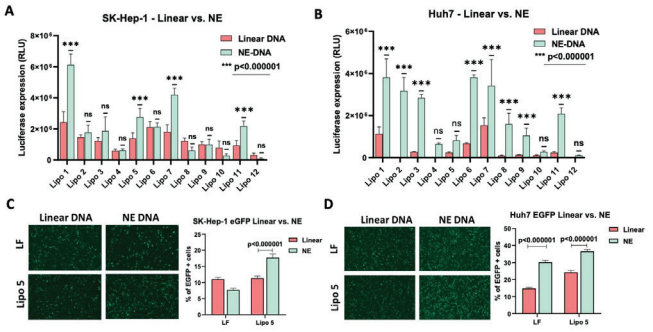

Figure 1: Firefly luciferase expression in human endothelial **(A)** and hepatic **(B)** cell lines mediated by LNPs containing linear- and NE-DNA. EGFP expression in human endothelial **(C)** and hepatic **(D)** cell lines mediated by Lipofectamine (LF) and Lipo 1 LNPs containing linear and NE-DNA. Transgene expression was determined 96 hrs post-transduction.

1243. Spatial Resolution of mRNA Lipid Nanoparticle-Based *In Vivo* Base Editing in the Liver of Mice and Monkeys

Thomas Chamberlain[1], Sharan Janjuha[2], Tatjana Haenggi[2], Kim Marquart[2], Merete Eisenhardt[1], Sean C. Semple[1], Gerald Schwank[2], Ying Tam[1]

[1]Acuitas Therapeutics Inc, Vancouver, BC, Canada,[2]Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland

mRNA lipid nanoparticles (mRNA-LNP) enable effective delivery of gene editing systems following intravenous administration, particularly in the liver. This strategy offers several potential advantages compared to viral delivery approaches, including an improved safety profile (no likelihood of insertional mutagenesis, limited duration of expression), larger payload capacity, and the opportunity to repeat dose. In recent years, the mRNA-LNP platform has been utilized in preclinical and clinical studies to enable various gene editing tools, including CRISPR/Cas9 nucleases, zinc-finger nucleases, TALENs and base and epigenetic editors. However, to fully realize the potential of mRNA LNP delivered gene editors for treatment of diverse genetic diseases, it is important to rigorously assess, validate and optimize the in vivo activity of mRNA-LNP. For example, since there are differences in the properties and functions between hepatocytes in the liver (ie. pericentral and periportal), it is important to understand and quantify the relative editing that can be achieved in the different subpopulations of hepatocytes. To address this question, we adopted imaging-based in situ sequencing and quantified in vivo base editing rates in native liver tissues. Mice and non-human primates were treated with two doses of LNP encapsulating mRNA encoding base editors that installed A to G mutations at two different loci. The sequence of dosing (ie. first locus 1 and then locus 2 or vice versa) did not affect editing rates, and we frequently observed hepatocytes that were edited on both loci. Moreover, we found that base editing was similarly effective in both periportal and pericentral hepatocytes. These findings suggest that mRNA-LNP delivery of base editors following intravenous administration is a feasible approach for in vivo targeting of a wide spectrum of genetic liver diseases.

1244. Delivery of mRNA in Porcine Kidneys by Iontophoresis: A Promising Alternative Delivery Approach for Extra-Hepatic Genomic Medicine Delivery

Maria P. Torres-Gonzalez[1], Raquel Maeso-Diaz[1], Leigh Dement[1], Brendan Berkel[1], Justin Stegeman[1], Ahmed Hassan[2], Andrew S. Barbas[2], William Daunch[1]

[1]Research and Development, Focal Medical, Inc., Cary, NC,[2]Duke Department of Surgery, Duke University, Durham, NC

Among novel genomic medicines with promising potential, mRNA therapeutics are at the forefront for targeted treatments. However, delivering these molecules effectively to target cells without eliciting undesirable immune responses remains a significant challenge. The delivery of mRNA molecules by iontophoresis (IOP) represents a promising alternative to achieve targeted delivery to a specific organ, potentially minimizing off-target effects and extending therapeutic kinetics in comparison to standard delivery methods. The following study investigated the feasibility of IOP to deliver mRNA in a benchtop agarose model, *in-vitro* on porcine kidney cell lines, and *in-vivo* to porcine kidney tissue. The successful delivery of mRNA by IOP was first evaluated using a benchtop agarose gel model, in which numerous parameters were optimized including electrode type/material, electrode design/configuration, current, and treatment duration. After multiple iterations of these parameters, the optimum delivery of mRNA mimicking a kidney cortex delivery depth was obtained at 5mA treatment for 90min (Figure 1A). The transfection efficiency of IOP delivery of liposome-encapsulated EGFP-mRNA was optimized on porcine kidney cell lines embedded in 3D bioprinted GelMA Alginate hydrogel models. Representative microscopy data clearly shows that IOP-treated cells expressed fluorescence (i.e. EGFP) as opposed to cells treated by diffusion alone after 24hr of treatment (Figure 1B), which was further confirmed by One-step-RT-PCR (data not shown). Collectively, results obtained from these tissue surrogate models' experiments were used to systematically design *in-vivo* studies to deliver encapsulated mRNA by IOP directly to kidney tissue. Briefly, a prototype iontophoretic device was placed directly on the kidney of anesthetized Yorkshire female pigs and IOP treatment was administered at 5mA for 90min. After 24hr recovery, and following IACUC guidelines, necropsy was executed, and kidney tissue biopsies were collected and preserved for subsequent analysis. Overall animal health was excellent and no adverse kidney tissue/systemic toxicity reactions were observed. In agreement with results from tissue surrogate models, EGFP-mRNA expression was significantly upregulated in porcine kidney cortex biopsies when compared to passive diffusion delivery (Figure 1C), which was further confirmed by fluorescence microscopy (data not shown). Altogether these results validated the usefulness of surrogate tissue models used in the study by demonstrating that the device configuration selected, and the treatment conditions identified in these, were indeed mimicking *in-vivo* kidney delivery of mRNA, including tissue depth, coverage and transfection efficiency. Overall, the efficient delivery of functional mRNA by IOP was demonstrated across different models evaluated on this study. Potential benefits from this novel delivery platform include precise delivery, lower dose administered, greater efficacy, and minimized toxicity. Altogether, taking into consideration that extra-hepatic delivery of mRNA is desired to treat a vast array of common and rare, monogenic, and polygenic diseases, IOP technology represents a promising alternative to viral and non-viral vector delivery approaches to a wide range of solid organs other than the liver.

Figure 1. 1245. Efficient Gene Editing in CD34+ Hematopoietic Stem and Progenitor Cells Using Non-Viral Lipid Nanoparticles

Aruna Balgi, Stella Park, Rita Zhao, Meenakshi Swaminathan, Nikita Jain, Anitha Thomas, Samuel Clarke, Angela Zhang, Reka Geczy

Cytiva, Vancouver, BC, Canada

Background and Aims: CRISPR-Cas9 gene knockouts in CD34+ hematopoietic stem and progenitor (HSPC) cells is emerging as a transformative tool for the correction of mutations that cause genetic blood diseases. This study expands on previous work, where we used a novel lipid nanoparticle (LNP) reagent for the multiplex gene editing of CAR T cells, yielding high viability and efficient editing. In this work, we explore the use of LNPs for the efficient CRISPR-Cas9 editing of CD34+ HSPCs, highlighting the vast potential of LNPs for pioneering gene therapeutics. **Methods:** LNPs encapsulating S.p. Cas9 mRNA and sgRNAs targeting CD33 or CD45 were formulated using the NxGen mixing platform allowing for scalable LNP production. The LNP composition was optimized for RNA delivery to HSC/HSPCs. Frozen, isolated human CD34+ cells were stimulated and RNA-LNPs directly added to the cells. Cells from various sources, such as mobilized peripheral, bone marrow and cord blood were evaluated. Further, various cell culture conditions, such as treatment kinetics, media and supplements were evaluated and optimized for efficient LNP delivery. Gene editing efficiency and cell viability was assessed via flow cytometry, proliferation using an automated counter, and differentiation potential through CFU assays. **Results:** Direct LNP addition to CD34+ HSPCs achieved an average of 84 ± 6% of CD33 and 81 ± 2% of CD45 knockout efficiencies in six separate experiments. Post-treatment, the cells retained an average of 95 ± 3% viability. The LNP-treated HSPCs showed strong cell proliferation, maintaining >90% proliferation relative to untreated controls. The CFU assays indicated unchanged lineage formation in both RNA-LNP and empty LNP controls. Additionally, the study successfully scaled up LNP production from research to pre-clinical scales using the microfluidic technology. **Conclusions:** This study demonstrates the potential of LNP-mediated CRISPR-Cas9 mRNA delivery as a promising approach for gene editing in HSPCs. The simple and gentle nature of LNP cell treatment allows for multiple genetic alterations for simultaneous expression and deletion of proteins paving the way for innovative gene therapies. The scalability of LNPs, enabled by novel mixing technology, permits efficient RNA library screening at small scales, and facilitates swift transition to large-scale clinical applications.

1246. Fractionation of Distinct Extracellular Vesicle Populations by Charge and Density to Evaluate the Heterogeneity and Purity of ARMMs

Kristin Luther, Adam Francouer, Leah Gens, Steven Greenway, Alysia Bryant, Ishaan Tiwari, Zachary Shelnitz, Gary Hao, Joseph Nabhan
Vesigen Therapeutics, Cambridge, MA

The class of extracellular vesicles (EVs) known as ARMMs (ARRDC1 mediated microvesicles) has recently been established as a platform for delivery of therapeutic proteins such as Cas9/gRNA complexes to specific tissues in vivo. This is accomplished by expressing the therapeutic protein fused with ARRDC1, leading to its incorporation in ARMMs. However, little is known about the physicochemical characteristics of ARMMs and how they differ from other types of extracellular vesicles, which can be concomitantly produced during upstream culture. Understanding this may enable us to achieve better separation of ARMMs from other vesicles, as well as provide insights into the unique properties of individual subclasses of EV. We used anion exchange and density gradient ultracentrifugation to fractionate crude EV preparations. We found that vesicles eluted in two distinct peaks during anion exchange (AEX), while during density gradient separation, they distributed over a range of densities from 1.02-1.11 g/cm3. Next we subjected the particles from both AEX peaks to density gradient separation. Both AEX peaks contained ARMMs, but the first peak had lower payloading, a less negative zeta potential, and lower gene editing activity than the second peak. With density gradient separation, the vesicles gradually became smaller and more negatively charged as the density increased until reaching 1.11 g/cm3, and the number of ARRDC1 molecules per particle increased. This increase was associated with enhanced gene editing potency in vitro and in vivo. Another population of particles was detected at a density of 1.17 g/cm3 that were of similar size to the vesicles, but had neutral zeta potential, and low expression of vesicle markers or ARRDC1. Taken together, the data suggest that ARMMs are smaller, denser, and more negatively charged than other types of EVs secreted by the current producer cells, and that combining purification methods can lead to higher enrichment of ARMMs in our product.

1247. ARMMs as a Versatile and Modular Non-Viral Platform for the Functional Delivery of Genome Editors

Qiyu Wang, Wendy Zhao, Mike Thomas, Shu-Lin Liu, Lucy Sun, Ryan von Kleeck, Zahra Baghbantaraghdari, Chou-Wei Chang, Jennifer A. Badji, Komal Vyas, Qin Yu, Joseph F. Nabhan
Vesigen Therapeutics, Cambridge, MA

An expanding array of genome editing tools and their derivatives are broadening the scope of potential therapeutic applications. However, a substantial majority of these applications face challenges in efficiently delivering gene editing technologies to tissues and cell types affected by diseases without inducing any toxicity. The primary obstacle lies in identifying non-viral carriers capable of ensuring safe, transient, and highly efficient functional delivery. In response to this challenge, we have developed ARMMs (ARrestin-domain 1 Mediated Microvesicles) as a targeted and re-dosable therapeutic platform for delivery of genome editors. This study details the successful loading of ARMMs with Cas9, ABE (Adenine base editor), and CBE (Cytidine base editors) complexed with guide RNA (gRNA) as fully functional ribonucleoproteins (RNPs) within ARMMs. We assess the functional delivery of these loaded payloads in vitro across various cell types, including post-mitotic cells. Moreover, our investigation extends to in vivo genome editing, revealing remarkably high levels, exceeding 60% in certain instances. Our data showcase robust editing of druggable or undruggable immune modulation targets, such as NLRP3 or IRF5, in both alveolar macrophages and Kupffer cells in mice and non-human primates (NHP). Importantly, in macrophages we demonstrate a significant reduction in downstream pro-inflammatory signals when we disrupt expression of NLRP3 or IRF5 using ARMMs. Collectively, our findings suggest that ARMMs serve as a versatile and modular non-viral platform for the functional delivery of genome editors, presenting a promising avenue for disease modification.

1248. Engineering ARMMs with Modular T Cell-Specific Engagers for Non-Viral Delivery of Therapeutic Payloads

Wendy Zhao, Lucy Sun, Qiyu Wang, Pearl Moharil, Mike Thomas, Silvia Piccinotti, Zahra Baghbantaraghdari, Chou-Wei Chang, Qin Yu, Joseph F. Nabhan
Vesigen, Cambridge, MA

Intracellular delivery of therapeutic payloads, such as RNA, protein, or genome editors, holds the key to treating a wide range of diseases. A major hurdle for payload delivery is the limited biodistribution of existing delivery vehicles to target cell-types. Overcoming this major hurdle, which involves identifying a versatile vehicle conducive to safe and functional delivery of these payloads to specific cell types through various administration routes, has been challenging. In this study, we engineered membranes of ARRDC1 mediated microvesicles (ARMMs) to display anti-CD8 or CD4 antibodies that interact with specific T cell populations. This approach demonstrated the ability to specifically retarget these vehicles to CD8+ or CD4+ T cells in in vitro cell lines and ex vivo primary cells. We also demonstrated targeted functional delivery of gene editing complexes to specific T cells in ex vivo primary cells, as well as robust detargeting of cells not expressing the target receptors. This demonstrated the adaptability of ARMMs to deliver therapeutic payloads to specific immune cell types and suggests that it may be possible to envision in vivo T-cell based therapeutic strategies.

1249. Engineering Directed Tropism in the Non-Viral ARMMs Delivery Platform

Silvia Piccinotti, Mike Thomas, Wendy Zhao, Nelly Valkov, Patrick Schupp, Qiyu Wang, Lucy Sun, Shu-Lin Liu, Zahra Baghbantaraghdari, Chou-Wei Chang, Hongru Zhou, Qin Yu, Joseph Nabhan
Vesigen Therapeutics, Cambridge, MA

Therapeutic macromolecules such as RNA, proteins and genome editors are poised to bring novel treatments for diseases with high unmet need. A persistent hurdle for the development of intracellular

large molecule therapeutics is their dependence on delivery vehicles with often limited biodistribution to introduce them into target cell-types. The biodistribution of adeno-associated viral (AAV) vectors and lipid nanoparticles remains largely limited to the liver and a few other tissue types. No major advances have been made to identify or engineer novel AAVs or to modify the tropism of LNPs. Therefore, many medically important tissues remain inaccessible. Pre-existing and emerging immunity to AAV and LNP components from natural or widespread vaccine exposure further limit the efficaciousness of these carriers. New delivery platforms amenable to tissue tropism engineering are crucial to sustain the development of macromolecular therapies. We report ARRDC1-mediated microvesicles (ARMMs) as a non-viral delivery platform with robust surface customization potential. We demonstrate that ARMMs can incorporate high densities of plasma membrane and endosomal fusogens as well as chimeric surface proteins engineered to bind specific cellular receptors. By altering surface binders, we have engineered ARMMs that selectively target cell types of interest in mixed in vitro and ex vivo cell cultures. These results suggest that ARMMs can be engineered to deliver therapeutic payloads to a variety of target tissues and cell types.

1250. An *In Vitro* Screening of Lipidnanoparticle (LNP) Formulations to Assess Intrinsic Cellular Targeting for Non-Viral Delivery

Anna Potenski[1], Gabriel Gamber[2], Lakshmi Raj[2], Hon-Ren Huang[3]

[1]Biologics Research Center, Novartis, Cambridge, MA,[2]Novartis, Cambridge, MA,[3]Novartis Pharma AG, Lexington, MA

Lipid nanoparticles (LNPs) have emerged as a promising non-viral delivery modality for cell and gene therapies due to their adaptability and chemical customizability. While there have been commercially successful uses of LNPs for vaccines and liver-targeted siRNA drugs, targeted delivery to extrahepatic tissues remains a challenge to expanding the development of this modality, and there is significant interest in understanding the inherent targeting capabilities of different LNP formulations. To understand the intrinsic cellular targeting preferences of different LNP formulations, we executed an *in vitro* screen of LNP formulations in multiple different cell lines, including primary cells. By utilizing GFP mRNA as the delivery cargo, we were able to use Incucyte imaging to track which LNPs are able to successfully transfect each cell type, as well as follow the kinetics of delivery and protein expression for each formulation. A screen like this has not been done before in this capacity and the data obtained provides a fingerprint of the cell type specificity of each formulation, which could identify lead LNPs for further development in extrahepatic indications.

1251. Streamlining Antibody Lead Generation: An Integrated Prioritization and Production Solution

Crystal Richardson[1], Ilaria DeVito[1], Anthony Moore[1], Andrea O'Hara[1], Zain Alvi[1], Pranay Vishwanath[1], Brian Sereni[1], Suhani Nagpal[2], Amy Migliori[2], M. Frank Erasmus[3], Laura Spector[3], Katheryn Perea-Schmittle[3], Michael Karney[1], Laure Turner[1], Sumit Kumar[1]

[1]Azenta Life Sciences, Burlington, MA,[2]OpenEye, Cadence Molecular Sciences, Santa Fe, NM,[3]Specifica, Santa Fe, NM

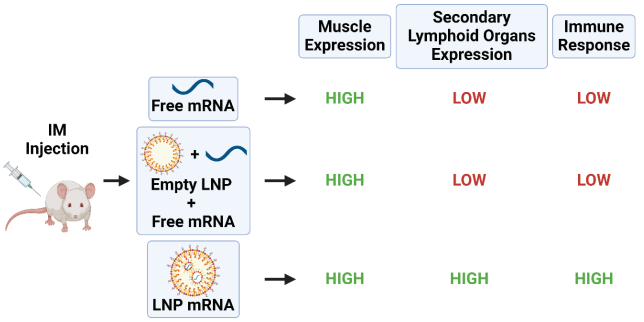
Harnessing the specificity and versatility of antibodies for cell and gene therapies as a delivery vehicle offers a transformative advance for precision medicines. From their ability for targeted delivery of therapeutic payloads to modulation of cellular interactions, antibodies hold immense potential in refining the precision, efficacy, and safety of future therapies. However, finding the right antibody candidate can be laborious and inefficient. Herein, we introduce an advanced and comprehensive solution to quickly identify and produce antibody leads for cell and gene therapy. This method involves the use of next-generation sequencing of outputs derived from both *in vivo* (i.e., B-cells and PBMCs) and *in vitro* (i.e., phage display) discovery campaigns. We pair this with an advanced bioinformatics platform that leverages machine learning to optimize the selection of potential antibody candidates. With this approach, it uncovered 5 - 50x more of the population diversity compared to traditional methods (e.g., random colony screening with Sanger). While next-generation sequencing expands the coverage of the underlying sequence diversity, top candidates are prioritizes using machine learning, selecting diverse leads from distinct clusters and prioritizing leads within clusters that have a reduced number of sequence-based liabilities. Once candidates are selected, they can be efficiently produced because we optimized expression vectors for high production rates. Thus, resulting in a quick and effective solution to generate candidates for vehicles in cell and gene therapy. In summary, we present our advanced end-to-end solution that uses next-generation sequencing, machine learning-based lead prioritization, and optimized antibody expression. Taken together, this platform consistently elevates the number of diverse leads and helps to uncover rare clones with favorable biophysical properties.

1252. Hermes™ Lipopolyplex Nanoparticles for Linear hpDNA™ Delivery

Emily Young, Amine Bouchareb, Gözde Tezcan, Matthew Walker, Hassan Idris, Amy Walker

4basebio, Cambridge, United Kingdom

Non-viral mRNA vaccines have been hugely successful, but instability of mRNA payloads and cold chain storage requirements remain a challenge. DNA is known to be more stable than mRNA. 4basebio's hpDNA™ is synthesised with a size and sequence independent fully enzymatic process, enabling GMP gram scale manufacture. Here, Hermes™ nanoparticles were optimised for hpDNA delivery. These formulations employ both lipid components & cationic ligands to drive payload encapsulation and stability in the liquid state. First, a one-step microfluidics method for combining lipids, ligand & hpDNA was developed. Notably, lipids and ratios used in conventional mRNA lipid nanoparticles (LNPs) precipitated following dialysis in PBS.



Using DOE, lipid & ligand molar ratios were optimised for hpDNA encapsulation. Including a fifth lipid prevented precipitation and had favourable biophysical characteristics and *in vitro* transfection efficiency. Bioluminescent imaging in mice noted luciferase expression >1-log higher with the optimised formulation than a commercial LNP control, and hpDNA™ formulations outperformed those encapsulating plasmid DNA. Finally, storage stability at 4°C of the optimised formulation was assessed. Hermes™ formulations including ligand maintained their size, PDI and encapsulation over the 28-day duration, whereas conventional LNPs displayed a ~40% drop in encapsulation efficiency. This enhanced stability at 4°C promises to overcome the cold chain issues of conventional LNPs. Combined with hpDNA™ stability and improved *in vivo* delivery, Hermes™ is ideally suited to both infectious disease and personalised medicine applications.

1253. The Main Driver of Immune Response to Lipid Nanoparticle-mRNA Vaccines after Intramuscular Injection is the Delivery and Expression of mRNA in the Secondary Lymphoid Organs

Asuka Takanashi

Drug Delivery Disposition and Dynamics (D4), Monash University, Parkville, Australia

Lipid nanoparticles, known as LNPs, have been the primary delivery system used in mRNA vaccines. Past studies have proposed the innate reactogenicity of LNPs to be responsible for producing the vaccine's adaptive immune response. However, it has not been clear whether the main drive for adaptive immune response is due to the adjuvant properties of LNPs in the muscle or the delivery of the formulation to the secondary lymphatic organs. To address this problem, we have formulated mRNA encoding either reporter gene (NLuc), OVA, or SARS-CoV-2 spike protein into LNP or coadministered the mRNA with empty LNP. We injected the formulations via intramuscular administration to correlate the delivery of the formulation with the adaptive immune responses. Compared to the unformulated mRNA or co-administered empty LNPs, high levels of nanoluciferase proteins were detected in the secondary lymphoid organs from LNP-formulated mRNA. Likewise, the LNP-mRNA encoding OVA showed the highest cellular immune response, while the unformulated mRNA or co-administered empty LNPs showed little to no response. Furthermore, only mice vaccinated with LNP-formulated mRNA encoding SARS-CoV-2 spike protein elicited robust cellular and humoral immune responses. Our results suggest that the delivery and the transfection of mRNA in the secondary lymphoid organs are the primary drivers for producing adaptive immune responses in mice. This study will help us design an mRNA delivery system that targets the secondary lymphoid organs for a better vaccine response.

1254. Comprehensive Characterization and Quantitation of Lipid Nanoparticle-Based RNA Formulations

William Penny, Michelle Chen

Waters | Wyatt Technology, Goleta, CA

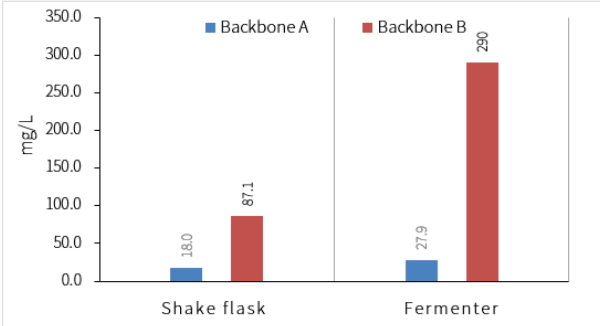
The therapeutic potential of lipid nanoparticles (LNPs) as delivery vehicles has been demonstrated in recent years cumulating in the current emergency use of the mRNA based SARS-CoV-2 vaccines. In order to ensure the safety and efficacy of the LNP-RNA vaccine or therapeutics, various quality attributes of LNP-RNA products need to be measured throughput the product development cycle. In this poster, we will demonstrate the use of a dynamics light scattering (DLS) Plate Reader for fast screening and quality control of the LNP preparations, and multi-angle light scattering (MALS) combined with ultraviolet (UV) and refractive index (dRI) detectors following size exclusion chromatography (SEC) or field flow fractionation (FFF) separation for in-depth characterization. SEC or FFF provides sized based separation, and MALS, UV, and dRI detectors, on the other hand, enables biophysical characterization. We will show the data from the online detectors for the quantitation of particle size distribution, particle concentration, molecular weights of RNA and lipids, and sized-based RNA payload distribution of the LNP-RNA samples.

1255. An Innovative Cationic Lipid Library for Efficient and Tunable mRNA-LNPs

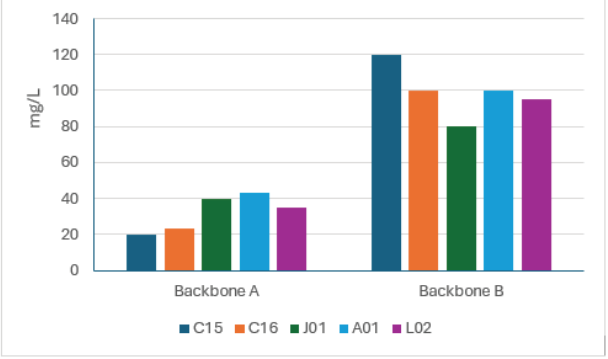
Quentin Huaulme[1], Margaux Briand[1], Kassandra Renaud[1], Eva Thiry[1], Malik Hellal[2], Claire Gueguen[2], Thibaut Ben Chimol[1], Melodie Seiler[1], Morgan Ziesel[1], Patrick Erbacher[1]

[1]Polyplus-Transfection, Illkirch Graffenstaden, France,[2]Polyplus-Transfection, Illkirch, France

Lipid nanoparticles (LNP) have demonstrated high efficiency in delivering RNA therapeutics *in vivo*. However, the properties of such nanoparticles obtained with conventional ionizable lipids are often difficult to modulate, and especially their biodistribution profile. These ionizable lipid-based nanoparticles often predominantly end up targeting the liver. One of the current challenges in the field consists of adjusting the chemical composition of the LNPs to the intended application. Here, we characterized a library of 10 innovative imidazolium-based cationic lipids as key component of cationic LNP (cLNP). We disclose their chemical structures and demonstrate



their efficacy in generating LNPs through characterization of their hydrodynamic diameters, Zeta potentials, and mRNA encapsulation efficiencies. The resulting particles display high transfection efficiencies and have little to no impact on cell viability *in vitro*, on HEK293 and CaCo-2 cell lines. *In vivo*, the biodistribution of the cLNP highly depends on the cationic lipid chemical structures, targeting mainly lungs and spleen. Among this library, we have also identified one cationic lipid as a potent additive in Moderna's Spikevax formulation.



1256. Optimization of Vector Backbone for Increased Yield of Plasmid DNA for mRNA Generation

Guoze Chen

OBiO Technology (Shanghai) Corp., Ltd., Shanghai, China

The sequence elements of mRNA plasmids generally include resistance genes, replication initiation sites, and the GOI (Gene of Interest). The antibiotic resistance in plasmids is typically provided by kanamycin resistance gene to comply with regulatory requirements. Plasmid vectors used for mRNA template or virus packaging are usually high-copy-number plasmids including pUC, pBluescript, and pTZ vectors, typically with pMB1 or CoIE1 as the replication initiation sites. Using a commercial plasmid backbone to construct recombinant plasmids, followed by transformation into E. coli competent cells, and fermentation, we observed that significant differences in fermentation yield occurred if the same GOI gene was cloned into plasmid with different backbone. In a case study, the GOI of code C03 was constructed on backbone A and backbone B, respectively. After transformation into stbl3 competent cells, the cultivation of single clone in shake flasks at 37°C for 12 hours generated a different yield of 18 mg/L for plasmid with background A and 87 mg/L for plasmid with backbone. Moreover, fermentation of the same stain in a fermenter under similar conditions (37°C, 24h), the yields were 27.9 mg/L for plasmid with backbone A and 290 mg/L for plasmid with backbone B. This result indicates that changing the plasmid backbone can significantly increase the fermentation yield by approximately 5 fold in shake flasks and more than 10 fold in fermenters (see Figure 1). Figure1. Shake flask and fermenter yields of Plasmid C03 in backbone A and B. To further demonstrate whether the yield differences caused by plasmid backbones are universal, more Genes of Interest (GOI) were separately constructed into Backbone A and Backbone B, and subjected to shake flask cultivation under the same conditions. The yield of shake flask cultivation is shown in Figure 2. These results further confirm the impact of plasmid backbone on the fermentation yield of those plasmids used as mRNA template. Therefore, when constructing recombinant plasmids, it is essential to compare and optimize the plasmid backbone sequence in order to obtain a plasmid with excellent fermentation yield and superior quality attributes for construction the RCB of bacteria strain. Figure2. The plasmid yields from shake flask cultivation after cloning various GOI into backbone A and backbone B

1257. Novel Ionizable Lipids Derived from Biorenewable Sources Efficiently Deliver Candidate Vaccine mRNA *In Vivo*

Dylan Kairuz[1], Robin Klintworth[2], Aneesa Gani[2], Connor Stockly[2], Abdullah Ely[3], Kristie Bloom[4], Charles de Koning[5], Patrick B. Arbuthnot[4]

[1]University of the Witwatersrand, Johannesburg, South Africa,[2]School of Chemistry, University of the Witwatersrand, Infectious Diseases and Oncology Research Institute, Johannesburg, South Africa,[3]University of the Witwatersrand, Infectious Diseases and Oncology Research Institute, Johannesburg, South Africa,[4]Antiviral Gene Therapy Research Unit, University of the Witwatersrand, Infectious Diseases and Oncology Research Institute, Johannesburg, South Africa,[5]School of Chemistry, University of the Witwatersrand, Johannesburg, South Africa

Lipid nanoparticles (LNPs) are an important class of synthetic nucleic acid vectors. They demonstrated excellent properties as carriers of SARS-CoV-2 spike protein-encoding mRNA, and LNP-mRNA vaccines were vital to counter the COVID-19 pandemic. Nevertheless, clinical translation of LNP-mRNA therapies and vaccines is largely dependent on conveniently scalable and affordable production of the vectors. Traditionally four-component LNPs comprise an ionizable lipid, cholesterol, phospholipid and PEG-modified lipid. The ionizable lipid is an essential constituent that is required for stable particle assembly, cellular uptake and endosomal mRNA release. Currently available ionizable lipids are costly, difficult to prepare and derived from petroleum industry products. To address these limitations, we developed efficient methods for generating ionizable lipids from bio-renewable sources. Components of cashew nut shell liquid (CNSL)

were used as the primary supply of ionizable lipid building blocks. Useful features of CSNL are: 1) unlike other natural oils, CNSL contains only three related lipids, (cardol, cardanol and anacardic acid) which simplifies precursor purification, 2) CNSL is an abundant inexpensive agricultural waste product, and 3) the source is bio-renewable. Hydrogenated cardanol, which comprises a 14-carbon unsaturated lipid chain linked to a benzene ring, was purified from CNSL. A panel of ionizable derivatives of this compound was prepared with side groups on 1,2,4 or 1,3,5 positions of the benzene ring. To vary lipid shapes, different branched and unbranched side chains were added. Ionizable N atoms were included as part of the side chains or within coupled piperazine groups. This enabled pKas to be adjusted and provided further structural variation. Ester bonds were added to enhance metabolic degradation. Synthesis steps were high-yielding, and chromatographic purification was only necessary for the final product, which is useful for scalable synthesis. Four-component novel mRNA-containing LNP formulations were assembled using microfluidics. Encapsulation efficiencies of more than 90% were routinely achieved. Excellent particle diameters, typically approximately 80 nm with polydispersity indices less than 0.3, were consistently obtained. Injection of formulations containing lead ionizable lipids showed good reporter gene expression in vivo after intramuscular or intradermal injection (Figure 1), without evidence of toxicity. Immunogenic mRNA formulations encoding SARS-CoV-2 and *Mycobacterium tuberculosis* antigens are currently being formulated to evaluate immunogenicity and suitability for vaccines. Data from this work, which are being prepared for publication, lay the foundation for advancing a new class of LNPs with diverse applications. Low-cost and bio-renewable properties are unique features that address some of the limitations of current LNP technology.

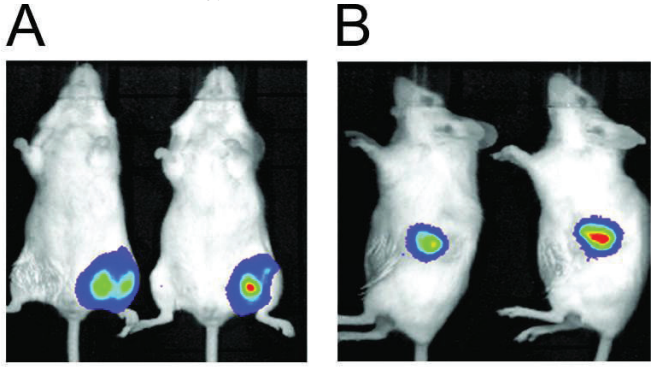


Figure 1. Representative example of Firefly luciferase (FLuc) expression in vivo following (A) IM and (B) intradermal injection of a four-component Fluc mRNA-LNP containing a CNSL-derived ionizable lipid. Imaging of mice was carried out 6 hours after injection.

1258. Strategies for Producing Clinical and Commercial RNA-LNP Drug Products

Samuel Clarke, Ian Johnston, Ashley Braun, Robert Young, Maria Kerin, Deepkanwal Singh, Braeden McDougall, Brian Ma, Anastasia Lazic, Leanna Yee, Curtis Robin, Felix Yuen, Pierrot Harvie, Suraj Abraham

Cytiva, Vancouver, BC, Canada

BACKGROUND The RNA-lipid nanoparticle (LNP) vaccines for the SARS-CoV-2 pandemic highlight the impact of genomic medicines deployed at scale. RNA-LNP applications also include gene expression and gene editing, which have utility for in vivo therapeutics for rare disease, and ex vivo engineering of cell therapies for cancer. Despite growing momentum, developing RNA-LNPs still faces significant manufacturing challenges. The mixing process to encapsulate RNA within LNPs is among the most difficult unit operations to scale-up to commercial throughput rates and batch sizes, while maintaining critical quality attributes (CQAs) such as size and biological potency. **METHODS** We have developed the new NanoAssemblr® commercial formulation system (CFS) for commercial-scale production of RNA-LNPs. This system utilizes the same NxGen™ mixing technology across the complete NanoAssembr suite of instrumentation to enable rapid scale-up and production. To demonstrate the scale-up capability of the suite, we produced and characterized a SARS-CoV-2 saRNA-LNP vaccine candidate under increasing flow rates and batch volumes to mimic the drug development process from discovery through to commercial production. The formulation flow rate was stepwise increased from 12 mL/min using the NanoAssemblr® Ignite+™ through to 800 mL/min using the new NanoAssemblr CFS. The LNP quality was evaluated by measuring size, polydispersity index (PDI), nucleic acid encapsulation efficiency, saRNA integrity, in vitro expression, and in vivo expression. **RESULTS** The saRNA-LNPs were of similar quality with sizes ranging from 61 - 83 nm, PDI < 0.18 and RNA encapsulation efficiency > 94%. ANOVA testing showed no significant differences in size, PDI, or encapsulation efficiency when comparing instruments or mixers. In vitro potency assays showed similar dose response curves between samples and consistent EC50 values between 1.3 to 3.6 ng/mL. Finally, in vivo immunization studies showed a robust SARS-CoV-2 specific IgG response in all instrument-mixer combinations with titers varying between 1.94x105 to 2.83x106 ng/mL. **CONCLUSIONS** This work demonstrates that production of nucleic acid-LNPs with consistent CQAs can be achieved on a wide range of scales using NanoAssemblr instruments and NxGen mixers. The NanoAssemblr CFS can prepare RNA-LNPs at the scale and throughput needed to meet commercial manufacturing goals for range of applications including vaccines, in vivo therapeutics, and ex vivo cell therapies.

1259. Elucidating the Mechanism in Microfluidics-Enabled Lipid Nanoparticle Dialysis Process via Single-Particle Cylindrical Illumination Confocal Spectroscopy

Fangchi Shao

Biomedical Engineering, Johns Hopkins University School of Medicine, Baltimore, MD

Introduction Lipid Nanoparticles (LNPs) have emerged as highly efficient carriers for delivering mRNA-based vaccines and therapeutics. After the formulation of aqueous mRNA solution with an alcohol solution of lipids, dialysis is employed as a purification method to remove ethanol from the medium and exchange it with a physiological PBS buffer, rendering LNPs suitable for cell culture and *in vivo* administration [1]. Current dialysis approaches typically rely on dialysis membranes to enable the diffusion of buffer exchange, which can entail a lengthy process and add the risk of composition drift. Microfluidics as an emerging platform presents a promising alternative for LNP dialysis for precise fluidic exchange [2]. Here we develop a microfluidics-enabled LNP dialysis process and present a mechanistic understanding of the effect of medium component (salt, pH, and polarity) on LNP quality and transfection activity. **Materials and Methods** In this study, LNPs were formulated using T-junction. Dialysis was achieved in microfluidics with a flow rate ratio of 1:24 for LNP solution to PBS. Multi-color cylindrical illumination confocal spectroscopy (CICS) analyzed single-particle fluorescence burst quantification, enabling particle classification and mRNA payload characterization [3,4]. **Results and Discussion** Cy-5 mRNA and TopFluor-PC aided LNP categorization into three groups: empty, loaded, and free mRNA, corresponding to TopFluor-PC signal only, Cy-5 signal only, and coincident signals (Fig. 1A&B). Using a microfluidics system for on-chip dialysis (Fig. 1C), we compared its performance with a standard 18-h dialysis. Despite comparable sizes, slightly reduced empty particle fraction and increased the average payload per particle, microfluidic-based purification exhibited a lower polydispersity index (PDI) and a >10-fold increase in transfection efficiency (Fig. 1D). Additionally, increasing pH from 4.0 to 7.4, while holding other solvent conditions constant led to larger sizes but lower PDIs (Fig. 1E). Our data supports a mechanistic framework suggesting that ionizable lipids remain positively charged in acidic conditions, reducing merging events. At pH 7.4, neutral ionizable lipids have made merging events to happen that lead to increased size and payload, while decreasing empty particles and encapsulation efficiency. Similar approaches were applied to study effects of ionic strength and solvent polarity on LNP quality and bioactivity. This platform offers an unique opportunity to understand the structural feature and stability of LNPs and optimize their purification process. **References** [1] R. Vargas, *et al.*, *Colloids Interface Sci. Comm.* 54: 100709 (2023). [2] S. Haeberle and R. Zengerle, *Lab Chip*, 7(9): 1094 (2007). [3] K.J. Liu and T.H. Wang, *Biophys. J.*, 95(6): 2964 (2008). 1260. Detargeting Lipid Nanoparticle mRNA Therapeutics from the Liver Using miR-122 Targets

Brian J. Parrett, Nick M. G. Hoopingarner, Michael A. Barry

Mayo Clinic, Rochester, MN

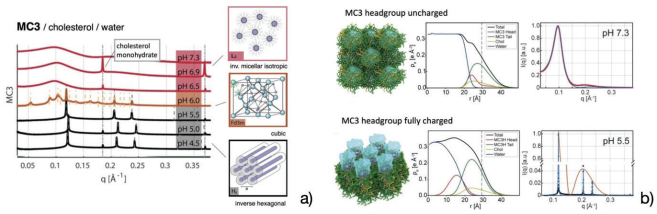
Non-viral mRNA therapeutics have great potential to prevent and treat a variety of diseases making them an important tool in the molecular therapy toolbox. The most clinically advanced non-viral delivery systems are four component lipid nanoparticles (LNPs). A significant challenge in the development of LNP-mRNA therapeutics is strong liver tropism, limiting their use for non-hepatic molecular therapy. LNPs utilize the ubiquitous low density lipoprotein receptor (LDLR) and can transfect a variety of cell types, making them a potentially effective therapeutic for non-hepatic tissues if off-target effects in the liver can be avoided. Local injections, such as intramuscular injections (IM) of mRNA vaccines can reduce LNP deposition in the liver. However, it has been documented in preclinical studies that IM injection of the LNPs used in the COVID-19 LNP-mRNA vaccines can result in up to 21.5% of the injected dose escaping the muscle and transfecting liver. Given the problems of off-target mRNA expression in the liver, we use an endogenous liver specific microRNA-122 (miR-122) target sequence to ablate LNP-mRNA expression in the liver. We compared the effect of different quantities and locations of miR-122 target sequences on LNP-mRNA expression in the liver. miR-122 target sequences were inserted into the 5' or 3' untranslated region (UTR) of mRNAs encoding firefly luciferase. *In vitro* experiments were performed in hepatic (Huh7) and non-hepatic (293T, A549) cells with modified and unmodified LNP-mRNA to determine the effect of different quantities of miR-122 targets as well as their location in the 5' or 3' UTR on the translation

of luciferase mRNA. Modification of LNP-mRNA with miR-122 target sequences did not affect the normal translation of luciferase in non-hepatic cells but led to an ~80% reduction in hepatic cells. *In vivo*, mice injected intravenously (IV) with miR-122 modified LNP-mRNA showed up to a 99% decrease in luciferase activity in the liver. Injection of luciferase mRNA into the muscle and into other organs and sites resulted in significant off-target expression in the liver. In contrast, LNP-mRNA modified with miR-122 target sequences reduced liver luciferase activity as much as 95%. Due to the tolerogenic nature of the liver, leakage of LNP-mRNA could reduce the efficiency of immune responses to vaccine antigens. To test this, mice were vaccinated IM with LNP-mRNA encoding Ebola virus VP40 or VP40 modified with miR-122 target sequences to determine if off-target expression in the liver reduces the efficacy of vaccination. This data shows the utility of miR-122 target sequences to prevent off-target translation of LNP-mRNA therapies in the liver and has a broad range of applications in the development of vaccines and treatment of non-hepatic diseases.

1261. Lipid Nanoparticle Delivery of Plasmid DNA Elicits Robust Adaptive Immunity

Nicholas J. Tursi[1,2], Sachchidanand Tiwari[3], Nicole Bedanova[1], Elizabeth Parzych[1], Kevin Liaw[1], András Sárközy[3], Ebony Gary[1], Serena Omo-Lamai[4], Hiromi Muramatsu[3], Kerry Blatney[1], Ami Patel[1], Jacob S. Brenner[4], Norbert Pardi[3], David B. Weiner[1]

[1]Vaccine and Immunotherapy Center, The Wistar Institute, Philadelphia, PA,[2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[3]Department of Microbiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[4]Department of Systems Pharmacology and Translational Therapeutics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA



Gene-vectored vaccines induce immunity while circumventing manufacturing constraints of traditional platforms, exemplified by the approvals of lipid nanoparticle (LNP)-formulated mRNA, viral-vectored vaccines, and a DNA vaccine for SARS-CoV-2. DNA vaccines exhibit reduced manufacturing complexity but attenuated humoral immunity compared to mRNA-LNPs or adjuvanted protein. Here, we describe a four-component ionizable LNP-plasmid DNA formulation (DNA-LNPs) which induces similar adaptive immunity to mRNA-LNPs at the same dose. SARS-CoV-2 spike-encoding DNA-LNPs induced germinal center, serological, and T cell responses comparable to mRNA-LNPs. Extending these findings, Influenza hemagglutinin-encoding DNA-LNPs induced robust germinal center responses with functional serum antibodies equivalent to both mRNA-LNPs and adjuvanted protein. Moreover, DNA-LNPs induced superior hemagglutinin-specific $CD8^+$ T cell responses to these compared platforms. DNA-LNPs exhibited a favorable thermostability profile at 4°C or room temperature. This study identifies formulations for DNA-LNPs which induce robust immunity at doses comparable to mRNA-LNPs , exhibiting a unique profile important for additional development.

1262. How Mesoscopic Bulk Structure of mRNA Lipid Nanoparticles Relates to Gene Expression Kinetics at the Single Cell Level

Joachim Rädler

Ludwig-Maximilians-Universität München, München, Germany

Introduction Lipid nanoparticles (LNPs) developed into the most powerful delivery platform for mRNA based vaccination and therapies. Yet the physico-chemical mechanisms of pH-dependent endosomal fusion, mRNA release and subsequent expression are not fully understood. In particular the role of cationic ionizable lipids (CILs) is of interest as electrostatic interactions play a key role in the architecture of the LNPs core-shell structure. Using X-ray scattering we study the structures of the CIL/cholesterol/nucleic acid phases of three prototypical CILs, namely DLin-MC3-DMA (MC3), DLin-KC2-DMA (KC2), and DLinDMA (DD) and relate structures to all-atom molecular dynamics (MD) simulations and single cell gene expression timing and efficiency. **Results** Small angle X-ray scattering (SAXS) exhibits a rich pH-dependence of CIL-mesostructures (Fig.1a). In particular all three lipids exhibit a distinct order of liquid crystalline phases with decreasing pH: isotropic inverse micellar, cubic F_{d3m} inverse micellar, inverse hexagonal H_{II} and bicontinuous cubic P_{n3m}. In the presence of polyadenylic acid, in addition to the CIL/chol/water phases a condensed nucleic acid lipid H^c_{II} phase appears. The next-neighbor distance in the excess phase shows a discontinuity at the F_{d3m} inverse micellar to inverse hexagonal H_{II} transition occurring at pH 6 with distinctly larger spacing and hydration for DD vs. MC3 and KC2. MD simulations reproduce the observed inverse micellar to inverse hexagonal transition as a function of lipid head group charging (Fig.1b). We followed GFP-mRNA reporter gene expression mediated by CIL-LNPs taking time courses of single cell fluorescence in high-throughput by employing automated time-lapse microscopy in combination with micro-patterned surfaces. Late gene expression is found to correlates with lower expression levels. The data reveal a systematically delayed and hence less efficient gene expression of DLin-LNPs compared to MC3- and KC2-LNPs. **Conclusion** Our data suggest that the pH-driven F_{d3m}-H_{II} transition in bulk phases is a hallmark of CIL-specific differences in mRNA LNP efficacy. DLin lipid mesophases differ from MC3 and KC2 mesophases in distinctly larger next neighbor distances. Since DLin-LNPs also exhibits distinctly delayed and less efficient gene expression, it is hypothesized that the pH dependent structural transition is causal for endosomal fusion. Correlating physico-chemical properties with time resolved activity of LNPs in living cells provides a basis to further improve LNPs for development of improved non-viral mRNA delivery. **Reference** J. 1263. Novel Humanized Particles for Efficient Delivery of CRISPR and Other Gene Editors

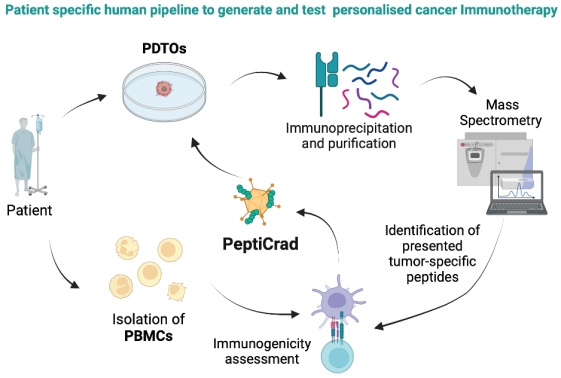
Peter K. Cabeceiras[1,2,3,4,5], Noah Adams[1], Tian Duo Wang[2,3,5,6], Christopher Woodilla[2,3,5], Caitlin Crandall[1], Bevan Bsharah[1], Xiaozhi Ren[1], Yanjing Li[1], Andrew Kane[1], Jeffrey Lee[1], Molly Riley[1], Annie Elliott[1], Vy Phan[1], Carrie Ng[7,8], Cosmin Mihai[1], Jason Auer[1], Casey A. Maguire[7,8], Melissa Bonner[1], J. Keith Joung[2,3,4,5,6]

[1]Nvelop Therapeutics, Cambridge, MA,[2]Molecular Pathology Unit, Massachusetts General Hospital, Charlestown, MA,[3]Center for Cancer Research, Massachusetts General Hospital, Charlestown, MA,[4]Program in Biological and Biomedical Sciences, Harvard Medical School, Boston, MA,[5]Center for Computational and Integrative Biology, Massachusetts General Hospital, Charlestown, MA,[6]Department of Pathology, Harvard Medical School, Boston, MA,[7]Department of Neurology, Massachusetts General Hospital, Boston, MA,[8]Harvard Medical School, Boston, MA

An urgent need exists for novel delivery modalities to fully realize the therapeutic potential of gene editing technologies including CRISPR. Recently described virus-like particles (VLPs) provide an alternative to more commonly used viral vectors such as AAV, offering advantages including delivery of a wide range of larger cargos (including ribonucleoproteins [RNPs]), transient cargo expression, and lack of potentially integrative DNA. However, VLPs still harbor multiple viral proteins, such as GAG, POL, and ENV, which may elicit immunogenicity and present potential challenges for manufacturing. Here we describe the development and optimization of Enveloped Delivery for Generalized Entry (EDGE) and humanized-EDGE (h-EDGE) particles, novel delivery platforms offering the same advantages of VLPs but harboring fewer or no viral proteins, respectively. EDGE particles do not contain viral GAG and POL proteins found in VLPs but instead utilize a compact human protein-derived architecture that we optimized to efficiently and non-covalently anchor cargos of interest to inner leaflet plasma membrane surfaces in EDGE producer cells. EDGE particles also harbor a viral ENV protein that enables high transduction efficiency and that distinguishes them from native extracellular vesicles. We show that EDGE particles can be used to deliver a wide range of gene editing cargos (CRISPR and non-CRISPR nucleases, base editors, and prime editors) and induce high frequency targeted edits into a wide variety of different cell types in culture (including primary human hepatocytes and primary human T cells). Importantly, we also show that EDGE particles can induce robust and efficient adenine base editing *in vivo* in mouse liver on a therapeutically relevant gene target (*PCSK9*). We also describe the initial development and engineering of h-EDGE particles, which use the same non-covalent membrane anchoring technology in EDGE particles but utilize one of several human-derived ENV-alternative (ENV-alt) proteins instead of viral ENV proteins to achieve high transduction efficiencies. We show that h-EDGE particles pseudotyped with different ENV-alt proteins exhibit varied cell-type tropisms. These h-EDGE particles can deliver CRISPR gene editing nucleases and base editors into a broad range of therapeutically relevant primary human cells including HSCs, neurons, hepatocytes, and skeletal muscle, inducing highly efficient editing of as high as 50% or more. Because h-EDGE particles lack any viral proteins, they offer the potential for reduced immunogenicity and redosing in addition to a range of novel cell-type tropisms. The EDGE and h-EDGE platforms provide new capabilities for delivering a wide range of diverse cargos to a variety of different cell types with potentially reduced immunogenicity and simplified profiles for manufacturing relative to VLPs. We anticipate that these new particles will be broadly useful for many research and therapeutics applications currently limited by the capabilities and characteristics of existing delivery modalities.

Thursday Posters: Cancer - Immunotherapy and Cancer Vaccines



1264. Patient-Derived Tumor Organoids (PDTOs) as Preclinical Testing Platform for Personalized Cancer Immunotherapy

Gabriella Antignani

University of Helsinki, Helsinki, Finland

Currently available models to validate preclinical efficiency of Immunotherapies lack in mirroring or poorly recapitulate the original patient's tumor. Active immunotherapy, which is dependent on HLA-TCR interaction, cannot be tested in any other system than fully human based in vitro systems or humanized mice (complex, expensive, and time-consuming). Plus, only a fraction of patients will gain benefit from immunotherapy treatments and finding responsive patients in advance would be crucial. Therefore, we need to develop more sophisticated systems to address immunotherapies correct mode of actions in humans. Organoids are 3D multicellular structures that retain morphology and function of human tissues and organs. Patient-Derived Tumor Organoids (PDTOs) can be established from primary patient material, cultured long term, and cryopreserved. Successful in recalling the tumor heterogeneity and complexity in vitro, PDTOs can provide a robust ex vivo system for modelling human cancer, holding great potential as pre-clinical human platform for testing personalized therapies. Our work is focused on combining patient-derived immune cells and PDTOs to develop complex immuno-organoids that retain both patient's tumor unique features and immune system-mediated response. This allows to test tumor cell killing by the patient's own immune system after a personalized immunotherapy treatment. Moreover, after in-depth patient's tumor characterization, we design a personalized immunotherapy approach to specifically target the patient's tumor. Oncolytic vaccines have a dual mechanism: direct oncolysis of cancer cells and release of tumor antigens, causing cytotoxic T cell activation against cancer cells. To develop patient-specific oncolytic vaccine-based immunotherapies, our strategy is coating oncolytic vaccines with patient-specific tumor peptides (PeptiCRAd technology). We established PDTOs from

Renal Cell Carcinoma and Bladder Cancer, which we characterized by DNA sequencing, immunofluorescence, drug screens. HLA ligandome analysis of the PDTOs allowed the identification of 52 patient-specific tumor peptides. We validated the immunogenicity of these peptides by stimulating healthy donor Peripheral Blood Mononuclear Cells (PBMCs) and analyzing IFN-gamma secretion or CD107a degranulation. These peptides were not only capable of activating CD8+ T cells but also promoting the killing of tumor cells from the patients, showing their tumor specific activity. We also used patient-derived PBMCs to unravel the best candidate peptides able to recall a T cell antitumor response. Finally, we will investigate how an oncolytic vaccine decorated with patient-specific tumor peptides (personalized PeptiCRAd) is able to trigger tumor-specific adaptive immune response, measuring specific T cell killing of PDTOs with impedance-based Xcelligence system, LDH release and live cell microscopy. Establishing such a pre-clinical human model will pave the way for testing patient-specific responses, developing individualized treatments and accelerate their track to the clinic.

1265. Dendritic Cell Therapy in Pancreatic Adenocarcinoma Treatment: A Case Report

Taruna Ikrar

Medicine, Army Cellcure Center, RSPAD, Jakarta Pusat, Indonesia

Pancreatic cancer (PC) remains a devastating and fatal disease with high mortality rates. Immunotherapy offers a promising avenue for enhancing the treatment outcomes of this cancer. ***Methods and Results:*** This case report describes a 46-year-old male patient with pancreatic adenocarcinoma who received dendritic cell (DC) therapy as an immunotherapeutic approach to stimulate the patient's immune system. The number and proportion of viable cells were critical factors in determining the suitability of the therapy for the patient. The patient demonstrated improvement after treatment, such as an increase in hemoglobin levels to 10.4 g/dL and a decrease in CA 19-9 levels from 21.6 to 9.5 U/mL. ***Conclusion:*** Specific immunotherapies, such as DC therapy, can potentially prolong survival and enhance immune responses in the treated patients. Early diagnosis and timely treatment are crucial for improving the prognosis of PC.

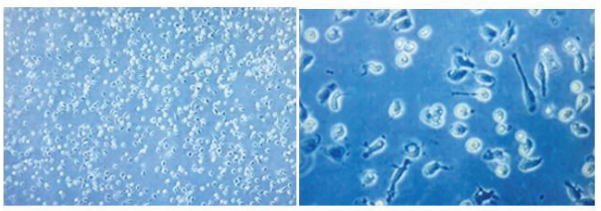


Figure 1 (A) 24 Nov. 2021 Figure 1 (B) 24 Nov. 2021

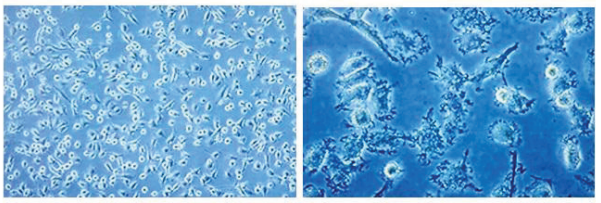

Figure 1 (C) 30 Nov. 2021 Figure 1 (D) 30 Nov. 2021

Figure 1.

Viable cell count and proportion of viable cells in the patient.

The patient had a viable cell count of 1246×10^7 cells, which is above the normal range of $1 \times 10^6 - 60 \times 10^6$. The high viable cell count indicates that the patient had enough cells to undergo certain therapies or treatments.

1266. Development of Immunotherapies for Osteosarcoma

Theresa Higgins[1], Daniel Patton[1], Timothy L. Eller[1], Isabella Shimko-Lofano[1], Payal Agarwal[2]

[1]Scott Ritchey Research Center, Auburn University, Auburn, AL,[2]Scott Ritchey Research Center, Auburn University, Auburn University, AL

Osteosarcoma (OS) is a highly aggressive and metastatic bone malignancy with a low survival rate and poor patient prognosis. In recent years, immunotherapies, such as chimeric antigen (CAR) T cells and conditionally replicative Adenoviruses (CRAds), have shown promise in treating various cancers. We have developed and characterized a next-generation conditionally replicative canine adenovirus CAV2-AU-M2 armed with anti-PD1 sdAb. The infectious and cytolytic effects of CAV2-AU-M2 were tested in four different canine OS cell lines in 2-dimensional (2D) and three-dimensional (3D) cell cultures. CAV2-AU-M2 showed selective replication in OS cells and induced efficient tumor cell lysis. Moreover, CAV2-AU-M2 produced anti-PD-1 sdAb that demonstrated effective binding to PD-1 receptors. This combination approach of two distinct immunotherapies is intended to stimulate and enhance the anti-tumor immune response in the tumor microenvironment. We also aim to develop CAR T cells targeting the cancer-specific B7H3 receptor. The cytotoxic effects of anti-B7H3 CAR T cells will be tested in 2-dimensional (2D) and three-dimensional (3D) cell cultures. We expect cell lysis only in B7H3-positive cell lines. We will also assay the immunogenic effects of CAR T cells by analyzing IFNγ, TNFα, and IL-2 cytokine levels in OS cell lines post-CAR T therapy.

1267. Inhibiting the PD1 Immune Checkpoint and the VEGFA Growth Factor Enhances the Cytotoxicity of Exhausted T Cells in Glioblastoma *In Vitro*

Shriya Madan, Anna Andrzejewska, David Gulisashvili, Graeme Woodworth, Debra Kukuruga, Yajie Liang, Piotr Walczak, Miroslaw Janowski
University of Maryland, Baltimore, MD

Introduction: Glioblastoma, a highly aggressive brain cancer, remains elusive to all therapeutic strategies, including the Nobel Prize-winning immune checkpoint inhibitors (ICIs). We hypothesize that the pro-tumoral growth factor VEGF-A may further inhibit the anti-tumor function of exhausted T cells. Therefore, we studied combinations of ICIs with bevacizumab (anti-VEGF-A antibody) in co-cultures of glioblastoma cells with T cells at various states (activated, primed, and bead- or cell-exhausted) in addition to assessing the levels of VEGF-A produced by GBM cells *in-vitro,* with or without the treatment of bevacizumab. **Methods:** HLA-matched T cells were activated using anti-CD3/CD28 beads, then primed through exposure to GBM1-luc cells and exhausted using consistent exposure to anti-CD3/CD28 beads or by culturing them with GBM1 cells. Co-cultures of these T cells at each of the four states with GBM1-luc at a 1:1 ratio were used to study the effect of 3 concentrations of nivolumab, ipilimumab, anti-PDL1 antibody, and bevacizumab over five days. Normalized bioluminescence served as a dependent variable to report on GBM1-luc cell death. Independent variables included 1) antibodies, 2) concentrations, 3) T cell status, and 4) observation period. All experiments were performed with three biological and three technical replicates. The dataset was subjected to multivariate, hierarchical regression using fixed and random effects (PROC MIXED, SAS 9.4). VEGF-A levels in supernatants were measured with ELISA with technical duplicates for each group. **Results:** Data analysis of post-hoc tests revealed the highest therapeutic effect of anti-PD1 and anti-VEGFA co-targeting in GBM1 cell-exhausted T cells, which was statistically significant. VEGF-A ELISA results showed significant production of VEGFA by GBM1 cells and that the addition of bevacizumab to the GBM1 cells scavenges VEGF-A from the cell culture medium. **Conclusions:** Combining PD-1 and VEGF-A blockade can be a potential treatment for glioblastoma as it enhances T cell function during exhaustion *via* consistent exposure to GBM1-luc cells.

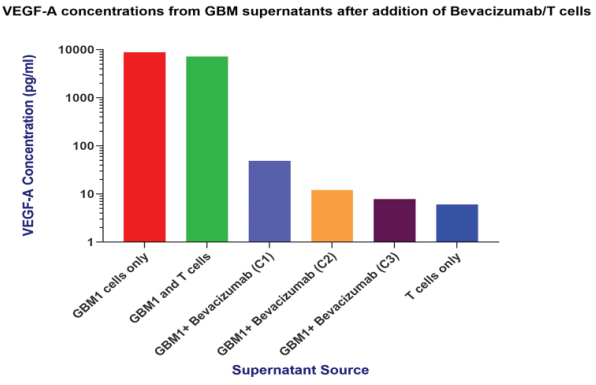

Figure 1: VEGFA measured by ELISA in supernatants of GBM cells with or without treatment of bevacizumab. NOTE: y-axis denotes a log scale.

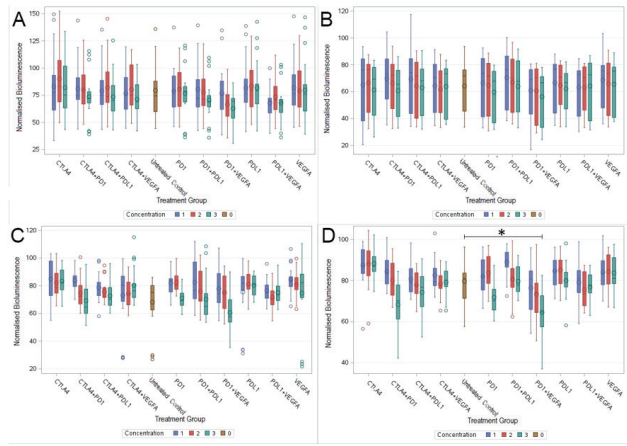

Figure 2: *In vitro* therapeutic efficacy of T cells at various stages (A - activation, B - priming, C - anti-CD3/CD28 bead-induced exhaustion, D - GBM cell-induced exhaustion) against GBM1 cells. A combination of VEGF-A and PD-1 blockade is the most effective in co-culture GBM1-luc with cell-exhausted T cells (*p-value< 0.05)

1268. Enhancing Anti-Tumorigenic Macrophage Differentiation and Potentiates PD-L1 Blockade in Melanoma through CD244 Deletion on Monocytes

Jeongsoo Kim[1], Tae-Jin Kim[2], Sehyun Chae[3], Hyojeong Ha[1], Yejin Park[1], Seon Ah Lim[4], Hyemin Lee[1], Younji Sim[1], Seyoung Oh[1], Geon Mo Koo[1], Minkyung Jo[1], Daehee Hwang[5], Kyung-Mi Lee[1]
[1]Korea University, Seoul, Korea, Republic of,[2]Korea Institute of Radiological and Medical Sciences, Seoul, Korea, Republic of,[3]Korea Brain Research Institute, Daegu, Korea, Republic of,[4]Ewha Womans University, Seoul, Korea, Republic of,[5]Seoul National University, Seoul, Korea, Republic of

Background: In the myeloid compartment of the tumor microenvironment, CD244 signaling has been implicated in immunosuppressive phenotype of monocytes. However, the precise molecular mechanism and contribution of CD244 to tumor immunity in monocytes/macrophages remains elusive due to the co-existing lymphoid cells expressing CD244. **Methods:** To directly assess the role of CD244 in tumor-associated macrophages, monocyte-lineage-specific CD244-deficient mice were generated using cre-lox recombination and challenged with B16F10 melanoma. The phenotype and function of tumor-infiltrating macrophages along with antigen-specific CD8 T cells were analyzed by flow cytometry and single cell RNA sequencing data analysis, and the molecular mechanism underlying anti-tumorigenic macrophage differentiation, antigen presentation, phagocytosis was investigated ex vivo. Finally, the clinical feasibility of CD244-negative monocytes as a therapeutic modality in melanoma was confirmed by adoptive transfer experiments. **Results:** $CD244^{fl/fl}LysM^{cre}$ mice demonstrated a significant reduction in tumor volume (61% relative to that of the $CD244^{fl/fl}$ control group) 14 days after

tumor implantation. Within tumor mass, $CD244^{fl/fl}LysM^{cre}$ mice also showed higher percentages of $Ly6C^{low}$ macrophages, along with elevated $gp100^{+}IFN\text{-}\gamma^{+}$ CD8 T cells. Flow cytometry and RNA sequencing data demonstrated that ER stress resulted in increased CD244 expression on monocytes. This, in turn, impeded the generation of anti-tumorigenic $Ly6C^{low}$ macrophages, phagocytosis and MHC-I antigen presentation by suppressing autophagy pathways. Combining anti-PD-L1 antibody with $CD244^{-/-}$ bone marrow-derived macrophages markedly improved tumor rejection compared to the anti-PD-L1 antibody alone or in combination with wild-type macrophages. Consistent with the murine data, transcriptome analysis of human melanoma tissue single-cell RNA-sequencing dataset revealed close association between CD244 and the inhibition of macrophage maturation and function. Furthermore, the presence of CD244-negative monocytes/macrophages significantly increased patient survival in primary and metastatic tumors. **Conclusion:** Our study highlights the novel role of CD244 on monocytes/macrophages in restraining anti-tumorigenic macrophage generation and tumor antigen-specific T cell response in melanoma. Importantly, our findings suggest that CD244-deficient macrophages could potentially be used as a therapeutic agent in combination with immune checkpoint inhibitors. Furthermore, CD244 expression in monocyte-lineage cells serve as a prognostic marker in cancer patients.

1269. The Discovery and Development of GT316 as a CRISPR/Cas9-Dual KO Anti-Exhaustion TIL Product for Advanced Solid Tumors

Jingwei Sun[1], Yao Sheng[1], Jingman Wang[1], Jiahui Jin[1], Yanbin Liu[1], Zhao Xu[1], Haibao Li[1], Jun Cui[1], Jing Yu[1], Pin Wang[2], Yarong Liu[1]

[1]Grit Biotechnology, Shanghai, China,[2]University of Southern California, Los Angeles, CA

Adoptive cell therapy by tumor-infiltrating lymphocytes (TILs) has demonstrated promising therapeutic effects in several types of solid tumors and significantly prolonged the survival of late-stage patients. However, the "prone-to-exhaustion" phenotype of the final TIL product after rapid expansion during manufacture and the presence of various immunosuppressive mechanisms in tumor microenvironment (TME) compromise the persistence and anti-tumor efficacy of TIL post infusion. Besides, clinical efficacy of TIL therapy is still limited to some indications. To discover potential immunoregulatory targets that could maximize the function of TIL and expand its clinical application, we established a genome-wide CRISPR/Cas9 screening platform, ImmuT Finder®, to unbiasedly identify key immunoregulatory targets for T cell product. Different *in vitro* and *in vivo* screening models were built to simulate the major challenges of T cell therapies. Comprehensive functional validations of 120+ hits were performed in TCR-T cells in a 96-well array. Then, the combinational effects of top targets validated in TCR-T were further tested in TIL by different *in vitro* and *in vivo* systems. Finally, a double KO combination of GT304 and GT312, GT316, stands out as the most potent combination, which significantly improves TIL proliferation and cytokine release, eradicates tumor growth in both CDX and PDX mouse models and promotes long-term *in vivo* persistence with low-dependence on IL-2. Bioinformatic analysis of TCGA database showed positive correlation of GT304 and GT312 mRNA expression with immune signature genes across multiple solid tumors, further indicating their clinical relevance. RNA-seq analysis of GT316 in comparison to unedited control product suggests GT316 ameliorates TIL exhaustion and promotes T cell activation, function as well as migration. Specific and potent sgRNAs targeting both targets have been selected, and manufacturing process of GT316 TIL product has been developed (KOReTIL®). First-in-human trial of GT316 in advanced solid tumor patients showed good tolerance with no AE of Grade≥3. One PR and one CR have been observed as early as 4 weeks post GT316 infusion. In summary, these data demonstrated that our ImmuT Finder® platform enables unbiased discovery of potent and novel targets for the development of T cell therapy and support further clinical assessment of GT316 as a next-generation TIL therapy.

1270. In-Depth Characterization of T-Cell Populations Utilizing a 36-Color Panel and Spectral Flow Cytometry

Gage Paul[1], Patrick J. Hanley[1,2], Christopher A. Lazarski[1,2]

[1]Children's National Medical Center, Washington, DC,[2]The George Washington University, Washington, DC

Background: Traditional polychromatic flow assays are limited in size to twenty colors due to spillover between fluorochromes. For clinical samples of small volumes, this can limit the ability to directly compare the activation and frequency of specialized T-cell subsets within the same sample. Spectral flow cytometry can however overcome this barrier by expanding the number of markers within one panel to as many as forty separate markers. Here, we developed a novel 36-color panel which combines measurement of lymphocyte subset frequency with in-depth analysis of T-cell activation, exhaustion, and intracellular cytokine production. **Objective:** Establish spectral cytometry as a service within CNRI and validate a novel 36-color fluorochrome panel utilizing spectral cytometry for in-depth characterization of T-cell subsets within research samples. **Methods:** Peripheral blood mononuclear cells (PBMCs) were isolated from buffy coats and frozen in multiple aliquots. Individual aliquots were activated using antigen-specific and non-specific stimulations to expand T-cells derived from fresh or frozen sources. Non-specific expansion was achieved using CD3/CD28 beads to proliferate cells that were not specific for any one stimulation condition. Expansion of T-cell populations under antigen-specific stimulation was accomplished utilizing a ten-day VST expansion protocol culturing cells with CMV matrix protein 65 (PP65) and immediate early protein 1 (IE-1) peptides in the presence of IL4 and IL7. Cells were stained with panels for spectral cytometry in parallel with panels for traditional cytometry to compare surface phenotype. Additionally, multiple iterations of spectral staining protocols were evaluated for median marker fluorescence intensity and fluorochrome compatibility. T-cells were analyzed for appearance of classical exhaustion and activation markers within spectral cytometry panels. **Results:** We compared the percentage of T-cells phenotyped using our 36-color stain to a validated 8-color panel. Using buffy coats from two separate donors to provide sufficient cells for both the generation of single stain controls and testing conditions, we identified CD3+CD4+ cells within ±9%, and CD56+CD3-, CD19+CD3-, and CD3+CD8+ cells all within ±4%. Additionally, we investigated whether this panel

sufficiently quantifed TNF-α and IFN-γ cytokine-producing cells from frozen PBMC samples before and after expansion with CMV peptides. The proportion of CMV reactive CD8+ IFN-γ+ TNF-α+ multi-cytokine producing cells were detectable pre-expansion and increased by two-fold after the ten-day VST expansion protocol. Furthermore, we were able to characterize the activation and exhaustion markers that are present on expanded cells. The overall CD8+ population of expanded T-cells expressed exhaustion markers TIGIT (17.79%), KLRG1 (6.29%), and PD1 (3.03%). Additionally, activation markers for CD8+ cells were identified for CD62L (6.17%) and CD40L (3.00%). Furthermore, CD8+ IFN-γ+ TNF-α+ multi-cytokine producing were characterized as TIGIT-, TIM3-, LAG3-, KLRG1low, CD45RA+, CD45RO-, CCR7-, and CD107a+. This spectral panel was used to identify differentiating T-cell subsets within heterogenous cell populations derived from multiple source conditions, including fresh blood, frozen PBMCs, and cultured cells. These investigations demonstrate our 36-color spectral panel as efficient for comprehensive analysis of reactive T-cell populations. Going forward, the Flow Core within Children's National Research Institute will work to qualify the efficiency and validity of spectral flow cytometry for research and in longitudinal studies across gene and cell therapy products.

1271. The Effect of CD9 on Natural Killer Cell Exhaustion and Dysfunction in Glioblastoma

Yuning Liu

Industrial and Molecular Pharmaceutics, Purdue University, West Lafayette, IN

In the battle against glioblastoma, the most malignant form of brain cancer, the efficacy of the immune system's natural killer (NK) cells is critical. These cells are a important component of the innate immune response, with the capacity to identify and exterminate tumor cells. However, their functionality is often compromised within the immunosuppressive microenvironment in glioblastoma. The tetraspanin CD9 has been implicated in various cellular processes, including cell adhesion, motility, and proliferation. This study aims to delineate the role of CD9 in modulating NK cell activity in glioblastoma. We began with a series of in vitro assays to determine the effects of prolonged stimulation on NK cells. Results indicated a shift towards an exhausted NK cell phenotype, as evidenced by increased CD9 and CD49a expression and decreased Granzyme B and Perforin release. To directly assess the influence of CD9, we knockout CD9 gene in NK cells via CRISPR-Cas9. These CD9-deficient NK cells demonstrated a significant increase in their ability to target and kill glioblastoma cells, suggesting that CD9 expression impairs NK cell cytotoxicity. Further investigation involved the examination of NK cells extracted from the blood of glioblastoma patients. These cells were found to have elevated levels of CD9 when compared to those from healthy controls, consistent with our in vitro findings and indicating a possible mechanism for NK cell dysfunction in vivo. Through immunohistochemical analysis of glioblastoma tissue samples, we observed that areas with higher CD9 expression coincided with regions showing NK cell infiltration. The study's findings provide evidence that CD9 plays a significant role in inducing NK cell exhaustion and dysfunction in the glioblastoma microenvironment. Our research suggests that inhibition of CD9 may offer a novel therapeutic approach to improve NK cell-mediated anti-tumor activity. Such strategies could potentially be integrated into current glioblastoma treatment regimens, offering hope for improved patient outcomes in this challenging disease.

1272. STX-003: A Novel Systemically-Delivered mRNA-Based Cancer Therapy Utilizing a Programmable Genetic Circuit Platform for Tumor-Specific Protein Expression and Reduced Toxicity

Wen Allen Tseng, Jaspreet S. Khurana, Justin H. Letendre, Gautam N. Shenoy, Rachel G. Eichman, Ashley G. Njiru, John T. Sexton, Emily Tjon, Dahyana Arias Escayola, Emily A. Clinton, Ryan A. Patenaude, Wuhbet Abraham, Zhijun Su, Madhuri Dey, Nandita Satish Menon, Isma Zarin, Breanna Burgett, Sarah O'Bryan, Mae Kingsbury, Aidan Coia, Akshay Mavani, Weiyu Zhao, Kevin Shi, Alexander C. Lemaire, Julian Quiñones, Ryan T. Sowell, Prashant R. Nambiar, Jacob R. Becraft, Tasuku Kitada

Strand Therapeutics, Boston, MA

Cancer accounts for approximately one in six deaths globally, with solid tumors representing roughly 90% of adult cancers. Significant effort has been applied toward the development of therapeutics that precisely attack tumors while sparing healthy tissue. The advent of mRNA technology, coupled with advances in LNP-mediated delivery and in silico gene expression analysis, presents new opportunities for developing precision cancer therapies. We have developed a platform in which we design programmable genetic "circuits" that detect molecular cues in a cell. These circuits are encoded as RNA and incorporated into mRNA molecules to specifically express a payload protein in cells that exhibit a particular molecular signature. Through in silico modeling and high-throughput in vitro screening, we select candidate circuits and characterize their effectiveness for classifying a particular cell type. We then evaluate a circuit's effect on payload expression in vivo, first using a luciferase reporter payload, and then using the immunomodulatory cytokine IL-12 as an anti-tumor therapeutic payload. We applied this platform to the development of STX-003, a self-replicating mRNA bearing programmable genetic circuitry that selectively expresses IL-12 in tumors. Upon systemic administration into healthy non-human primates, STX-003 demonstrates a >99% reduction in circulating IL-12 levels compared to a control without genetic circuitry, while STX-003 and the uncircuited control show similar IL-12 expression levels when transfected into patient-derived tumor organoids and the cancer cell line A549. Furthermore, intravenous injection of a murine STX-003 surrogate induces anti-tumor responses in a syngeneic mouse model and results in similar mIL-12 levels in tumors compared to an uncircuited control. However, in the spleen, which is a major target organ of LNPs formulated with mRNA, mSTX-003 induces markedly lower mIL-12 levels compared to the uncircuited control. These data demonstrate the potential of our programmable RNA circuit platform for the development of precision mRNA therapies for cancer.

1273. Bispecific T-Cell Engager Delivered through Tissue Targeting LNP Demonstrated Potent Antitumor Effects on Both Hematological Malignancies and Solid Tumors

Xin Kai, Yixin Zhang, Benjamin Wei, Daniella Tatang, Stu Angus, Caining Jin, Kun Huang, Changfeng Huang, Haishan Li, Lou Brenner, Qiaobing Xu, Kate Zhang
Hopewell Therapeutics Inc, Woburn, MA

Background The recent success of LNP-mRNA COVID vaccines has accelerated the development of lipid nanoparticles (LNP) as an attractive delivery approach for next wave of genomic medicines. Bispecific T cell engager (BiTE) therapy is an approved immunotherapy to treat hematological malignancies, such as ALL, by redirecting cytotoxic T-cells to eliminate cancer cells. However, the relatively short serum half-life of recombinant BiTE, and reported CRS and neurotoxicity have limited its applications. Here, we describe tissue targeted LNP-mRNA encoding BiTE that expressed long-lasting and therapeutic levels of BiTE protein at the targeted tumor sites. The results from the preclinical studies have demonstrated activation of T-cells to eliminate tumor cells in hematological malignancy and solid tumor mouse models and deplete circulating B-cell in a NHP model. **Methods** The LNP formulated with Hopewell's proprietary ionizable lipid HTX-L01 was selected through in vitro biophysiochemical characterization and in vivo screening. HTX-L01-003 and HTX-L01-008 encapsulated with mRNA encoding optimized single chain sequence of CD19-CD3 and GPC3-CD3 respectively, were evaluated for PK/PD, biodistribution and bio-tolerability in WT mice and NHP (dose escalating at 0.01, 0.07 and 0.10mg/kg). The tumor control activities were assessed in the Raji-xenograft non-Hodgkin lymphoma (NHL) model for HTX-L01-003 at the dose of 0.08 mg/kg and Hep3B-orthotopic hepatocellular carcinoma (HCC) model for HTX-L01-008 at the dose of 0.5 mg/kg. Similar study using HTX-L02, lung targeting LNP encapsulating GPC3-CD3, has been explored. **Results** LNP-mRNA formulated with HTX-L01 primarily targets liver, spleen, and less extent BM via intravenous injection. High levels of transfection in hepatocytes, kupffer cells and immune cells were achieved. In a hPBMC-reconstituted Raji-luc xenograft model, a much lower dosage and less frequent administration of HTX-L01-003 achieved equivalent tumor regression/elimination as recombinant BiTEs. In a NHP study, dose-dependent protein expression was observed in 3-week repeat dosing and resulted in transient T-cell activation and complete and sustained B-cell depletion. HTX-L01-008 generated the extended GPC3-CD3 BiTE protein expression, and successfully eliminated orthotopic HCC tumors in mice. Early study with lung targeting LNP HTX-L02-mRNA has demonstrated highly enriched protein expression in lung over circulation after single dose and maintain robust protein expression over 5 weeks with weekly dosing in the range of 0.03-0.3 mg/kg. **Conclusions** Systemic administration of HTX-L01-003 demonstrated in-body and "local" production of CD19/CD3 BiTE protein which resulted in highly potent and long-lasting depletion of target cells in both mouse and NHP studies. HTX-L01-008 demonstrated the ability to eliminate solid tumors in situ via i.v. injection. HTX-L02 demonstrated the potential to treat lung cancer with repeat dosing of the same mechanism. The LNP-mRNAs were well-tolerated. Overall, the studies showed the tissue targeting LNP-mRNA encoding BiTE provides a unique platform with enhanced efficacy and reduced toxicity for the treatment of both liquid and solid tumors.

Thursday Posters: Cancer - Targeted Gene and Cell Therapy

1274. AAV Based Suicide Gene Therapy with Improvised Promoters in a Murine Model of Hepatocellular Carcinoma

Vijayata Singh, Subhajit Pathak, Narendra Kumar, Jayandharan G. Rao
Indian Institute of Technology, Kanpur, India

One of the leading causes of cancer-related mortality is hepatocellular carcinoma (HCC). Suicide gene therapy is a promising approach for the potential treatment of HCC. However, the lack of specificity in delivering suicide genes to HCC cells is a major impediment in its clinical translation. In this study, we addressed this by employing Adeno-associated virus serotype 6 (AAV6) and its exosomal version (exo-AAV), containing the inducible *Caspase 9* (*iCasp9*) transgene controlled by various promoters to specifically target HCC cells. We utilized, a liver-specific promoter (LP1), and the baculoviral IAP repeat-containing protein 5 (BIRC5) promoter with E2F1 transcription factor binding site for liver and cancer cell-specific expression, respectively and tested their efficacy against the ubiquitous cytomegalovirus immediate early enhancer/chicken beta actin promoter (CAG). Subsequently, we assessed the efficacy of these vectors in inducing cell death in Huh7 cells. The *iCasp9* vectors driven by the BIRC5 and LP1 promoters exhibited superior cytotoxicity compared to those driven by the CAG promoter. Further, *in vivo* testing in a mouse model of HCC revealed that AAV6 vectors based on LP1-iCasp9 or E2F1Birc5-iCasp9 achieved tumor regression at a rate of approximately 2-fold, demonstrating comparable effectiveness to AAV6-CAG-iCasp9 vectors. Likewise, exo-AAV6 vectors also demonstrated a superior *in vivo* tumor regression of approximately 2.1-2.8-fold when compared to animals treated with a mock intervention. Our study has explored tissue/cancer specific promoters (LP1 or BIRC5) that exhibit comparable efficacy to a potent ubiquitous promoter within both the AAV6 and exo-AAV6 systems. This broadens the range of AAV vectors available, for a safe and efficacious treatment of HCC.

1275. Microbubble-Enhanced Focused Ultrasound-Assisted Delivery of Adeno-Associated Viruses in Brain Tumors with PET Imaging Monitoring

Yutong Guo, Josquin Foiret, Jai Woong Seo, Nisi Zhang, Bo Wu, Marina Nura Raie, Spencer Tumbale, Katherine Ferrara
Molecular Imaging Program, Stanford University, Stanford, CA

Introduction Improved therapeutic efficacy and enhanced survival rate are unmet needs in the treatment of brain cancers. Gene therapy utilizing adeno-associated viruses (AAVs) as a delivery vehicle presents

a promising therapeutic approach because of the high efficiency in gene transduction and low immunogenicity. However, a major obstacle to the systemic delivery of AAVs in treating brain tumors is their limited penetration across the blood-brain and blood-tumor barriers (BBB/BTB). Focused ultrasound (FUS) combined with circulating microbubbles (MB) provides a noninvasive method to locally and transiently open the BBB/BTB. Therefore, we hypothesized that MB-FUS could lead to improved and targeted delivery of AAVs into brain tumors. **Methods** To test our hypothesis, we employed positron emission tomography (PET) imaging to assess the *in vivo* spatial distribution of systemically administered ^{64}Cu-AAV9:CAG-mNeonGreen following the MB-FUS treatment of a GL26 glioma mouse model. Additionally, to verify the accumulation of AAVs in the brain tumor as observed in PET imaging, we conducted a quantitative polymerase chain reaction (qPCR) analysis of AAV9 transgene (mNeonGreen) in the tumor tissue. We performed MB-FUS experiments immediately following the AAV administration using an ultrasound-guided focused-ultrasound (USgFUS) system (1.5 MHz, 1 msec bursts, 5 Hz repetition rate, at 600 kPa) and concurrent i.v. administration of monodispersed lipid microbubbles (5 μm, 2.5×10^8 MB/kg). The USgFUS system consists of a 128-element 2D therapeutic array with a 1.5 MHz center frequency and an imaging transducer (L12-5, 38 mm aperture, Phillips/ATL) positioned in the central opening of the 2D therapeutic array to allow ultrasound guidance and treatment monitoring via passive acoustic mapping (PAM) during sonication. **Results** Firstly, to confirm the proposed protocol and FUS parameters can open the BBB/BTB and enhance the delivery of therapeutic agents, we assessed the delivery of 70 kDa fluorescently labeled dextran particles (14 nm) in the brain tumors with and without the application of MB-FUS. *Ex vivo* fluorescence imaging of the brain indicated a 2-fold increase in the accumulation of dextran particles in the MB-FUS-treated tumor as compared to the non-FUS-treated tumor (n=5, p = 0.0015). Next, we assessed the delivery of the ^{64}Cu-AAV9:CAG-mNeonGreen in brain tumors using PET imaging and qPCR. At 21 h post-injection, we observed targeted radiolabeled capsid delivery in the tumor as compared to the contralateral brain and a higher radiolabeled capsid accumulation in the MB-FUS-treated tumor as compared to the non-FUS-treated tumor in PET images (1.3-fold, n = 3, p = 0.47). Subsequently, we quantified mNeonGreen ssDNA copies in the tumor using qPCR and found a 6.4-fold increase in vector genome copies (ΔΔCt) in MB-FUS-treated tumor as compared to the non-FUS-treated tumor (n = 5, p = 0.01). **Conclusions** PET imaging and radiolabeling of AAV9 provide a method to quantitatively and longitudinally examine the spatial distribution of AAV9 after the MB-FUS treatment *in vivo*. Our results suggest that FUS combined with microbubbles provides unique opportunities to open the vascular barrier for the delivery of therapeutic agents and achieve improved targeted delivery of AAVs in the brain tumor microenvironment. A repeated PET imaging experiment with a larger sample size is warranted.

1276. Adeno-Associated Viral (AAV) Vectors Specifically Targeting the GNAQ Mutant Driver Gene Result in Uveal Melanoma Cell Death

Trace F. McCall[1,2,3], Emma J. Sawyer[1,2,3], Joshua Darnell[1,2,3], Matthew L. Hirsch[1,2,4], Jacquelyn J. Bower[1,2,3]

[1]Ophthalmology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Carolina Eye Research Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Gene Therapy Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Uveal melanoma (UM) is a rare and highly aggressive cancer arising from melanocytes within the uveal tract of the eye. Often fatal for patients, especially for metastatic cases, there is currently little success in the development and distribution of a clinically beneficial treatment. In contrast to most cancers, 80-90% of UM tumors are initiated by a unique single-point mutation in *GNAQ or GNA11* at codon 209 on a single allele, leading to constitutive activation of downstream cell proliferation pathways responsible for disease progression and metastasis. It was hypothesized that the unique properties of UM-initiating mutations could be exploited to specifically knockdown the *GNAQ*-mutant transcript, while leaving expression of the wild-type transcript in-tact, which would result in the reduction of downstream oncogenic signaling required for UM survival/progression, culminate in UM cell death, and minimize any potential off-target effects. In this study, both RNA interference and recombinant Adeno-associated virus (AAV) serotype 2 were employed to selectively target *GNAQ*-mutant transcripts in uveal melanoma in vitro. A short interfering-RNA rationally designed to target the A/T *GNAQ* mutation induced significant toxicity in multiple *GNAQ*-mutant cell lines (>50%) in clonogenic survival and alamarBlue fluorescence assays when compared to a non-targeting siRNA. Using RT-qPCR, next-generation sequencing, and western immunoblotting, selective knock-down of the mutant *GNAQ* transcript and attenuation of downstream oncogenic activity was confirmed. Towards the development of a longer lasting therapeutic, a rAAV2 viral vector was generated with a short-hairpin RNA cassette based on the successful siRNA sequence targeting the *GNAQ* A/T mutation (AAV-shGNAQ). Compared to siRNA transfection alone, delivery of AAV-shGNAQ resulted in a significant increase in death of multiple *GNAQ* A/T mutant UM cell lines. This trend was not observed upon delivery of AAV-shGNAQ to a *GNAQ*-wildtype UM cell line. Surprisingly, rAAV2-GFP transduction lacking a therapeutic gene insert also induced toxicity in *GNAQ*-mutant cell lines but not in a *GNAQ*-wildtype cell line or HEK293 cells. In summary, this work is the first to demonstrate the distinct specificity of siRNA targeting a single-point mutation in *GNAQ* that successfully discriminates between wild-type and mutant alleles differing by a single nucleotide. This ultimately resulted in significant death of multiple UM cell lines. Additionally, a rAAV2 vector expressing a shRNA cassette that can efficiently deliver our potential therapeutic was confirmed to exhibit high potency towards *GNAQ* mutant UM cells in vitro. Further studies will seek to characterize in vivo delivery of AAV-shGNAQ to treat uveal melanoma in xenograft animal models and to elucidate the mechanisms of AAV vector-induced cell death in *GNAQ* mutant UM cells.

1277. Tumor-Targeted DART-AAVs as Gene Delivery Platform for Immune-Modulators

Muhammed Burak Demircan[1], Luca Zinser[1], Florian Strassheimer[2,3], Philipp Elleringmann[2], Dirk Grimm[4], Frederic B. Thalheimer[1], Michael C. Burger[2,3], Christian J. Buchholz[1,3]

[1]Molecular Biotechnology and Gene Therapy, Paul-Ehrlich-Institut, Langen, Germany,[2]Dr. Senckenberg Institute of Neurooncology, Goethe University Hospital, Frankfurt am Main, Germany,[3]Frankfurt Cancer Institute, Goethe University, Frankfurt am Main, Germany,[4]Department of Infectious Diseases/Virology, Medical Faculty, University of Heidelberg, BioQuant, Heidelberg, Germany

In the context of cancer immunotherapy, successful administration of immunotherapeutic agents within the tumour microenvironment plays a pivotal role in maximizing therapeutic efficacy. Given the immunosuppressive characteristics of the tumour microenvironment, novel delivery approaches are currently being explored. Adeno-associated virus (AAV) vectors are the leading platform for *in vivo* gene delivery and have great potential to deliver immunotherapeutic to the tumour microenvironment. However, one of the crucial challenges associated with the delivery is off-target activities, resulting in unintended transduction of therapy-irrelevant tissues, most notably the liver. This phenomenon can lead to potential toxicity and significantly limit the applicability of the therapy. To address this issue, we have developed a rational design strategy for AAVs based on display of high-affinity binders for a tumour surface antigen, such as the HER2/neu-specific designed ankyrin repeat protein (DARPin), at the VP2 N-terminus. We have recently shown that the resulting HER2-AAV enables tumour-specific delivery of checkpoint-inhibitors. In context of glioblastoma, this resulted in substantially improved therapeutic activity in a subcutaneous tumour mouse model when combined with CAR-mediated tumour cell killing (Strecker et al., 2022). Here, we generated and analysed a second-generation targeted platform called DART-AAV, in which DARPins are inserted into the VP1 GH2/GH3 loop. The corresponding second-generation HER2-AAV selectively transduced cancer cells only if they express human HER2/neu. Compared to the first generation, they exhibited a substantial increase in gene delivery activity of more than 20-fold without being compromised in selectivity. When equipped with the coding sequence for the checkpoint-inhibitor Nivolumab, transduced HER2-positive tumour cells released functional Nivolumab at high amounts *in vitro*. When administered into nude mice subcutaneously engrafted with HER2-positive SKOV-3 cells, HER2-AAV2 delivered luciferase specifically into the tumour tissue with the absence of detectable transduction in liver. As an additional tumour cell target, we have developed DART-AAV displaying DARPins specific for programmed death-ligand 1 (PDL1). PDL1-AAV demonstrated efficient transduction of PDL1-positive tumour cells, while PDL1-negative cells did not exhibit significant reporter gene expression. This additional example confirms the high selectivity of DART-AAVs for their target cells. Ongoing investigations explore the extension of tumour-targeted DART-AAVs to other AAV serotypes as well as their therapeutic capacity in tumour mouse models. They appear especially suited for the delivery of immune checkpoint inhibitors and cytokines into the tumour microenvironment.

1278. Smart RNA Sequence Design for Onco-Selective Translation in Cancer Cells

Isaak Mueller, Kelly Brock, Leona Lee, Thomas Addison, Sadik Yildiz, Yusuf Erkul, Burak Yilmaz, Cafer Ozdemir

Kernal Biologics, Cambridge, MA

Cancer therapies must precisely target cancer cells for destruction while avoiding healthy cells, as off-target effects could present significant patient morbidity. To avoid toxicity from these therapeutics, one approach is to have an mRNA-based design where the encoded payload is preferentially expressed in cells of interest. These onco-selective sequences can be designed for multiple cancer subtypes. Here, we present the results of a novel integrated computational and experimental pipeline that has identified multiple sequence elements with significant onco-selectivity. As part of this pipeline, we employ both hypothesis-driven screenings based on machine learning on large scale transcriptomics, proteomics, and structural datasets, as well as agnostic massively parallel reporter assays, to identify onco-selectively translated sequences and their associated biomarkers. Additionally, codon optimization of complex sequence elements and process optimization enabled us to utilize our platform more broadly for complex therapeutic payloads. This iterative computational and synthetic biology approach allows us to engineer our mRNA sequences for cell-specific translation of modular therapeutic payloads with reduced immunogenicity. We have demonstrated our sequences' onco-selectivity in both murine melanoma and colorectal cancer models, and our pipeline is transferrable to other tumor types. From a broader perspective, our platform can be used to selectively express proteins for other applications, including cell-specific CRISPR gene editing or selective activation of DNA repair mechanisms.

1279. Design of Retinoid-Responsive Toxin Gene Systems for Neuroblastoma Treatment

Enzo M. Giardina[1], Stephen L. Hart[2], Andrew W. Stoker[1]

[1]Developmental Biology & Cancer, UCL Great Ormond Street Institute of Child Health, London, United Kingdom,[2]Genetics & Genomic Medicine, UCL Great Ormond Street Institute of Child Health, London, United Kingdom

Background Retinoic acid (RA) has been shown to improve clinical outcomes for neuroblastoma (NB) patients due to its ability to induce differentiation in tumour cells. However, its use has been limited by toxicity and tumour-acquired resistance after prolonged treatment, following which patients relapse and this is often fatal. **Aims** To increase the efficacy of RA, we aim to design a "toxin gene" therapeutic that is highly sensitive to transcriptional activation by RA. When tumour cells take up the DNA-based agent, they will be bathed in exogenous RA and be rapidly killed. This will effectively re-purpose RA, converting the differentiation response from a cytostatic to a cytotoxic response. Moreover, we aim to deliver the therapeutic in culture and in vivo using our tumour-targeting, liposome-based nanotechnology. **Methods** We have linked the toxin gene diphtheria toxin A (DTA) to RA-responsive promoters in plasmids and tested their cytotoxic capabilities under a range of RA concentrations in cultured cell lines. MicroRNA-response-elements (MREs) were also cloned into the plasmids to minimise

expression in off-target tissues, primarily the liver. Luciferase assays were used to quantify expression with and without the MREs, while fluorescence-based assays were used to assess cell survival. We have then used our previously documented liposomes coated with NB-targeting peptides (ref 1) to assess delivery of our plasmids to cells in culture. **Results** The RA-driven DTA vector, after transfection into NB cells, is highly sensitive to RA, requiring minimal exogenous RA (<100 nM) for maximal cytotoxic activity. Compared to RA alone, the vector shows greater toxicity at all concentrations of RA, shown by the complete loss of positively transfected NB cells following RA treatment; this is seen even in the more RA-resistant SK-N-AS cell line. Liver-specific MREs knocked down transcription by 98% in the hepatoma-derived Huh7 cell line, and also reduced cytotoxicity in this line; however, decreased activity was seen in some NB cells. The liposome-based nanocomplexes also delivered sufficient levels of DTA-expression plasmid *in vitro* to trigger efficient cell death in a range of NB-derived tumour cell lines. **Conclusion** We have developed an inducible gene therapy approach that is able to achieve greater tumour cell cytotoxicity in culture than RA alone. Liver-specific MREs provided some protection against toxicity in liver cells, while cytotoxicity in NB lines was sufficiently maintained. Next steps are to improve the tumour-selectivity of the toxin gene and to carry out proof of principle testing *in vivo* using our targeted deliver system. If successful, this novel approach could be developed as a combination treatment alongside RA in patients, as a route to more effectively remove residual tumour cells.

1280. miR-590-3p Inhibits Growth of Recurrent GBM by Blocking Multiple Oncogenic Nodes

Hernando Lopez-Bertoni[1], Sophie Sall[2]

[1]Neurology, Johns Hopkins School Of Medicine, Baltimore, MD,[2]Kennedy Krieger Institute Inc, Baltimore, MD

Glioblastoma (GBM) is the most lethal and aggressive form of brain cancer. Despite aggressive therapy consisting of surgery followed by radio/chemotherapy GBM recurs in almost all patients and, currently, there are no proven therapies to treat recurrent GBM (rGBM). Recent developments in nanomedicine provide new and promising opportunities to develop new targeted therapeutics to treat brain tumors. We have recently developed PBAE nanoparticle formulations optimized for in vivo miRNA delivery to brain tumor stem cells, or GSCs. Carefully selecting one miRNA to target several mRNAs dysregulated within a pathway can allow the targeting of multiple nodes using a single agent, mimicking combinatorial therapies. To test this hypothesis, we performed bioinformatic analysis of RNA sequencing from GSCs and clinical rGBM specimens combined with gene set enrichment analysis (GSEA) and identified TGFBR2 signaling as a targetable pathway in rGBM. We show that SMAD2/3 signaling, a downstream effector of TGFBR2, is enriched in rGBM and that patients with elevated TGFBR2 transcripts respond poorly to current standard of care. Utilizing patient-derived xenograft lines from rGBM, we show that blocking TGFBR2 signaling using siRNAs or ITD1, a selective TGFBR2 inhibitor, decreases the stem cell capacity, cell viability and re-sensitizes clinical rGBM cells to temozolomide (TMZ) in-vitro. In vivo, we show that ITD1 is modestly effective in subcutaneous and ineffective in orthotopic rGBM models. Not surprisingly, these tumors exhibited classical growth patterns associated with acquisition of resistance. To overcome this obstacle, we performed a miRNA-based network analysis in rGBM and identified miR-590-3p as a putative tumor suppressor that targets SMAD2/3 signaling at multiple nodes in rGBM. In-vitro, nanoparticle-mediated delivery of transgenic miR-590-3p robustly decreased the expression of 37 putative oncogenes simultaneously concurrent with decreasing stem cell capacity, cell viability and re-sensitizing rGBM PDX cells to TMZ. In vivo delivery of miR-590-3p to established PDX-derived rGBM orthotopic tumors using novel PBAE nanocarriers robustly decreased tumor sizes and increased tumor necrosis. These results show that the promiscuous nature of miRNAs, in combination with cutting-edge nucleic acid delivery vehicles, can be leveraged as advanced targeted therapeutics for rGBM bypasses the resistance that is developed to standard of care and available small molecules.

1281. *In Vivo* CRISPR Nanoformulations Targeting Castration-Resistant Prostate Cancer

Noah H. Richardson[1], Sanam Rezaei Benam[1], Samaneh Maleknia[1], Reza Shahbazi[1,2,3]

[1]Division of Hematology/Oncology, Indiana University School of Medicine, Indianapolis, IN,[2]Brown Center for Immunotherapy, Indiana University School of Medicine, Indianapolis, IN,[3]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Advanced metastatic prostate cancer remains an incurable disease and novel therapies are greatly needed to improve outcomes. Initially, metastatic prostate cancer responds to androgen deprivation therapy (ADT) blocking the androgen receptor (AR) signaling pathway responsible for growth and proliferation. Eventually, resistance develops and although circulating androgens remain reduced, signaling through the AR pathway continues through alternative mechanisms. This stage, known as castrate-resistant prostate cancer (CRPC), is characterized by relentless disease progression despite ongoing ADT. Changes in the AR signaling axis, such as receptor duplications, constitutively active splice variants, and point mutations, confer resistance to ADT by circumventing systemic androgen depletion. Furthermore, intratumoral androgen synthesis and receptor responsiveness to other steroid ligands contribute to the persistent activity of the AR. The continued biological significance and reliance of AR signaling in CRPC has made the definitive knockout (KO) of the gene an enticing target. We have used antibody-coated lipid nanoparticles (LNP) to specifically direct CRISPR nanoformulations to prostate-specific membrane antigen (PSMA) positive CRPC cells and knock out the AR. Our CRISPR formulation has increased safety and specificity with both extracellular and intracellular prerequisites for CRISPR activity. Intracellular activation of the CRISPR sgRNA complex is mediated by sensing cell-specific miRNA uniquely identified in malignant cells. We have screened miRNA databases and C4-2B cell lines identifying specific miRNA not expressed significantly in other healthy tissues. Using miRNA-flanked sgRNA CRISPR formulations our system once shuttled to PSMA expressing C4-2B cells allows assembly of Cas9 protein and sgRNA in a cell-specific manner causing AR knock out and

cell death. Our western blot results show 50-80% AR knockout with 40-60% gene editing efficiency analyzed by T7EI, and TIDE analysis. Our time-lapse Incucyte analysis shows 100% targeting to PSMA-positive C4-2B cells by tracking GFP mRNA uptake (Fig. 1). Currently, we are continuing our studies through in vivo analysis of LNP delivery and gene editing specificity in a CRPC mouse model utilizing our unique CRISPR LNP formulation. Our findings demonstrate the feasibility of targeted in vivo CRISPR gene editing to treat prostate cancer and overcome known resistance mechanisms of AR-based therapeutics.

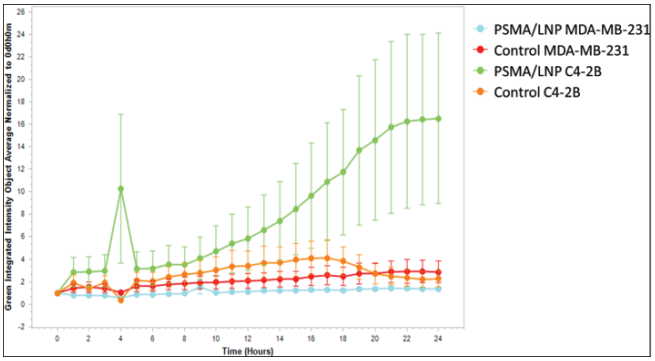

Fig. 1. Highly specific targeting of metastatic prostate cancer cells (C4-2B) by PSMA/LNP CRISPR nanoformulations. Triple negative breast cancer cells treated with the same nanoformulation was used as a control. Lines show GFP mRNA expression. All data are presented as mean ± SEM from experiments n=3.

1282. Identification the Role of Succinate and 5'-Deoxy-5'-Methylthioadenosine as Oncometabolites on Natural Killer Cell Activity Against NSCLC

Xinyu Wu

Purdue University, West Lafayette, IN

Research Summary - Background Natural killer (NK) cells are part of the innate immune system, and possess high cytolytic activity against tumor cells, along with the ability to secrete cytokines and chemokines. However, solid tumors have been largely resistant to attack by NK cells, owing to unfavorable interactions between immune cells and tumors driven by an immunosuppressive tumor microenvironment (TME). The TME of solid tumors is characterized by elevated levels of oncometabolites. However, how their presence affects the activity of NK cells against solid tumors is not known. Among oncometabolites, we have found that 5'-Deoxy-5'-methylthioadenosine (MTA), an adenosine receptor agonist, and disodium succinate, one of the metabolites of the TCA cycle, can alter NK cell behavior in the TME via different mechanisms. To understand how cancer cells respond to NK cell activity in an oncometabolite-rich environment, we studied their effects, and corresponding responses, via CRISPR screening of NK cell and solid tumor systems. - Methods and Results NK cells were isolated from lung cancer patients and healthy adult donors. To study the effect of oncometabolites, NK cells were treated with various concentrations of oncometabolites for 24 hours, then viability of NK cells was measured via the CCK8 assay. Lung adenocarcinoma (A549) cells were then cocultured with oncometabolite-treated NK cells in the absence or presence of oncometabolites to measure the cytotoxicity andIFN-γ production. Separately, oncometabolite-treated NK cells were used in a co-culture setting to identify drivers of response of cancer cells to NK-mediated killing via a genome-based CRISPR screen. A549 cells were transduced with the CRISPR pooled library and positively selected with puromycin. After co-culture with NK cells, DNA genome was isolated and sequenced. - Conclusions Our data showed that metabolites affect NK cell killing capacity. Interestingly, we found that oncometabolites heterogeneously modulates the killing ability of NK cells, suggesting that context- and receptor-specific activation - such as the continued presence of cytokines and metabolites - drives NK cell responses to metabolic factors in the TME. Among the tested oncometabolites, MTA could drastically decrease IFN-γ levels while increasing NK cell cytotoxicity, without affecting the viability. Conversely, succinic acid showed significantly detrimental effects on NK cell viability while increasing their killing ability. We also identified genetic markers of response of cancer cells to killing by NK cells in the presence of oncometabolites. Taken together, our data show divergent and heterogeneous effects of oncometabolites present in the TME and suggest possible genetic targets that can promote NK cell activation in these contexts.

1283. Characterize the Tissue Biodistribution of PD-1, PD-L1, and CD19 mRNA in Lung Carcinoma

Nirupama Chandel, Francesca Mazzoni, Kui Tian, Jack Coleman

R&D, Enzo Life Sciences Inc., Farmingdale, NY

Introduction: Cancer immunotherapy has recently been developed for effective treatments to improve the specificity and strength of the immune response against cancer. The PD-1/PD-L1 complex is known to attenuate immune response towards cancer therapy. Therefore, expression of PD-1 and PD-L1 is directly associated with the severity of cancer and insufficiency of the immune system. CD19 is a B-cell lineage marker that is also employed in CAR-T immunotherapy; the effectiveness of CAR-T cell therapy often hinges on the blockade of PD-1. Consequently, there is great value in target detection using *in situ* hybridization (ISH) to provide precise microscopic localization of nucleic acids in tissue samples. In this study, we used AMPIVIEW™ RNA probes, powered by Enzo's LoopRNA™ ISH technology, specifically targeting PD-1, PD-L1, and CD19 mRNAs to determine the gene expression level and spatial localization in lung carcinoma. **Methods:** The current study used highly sensitive and specific AMPIVIEW™ RNA probes for multiplexing ISH to detect PD-1, PD-L1, and CD19 in a single human lung carcinoma tissue section. **Results and Conclusion:** Understanding the regulatory proteins at the transcription level enables the identification, spatial localization, and quantification of transcript molecules. Deciphering the molecular mechanism of cancer cells is crucial for the development of cell therapy and personalized treatments. In this study, PD-1, PD-L1, and CD19 mRNA were detected in lung carcinoma tissue in a localized manner in stromal cells and around the tumor area. We are able to detect single targets, in addition to multiplex detection with AMPIVIEW™ RNA probes in a single tissue slide.

1284. *In Vivo* Programming of Immune Cells Using mRNA-LNP Chimeric Antigen Receptors

Shannon Argueta, Franciele K. Melber, Michael Gorgievski, Hongyun Zhao, Neha Diwangi, Edward Cochran, Thach Chu, Thomas Prod'homme, Yuxiao Wang, Robert Hofmeister, Jian Ding

Myeloid Therapeutics, Cambridge, MA

Adoptive cell therapies have provided significant clinical benefits to cancer patients. However, *ex vivo* cell therapies are costly and associated with long vein-to-vein times. To overcome these limitations, we deliver cancer-targeting chimeric antigen receptor (CAR) mRNA via lipid nanoparticles (LNPs) to reprogram immune cells directly *in vivo*. To avoid expression of the CAR in other than myeloid cells when adminsterd systemically, we created a new FcαR I (CD89) based CAR construct whose expression and function depends on the co-expression the FcR γ-chain, a signal adaptor protein that is primarily restricted to myeloid cells. Using the same design principle, we also generated CARs that are only operative in NK and T cells, respectively. Upon uptake of TROP2 CAR mRNA/LNPs *in vitro*, TROP2 CARs primarily expressed on mouse and human myeloid cells triggered CAR-dependent cytokine release and tumor cell lysis. Systemic mRNA/LNP delivery of the CAR showed robust anti-tumor efficacy against multiple tumor antigens in xenograft mouse models of human breast cancer, hepatocyte carcinoma, and ovarian cancer. Furthermore, using gp75-targeted CD89-based CAR/LNPs in the B16/F10 immunocompetent melanoma mouse tumor model, we demonstrated robust anti-tumor immune responses and profound changes in the tumor microenvironment characterized by tumoral infiltration of activated CD8+ T cells, diminished tumor-associated Tregs, systemic enhancement of dendritic cell activation and anti-tumor IgG production. Encouraged by our preclinical data, we advanced the TROP2-targeting CAR to a phase I clinical trial to assess the safety and efficacy in epithelial malignancies.

1285. Engineered IMiD Regulated Synthetic Transcriptional Switch for Controlled and Dose-Responsive Expression of Therapeutic Payload within FDA-Approved Drug Doses

Rebecca Cottman[1], Myles MacEachern[1], Michelle Hung[1], Andrew Banicki[2], Mengxi Tian[2], Chen-Ting Lee[2], Assen Roguev[1], Raghav Kannan[3], Chandra Verma[3], Chew-Li Soh[4], Conor McAuliffe[4], Mark Tomishima[4], Timothy K. Lu[2], Gordley Russell[1], Philip Lee[1]

[1]GeneFab, LLC, South San Francisco, CA,[2]Senti Biosciences, South San Francisco, CA,[3]Aplomex, Queensland, Singapore,[4]BlueRock Therapeutics, New York, NY

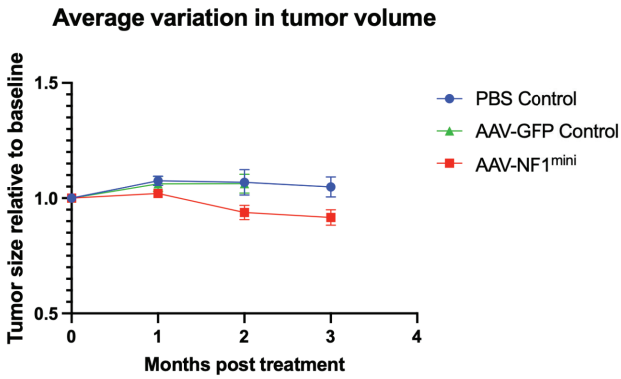
Background: Cell therapies have shown promise in the treatment of liquid tumors, but further engineering is required to effectively treat solid tumors. Use of potent payloads such as IL-12 could boost the efficacy of such therapies, but expression must be regulated to avoid toxicity. Transcriptional switches responsive to FDA-approved small molecules (SMs) are an attractive method for controlling payload expression, but many existing platforms are not responsive to drug concentrations typically achievable in human tissues, especially the brain. This critical limitation prevents their use in clinical applications. We set out to develop a transcriptional switch that can regulate a payload at pharmacologically relevant concentrations of an FDA-approved SM drug to enable novel cell therapies. Methods: The SM-regulated transcriptional switch is composed of a split synthetic transcription factor (SynTF) responsive to pomalidomide and an engineered inducible promoter that can be activated by the SynTF. The SynTF is composed of two parts, A and B. Part A is a zinc finger DNA binding domain (DBD) fused to del.CRBN, a modified human Cereblon that no longer complexes with ubiquitin ligases. Part B is a transcriptional activator fused to a CRBN-IMiD binding protein (CRIMP). In the presence of pomalidomide, A and B dimerize, forming a del.CRBN/CRIMP/pomalidomide complex. This dimerization brings the DBD and transcriptional activator together, forming a functional SynTF that drives payload expression from the inducible promoter. The target concentration of pomalidomide for SynTF function is 4 nM, based on estimates of pomalidomide concentration in the brain and solid tumors. The SynTF was evaluated for function at a range of pomalidomide concentrations and showed robust activity at > 100 nM, well above the 4 nM threshold. To address this, we computationally predicted mutations based on the del.CRBN-IMiD-CRIMP structure that could increase pomalidomide binding affinity. We then screened these mutants for their ability to enhance the SM sensitivity of the SynTF. Results: 112 del.CRBN mutants were evaluated, a subset of which improved the sensitivity of the SynTF to 4 nM pomalidomide. The top performing switch was used to induce expression of a therapeutic payload, IL-12, *in vitro*. This switch induced IL-12 expression at 4 nM pomalidomide from baseline of 8,650 pg/mL to 14,400 pg/mL per $1x10^6$ cells in 24h. We evaluated the engineered transcriptional switch containing our lead del.CRBN mutant for function *in vivo* by implanting NSG mice with engineered cell lines expressing the SynTF and a SynTF-inducible nanoluciferase reporter. We observed significant induction of nanoluciferase luminescence in pomalidomide-treated mice compared to the vehicle-only condition with ~5 fold activation of reporter at lowest dosage of 2 mg/kg, which is well within the dose range that can be delivered to humans. Conclusions: We have engineered a novel SynTF transcriptional gene circuit that has increased sensitivity to an FDA-approved SM drug at pharmacologically relevant concentrations for human clinical use, enabling its function in a wide range of tissues, including the brain. This circuit induces expression of therapeutic payload, IL-12, *in vitro* and functions *in vivo* in a mouse model with drug doses that simulate human dosing. This enables regulated expression of potent immune payloads for increasing the efficacy and safety of cell therapies for solid tumors and other difficult to target diseases.

1286. Versatile SpyTag-SpyCatcher System for Targeting Lentiviral Vectors

Gopal Naik Nenavath[1], Karina Krotova[1], Nandakumar Packiriswamy[1], Kah-Whye Peng[1,2], Miguel Ángel Muñoz-Alía[2], Stephen J. Russell[1,2]

[1]Imanis Life Sciences, Rochester, MN,[2]Vyriad, Rochester, MN

Several CAR-T and hematopoietic stem cell gene therapies are now FDA approved but the need for cell harvesting, ex vivo genetic modification and reimplantation brings high costs and limits these treatments to specialized centers only. Recently, the approach to modify



or engineer the target cells directly within the patient has become an attractive alternative but will require the development of robust cell-specific lentiviral vectors suitable for in vivo applications. Here we introduce a simple and efficient strategy for the creation of VSV-G pseudotyped lentiviral vectors specific to any desired target cell lineage. The VSV-G protein was engineered to ablate its interaction with the LDL receptor and a 13 amino acid SpyTag sequence was inserted close to its N-terminus. These modifications did not significantly impact the folding, intracellular trafficking or incorporation of the protein into lentiviral vector particles and its fusion triggering activity was well maintained. To covalently attach a receptor-targeting moiety to the virally incorporated SpyTag-modified G protein, SpyCatcher fusion proteins incorporating N-terminal cell targeting ligands were generated. Spontaneous isopeptide bond formation between the SpyTag and the SpyCatcher was subsequently shown to result in the generation of ligand-displaying lentiviral vectors and was achieved using two alternate approaches. In the first (coexpression) approach, VSV-G-SpyTag and SpyCatcher-Ligand plasmids were cotransfected into the lentivector producer cells, such that their encoded proteins could associate inside the producer cell. In the second (mixing) approach, lentivirus particles incorporating the SpyTag-modified G protein were mixed with cell supernatants containing the SpyCatcher-Ligand protein. For proof of concept, we first used this technology to display a modified EGFm123 domain on the lentivirus surface. Covalent attachment of the SpyCatcher-EGF fusion protein on the vector particles was confirmed by western blotting and they were shown to preferentially transduce EGF receptor (EGFR) positive target cells. These findings were confirmed and extended using SpyTagged lentiviral vector particles covalently bonded to SpyCatcher-aEGFRscFv, SpyCatcher-aHER2scFv or SpyCatcher-SCF (Stem Cell Factor) fusion proteins, all of which showed appropriate receptor-dependent cell entry specificity, suggesting the technology can accommodate a variety of small and larger targeting molecules. To enable the targeting of human T-lymphocytes, we generated five different SpyCatcher-aCD3scFv fusion proteins, displayed them on SpyTagged lentiviral vector particles and confirmed their ability to target CD3 receptor-positive Jurkat cells but not CD3 receptor-negative Nalm6 cells. We further showed that these retargeted lentiviruses specifically recognized and transduced T cells in a mixed population of human PBMCs. In-vivo targeting studies are ongoing. To conclude, the covalent attachment of cell targeting ligands to lentiviral vectors using the SpyTag-SpyCatcher system in conjunction with fusion-competent LDLR tropism-ablated VSV-G proteins offers a novel and versatile approach to the generation of fully retargeted lentiviral vectors.

1287. Intratumoral Gene Therapy for Plexiform Neurofibroma Utilizing AAV-NF1^{mini}

Rrita Daci[1], Simon Wentworth[2], McKenna Watson[2], Tyler Mola[2], Hannah Villeneuve[2], Pamela St Louis[2], Julie Aguiar[2], Karen Dresser[3], Thomas Smith[3], Robert King[4], Heather L. Gray-Edwards[4], Ana Rita Batista[2], Miguel Sena-Esteves[2]

[1]Neurosurgery, UMass Chan Medical School, Worcester, MA,[2]Neurology, UMass Chan Medical School, Worcester, MA,[3]Pathology, UMass Chan Medical School, Worcester, MA,[4]Radiology, UMass Chan Medical School, Worcester, MA

Introduction: Neurofibromatosis type 1 (NF1) is one of the most common human monogenetic diseases, with an incidence of 1 in 3000. The NF1 tumor suppressor gene encodes for the GTPase-activating protein, neurofibromin. Biallelic loss of *NF1* causes uninhibited GTPase RAS activity resulting in tumor proliferation. Patients with NF1 suffer from inoperable, and sometimes malignant, tumors which are only partially responsive to small molecule inhibitors. As an adjunct to surgical resection, we propose an intratumoral gene therapeutic that can initiate tumor senescence or decrease tumor growth. **Methods**: To accommodate the large size of the NF1 gene, we designed a mini-NF1 transgene (AAV9-NF1^{mini}) which encodes for the tumor suppressive GTPase-activating protein. For consistent *in vivo* vector testing, we created an induced neurofibroma model by injecting AAV1-Cre to the sciatic nerve of $Nf1^{R681*/4F}$ mice carrying an inactive ($Nf1^{R681*}$) and a floxed ($Nf1^{4F}$) allele. Precise analysis of tumor volume was done employing 7T magnetic resonance imaging (MRI). Volumetric analysis was completed by a blinded third party, utilizing ImageJ (NIH, Bethesda MD). We used western blot to assess deletion of *NF1* in the sciatic nerve plexiform neurofibroma tumor model. Since NF1 causes downstream regulation of the RAS pathway involving phosphorylation status of Erk, we also analyzed levels of phosphorylated Erk (pErk) relative to Erk in normal sciatic nerve and plexiform neurofibroma. Immunohistochemistry against Schwann cell markers S100 and Sox10 was done for tumor characterization. After establishing a reliable neurofibroma tumor model, mice were enrolled into three cohorts: treatment with AAV9-NF1^{mini} (N=12), PBS control (N=12) and AAV9-GFP control (N=5). The addition of a GFP control was done to assess for biological activity of the AAV9 capsid and any potential cross-reactivity with AAV1. **Results**: Histological evaluation of the AAV1-Cre injected sciatic nerve in $Nf1^{R681*/4F}$ mice revealed spindle cells with increased cellularity and with S100B and Sox-10 positivity, indicating tumor formation. Western blot analysis of these tumors showed deletion of NF1 and dysregulation of the pErk/Erk pathway. Initial 7T MRI evaluation showed T2 hyperintensity within the length of the AAV1-Cre injected sciatic nerve and subsequent MRIs showed slow growth of untreated tumors. Tumors treated with AAV-NF1^{mini} showed a significantly smaller difference in tumor volume as measured on MRI when compared to controls. The 1 month statistical significance (unpaired T test p=0.013) persisted at 3 months post treatment (unpaired T test p=0.025). Additionally, tumors treated with AAV-NF1^{mini} showed a reduction in tumor size at 3 months when compared to 1 month post treatment (paired T test: p=0.016)(Fig.1). **Conclusion**: We have established an induced NF1 mouse neurofibroma model in the sciatic nerve. Our data revealed that AAV-NF1^{mini} has some tumor suppressive function *in vivo*, as demonstrated by decreased tumor size in the treatment arm when compared to control. Our goal is to rapidly translate this approach for intratumoral treatment of plexiform neurofibromas that are challenging to treat surgically and/or fail to respond to Selumetinib.

1289. Suppression of PARKIN by Cigarette Smoke Through microRNA-Mediated Regulation: Implications for Impaired Mitophagy, Oxidative Stress, and Inflammation, and an Alternative Intervention Strategy

Maria Jose Santiago[1], Srinivasan Chinnapaiyan[2], Manal Imran[2], Zachary Grand[2], Kingshuk Panda[2], Suvankar Ghorai[2], Md Sohanur Rahman[2], Hoshang Unwalla[2]

[1]Chemistry & Biochemistry-Department of Cellular and Molecular Medicine, Florida International University, Miami, FL,[2]Department of Cellular and Molecular Medicine, Florida International University, Miami, FL

Cigarette smoke (CS) induces oxidative stress in airway cells, leading to disruptions in metabolic pathways and triggering inflammation. Interestingly, the mechanism by which CS leads to inflammation is not well-established. This project focuses on understanding how cigarette smoke induces inflammation to develop a therapeutic approach for mitigating its effects. Mitochondria play a pivotal role in regulating apoptotic and oxidative processes. If mitochondria are damaged or defective, they must undergo recycling or elimination through mitophagy. Improper mitophagy results in the retention of dysfunctional mitochondria, leading to the release of inflammatory molecules such as Damage-Associated Molecular Patterns (DAMPs), Senescence-Associated Secretory Phenotype (SASPs), mitochondrial DNA (mitDNA), and reactive oxygen species (ROS). Therefore, we hypothesize that CS suppresses the expression of PARKIN (mitophagy protein), culminating in defective mitophagy, senescence, and elevated ROS levels, causing inflammatory responses. To test this hypothesis, bronchial cells were exposed to CS, followed by the collection of supernatants, RNA, and proteins for comprehensive analysis. Additionally, electroporation procedures involving a microRNA, identified as a potential target for PARKIN and upregulated by CS, are currently underway. Various methodologies, including Western blotting (WB), reverse transcription-quantitative polymerase chain reaction (RT-qPCR), Amplex Red assay, staining procedures (MitoTracker Green and C12FDG dyes), and Luminex were employed to analyze factors such as PARKIN expression, H_2O_2 levels, defective mitophagy, senescence, and inflammatory profiles. Results demonstrate that CS suppresses PARKIN at the mRNA and protein levels by 70% and 40%, respectively, in bronchial epithelial cells. H_2O_2 levels increased nearly three-fold upon CS exposure. Staining procedures indicate a significant increase in defective mitophagy and senescence due to CS. A pro-inflammatory profile was established upon CS exposure by the Luminex assay. Currently, we are verifying and examining the inhibition of PARKIN facilitated by a candidate microRNA, which is upregulated by CS. We aim to confirm the regulatory role of this microRNA mediating PARKIN expression and consequently implement a therapeutic strategy that involves the synergistic combination of antioxidants with antagomirs to effectively restore PARKIN expression and alleviate the adverse effects of CS. This research provides insight into the intricate mechanisms by which CS induces an exacerbated redox state in airways, culminating in pulmonary inflammation. Furthermore, the study explores the potential of therapeutic interventions involving antagomirs and antioxidants to ameliorate the detrimental impact of cigarette smoke.

1290. Expressional & Mutational Deregulations of miRNA-146b and miRNA-181b in Papillary Thyroid Carcinoma

Rashida Khan[1], Ruqia Baig[2], Qaisar Mansoor[1]

[1]Istitute of Biomedical & Genetic Engineering Islamabad, Islamabad, Pakistan,[2]PMAS-Arid Agriculture University Rawalpindi, Rawalpindi, Pakistan

Background: Thyroid cancer is considered to exist among most common cancers and at the same time it is the most recurrent malignancy of the endocrine system. The most frequent type of thyroid cancer is papillary thyroid cancer (PTC), which contributes more than 80% globally & prevalent in females of Eastern and Western Asia, America and Iceland. The genetic elements known as MicroRNAs (miRNAs), endogenous non-coding RNAs operating as post-transcriptional regulators involved in development, proliferation and differentiation. miRNAs are gaining fame as druggable biomarkers and clinical management of neoplasm. The momentous stackeholding of miRNAs by virtue of gene expression variations in the cancer microenvironment has been witnessed in the PTC onset, amplification and apoptosis. The growing body of knowledge highlights the modifiable play at the miRNA level harbors potential in lessening the perpetuation of the disease with safe handlers. The genetic information leads to a big highway which can replace the unified yardstick to tailor PTC with the more targeted personalized disease treatment by monitoring the disease risk and aggression modalities.Objectives: The study aims to speculate the characteristic involvement of expression level changes in the miRNA genes miRNA-146b and miRNA-181b as tangible biomarkers for papillary thyroid cancer. Methodology: The present study was conducted on the PTC in Pakistan, a genetically less explored South Asian country. Specimen of cancer tissue, normal samples and multi nodular goiter (MNG) samples from patients were collected. The anthropometric and clinical parameters of patients were recorded after informed consent. Total RNA was isolated and cDNA was synthesized. Gene expression profile for miRNA-146b and miRNA-181b was done by quantitative Real-Time PCR. Relative gene expression was identified as fold change and mutational deregulations were checked through DNA sequencing showing the involvement of these miRNAs in PTC. Results: The statistically significant relative expression of genes miRNA-

146b; 5 to 20 folds and miRNA-181b; 4-60 folds were observed in PTC in comparison to MNG and healthy tissue specimens. Conclusion: The boosted gene expression of the miRNA genes miRNA-146b and miRNA-181b manifests the plausible misregulations in deployment of these molecular musketeers as foes in PTC. This forged maladaptation of the miRNA-146b and miRNA-181b in the cancer microenvironment may warrant analytically, therapeutically and genetically surmountable miRNA targets for PTC clinical management prevention

Thursday Posters: Challenges to Immunological Responses to Therapeutic Interventions

1291. Peptide-Mediated Activation of PI3K Class III Complex Containing Beclin1 and ATG14L Boosts Gene Delivery by Lentiviral Vector at the Stage of Cellular Entry

Saliha Majdoul, Scarlett Shi, Kazi Rahman, Alex A. Compton

HIV Dynamics and Replication Program, National Cancer Institute, Frederick, MD

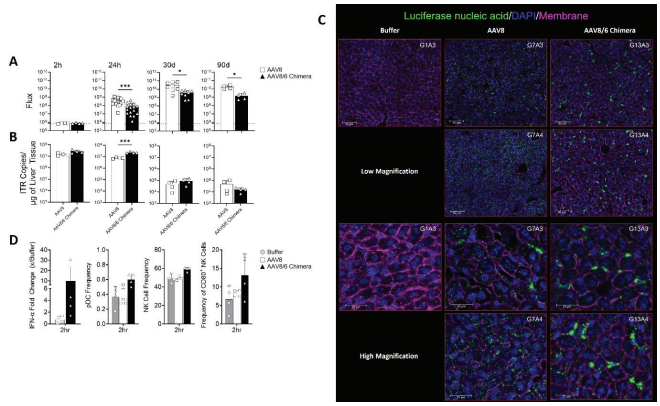
Cell-intrinsic barriers to enveloped virus infection constitute a major limitation to the effectiveness of lentivector-mediated gene therapy ex vivo and in vivo. We previously identified that triggering autophagy through mTOR inhibition resulted in increased cellular susceptibility to lentivector transduction at the stage of virus-cell membrane fusion. Here, we determined if and how autophagy induction by a Beclin1-derived peptide (Tat-Beclin1) impacted lentivector entry into hematopoietic and nonhematopoietic cells. We found that Tat-Beclin1 peptide boosted lentivector entry into cells, a process driven by vesicular stomatitis virus (VSV) glycoprotein, by more than an order of magnitude. In contrast, peptide mutated at phenylalanine-270 had no effect. Mechanistically, we found that lentivector entry enhancement by Tat-Beclin1 requires it to bind to and activate cellular Beclin1 protein in a F270-dependent manner. Beclin1 forms a complex with PI3K class III and ATG14L, and this complex produces phosphatidylinositol-3-phosphate (PI3P), a lipid essential for macroautophagy induction. Indeed, we found that Tat-Beclin1 promoted PI3P production in endosomal and autophagosomal membranes. By using a specific inhibitor of PI3K class III, we found that PI3P production is necessary for the enhancement of lentivector entry by Tat-Beclin1. Furthermore, specific knockdown of Beclin1 or ATG14L abrogated lentivector entry enhancement by the peptide, and a specific inhibitor of the Beclin1-ATG14L interaction blocked lentivector entry as well. Therefore, Tat-Beclin1 boosts lentivector transduction by activating the PI3K class III-Beclin1-ATG14L complex. In accordance with the lentivector entry step being affected, we also found that authentic VSV infection is dramatically boosted by Tat-Beclin1. Our findings can be leveraged to not only significantly improve the efficiency of lentivector-mediated gene therapy, but also immunotherapies that depend upon deployment of VSV, such as oncolytic virotherapy for cancer.

1292. Co-Stimulatory Blockade Regimen Prevents Anti-Transgene and Anti-Vector Immune Responses in Hemophilia a Mice After *In Vivo* LV Gene Therapy

Andrea Annoni[1], Michela Milani[1], Cesare Canepari[1], Silvia Iaia[1], Fabio Russo[1], Mauro Biffi[1], Luigi M. Naldini[1,2], Alessio Cantore[1,2]

[1]San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), IRCCS San Raffaele Scientific Institute, Milan, Italy,[2]"Vita-Salute San Raffaele" University, Milan, Italy

Lentiviral vector (LV)-based in vivo gene therapy is attractive for its potential applicability to permanently correct monogenic diseases, even in childhood, with negligible limitations derived from pre-existing immunity towards the parental virus. Although stable transgene expression by hepatocytes have been achieved in mice, dogs and non-human primates by a single systemic LV administration, immunity towards transgene and vector may limit the therapeutic outcome and LV redosing. In a mouse model of Hemophilia A (HA), LV-mediated factor VIII (FVIII) expression by hepatocytes revealed that multiple factors may contribute to its immunogenicity, such as the protein structure, the proportion of transduced hepatocytes, the translation rate and the protein half-life. High dose of LV encoding for human (hu)FVIII (5E10 TU/kg) in adult HA mice established stable expression of huFVIII (50% of normal) in absence of anti-FVIII immune responses in 80% of treated mice, by a combination of fasting and type-I interferon (IFN) signaling blockade (anti-IFNa receptor, IFNAR) which allowed maximizing LV transduction efficiency and dampening innate immunity. Conversely, administration of LV alone, did not result in detectable huFVIII and induced anti-FVIII immunity. Comparable doses of LV encoding for half-life extended huFVIII. XTEN resulted in minimal and only transient FVIII expression in vivo, again abrogated by anti-FVIII immunity. In order to improve FVIII output in vivo at lower LV doses, the transgene sequence was codon-optimized (coFVIII) enabling 10-fold increased expression compared to huFVIII. This strategy allowed to obtain high levels of circulating FVIII produced by a limited proportion of hepatocytes but resulted in the induction of a strong anti-FVIII humoral and cellular immune response leading to clearance of LV-corrected hepatocytes. Therefore, we tested T cell targeted immunotherapies to control anti-transgene immunity. We found that the administration of anti-IFNAR immediately before coFVIII-LV or coFVIII-XTEN-LV administration combined with co-stimulation blockade regimen allowed stable huFVIII expression at 110% and 500% of normal, respectively, in HA adult mice by lower LV doses (2E10 TU/kg). This immunotherapeutic regimen abrogated the induction of anti-FVIII antibodies and CD8+ T cell allowing persistence of LV-modified hepatocytes releasing FVIII in absence of antibody-mediated neutralization, largely beyond the time of its administration. Furthermore, we did not detect any neutralizing anti-VSV.G humoral response, which is typically induced by in vivo administration of VSV.G-pseudotyped LV. Overall, these data indicate that FVIII immunogenicity can be controlled by i) increasing the proportion of transduced hepatocytes and lowering the amount of huFVIII produced *per* cell and ii) applying a co-stimulation blockade regimen to achieve stable FVIII expression at therapeutic levels even increasing the rate of transgene translation in a reduced fraction of



hepatocytes. Moreover, the use of the latter strategy allows to adjust transgene output by administering a second LV infusion thanks to the absence of immunity to FVIII or LV particles.

1293. Preclinical Modeling of Immunity in Murine Liver Following Adeno-Associated Virus Delivery: A Cross-Sectional Comparison of AAV8 and an AAV8/6 Chimeric Capsid

Alan D. Curtis[1], Rachel Hedinger[1], Kelsey Higgins[1], Youjun Chen[1], Abbie Svancarek[1], Charles Krause[1], Joshua Hatfield[1], Layth Awartani[1], Dylan Southers[1], Erik Wielechowski[1], Rachel Reynolds[1], Audry Fernandez[1], Angela Mote[1], Scott Hammond[1], Sherif Gabriel[1], Anna Tretiakova[1], Shari Gordon[1], Xiao Xiao[2], R. Jude Samulski[1,3]

[1]Asklepios BioPharmaceutical, Inc., Durham, NC,[2]Belief Biomed, Shanghai, China,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Adeno-associated virus (AAV) vectors are leading candidates for gene therapy product delivery. However, the developing capsid specific immune response has been associated with waning transgene expression and immune-related adverse events. AAV8 is a well-described liver tropic capsid with strong transduction efficiency. However, liver inflammation and in rare cases liver toxicity has been observed after high-dose AAV8 administration (Konkle, 2021; Wilson & Flotte, 2020). Conversely, a recently described liver tropic AAV8/6 chimera capsid demonstrated safety, minimal liver inflammation, and sustained transgene expression (median 58 weeks) in a clinical trial in hemophilia B patients (Xue, 2022). Better understanding of innate and adaptive immune pathways induced by AAV in the liver has the potential to inform capsid design, immunomodulatory regimens, and enhance clinical trial outcomes. The current cross-sectional study aimed to directly compare the immunogenicity, transgene expression and biology of AAV8 and an AAV8/6 chimera. We assigned groups (n=4) of adult female B6(Cg)-Tyrc-2J/J albino mice to receive $1E^{11}$ vg (~$5E^{12}$ vg/kg) of AAV8 (AAV8-Luc) or AAV8/6 chimera (AAV8/6 chimera-Luc) carrying a luciferase reporter. Control mice received formulation buffer. All dosing was conducted by tail vein injection and mice were sequentially culled at 2, 5, 8, 16, 24, 72 hours (h) or 7, 30, or 90 days (d) post-dose. Both whole body IVIS imaging and ex-vivo imaging of the liver showed significantly higher transgene expression from AAV8 compared to AAV8/6 chimera (Figure A). Intriguingly, AAV8/6 chimera exhibited higher (~0.5 log) viral DNA copies in liver compared to AAV8 at early timepoints (Figure B). In situ hybridization of luciferase DNA/RNA in liver revealed distinct vector distribution patterns 2h post dose. AAV8 nucleic acids were as small, punctate foci that were uniformly distributed. In contrast, AAV8/6 chimera was organized into large areas of intense staining with an increased number of membrane-associated aggregates, suggesting vector amalgamation (Figure C). AST and ALT liver enzyme levels in serum were similar across all groups and time points and apoptotic hepatocytes were not observed by TUNEL staining, implying normal liver function despite AAV aggregates at early timepoints. We used flow cytometric techniques and qPCR to quantify the fraction of infiltrating immune cells in liver and changes in gene expression of specific cytokines at the various timepoints post AAV administration. At 2h post-dose, AAV8/6 chimera transiently elicited an upregulation of select innate genes including interferon alpha (~10 fold), increased plasmacytoid dendritic cell frequency and natural killer cell activation relative to AAV8 and mock controls (Figure D). At later timepoints we observed similar levels of activated T cells in the liver and circulating AAV binding antibodies induced by both capsids. Overall, this study suggests capsid specific differences in the early host response may impact transgene expression.

1294. iqDNA is an Engineered DNA Cargo That Avoids Innate Immune Activation While Retaining Durable Transgene Expression

Russell Monds, Kelly Miller, Andrew O'Hagan, Nicholas Parsonnet, Joris Cipi, Nick Hanovice, Christian Slubowski, Luis Agosto, Anastasia Lymar, Matthew Stanton

Generation Bio, Cambridge, MA

Non-viral delivery of large DNA molecules offers the potential for re-dosable gene therapy and may broaden the scope of in vivo gene editing to support full gene correction or insertion. One of the central challenges to realizing this enormous potential is the acute toxicity of DNA-mediated activation of the innate immune system. Immune quiet DNA (iqDNA) is a derivative of closed ended DNA (ceDNA) that was engineered to avoid recognition and activation of Pattern Recognition Receptor (PRR) systems, including cGAS/ STING, TLR9 and inflammasome pathways. When iqDNA is administered systemically using lipid nanoparticle delivery, mice show baseline levels for a broad range of cytokines across a dose range (Fig. 1). This profile is comparable to chemically-modified mRNA and a stark contrast to existing DNA formats, including ceDNA which elicits cytokines when dosed above 0.1 mg/kg. The immune-quiet profile of iqDNA is robust across species, avoiding innate immune activation in non-human primates and human PBMCs. Importantly, despite being designed to avoid immune recognition, iqDNA retains the capacity for robust and stable episomal transgene expression. iqDNA encoding a luciferase reporter showed similar expression to that of ceDNA (~ 10^8 total flux, @ 0.25 mg/kg) when delivered to mice by LNP. Furthermore, expression of luciferase was durable, showing no change over the course of a 30-day study. To support the therapeutic potential of iqDNA, a FVIII transgene cassette was synthesized in an iqDNA format and tested for innate immune activation and expression. Similar to the results with luciferase, little to no elevation of cytokines was observed

in mice or monkeys treated with 2 mg/kg and 0.5 mg/kg, respectively. The immune-quiet profile of DNA was consistent across five different LNP compositions, reinforcing the generality of the iqDNA's ability to avoid innate immune system detection. FVIII expression was detected in mice treated with iqDNA at a level of 0.06 IU/ml (6% normal levels). Potency of FVIII iqDNA is being optimized to facilitate robust translation to NHP. Progress towards this goal is presented as well as insights into the mechanisms by which iqDNA avoids immune system recognition. The toxicity of exogenous DNA severely limits the safety and efficacy of DNA gene therapy technologies. iqDNA represents a pivotal step forward, and sets a framework to enable functional, durable, and re-dosable non-viral gene therapies.

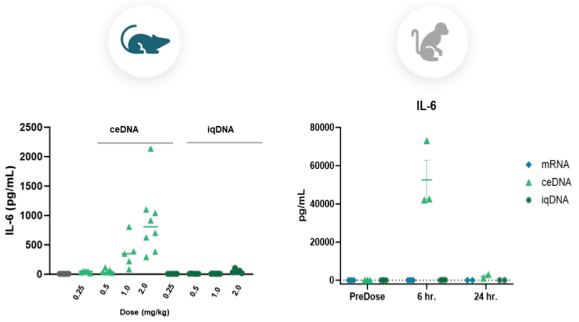


Figure 1. iqDNA does not activate the innate immune system in mice or NHP. Left) Systemic IL-6 concentration 6 hours after dosing CD-1 mice intravenously with formulated ceDNA or iqDNA. Right) Systemic IL-6 concentration before and after dosing cynomolgus monkeys intravenously with formulated mRNA, ceDNA or iqDNA at 1.0 mg/kg.

1295. B cell Production of the eCD4-Ig-Knob-in Hole-Reversed HIV-1 Immunoadhesin in Humanized NBSGW Mice

Chet Ojha[1], Craig Schindewolf[1], Anna Helmers[1], Amalia Icreverzi[1], Neele Thom[1], Gregory Asher[1], Meagan Neu[1], Andrea Repele[1], Richard James[2], David J. Rawlings[2], Bruce E. Torbett[2]

[1]Center for Immunity and Immunotherapies, Seattle Children's Research Institute, Seattle, WA,[2]Department of Pediatrics, University of Washington School of Medicine, Seattle, WA

B cells have the capacity to produce high levels of IgG proteins and may persist for years as long-lived plasma cells. Moreover, B cell-produced exogenous proteins have been reported to be immune system tolerant. These properties support the concept that B cells are an attractive cellular target for gene therapy. The HIV-1 immunoadhesin molecule, eCD4-Ig-Knob-in-Hole-Reversed (KiHR), is a CD4- and CCR5/CXCR4-mimetic antibody-like protein which we have engineered so as not to interact with B cell immunoglobulin Fc domains, and it has been shown to have nanomolar HIV-1 neutralizing potency against primary isolates. We have previously shown that the B cell-specific enhancer and promoter, EμB29, promotes eCD4-Ig-KiHR expression in B cells *ex vivo* (PMID-36879849). We hypothesized that the presence of the eCD4-Ig-KiHR transgene in CD34$^+$ HSPCs could provide for long-term generation of eCD4-Ig-KiHR protein-expressing B cells. To evaluate whether eCD4-Ig-KiHR could be produced long-term from B cells in humanized NBSGW mice, we transduced adult CD34$^+$ hematopoietic stem and progenitor cells (HSPCs) with a VSV-G-pseudotyped EμB29-GFP-P2A-eCD4-Ig-KiHR lentiviral (LV) vector. CD34$^+$ HSPCs were transduced to achieve viral copy numbers (VCN) of 1, 3 or 8 and then HSPCs were adoptively transferred to busulfan-treated NBSGW mice. Mouse peripheral blood human CD45$^+$/GFP$^+$ cells and serum eCD4-Ig-KiHR levels varied depending on the transduction levels in CD34$^+$ HPSCs. VCNs of 1, 3 and 8 resulted in 10 - 15%, 25 - 35% and 50 - 70% human CD45$^+$/GFP$^+$ cells in peripheral blood of humanized mice and 1 - 2 ng/mL, 3 - 4 ng/mL, and 15 - 20 ng/mL of eCD4-Ig-KiHR in sera, respectively. eCD4-IgKiHR levels were maintained until week 24 post-transfer. Since B cell maturation is restricted in humanized mice to IgM-producing B cells, we evaluated whether differentiation *ex vivo* of IgM$^+$ B cells isolated from spleens of humanized mice would result in greater eCD4-Ig-KiHR protein production. Indeed, differentiation *ex vivo* of IgM$^+$ B cells resulted in IgG$^+$ class-switched CD138$^+$ plasmablasts after 10 days. Importantly, differentiated B cells produced higher amounts of eCD4-Ig-KiHR (up to 100 ng/million cells/day). We also quantified eCD4-Ig-KiHR production at the single cell level by eCD4-Ig enzyme-linked immunosorbent spot (ELISpot), and we detected a 90-fold increase in the proportion of eCD4-Ig-KiHR-expressing B cells during culture. These data suggest that the B cell population derived from transferred eCD4Ig-KiHR-transduced CD34$^+$ HSPCs is capable of expressing high amounts of transgene from a B cell-specific enhancer/promoter when allowed to mature. Our findings indicate that at all levels of B cell GFP-marking we observed, eCD4-Ig-KiHR could be detected in humanized mouse sera at levels sufficient for HIV neutralization (> 1 ng/mL). The findings support the promising strategy that LV-mediated delivery of the HIV-1 immunoadhesin eCD4-Ig-KiHR under the control of a B-cell specific enhancer/promoter to CD34$^+$ HSPCs may lead to the production of high levels of eCD4-Ig-KiHR by mature B cells *in vivo*.

1296. Generation of Highly Potent HIV/SIV Neutralizing Molecules after *In Vivo* HSC Transduction of Rhesus Macaques with a Novel HDAd Strategy

John K. Bui[1], Chang Li[1], Anne-Sophie Kuhlmann[2], Anna K. Anderson[1], Hongjie Wang[1], Donna J. Palmer[3], Philip Ng[3], Andrew Riker[2], Michael Farzan[4], Jasmin Martinez-Reyes[2], Michael Alpert[5], Brandon Keele[6], Hans-Peter Kiem[7], Andre Lieber[1]

In vivo gene delivery using helper-dependent adenovirus vectors (HDAd) promises accessible and versatile treatment for various diseases. HDAd vectors offer the potential for sustained therapeutic delivery, addressing challenges posed by chronic diseases, notably HIV, that require lifelong treatment. We are pioneering *in vivo* transduction approaches using HDAd vectors to transduce hematopoietic stem cells (HSCs) for the *in vivo* delivery of HIV therapeutics, including eCD4-Ig. This broadly neutralizing molecule possesses exceptional breadth against diverse HIV isolates and has a high barrier to HIV resistance. *In vivo* delivery of eCD4-Ig eliminates the need for repeated passive eCD4-Ig infusions, offering a scalable and accessible approach for

middle and low-income countries that face a disproportionate burden of HIV/AIDS. We have previously shown that our HDAd platform can achieve stable therapeutic levels of eCD4-Ig in non-human primate (NHP) models. Here, we used an improved HDAd (HDAd6/3+-cxcr4) to deliver an enhanced eCD4-Ig variant ("eCD4-Ig-Emm006") that was modified for improved potency, *in vivo* stability, and immunogenicity. eCD4-Ig-Emm006 vectors also contained a TPST2 cassette to sulfonate the eCD4-Ig-Emm006 molecule for increased binding affinity to HIV/SIV. Both the eCD4Ig-Emm006 and TPST2 cassettes were under the control of ubiquitously active promoters, thus allowing for expression in all HSC progeny cells that could be targets for SIV/HIV infection. To test the ability of *in vivo*-delivered eCD4-Ig-Emm006 to protect against SIV infection (an HIV-like virus), we compared two groups of rhesus macaques that received the eCD4-Ig-Emm006 vector (N=4) or a control vector (N=3). HSCs were mobilized using AMD3100 and G-CSF followed by intravenous infusion of integrating HDAd vectors. HDAd vectors were well-tolerated. Using our enhanced HDAd6/3+-cxcr4 vector platform, we achieved stable vector copy numbers (VCN) in the range of 0.1 vector copies in bone marrow mononuclear cells and PBMCs after an in vivo enrichment step, reflecting ~10-fold improvement compared to our prior HDAd vectors. The eCD4-Ig-Emm006 variant had exceptional SIV neutralization potency: *in vivo* serum-derived eCD4-Ig-Emm006 IC50s ranged from 10.6 to 34.7 ng/mL. eCD4-Ig-Emm006 serum levels stabilized at 2.1 μg/mL to 38.3 μg/mL, which are ~1,000x fold higher than the measured IC50. We are currently challenging animals with SIV to assess the protective efficacy of our approach. Pending analyses include determinations of SIV serum titers, gene-marking in hematopoietic subsets and systemic tissues, as well as flow-based immunophenotypic analyses. These data demonstrate the ability of our *in vivo* approach to achieve stable, long-term *in vivo* levels of eCD4-Ig for the prevention and treatment of HIV. The results of this proof-of-concept study demonstrate the capacity of our HDAd platform to deliver therapeutic proteins with the prospect of addressing infectious diseases, including HIV and COVID-19. Our HDAd platform could emerge as a viable alternative for vaccines, particular benefitting immunocompromised hosts who are unable to mount protective endogenous immune responses. This evidence not only underscores the platform's potential but also positions it as a promising therapeutic modality for infectious disease prevention and management.

1297. A Deep Learning Model for Predicting Patient Response to Virus-Specific T Cell Therapy

Pamela A. Chansky[1], Wei Li[1], Michael D. Keller[2], Catherine M. Bollard[2]

[1]Center for Genetic Medicine, Children's National Hospital, Washington, DC,[2]Center for Cancer & Immunology Research, Children's National Hospital, Washington, DC

Viral infections are a significant risk for many immunocompromised patients, including recipients of bone marrow transplantation. Virus-specific T cell (VST) therapy allows rapid reconstitution of antiviral T cell immunity, with 70-90% response rates following HLA-mismatched VST therapy. However, failure of VST therapy to control viral infections remains a frequent problem. Aside from immunosuppressive agents, there is limited understanding of why patients fail VST therapy. VST response is defined as the viral load reaching an undetectable level via PCR or a noticeable reduction in viral load combined with other clinical indicators of improved health. We hypothesized that a variety of commonly collected clinical variables from the period prior to VST therapy, such as pre-treatment viral load, prior drugs received, and diagnostic category, could be used in a deep learning model to predict the likelihood of response to VST therapy. We used a clinical dataset comprised of patient records from prior VST studies as input to a variational autoencoder (VAE) to overcome the limited sample size (n=79). The VAE generated tens of thousands of unique records with high similarity to the real infusion records, as determined by correlation tests, thus improving the ability to draw statistically meaningful conclusions and generate accurate predictions. A combination of the real and synthetic data was then used to train a deep learning model of VST response. The deep learning model was tested on a subset of the real records which were withheld from the data generation and training processes and was found to accurately predict the likelihood of response given a patient's pre-treatment clinical variables. Averaging over 100 iterations, the model achieved over 80% accuracy, recall and precision, indicating model's usefulness in predicting patient response to VST therapy. The in-silico model will help identify the best VST therapy candidates to optimize treatment planning.

1298. Elucidating Complement Activation Mechanisms in AAV Gene Therapy: Development of a Novel ELISA-Based Assay for Enhanced Safety and Efficacy

Gene therapy utilizing adeno-associated virus (AAV) vectors demonstrates excellent safety profiles and remarkable clinical efficacy in treating diverse diseases. Despite its relative safety, evidence from clinical trials has shown that AAV can trigger severe life-threatening inflammatory responses. Many of these adverse reactions are associated with the secondary activation of the complement system, leading to complications such as acute kidney injury due to atypical hemolytic uremic syndrome-like (aHUS-like) complement activation, thrombotic microangiopathy (TMA), thrombocytopenia, and immune-mediated myocardial inflammation. Though AAV-mediated complement activation is a major safety concern, we still lack understanding of the activation mechanism and a predictive method to prevent or mitigate activation in administered patients. In this context, our research has been focused on the development and evaluation of an ELISA-based AAV-mediated Complement Activation assay. The technique combines an AAV-coated plate with a tailored buffer composition, selectively allowing evaluation of the distinct classical, lectin or alternative complement system pathways. The assay detects *ex vivo*-generated terminal complement complex (TCC) deposition, making it a robust tool for testing and predicting complement reactions to AAV in analyzed sera. Utilizing this assay, we have explored the impact of each pathway on AAV-mediated activation and investigated the potential of anti-AAV antibodies to initiate the classical pathway. The platform

is also designed to assess the potential presence and impact of other AAV-specific motifs capable of activating the lectin pathway. Given the complexity of serum interactions with anti-AAV antibodies and the complement system, our assay holds promise in shedding light on pivotal immune interactions and offers valuable insights to enhance the safety and efficacy of AAV-based gene therapies, thus, advancing the field.

1299. Pre-Existing Immunity in the Human Population to Cas Proteins Derived from Bacteriophage, Casϕ, and Acidaminococcus sp., Cas12a

Pratima Bajgain, Vijaya L. Simhadri, Atul Rawal, Zuben E. Sauna

Center for Biologics Evaluation and Research, Food and Drug Adminstration, Silver Spring, MD

Introduction: The clinical use of the CRISPR/Cas system requires in vivo delivery of Cas proteins, and it could induce immune responses which would limit the utility of the technology. Pre-existing immunity to Cas9 which is of microbial origin has been demonstrated. Here, we evaluate pre-existing T- and B-cell immunity to two alternatives to Cas9: AsCas12a (derived from *Acidaminococcus* sp bacteria, normal fecal flora) and Casφ (derived from a huge bacteriophage). Methods: The study was performed using blood from 40 healthy donors obtained from the National Institute of Health blood bank. Pre-existing antibodies to SaCas9, AsCas12a and Casφ were identified using ELISA while memory T-cell responses were measured using the ELISpot assay. Results: We determined the percentage of donors who exhibited pre-existing antibodies to Cas9 in the serum using an ELISA assay. Compared to 90% of donors with pre-existing antibodies to Cas9, preexisting antibodies to Casφ and Cas12a were identified in 97.5% and 82.5% of donors respectively. We also measured the memory T-cell response to Cas proteins in an ELISpot assay. PBMCs from 95%, 72.5% and 97.5% of donors showed memory T-cell responses to Cas9, Casφ and Cas12a respectively. Conclusion: It has been speculated that pre-existing immunity to AsCas12a and Casφ may be lower than that found in Cas9 which is derived from human pathogens. Our study finds that this is not the case and that immune responses may affect the safety and efficacy to alternatives to Cas9 when used in the clinic.

1300. Utilizing Platelet-Targeted Gene Therapy to Induce Immune Tolerance in Food Allergy

Saurabh Kumar[1], Jocelyn A. Schroeder[1,2], Hongyin Yu[1,2], Talal Chatila[3], Calvin B. Williams[2], Qizhen Shi[1,2]

Background: Food allergy is a serious public health and economic issue which is an increasing concern for families and clinicians. Food allergy emerges in the context of oral immune tolerance failure, with no cure currently. Our previous studies have demonstrated that platelet-specific gene therapy can effectively induce antigen-specific IgG-mediated immune tolerance in hemophilia A and B models. We hypothesize that targeting allergen expression specifically to platelets will induce IgE-mediated immune tolerance in food allergies. *Objective*: The goal of this project is to develop a novel approach to induce immune tolerance to the allergen. *Methods*: Here, we used OVA as a surrogate allergen for this study. Two mouse models were used in our studies. One was the OVA-specific OT-II model, in which 98% of CD4 T cells are OVA-specific. The other was IL4ra^{F709} mutant mice, a model prone to allergic response. Platelet-targeted OVA expression was introduced via 2bOVA lentivirus transduction of hematopoietic stem cells (HSC) followed by HSC transplantation (HSCT). After HSCT, mice were assessed by PCR for proviral DNA expression and ELISA for platelet-OVA expression levels to ensure successful gene transfer. After bone marrow was fully reconstituted, animals were sensitized by gavage treatment with OVA (10 mg/kg) plus staphylococcal enterotoxin B (SEB, 0.4 mg/kg) weekly for 8 weeks, followed by a high dose of OVA (6 g/kg) challenge. After the challenge, the anaphylaxis reaction was monitored by measuring the changes in body temperature, and tissue samples were collected to investigate if immune tolerance was established in 2bOVA-transduced recipients. *Results:* PCR analysis showed that 2bOVA proviral DNA was detected in all 2bOVA-transduced recipients. Average platelet-OVA expression levels were 11.49 ± 7.49 ng/10^8 platelets in 2bOVA-transduced OT-II HSCs in wild-type recipients (the OT-II model) and 6.82 ± 6.89 ng/10^8 platelets in 2bOVA-transduced IL4ra^{F709} recipients (the IL4ra^{F709} model). After the OVA challenge, within 20 min, the body temperature dropped 1.89 ± 1.29 ^oC and 2.05 ± 0.59 ^oC in the 2bGFP-transduced control mice in the OT-II model and the IL4ra^{F709} model, respectively, but did not change in the 2bOVA-transduced animals. The anti-OVA IgE titers in the 2bGFP group significantly increased, but not in the 2bOVA group. Flow cytometry analysis showed that Th2 cells, a subset of T helper cells that mediate IgE immune responses, in the control group (3.18 ± 2.11% and 2.89 ± 1.39% in the OT-II and IL4ra^{F709} model, respectively) were significantly higher than in the 2bOVA group (0.87 ± 0.60% and 0.40 ± 0.33%). Of note, both Treg and Tr1 cells significantly increased in the 2bOVA-transduced group compared to the control group in both OT-II and IL4ra^{F409} models. Furthermore, Helios$^+$ Treg cells were significantly increased in the 2bOVA-transduced recipients compared to the control group, indicating that platelet-targeted gene therapy can induce Treg cell expansion. In summary, data from our study demonstrated that platelet-targeted gene therapy has the ability to induce immune tolerance through the Th2/IgE pathway. This study proved that ectopic expression of a neo-allergen in platelets is effective in preventing anaphylaxis in allergy models, even when under intense immune challenges. Our findings suggest that platelet-targeted gene therapy is a promising strategy for inducing immune tolerance in food allergy models.

1301. Gene Delivery Using Double Stranded DNA Vectors Triggers a RIG-I Mediated Intracellular Innate Immune Response in CD34+CD90+ Hematopoietic Stem and Progenitor Cells (HSPCs)

Christi Salisbury-Ruf[1], Richard H. Smith[1], Sudipto Das[2], Thorkell Andresson[2], Oladele Oluwayiose[3], Neelam Redekar[3], Pradeep K. Dagur[4], Andre Larochelle[1]

[1]Cellular and Molecular Therapeutics Branch, NHLBI, Bethesda, MD,[2]Protein Characterization Laboratory, Cancer Research Technology Program, Frederick National Laboratory, Frederick, MD,[3]Integrated Data Science Section, NIAID, Bethesda, MD,[4]Flow Cytometry Core Facility, NHLBI, Bethesda, MD

The innate ability of mammalian cells to detect and respond to foreign proteins and nucleic acids poses a significant challenge to many gene therapy applications. This obstacle is especially pertinent in the context of hematopoietic stem and progenitor cells (HSPCs), where such innate defenses can markedly impede the efficiency of successful gene editing. Overcoming these cellular barriers is crucial for the advancement of gene therapy strategies targeting HSPCs. Previous studies have explored various aspects of innate immune responses in HSPCs, but a comprehensive analysis, particularly in CD34+CD90+ phenotypically enriched hematopoietic stem cells, is lacking. To provide a broader understanding of the innate intracellular immune response to DNA and RNA delivery vehicles, we implemented multiplex tandem-mass-tag (TMT) proteomics in sorted CD34+CD90- and CD34+CD90+ HSPC populations exposed to plasmid DNA, the double stranded DNA (dsDNA) virus baculovirus (BV), and the single stranded DNA (ssDNA) virus AAV6. Additionally, as a comparative measure, we included treatments with an RNA-based vector, specifically an integrase-deficient lentivirus (IDLV). Each vector was constructed using the same reporter expression cassette encoding EGFP. Following treatment, sorted cells were harvested at 24 hours for global protein analysis. A total of 4,779 and 5,962 proteins were identified in CD90- and CD90+ cells across all treatments, respectively. Treatment with double stranded plasmid DNA induced 90 and 57 differentially expressed proteins ($p<0.01$, $FC>1.5$) in CD90+ and CD90- cells, respectively, when compared to an electroporation control. The most prominent proteins in the CD90+ group were well-characterized markers of the intracellular innate immune response ISG15, IFIT2, and MX2. We also noted a significant upregulation of the RNA sensor DDX58 (RIG-I) by 7.5-fold in CD90+ cells and 6.1-fold in CD90- cells, along with other RIG-I regulator proteins, namely DHX58 (FC=5.9 in CD90+ cells) and DDX60 ($FC\geq4.1$ in both CD90+ and CD90- cells). Likewise, transduction with a dsDNA vector, baculovirus, elicited a pronounced interferon response, with IFIT3, an enhancer of RIG-I mediated signaling, as the most prominently upregulated protein (FC=6.2). Contrasting with the response elicited by dsDNA vectors, ssDNA vectors, specifically AAV6, did not activate the RIG-I pathway. Among the 52 and 51 differentially expressed proteins ($p<0.01$, $FC>1.5$) in CD90- and CD90+ cell populations, respectively, the top enriched pathway in both groups was p53 signaling, aligning with existing AAV6 literature. Furthermore, our proteomic investigations did not indicate the RIG-I pathway as a major response mechanism to the RNA-based IDLV in either CD90+ or CD90- cells. The overall response to IDLV was less robust compared with other vectors, with only 17 and 15 differentially expressed proteins identified in CD90+ and CD90- cells, respectively, relative to untreated controls. These findings collectively indicate a heightened sensitivity of CD34+CD90+ HSPCs to foreign dsDNA, leading to an inflammatory response mediated through the RIG-I pathway. This unexpected intersection between RNA sensing and exposure to dsDNA has important implications not only for our understanding of how HSPCs sense foreign nucleic acids, but also reveals potential therapeutic targets which can be leveraged to improve HSPC gene editing.

Thursday Posters: Immune Targeting and Approaches with Genetically-Modified Cells and Cell Therapies

1302. Efficient Ggeneration of CD8$^+$ T_{SCM} CAR-Ts by Treatment with Novel Cytokine-Based Scaffolds
