Despite the success of CAR-T therapy in treating B-cell malignancies, >40% of patients experience relapse in part due to poor persistence of circulating CAR-T cells. Activation of T-cells with αCD3/αCD28-based reagents prior to transduction with CAR encoding gene vectors is associated with production of a more differentiated phenotype and is associated with reduced functional persistence. T_{SCM}-cells are the least differentiated T-cell population and have a self-renewal capacity that facilitates the diversification of immune memory. We hypothesize that treatment of T-cells with specific cytokines will both drive cell-cycle transitioning to enable lentiviral transduction and allow expansion of T_{SCM}-like CAR-T cells. Using cytokine scaffolds, we evaluated the impact that IL-7-, IL-15-, and IL-21-based activation have on the generation of T_{SCM}-like CAR-T cells specific for either CD19$^+$ B-cell malignancies or HIV-1. HCW Biologics has developed a fusion molecule, which incorporates IL-7, IL-15 and IL-21 cytokine motifs into a tissue factor scaffold (HCW9206) in addition to a scaffold comprised of only the IL-15 motif (HCW9238). To generate CAR-T cells, donor-derived CD8$^+$ T-cells are treated with HCW scaffolds prior to transduction with an αHIV-duoCAR lentivector targeting two epitopes of gp120 or a vector expressing an αCD19-CAR. 5-7 days post transduction we compared T-memory differentiation of HCW-treated to αCD3/αCD28-treated CAR-T cells by flow cytometry. The functional activity of HCW-treated duoCAR-Ts was determined by an HIV suppression assay against autologous CD4$^+$ T-cells infected with an HIV-Renilla luciferase (HIV-LucR) virus expressing either BaL **(Fig. 1D)** or JRCSF **(Fig. 1E)** HIV-1 Env glycoprotein. Cytotoxicity of CD19 CAR-T cells was assessed in a PKH26 cytotoxicity assay against a NALM6 tumor cell line. In addition, cytokine secretion was evaluated following a 16hr co-culture with cell lines expressing the target antigen

using intracellular cytokine staining **(Fig. 2)**. After stimulation with HCW scaffolds, the resulting population of T-cells were enriched in a T_{SCM}-like phenotype, allowing the generation of CAR-T_{SCM}s defined by a $CD45RO^{-}CCR7^{+}CD45RA^{+}CD95^{+}CD27^{+}$ phenotype **(Fig. 1A-B)**. HCW-stimulated CD19 CAR-Ts demonstrated more potent cytotoxic function towards NALM6 than CAR-Ts generated using αCD3/αCD28 crosslinking-based activation **(Fig. 1C)**. Both HCW-stimulated and αCD3/αCD28 activated duoCAR-Ts displayed potent activity against autologous HIV-infected $CD4^{+}$ cells **(Fig. 1D-E)**. Finally, we demonstrated that cytokine stimulation with HCW proteins led to increased expression of pro-inflammatory cytokines by CAR-T cells following co-culture with the target antigen **(Fig. 2)**. Our results indicate that treatment with cytokine scaffolds generates a large population of T_{SCM}-like CAR-Ts which will likely enhance long-term *in vivo* survival of CAR-T therapy across multiple disease types and enable sustained suppression of both cancer and viral malignancies.

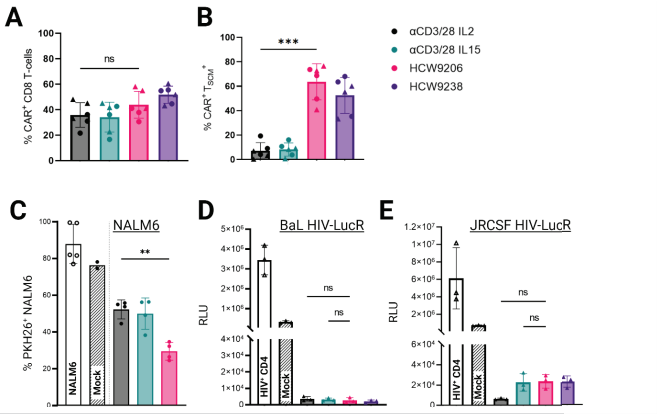

Figure 1: **(A)** CAR expression in $CD8^{+}$ T-cells (triangle: duoCAR; circle: CD19 CAR). **(B)** T_{SCM} enrichment of CAR-Ts (n = 3 donors). **(C)** CD19 CAR-T cytotoxicity of NALM6 at 1:1 E:T. **(D-E)** duoCAR-T suppression of HIV-1^{+} $CD4^{+}$ T-cells at 1:1 E:T (RLU, relative light units) (n = 1 donor). (n = 2 donors). Data is presented as mean ± SEM and statistical significance is calculated by 2-way ANOVA. ****P < 0.0001, ***P < 0.001, **P < 0.01, and *P < 0.05.

1303. Follicular Targeting CAR-T Cells with PD-1 and CCR5 Knocked Out to Treat HIV Infections

Liliana Kopeck Thron[1], Pongthorn Pumtang-on[1], Jae Woong Chang[1], Joshua B. Krueger[1], Max Cantor[1], Mary Pampusch[1], Sofia Casares[2], Vaiva Vezys[1], Branden Moriarity[1], Pamela J. Skinner[1]

[1]University of Minnesota, Minneapolis, MN,[2]US Navy, Silver Spring, MD

As of 2021, at least 38.4 million people are living with HIV globally. Although ART therapy has dramatically improved patients' survival rate and quality of life, these drugs impose great financial and practical burdens and cannot cure patients of the disease. Recent research has focused on cell therapy as an alternative to small-molecule antiretrovirals. Engineered cell therapies that target viral-producing cells are promising candidates, however, they are not yet being used to treat humans with HIV. One barrier that these treatments face is their inability to access infected cells in the immune-privileged B-cell follicle. To overcome this obstacle, we have developed HIV-specific chimeric antigen receptor (CAR) T cell therapies that employ the CXCR5 receptor to direct CAR cells to the lymphoid follicles. We further engineered the CAR/CXCR5 T cells with CCR5 KO to prevent HIV infection, as well as PD-1 KO to prevent exhaustion. We hypothesize that these optimized CAR/CXCR5 T cells will lead to the suppression of HIV in vitro and in vivo in the absence of ART. To test this hypothesis, we have designed cell constructs and tested them using transposon engineering and in vitro assays. Results from the in vitro studies showed successful dual expression of CAR and CXCR5, KO of CCR5 and PD-1 expression. Engineered cells migrated to the CXCR5 ligand CXCL13 in Transwell assays. When exposed to antigen expressing cells the engineered cells secreted cytokines. When mixed with HIV-infected cells, they reduced the spreading of HIV infections. Compared to mock-engineered cells, the engineered cells were resistant to HIV infection. These studies demonstrate that PD-1KOCCR5KO CAR/CXCR5 T cells are functional in vitro. We next plan to evaluate the efficacy of these optimized CAR T cells in vivo using HIV-infected-humanized mice. These studies may further the development of cell-based interventions for the durable remission of HIV in the absence of antiretroviral drugs.

1304. Follicular Targeting CAR-NK Cells Armored with IL-15 and with PD-1 Knocked out to Treat HIV Infections

Pongthorn Pumtang-on[1], Jae Woong Chang[2], Liliana Kopeck Thron[3], Joshua B. Krueger[3], Max Cantor[3], Mary S. Pampusch[3], Sofia Casares[4], Vaiva Vezys[3], Branden S. Moriarity[3], Pamela J. Skinner[3]

[1]Veterinary and Biomedical Sciences, University of Minnesota, Minneapolis, MN,[2]Department of Pediatrics, University of Minnesota, Minneapolis, MN,[3]University of Minnesota, Minneapolis, MN,[4]US Navy, Silver Spring, MD

Currently there are over 39 million people living with HIV. Although antiretroviral therapy (ART) regimens have produced substantial reductions in HIV-1-related morbidity and mortality, they are not a cure, requiring life-long and strict ART adherence to maintain viral

loads at undetectable levels. Alarmingly, it is estimated that 35% of people living with HIV in the US are not virally suppressed with ART. Moreover, non-adherence to ART can lead to the emergence of ART-resistant HIV. Thus, novel HIV therapies that do not involve ART are critically needed. HIV replication is concentrated in lymph node follicles, where low in vivo effector T cell to target cell ratios permit ongoing replication. Given this, we are developing engineered CAR-NK cells that target lymphoid follicles. We hypothesize that follicular targeted HIV-specific CAR-NK cells will eliminate HIV-producing cells in follicles and lead to the sustained remission of HIV. We have engineered NK cells that express an HIV-targeting CAR as well as the lymphoid follicle-homing molecule CXCR5. In addition, we knocked out the inhibitory PD-1 molecule (95% reduction) to prevent exhaustion and armored the cells with constitutive IL-15 expression to promote replication and persistence. These engineered cells secreted cytokines when exposed to antigen expressing cells, and killed antigen expressing cells. Thus, the PD-1KO IL-15 armored CAR/CXCR5-NK cells were functional in vitro. We are now proceeding to evaluate these engineered cells in vivo in HIV-infected-humanized mice. Humanized-DRAGA mice were infected with HIV and are being treated with ART. Engineered cells or control cells will be infused into the mice to evaluate safety and efficacy. These studies aid in the advancement of novel cell therapies for HIV to achieve durable remission of HIV without ART.

1305. Rapamycin Modifies Transcriptome and Improves Functions of HSCs Based CAR T Cells in HIV Infected Humanized Mice

Wenli Mu[1,2], Shallu Tomer[1,2], Jeffrey Harding[1,2], Nandita Kedia[1,2], Valerie Rezek[1,2], Vaibahavi Patankar[1,2], Ethan Cook[1,2], Heather Martin[1,2], Mayra Carrillo[1,2], Matthew Marsden[3], Scott G. Kitchen[1,2], Anjie Zhen[1,2]

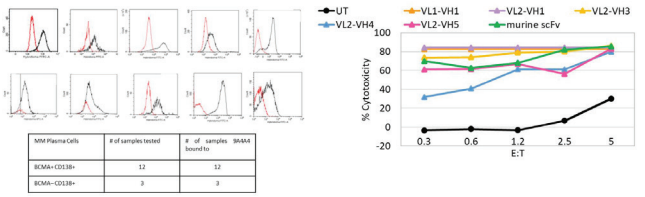
Chimeric Antigen Receptor (CAR) T cell therapy has emerged as a powerful immune therapy for various cancer. Recent studies demonstrated that anti-HIV CAR T cell therapy also have the potential to improve anti-HIV immunity for functional cure. We showed that CAR modified hematopoietic stem cells (HSCs) are capable of lifelong engraftment and allow development of functional CAR-T cells in vivo. Our studies in humanized mice and non-human primates (NHPs) showed that CAR-HSCs transplanted animals have significantly reduced viral rebound after ART withdrawal. However, driven by chronic immune activation, T cell exhaustion remains a major challenge for CAR T therapy and additional measures are needed to achieve functional cure. Our recent studies demonstrated that in vivo treatment of low dose autophagy inducer rapamycin reduced chronic inflammation and improved anti-HIV T cell function in HIV infected humanized mice. Combined treatment of rapamycin and anti-retroviral therapy (ART) resulted in accelerated viral suppression and reduced viral rebound after ART withdrawal. Here we report that rapamycin significantly improved CAR-T cell function both in vitro and in vivo. In vitro treatment of rapamycin improved CAR-T cell mitochondria respiration and cytotoxicity. In vivo treatment of low dose rapamycin in HIV infected, CAR-HSCs treated mice reduced chronic inflammation, prevented exhaustion of CAR-T cells and further lowered viral load compared to CAR-HSCs treatment alone. We also observed significant delayed viral rebound after ART withdrawal and smaller reservoir in mice that were treated with rapamycin and CAR-HSCs as compared to CAR-HSCs treatment alone. RNAseq analysis of sorted CAR-T cells from humanized mice showed that rapamycin significantly modified CAR-T cell transcriptome, including down regulation of multiple check point inhibitors and upregulation of genes related to cell survival. Taken together, our data suggest that HSCs-based anti-HIV CAR-T combined with rapamycin treatment is a promising approach for treating persistent inflammation and improving immune control of HIV replication.

1306. Preclinical Development of Humanized CD19.CD20 Dual CAR Ts for B Cell Malignancies

Hascitha J[1], Dhivya Bharathi[2], Melina Soares[1], Lakshmikanth Satya Gandikota[3]

[1]Research and Development, Immuneel Therapeutics, Bengaluru, India,[2]R&D, Dhivya Bharathi, Bengaluru, India,[3]Immuneel Therapeutics, Bengaluru, India

Background: CD19 CAR T therapies have radically improved the treatment outcomes for patients with B cell malignancies. However, downregulation or loss of CD19 expression remains a challenge and accounts for 27-100% of the relapses seen in B cell malignancies. To address this need, We are developing humanized CD19-CD20 dual CAR Ts. We describe and compare here the preclinical phenotypic and functional characterization of humanized CD19-CD20 dual CAR Ts generated *in vitro* using a single bicistronic lentiviral vector expressing both CD19 and CD20 CARs or generated by co-transduction with two different lentiviral vectors expressing CD19 and CD20 respectively. **Methods:** CD19, CD20 and bicistronic CD19-CD20 CAR lentiviral vectors were designed and synthesized. Different co-transduction conditions were evaluated using our in-house platform to generate CAR T cells expressing > 20% of both CD19-CD20 CARs on the surface. Dual CAR Ts expressing >20% of both CD19-CD20 were also generated using bicistronic CD19-CD20 lentiviral vectors. The dual CAR T cells have been characterized both phenotypically and functionally against tumors cells expressing the target CD19 and CD20 antigens. **Results:** Our results indicate that the CAR Ts had a higher % CAR when generated by sequential transduction with CD19 and CD20 LV as compared to those generated by co-transduction at Day 3. The % CAR in both are comparable at later time points during the process. The current design of the humanized bicistronic CD19-CD20 construct resulted in >20% CAR only after day 7 of the process. We will also present 1) the impact of bicistronic design changed on dual CAR expression at earlier time points in the process and 2) the phenotypic and functional characterization of the CAR Ts. **Conclusion:** Our results indicate that the method of transduction (co vs sequential) and the Bicistronic CAR design affect dual CAR expression. This has implications on the CAR T manufacturing process and design of bicistronic CAR constructs. **Figure 1:** % CD19-CD20 dual CAR Expression on CAR T cells at days 3 and 9. CD19 and CD20 CARs were detected using CD19 and CD20 recombinant proteins respectively.



1307. A Novel Membrane-Proximal Humanized CD307e-Specific CAR T (IMN-005) for Multiple Myeloma: Preclinical Development and Potency

Dhivya Bharathi[1], Xing Du[2], Hascitha J[1], Rohan Kamat[1], Giridhar Chenji[3], Lakshmikanth Satya Gandikota[1], Abdullah Ali[2], Melina Soares[1], Siddhartha Mukherjee[2]

[1]Research and Development, Immuneel Therapeutics, Bengaluru, India,[2]Medicine, Columbia University, New York, NY,[3]Manufacturing, Immuneel Therapeutics, Bengaluru, India

Background: Multiple Myeloma (MM) remains an incurable disease. CAR-T cell therapy, targeting antigens such as BCMA have shown proven therapeutic efficacy in MM. Consistent with previous reports, our analysis of bulk and single cell transcriptomes from normal and cancer tissues identified CD307e as an attractive immunotherapeutic target on Multiple myeloma. We are developing IMN-005, a novel anti-CD307e humanized CAR T cell product. This comprises a humanized scFv with a 4-1BB co-stimulatory domain that recognizes a membrane proximal region of the CD307e molecule. We describe here the identification and characterization of anti-CD307e scFv's. We also demonstrate its binding specificity for MM patient samples. In vitro functional potency of several humanized IMN-005 CAR T cells (having different scFv modifications) against MM cells is also presented. These studies are the first to demonstrate the anti-myeloma potency of humanized anti-CD307e CAR T cells targeting a membrane proximal domain of CD307e. **Methods:** Hybridoma supernatants were generated after immunization of mice with peptides selected from the membrane proximal domain of CD307e and were screened *in vitro*. Clones were screened for cross-reactivity with FCRL proteins by ELISA and binding with CD307e expressing cell lines by flow cytometry. They were also analysed for binding with bone marrow plasma samples from MM patients. The murine and humanized version of scFv from the lead clone was used to make various CAR constructs. These constructs of IMN-005 CAR T cells were tested for their functional potency against CD307-expressing MM tumor cells. **Results:** A total of 44 hybridoma clones showing strong binding to the immunizing peptides were chosen for further screening. They differed in terms of their cross-reactivity profiles with other FCRL proteins within the FCRL family. Around 10% clones showed binding to CD307e-expressing cell lines. Of those clones, Clone 25 showed consistent binding to all the multiple myeloma patient bone marrow samples evaluated. SPR-based binding studies studies suggest that the K_D of clone 25 is in the nanomolar range. Humanized IMN-005 CAR T cells with different variations of scFv had significant cytotoxicity against CD307-expressing tumors *in vitro*. The cytotoxicity of the humanized CAR T cells against MM patient samples is currently being evaluated. **Conclusion:** Clone 25 binds to plasma cells in all the multiple myeloma bone marrow samples evaluated. Binding data from a limited number of multiple myeloma patient samples suggests that Clone 25 binds to both BCMA+ and BCMA- plasma cells. Humanized clone 25-derived IMN-005 CAR T cells have potent cytotoxic activity against CD307e-expressing multiple myeloma tumor cell lines *in vitro*. Both the binding data and the *in vitro* anti-tumor activity suggest that IMN-005 may have therapeutic efficacy in all multiple myeloma patients. This is the first report of the development of a membrane-proximal CD307e-directed humanized CAR T cell product. **Figure 1:** Binding of clone 25 to Multiple Myeloma patient plasma cells; Red = secondary alone, Black = clone 25 **Figure 2:** Cytotoxicity of clone 25 scFv-derived humanized CAR T cells (black = untransduced control T cells, colored lines = multiple humanized CAR T constructs, green = murine scFv CAR T cells))

1308. Immunosuppressive Monocytes Suppress CART19 Functions Through Modulation of the IL-1 Pathway

Kun Yun, Reona L. Sakemura, Ismail Can, Omar Gutierrez Ruiz, Ekene J. Ogbodo, Truc N. Huynh, Claudia Manriquez Roman, Olivia Sirpilla, Carli M. Stewart, James H. Girsch, Jennifer M. Feigin, Long Mai, Hong Xia, Brooke Kimball, Lionel A. Kankeu Fonkoua, Mehrdad Hefazi, Michael W. Ruff, Elizabeth L. Siegler, Saad S. Kenderian

Mayo Clinic, Rochester, MN

CD19-directed chimeric antigen receptor T (CART19) cell therapy has shown remarkable outcomes in B cell malignancies, but durable remissions are limited to 40%. Inhibitory myeloid cells have been found to contribute to CART19 failure. Here, we aimed to unravel interactions between monocytes, CART19 and tumor cells to understand how monocyte-CART19 interactions impact CART19 effector functions. First, CD28-costimulated CART19 cells generated from healthy donors were cocultured with JeKo-1, a $CD19^+$ mantle cell lymphoma (MCL) cell line, and freshly isolated monocytes or *ex vivo* differentiated M2-like macrophages. CART19 antigen-specific proliferation was significantly inhibited by M2-like macrophages but not fresh monocytes (*JeKo-1+CART19 vs JeKo-1+M2+CART19, p=0.00503*). Transwell assays indicated that suppression by M2-like macrophages was contact independent. Cytokine profile analysis of coculture supernatants showed significant elevation of interleukin-1 receptor antagonist (IL-1ra) in M2-like macrophage cocultures (*JeKo-1+Mono+CART19 vs JeKo-1+M2+CART19, p=0.0292*), which was further confirmed by IL-1ra intracellular staining in M2-like macrophages after coculture. This led us to hypothesize that M2-like macrophages inhibit CART19

by secreting IL-1ra to block IL-1 signaling in CART19. To test this hypothesis, we interrogated the role of IL-1ra in CART19. CART19 + JeKo-1 cocultures were supplemented with IL-1β + IL-1ra or IL-1β + IL-1ra + IL-1ra neutralizing antibody (neuAb). CART19 proliferation was improved by IL-1β (*PBS vs IL-1β, p<0.0001*). IL-1ra inhibited IL-1β-dependent CART19 proliferation (*IL-1β vs IL-1β+IL1ra, p=0.0006*), which was restored by IL-1ra neutralization (*IL-1β+IL-1ra vs IL-1β+IL-1ra+IL-1ra neuAb, p=0.0215*). Next, we assessed the impact of IL-1ra on CART functions in mouse MCL xenografts in presence of M2-like macrophages. NOD-SCID-γ-/- mice were subcutaneously injected with human macrophages and JeKo-1. Mice were then treated with CART19 with IL-1ra neuAb or control IgG for 3 weeks. Combination of CART19 cells and IL-1ra neuAb led to improved antitumor activity based on BLI measurements compared to control IgG (*IL-1ra neuAb vs Control IgG, p=0.0033*). Additionally, expression of IL-1RI, receptor of IL-1β and IL-1ra, was measured on T cells after coculturing CART19, JeKo-1, and M2-like macrophages. M2-like macrophages downregulated IL-1RI expression on CART cells, which might potentially desensitize CART response to IL-1β, resulting in further suppression in CART proliferation (*JeKo-1+M2+CART19 vs JeKo-1+CART19, p=0.001*). Overall, our study revealed a role of IL-1ra in macrophage-induced CART inhibition by blocking IL-1β—IL-1RI signaling.

1309. Harnessing Minicircle Vector to Engineer Potent CD19 Specific CAR T Cells for Targeted Leukemia Treatment

Ali Moghimi-Khorasgani, Naeimeh Rezaei, Abbas Kiani-Isfahani, Kianoush Dormiani

Department of Animal Biotechnology, Cell Science Research Center, Royan Institute, Royan Institute for Biotechnology, Isfahan, Iran, Islamic Republic of

Introduction: Chimeric antigen receptors (CARs) are designed receptor proteins that provide T-cells additional targeting abilities. Chimeric receptors combine antigen-binding and T-cell-activation processes. This technology for producing CAR T-cells targeting cancer-specific antigens has been safe and effective for treating hematological malignancies. For manipulating T cells, minicircle vectors to seem ideal due to long and high-level transgenic expression without viral vector side effects. Minicircle DNA is produced from a parental plasmid and is created by deleting prokaryotic sequences from parental plasmid DNA during enterobacterial recombination. Uncontrolled production of bacterial backbone sequences and antibiotic-resistance genes in classical plasmids may harm target cells. Practically, minicircles, as a minimal vector is, smaller and safer than the common plasmids because they lack the bacterial backbone. The outstanding features of minicircle make it a new nonviral vector with strong potential for various therapeutic applications including cancer immunotherapy. In the present study, we used minicircle as a safe nonviral vector to create CD19-specific CAR T-cells for leukemia treatment. **Material and Methods:** This study aimed to construct and clone the coding sequence of the second-generation CAR into a replicative minicircle (CAR-MC) that encodes CD19-specific CAR. By using electroporation, we could transfer this CAR encoding minicircle (CD19CAR-MC) into human T-cells isolated from peripheral blood. The resultant CAR T-cells were then co-cultured with the cancer cell line containing CD19 antigen and another cell line that did not include CD19 as the control. *In vitro* testing was carried out to examine the activities of the generated CAR T-cells including cytolytic effects, cytokine release, and cell proliferation. **Results:** Our results indicated that CAR-MC-based CD19-specific CAR T-cells preferentially targeted CD19-positive cancer cells with substantial lethal effects compared to CD19-negative cells. In addition, compared to the control T-cells, these CAR T-cells were able to secrete higher levels of some inflammatory cytokines compared to the control group, which confirmed the functionality of these cells for cancer immunotherapy. **Conclusion:** The current research demonstrated that the CAR-MC as a nonviral vector has the potential to induce the antitumor activity of T-cells, which was the primary objective of the study. The encoding of a functional CAR receptor by the minicircle confers upon the T-cells the ability to selectively target CD19 as a tumor-associated antigen and specifically eliminate CD19- containing leukemia cells. The successful generation of the functional CAR-MC-mediated CAR T-cells can be attributed to some of the advantages of the vector. These advantages include a higher transfection efficiency due to the smaller size, the capability of long and high-level transgene expression due to the absence of bacterial sequences, and the lack of immunogenicity and random integration into the genome of the host cells. **Keywords:** CAR T-cell, CD19, Cancer immunotherapy, Leukemia, Minicircle, Nonviral vector

1310. Disproportionality Analysis of T-Cell Malignancy Incidence Following CAR-T Therapy: Potential Causal Association

Nancy Lunney[1,2], Kausik Maiti[3]

[1]Cell and Gene Center of Excellence, Parexel, Newton, MA,[2]Cell and Gene Therapy Center of Excellence, Parexel, Newton, MA,[3]Global Safety Services, Parexel, Newton, MA

The incidence of T-cell malignancies after chimeric antigen receptor T-cell (CAR-T) therapy has warranted increased review following a U.S. FDA report in November of 2023 announcing potential risks following BCMA-directed or CD19-directed CAR-T administration. Herein, we describe a disproportionality analysis (DA) conducted to assess the relative reporting rates of T-cell malignancies as an adverse event in patients receiving FDA approved CAR-T therapy. DA using Bayesian and Frequentist methods was performed on all applicable data within the FDA Adverse Events Reporting System (FAERS). Analysis yielded mixed results in quantitative signal thresholds based on the therapeutic agent employed for the six FDA-approved CAR-Ts evaluated. Results showed increased reporting of T-cell malignancies in patients treated with some CAR-Ts relative to others. FAERS data indicated a total of 8 reports of T-cell malignancies, 6 for Kymriah and 2 for Yescarta. Kymriah demonstrated an Empirical Bayes Geometric Mean (EBGM) score (Lower bound) of 7.109 as compared to Yescarta with an EBGM (lower bound) of 0.987. Reporting Odds Ratio (ROR) was 52.44 for Kymriah and 12.266 for Yescarta, with a Proportional Reporting Ratio (PRR)/Chi Square scores of 52.639/301.954 for Kymriah and 12.259/20.637 for Yescarta. Limitations exist in FAERS data due to lack of harmonized reporting, data quality and under-reporting. Due to these limitations, a large Real World (RW) dataset, TriNetX, was further mined to explore the association of T-cell malignancies with CAR-Ts. RW data from 206,054,910 patients including 78,350 diagnosed with T-cell malignancies revealed 366,540 patients diagnosed with acute lymphoblastic leukemia (ALL), diffuse large B-cell lymphoma (DLBCL)

or follicular lymphoma (FL). Of these 366,540 patients, 14,290 were also diagnosed with T-cell lymphoma. Hence, the background incidence rate of T-cell lymphoma in patients diagnosed with ALL or DLBCL or FL was estimated to be 3.9%. The total number of patients who received Kymriah according to RW data was 960 for which lifetime incidence of T-Cell lymphoma was 2.08% (20 patients out of 960). Furthermore, only 10 out of these 20 patients developed T-cell lymphoma after Kymriah, yielding an incidence rate of 1.04%. This finding indicates that the incidence of T-cell malignancy temporally associated with Kymriah is not greater than the background incidence of T-cell malignancies in patients with ALL, DLBCL and FL. The higher incidence of T-cell malignancies may explain the higher disproportionality scores in the FAERS dataset and indicates this association may be due to the background incidence rate rather than being attributable to Kymriah therapy. Results of this DA, while identifying a quantitative signal for one FDA-approved CAR-Ts in the FAERS database, were refuted by subsequent analysis of RW data indicating that the background incidence contributed to disproportionality. Heightened vigilance in monitoring and reporting adverse events associated with CAR-T is therefore supported by the FAERS data.

1311. Multi-Epitope Specific Cytotoxic CD4+ T Cells for Adoptive Immunotherapy of Myelodysplastic Syndrome

Mithil Soni[1], Prabesh Khatiwada[1], Abdullah Ali[2], Azra Raza[2], Pawel J. Muranski[1]

[1]Columbia Center for Translational Immunology, Columbia University, New York, NY,[2]Department of Hematology & Oncology, Columbia University, New York, NY

Myelodysplastic Syndromes (MDS) are complex hematological disorders with limited treatment options, often progressing to acute myeloid leukemia (AML). Curative allogeneic hematopoietic stem cell transplant (HSCT) is reserved only for younger patients and relapses after HSCT remains common. Hypomethylating agents offer modest benefit to HSCT-ineligible patients. Thus, novel more effective therapies are needed. Several studies have shown safety and efficacy of multi-epitope specific T cell-based adoptive immunotherapy in subjects with high-risk AML or post-HSCT relapse. However, these are T cell population containing a variable mixture of $CD8^+$ and $CD4^+$ T cells with limited potency. $CD4^+$ T cells are often present in tumor infiltrating lymphocytes (TILs) and TIL-like products, displaying antigen-specific activity but have not been formally studied despite their central role in orchestrating the the immune response. In our realistic animal model of adoptive immunotherapy we have previously discovered that antigen-specific $CD4^+$ T cells have a capacity to completely eradicate advanced tumors. Here, we studied the feasibility of generating autologous TIL-like multi-TAA-specific $CD4^+$ T cells with enhanced potency for high-risk patients with MDS and AML.We evaluated a novel *ex vivo* priming strategy to generate highly active $CD4^+$ cytotoxic T cells ($CD4^+$ CTLs) simultaneously targeting multiple TAAs. Peripheral blood mononuclear cells (PBMCs) were isolated from healthy donors or MDS patients collected under the IRB-approved protocol (AAAF2693). Total $CD4^+$ T cells or naïve $CD4^+$ T cells were purified and cocultured with autologous monocyte derived dendritic cells (MoDCs) pulsed with overlapping peptide libraries spanning PRAME, WT1, NYESO-1 and MAGE-A3 and expanded with conventional cytokines or in the presence of pro-inflammatory cytokines for 10-14 days. Two rounds of stimulation were performed. The reactivity, expansion and proliferative capacity, phenotyping upon repetitive stimulation were assessed. The ability of the final $CD4^+$ CTLs to recognize naturally processed targets was tested by loading autologous antigen presenting cells with full length recombinant proteins.T cells cultured under Type 1/17 conditions displayed significantly increased reactivity against TAAs compared to T cells cultured under conventional conditions (defined here as Th1; Fig. 1A). Furthermore, Th1/17 antigen-specific reactivity was markedly enhanced by repetitive stimulation while Th1 cells showed gradual reduction in the secretion of effector cytokines. Th1/17 cells also expanded significantly better than Th1 cells (displayed enhanced polyfunctionality evidenced by increased IL-2 and Granzyme B secretion indicative of self-renewal and cytotoxicity, respectively (Fig. 1B/C). In CFSE assay Th1/17 cells showed marked proliferative capacity despite long term culture and repetitive stimulation (Fig. 1D). These cells also recognized naturally processed antigen indicating these cells are clinically relevant (Fig 1E). Next, we successfully generated multi-TAA CTLs cells from the PBMCs of multiple MDS patients where Th1/17 cells displayed superior reactivity, polyfunctionality and proliferative capacity, as seen in healthy subjects (Fig 1F/G). In conclusion, e*x vivo* priming with TAAs in the presence of pro-inflammatory cytokines reliably induces multi-TAA $CD4^+$ CTLs

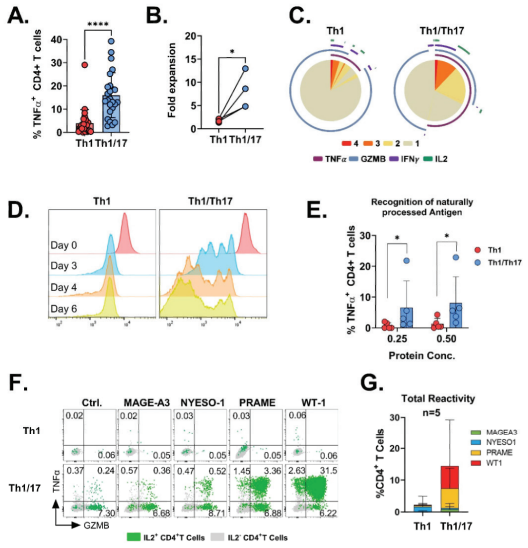

Fig. 1: Generation of autologous multi-epitope specific $CD4^+$ T cells from healthy donors and MDS patient samples. A-E. Generation of PRAME-specific $CD4^+$ T cells from PBMCs of healthy donors under conventional cytokines (Th1) or proinflammatory cytokines (Th1/17). **A.** Frequency of antigen-specific $CD4^+$ T cells after two rounds of stimulation (n=25). **B.** Fold expansion under both conditions after two rounds of stimulation (n=4). **C.** Comparison of Polyfunctionality between Th1 cytokine condition and Th1/17 cytokine condition. **D.** CFSE-based proliferation assay after two stimulations. CFSE labeled cells were re-challenged with antigen after two rounds of stimulation followed by flow cytometric analysis to measure antigen specific proliferation. **E.** Recognition of naturally processed full-length antigen. Antigen specific $CD4^+$T cells were co-cultured with recombinant full-length antigen pulsed autologous dendritic cells followed by intracellular cytokines release assay. **F-G.** Generation of multi-epitope specific $CD4^+$ T cells from PBMCs of MDS patients. **F.** Representative dot plot demonstrating successful generation of multi-epitope specific, polyfunctional, cytotoxic T cells from an MDS patient. **G.** Comparison of overall reactivity of $CD4^+$ T cells from five MDS patients against four TAAs between both conditions.

1312. Characterization of Short Production Cycle and Non-Genotoxic mRNA-Based Anti-CD19 and Anti-CD22 CAR-T Cells

Chenyun Zhang[1,2], Haizhou Liu[2], Hrithik Sangani[2], Yen-Michael S Hsu[2,3]

[1]School of Medicine, University of Tsinghua, Beijing, China,[2]Department of Medicine, Division of Hematology and Oncology, University of Pittsburgh, Pittsburgh, PA,[3]UPMC Hillman Cancer Center, Pittsburgh, PA

The chimeric antigen receptor (CAR) T cell therapy targeting CD19-positive malignancies has shown considerable efficacy in clinical settings. However, the potential genotoxicity of viral-based CAR-T therapy, their considerable manufacturing cycle and high costs, prompts questions about its safety and leads to limitations in clinical application. Aiming to explore a safe, efficient and low-cost mRNA-based CAR-T therapy, we characterize a non-viral, mRNA-based approach utilizing mRNA CAR and electroporation to generate CD19 and CD22-targeting CAR-T cells within only 48 hours with 75% CAR expression. We isolated fresh peripheral blood mononuclear cells from healthy donors and activate them for 30 hours before electroporating with mRNA constructs encoding anti-CD19 and anti-CD22 CAR on the 2nd generation CAR backbone via Maxcyte ExPERT GTx™ GMP Electroporator. Flow analysis indicated that approximately 78% of T cells expressed CD19-CAR eighteen hours post-electroporation, and this transient expression decreased to below 42% after 72 hours (p<0.034, ANOVA). To validate the *in vitro* tumor-killing ability of mRNA-based CAR-T cells, we co-cultured anti-CD19 and anti-CD22 CAR-T cells with ZsGreen-labeled NALM6 expressing CD19 and CD22 antigen. Flow results revealed that T cells electroporated with two mRNA CAR constructs demonstrate robust *in vitro* tumor-killing abilities (Figure 1A). At an E:T ratio of 1:1, 1:3, 1:5 and 1:10, anti-CD19 CAR-T cells can kill 97.24% (p<0.01, t-test), 83.52% (p<0.0001, t-test), 61.75% (p<0.01, t-test), 50.48% (p<0.01, t-test) of NALM6 cells within 24 hours compared to the control T cells. Anti-CD22 CAR-T cells also exhibit similar tumor-killing capability. At the E:T ratio of 1:3, CAR-T cells exhibited a nearly five-fold proliferation (p<0.01, t-test) compared to the MOCK-EP control within 48 hours (Figure 1B). When focusing on the CAR-positive and CAR-negative populations within total T cells, we observed that these two cell populations proliferated at different rates during co-culture. In the presence of target cells, the CAR expression ratio significantly decreased from initial value of 4.48 to 0.47 (p=0.0814, ANOVA) and 1.92 to 0.35 (p<0.05, ANOVA), respectively, for anti-CD19 and anti-CD22 CAR expression detected (Figure 1C). When co-cultured with NALM6 cells, mRNA CAR-T showed a significantly higher intracellular TNFα, IFNγ and IL-2 production (p<0.001, p<0.01, p<0.05, by t-test respectively) compared to MOCK-EP control. Additionally, mRNA CAR-T with higher proliferation index were noted to have a higher Ki67 expression (p<0.01, t-test). In this study, we also focus on the application of CAR-T manufacture in clinical settings which often involves cryopreserving the cells. We find out that short-term cell cryopreservation before and after electroporation does not significantly impact cell viability, CAR expression and anti-tumor functionality. We believe this approach holds promise as a viable alternative that addresses the limitations of current CAR-T therapies, offering a potential solution for future non-viral CAR-T clinical application.

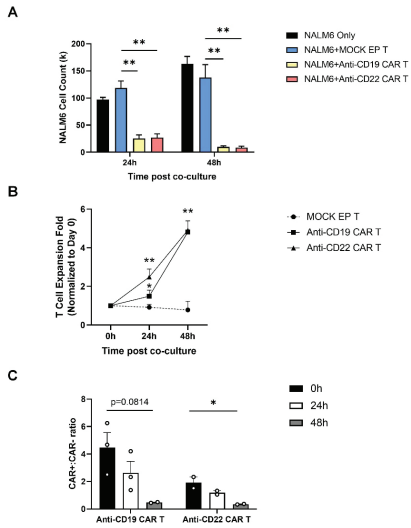

Figure 1. T cells electroporated with mRNA CAR showed in-vitro tumor killing capacity during NALM6 co-culture. Activated T cells electroporated with anti-CD19 and anti-CD22 were co-cultured with ZsGreen NALM6 at an E:T ratio of 1:3 (25k+75k). NALM6 cell count (A), T cell count (B) and CAR-T cell count (C) were measured by flow cytometry at 24h and 48h post co-culture. *p<0.05, **p<0.01, ***p<0.001 by t-test and ANOVA.

1313. Enhanced CAR-T Transduction with Lentiviral Vector (LVV) in Medium Supplemented with Poloxamers P 188 and P 338

Ying Xiong[1], Yanping Xie[1], Zhongyu Zhu[1], Meike-Maria Roskamp[2], Nadya Morales-Cummings[3], Mahsa Mohiti-Asli[3], Nadine Löw[2], Rimas J. Orentas[1], Boro Dropulic[1]

[1]Caring Cross, Inc., Gaithersburg, MD,[2]BASF SE, Ludwigshafen, Germany,[3]BASF Corporation, Tarrytown, NY

Poloxamers are nonionic triblock copolymers with amphiphilic structures. Different poloxamers have been widely applied in pharmaceuticals. By changing the hydrophilic/hydrophobic molar ratio of the subunits of the molecule, unique properties emerge, facilitating delivery of drugs into different cell types or physiological compartments. In combination with polybrene, Kolliphor® P 338 (Synperonic® F 108) has a demonstrated positive effect on LVV transduction of adherent and suspension cell lines, CD34+ hematopoietic stem cells, and primary immune cells. Meanwhile, poloxamer P 188 (F 68) has been broadly applied in the treatment of numerous diseases, taking advantage of its ability to increase cell membrane stability. To further investigate the application of poloxamers in CAR-T cell generation, we explored the combination of these two poloxamers in the transduction and cell-expansion conditions used in the workflow. Purified T cells were activated with activation reagents (anti-CD3, -CD28) on Day 0. LVV were added on Day 1 of activation at different MOIs, followed by a complete medium replacement on Day 3. The transduced cells then were analyzed on Day 8, 10, 13 for CAR-T expression. X-vivo15 (Lonza) with 2% knockout serum replacement (Thermo Fisher) and 30IU/ml IL-2 (Miltenyi Biotec) were used as the basal culture medium. Our studies showed that supplementing both poloxamers in the medium in the transduction phase, and only P188 in the cell expansion phase,

significantly improved CAR T transduction efficiency. In addition, the transduction enhancement demonstrated with different activation reagents at different dilutions was explored. There were no negative effects on T cell expansion and viability throughout the whole process due to the inclusion of poloxamers. In conclusion, our study provides a new strategy to enhance CAR-T transduction with poloxamer supplementation in the culture medium. Improved transduction allowed for the use of less LVV in order to achieve clinically relevant transduction efficiency. This strategy not only helps lower the cost of CAR-T cell generation (as less vector is used), but also provides a novel way to raise transduction efficiency for some LVV applications with complex payloads that are more difficult to employ. Further testing with different culture media and the application of poloxamers in LVV production and stabilization are under further investigation. MarComm-2024-00032

1314. Changes in Glycosylation on the Cell Surface Result in Highly Potent and Long-Lasting Allogeneic CAR-T Therapy in Patients

Zeguang Wu[1], Pengfei Yuan[2], Feifei Liang[2], Yang Liu[3], Jinhong Shi[3], Qiezhong Lamao[1], Jinxin Yang[1], Yuanyuan Qiu[1], Wei Tang[1], Haixia Zhang[2], Zhonghan Yang[2], Ling Yang[2], Yongjian Zhang[2], Ming Jin[2], Weidong Han[3], Wensheng Wei[1]

[1]Peking University, Beijing, China,[2]EdiGene Inc., Beijing, China,[3]Chinese PLA General Hospital, Beijing, China

Adoptive CAR T-cell therapy, a breakthrough in treating aggressive B-cell malignancies, faces logistical and scalability challenges. Allogeneic CAR T-cell therapy, which utilizes donor T cells, offers a viable alternative. However, these cells encounter obstacles such as limited persistence due to host-versus-graft rejections and activation-induced cell death (AICD). Ongoing research aims to enhance the viability of allogeneic CAR T-cells by modifying B2M and HLA molecules, thereby reducing the risk of T-cell mediate rejection. However, this approach introduces new challenges, including the targeting of modified HLA-deficient cells by natural killer (NK) cells. Overcoming these obstacles, including host rejection and AICD, remains a crucial area of focus in T cell-based therapies. In our study, we employed a "bottom up" approach to identify gene targets that could enhance the persistence of primary T cells, counteracting attacks from allogeneic NK and T cells, and the detrimental effects of AICD. Through a combination of whole-genome CRISPR screenings, we have made a significant discovery regarding the role of GeneX in primary T cells. Our findings demonstrate its active inhibitory function on glycan-processing enzymes and its consequential influence on the glycan composition of immune molecules. This influence is pivotal in several immune processes, including potent rejection responses by allogeneic NK and T cells, antibody binding, and the initiation of AICD. Both *in vitro* and *in vivo* testing, using GeneX^{KO}/TCR^{KO}/anti-CD19 CAR T cells, demonstrated that these engineered cells were able to resist the killing of by allogeneic effectors while retaining their anti-tumor activity, without inducing graft-versus-host disease (GvHD). In an on-going related clinical trial (NCT06014073), GeneX^{KO}/TCR^{KO}/anti-CD19 allogeneic CART has demonstrated high anti-tumor activity and persistence for more than 3 months in the first 5 evaluable R/R NHL patients (Data cut-off date is January 20, 2024), with 100% ORR and 60% CR, while maintaining a manageable safety profile. Continuous observation is ongoing. Our research enhances the understanding of the complex interactions among immune effectors and positions GeneX engineering as a promising strategy for creating universal therapeutic cells.

1315. Efficient Genome Editing of Human T Cells with Innovative Transformer Base Editor (tBE) for Construction of Next Generation CAR-T Therapies

Peixue Li[1], Qing Su[1], Ya Xu[1], Jing He[1], Lijie Wang[1], Yichuan Wang[1], Huanyu Li[1], Keiwei Lan[1], Huiming Zheng[1], Di Zhu[1], Lang Zhang[1], Yuchen Zhang[1], Jia Chen[2], Xiaodun Mou[1]

[1]CorrectSequence Therapeutics Co., Ltd, Shanghai, China,[2]ShanghaiTech University, Shanghai, China

Background: Autologous chimeric antigen receptor T (CAR-T) cell therapy has achieved great success for antitumor treatments especially against hematological malignancies, and several autologous CAR-T therapies have been approved across the world. However, autologous CAR-T therapies are highly personalized as the T cells are derived from individual patient and thus also involve complex manufacturing process. This gives rise to some limitations that hinder the broader application of autologous CAR-T cell therapy, such as the long manufacturing periods, the high cost, and the occasional manufacturing failure due to suboptimal cell quality from the patient after earlier lines of cancer treatment.Regarding to the above problems currently faced by the autologous CAR-T therapies, the development of off-the-shelf universal CAR-T cell therapy with donor derived healthy T cells has been proposed to be a promising solution by many companies globally, in which case allogenic T cells need to be genome modified to avoid immune rejection between the T cells and the host. **Methods:** The transformer base editor (tBE) exclusively licensed to CorrectSequence Therapeutics is a recently developed innovative base editing system with high editing efficiency and significantly reduced off-target activity. Here we evaluated the feasibility of tBE system for multiplex editing in primary T cells to construct off-the-shelf CAR-T cell therapy. The simultaneous knockout (KO) efficiency for *TRAC*, *CD52* and *PDCD1* in primary T cells was tested then CAR-T cells were constructed with *TRAC*, *CD52* and *PDCD1* triple KO. The risk for off-target mutations and chromosome translocation was verified and the cytotoxicity efficacy against tumor cells was tested. **Results:** With optimized electroporation conditions for tBE system, *TRAC*, *CD52* and *PDCD1* could be knocked out simultaneously in primary T cells with KO efficiency reaching ~90% for each target gene. None off-target mutation was detected at the potential off-target sites predicted by Cas-OFFinder and Digenome-Seq. Moreover, multiplex editing with tBE doesn't cause chromosome translocations as it won't induce double strand breaks while CRISPR/Cas9 does. CD19 directed CAR-T cells constructed with triplex base editing exhibits comparable antitumor efficacy in *in vitro* and *in vivo* efficacy models compared with unedited CAR-T cells. **Conclusion:** Our results proved that, with comparable editing efficiency and lower safety risk, tBE system might work better for construction of next generation universal or enhanced CAR-T therapies than CRISPR/Cas9 system.

1316. Preclinical Development of TRX103 as an Off-the-Shelf IL-10 Engineered CD4+T Cell Product for the Prevention of Graft-versus-Host Disease

Molly J. Uyeda, Audrey Re, Chunyi Tang, Daryl Humes, Matthew Breton, Michelle Nguyen, Maximilian Richter, Ryan Bjordahl, James Adams, Maria Grazia Roncarolo, Xavier Paliard

Tr1X, San Diego, CA

Hematopoietic stem cell transplantation (HSCT) is a curative therapeutic approach for many hematological malignancies, but its therapeutic potential is limited by a high incidence rate of graft-versus-host disease (GvHD) following transplantation. Type 1 regulatory T (Tr1) cells, an IL-10 secreting regulatory T cell subset, are an appealing therapeutic modality for GvHD prevention as clinical studies have demonstrated that the infusion of cellular products containing Tr1 cells were well tolerated and resulted in a lower GvHD incidence. Here we describe the preclinical characterization of TRX103, an engineered, allogenic cellular therapy product that recapitulates the major regulatory functions of Tr1 cells. TRX103 is designed to halt pathogenic immune responses and (re)-establish immune tolerance and is being developed to prevent the onset of GvHD in patients undergoing HSCT. TRX103 is engineered by separately transducing $CD4^+$ T cells from three donors with a bidirectional lentiviral vector encoding human IL-10 and a non-signaling form of the nerve growth factor receptor (NGFR, CD271). Transduced $CD4^+$ T cells from the three donors are then pooled at an even ratio (1:1:1) to yield the drug product. The TRX103 GMP-compatible manufacturing process consistently yields > 85% $CD4^+CD271^+$ transduced cells. TRX103 did not show activation-independent and IL-2 independent growth properties, demonstrating that its manufacturing process does not induce cellular or molecular alterations. TRX103 secreted IL-10 at rest and secreted high amounts of IL-10, low amounts of IL-4, and variable amounts of IFN-γ and TGF-β following TCR activation. TRX103 displayed a broad polyclonal TCR repertoire and a unique transcriptome profile. The regulatory activity of TRX103 was demonstrated in vitro by its ability to suppress the proliferation of effector $CD4^+$ and $CD8^+$ T cells and the production of pro-inflammatory cytokines by activated monocytes. In addition, TRX103 suppressed the expansion of human effector T cells and prevented the onset of GvHD in a humanized mouse model. Furthermore, the administration of high doses of TRX103 alone or in combination with allogeneic effector T cells in this humanized mouse model did not result in any remarkable pathological findings in the target organs.Together, these data describe the preclinical efficacy and safety of a novel off-the-shelf IL-10 engineered, Tr1-based cell therapy and support a first-in-human Phase 1 clinical study for the prevention of GvHD.

1317. Efficient Lentiviral Transduction of Genetically Barcoded AntiCD20-CAR-IL15 Cassette into Peripheral Blood-Derived Rhesus Macaque NK Cells Using Poloxamer 407

Taha Bartu Hayal[1], Chuanfeng Wu[1], David S. J. Allan[2], Brynn B. Duncan[1], Sogun Hong[1], Cynthia E. Dunbar[1]

[1]TSCBB NHLBI, Bethesda, MD,[2]LTI/CMTB NHLBI, Bethesda, MD

Natural killer (NK) cells can detect and eliminate virally infected and tumor cells, contributing to immunosurveillance and antitumor immunity. NK cell-based immunotherapies are emerging as promising treatments due to their specific killing capacity and lower risk of graft versus host disease in allogenic adoptive transfer settings. NK cell killing activity is optimized by approaches enhancing *in vivo* expansion and persistence of cells as well as genetic modifications improving specificity. Lentiviruses, with an excellent safety and efficiency profile for engineering of immune cells, have been widely used, particularly in engineering T cells with chimeric antigen receptors (CARs) for clinical testing against liquid tumors, notably targeting CD19. However, VSV-G pseudo-typed lentiviruses have proven inefficient in transducing NK cells, leading to the exploration of Baboon endogenous virus envelope (BaEV) lentiviruses. While BaEV can efficiently transduce NK cells, the low virus titer and lack of a clinical track record are hurdles to utilization.The rhesus macaque (RM) model offers a robust pre-clinical platform to evaluate the efficiency and safety of NK-based cell therapies. Our focus is on investigating the clonal dynamics and persistence of CAR-NK cells post adoptive transfer in this model, with and without inclusion of an IL15 transgene in the CAR vector. We inserted an antiCD20-CAR with or without the cDNA for RM sIL15 and linked to a high diversity genetic barcode library to generate VSV-G pseudo-typed lentiviruses and worked to improve primary RM NK cell transduction efficiency. We tested whether inclusion of 100μg/ml of Poloxamer 407 (P407), a non-ionic amphiphilic molecule previously proven to enhance transduction of RM HSPCs (Uchida, et al. 2019), would improve transduction of RM NK cells. We used magnetic cell separation to enrich for RM PB $CD3^{neg}NKG2A^{pos}$ NK cells. These cells were expanded *ex vivo* in 10% heat-inactivated RM serum, 500IU/ml rhIL2 and 2mM Glutamax supplemented X-Vivo20 media together with irradiated (100Gy) universal antigen-presenting (uAPC) feeder cells (Liu et al. 2021), for 5 days before transduction (Fig. A).Stable high transduction efficiencies of 40-60% for RM NK cells (n=4) were achieved with an MOI 20-50 (Fig. B) for a variety of vectors, including with control barcode-GFP, barcoded and non-barcoded CAR-CD20 and CAR-CD20/IL15 constructs. Notably, IL15 "armored" CAR-NK cells exhibited superior growth, even without IL2 supplementation, compared to cells transduced with the non-IL15 CAR vector (Fig .C). The functionality of *in vitro* expanded CAR-NK cells was assessed against ffluc-K562 ($CD20^{neg}$) and ffluc-Raji tumor cells ($CD20^{pos}$) on days 3, 7, and 14 post-transduction. The results indicated better maintenance of CAR-NK function after 14 days of culture for those cultures containing IL15 armored CAR-NK cells (Fig. D).These findings suggest that P407 serves as an efficient transduction enhancer for PB-derived NK cells, resulting in high efficiency transduction even with VSV-G pseudo-typed lentiviral vectors, even those with titer limitations due to the large size of complex CAR cassettes. Currently, we are generating IL15 armored and unarmored CAR-CD20 NK cells

with genetic barcode tags to analyze in both a xenograft tumor murine model and in a RM autologous model to track the function, persistence, and clonal dynamics of these cells *in vivo*.

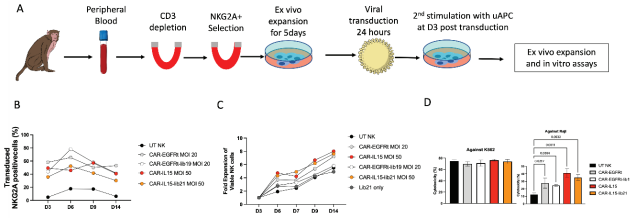

Figure. A) Experimental design. Rhesus macaque peripheral blood derived CD3^{pos}NKG2A^{pos} NK cells were isolated by magnetic cell sorting, and NK cells were expanded and activated *ex vivo* for 5 days. Activated NK cells were transduced with VSV-G enveloped lentivirus in NK growth media supplemented with 100μg/ml P407. After second stimulation with irradiated uAPC, NK cells were further expanded followed with and *in vitro* assays. B) NK transduction efficiency, and transgene expression levels over time compared to untransduced NK (UT NK) cells. C) NK expansion folds over time. D) The cytotoxicity of NK cells against K562 and Raji at 1:1 ratio was measured 2 hours after co-culturing on day 14 post-transduction.

1318. The Direct Addition of RetroNectin® Solutions in the Liquid Phase Improves the Efficiency of Lentiviral Gene Transduction

Yu Okubo, Yoko Kudo, Sachiko Okamoto

Takara Bio Inc., Kusatsu, Shiga, Japan

RetroNectin is a recombinant human fibronectin fragment CH-296 that contains three functional domains: the cell-binding domain (C-domain), the heparin-binding domain(H-domain), and the CS-1 sequence. RetroNectin can enhance lentiviral- and retroviral-mediated gene transduction by facilitating the colocalization of target cells and viral particles. This is achieved through specific interactions between RetroNectin and various cell surface integrin receptors. The H-domain of RetroNectin binds to viral particles, on the other hand, target cells primarily bind to RetroNectin through the interaction of their integrin receptors VLA-5 and VLA-4 with the fibronectin C-domain and CS-1, respectively. By promoting close physical proximity between viral particles and target cells, RetroNectin significantly enhances the efficiency of viral-mediated gene transfer. RetroNectin is now considered the gold standard for enhancing viral transduction in various clinical applications involving gene-engineered cells, including T cells and hematopoietic cells. There are several RetroNectin-mediated transduction protocols, such as the supernatant (SN) method and the RetroNectin-bound virus (RBV) method. In the SN method, cells are mixed with viruses and loaded onto a vessel coated with RetroNectin. In the RBV method, the viruses are first bound to the RetroNectin-coated vessel, and after removing the supernatant, cells are added to the vessel with the virus. The addition of centrifugation in these protocols can further increase the transduction efficiencies. Furthermore, we have also developed a method that combines the RBV method with low-temperature shaking (RBV-LTS method) for large-scale closed cell processing systems. This method has been successfully applied in the manufacturing of CAR/TCR-T cells to enhance transduction efficiency. CAR/TCR-T cell therapy holds great promise as an adoptive immunotherapy for cancer treatment. However, there are several challenges in manufacturing high-quality, clinical-grade gene-engineered T-cell products that must be addressed in order to standardize manufacturing methods and achieve consistent results. To simplify and streamline the gene transduction process, it is feasible to incorporate RetroNectin as a transduction enhancer directly into the liquid phase instead of using RetroNectin-coated vessels. This modification would reduce the number of steps involved and can be easily implemented in automated cell processing systems. In this study, we evaluated the efficiency of enhancing gene transduction by directly adding RetroNectin into the liquid phase during the transduction process of T cells using lentiviral vectors. The results showed that the direct addition of RetroNectin and lentiviruses to the activated PBMCs significantly improved transduction efficiency in T cells, with a 1.5 to 3-fold increase compared to viral infection without RetroNectin. This improvement was similar to the transduction efficiency achieved using the static SN infection method on RetroNectin-coated plate. Importantly, the addition of RetroNectin did not have any adverse effects on cell viability, cell growth, or cell phenotype. In summary, the direct addition of RetroNectin solutions without vessel coating can enhance viral transduction efficiencies. This approach simplifies the gene-engineered cell manufacturing process, including CAR-T and TCR-T production, by reducing the number of steps involved. Moreover, it can be easily integrated into automated cell processing systems.

1319. ML Guided High-Throughput Discovery Pipeline Identifies Best-in-Class CAR-T Candidates

Danielle L. Fairbrass, Arif Kirmizitas, Rui Rodrigues, Alice Godson, Edward King, Jake Leigh Watson, Jennie A. Drew, Jake Burton, Jonathan Lees, Annabel Ling, Benedikt Bornschein, Nils Y. Hammerla, Yulia Lampi, Simon Bornschein

coding.bio, Oxford, United Kingdom

Chimeric antigen receptor (CAR)-T cell therapy, a promising cancer treatment, is expanding its applications to target autoimmune disorders, neurobiology, and ageing. Industry standard CAR-T development relies heavily on i) selecting an antibody based on affinity screening and ii) selecting high-affinity binders in the context of a CAR. However, recent data challenge the notion that the strongest binder always leads to the best CAR, revealing that low-affinity binders can enhance CAR-T activity and improve patient responses (Ghorashian *et al.*, Nature Medicine 2019). We have developed a platform for holistic engineering of 5 key CAR domains, integrating *in vitro* library-based screening with ML-based generative modelling. Through high-throughput testing of 10,000s of CARs / binders we generate biologically relevant datasets at scale enabling the fine-tuning of large transformer-based sequence models (Vaswani *et al.*, NIPS 2017). Beyond merely identifying optimal CARs, our platform facilitates the design and functional exploration of novel CARs with best-in-class performance. Further, our data confirms that the strongest binder is not always the best CAR, and we observe that even subtle modifications within coding regions have a profound impact on performance. Our collaborative wet-lab and *in silico* approach has demonstrated efficacy in identifying best-in-class CARs and dual CARs for clinically relevant targets. We are developing the platform further to expand its applicability to multiple cell types, targets, and modalities, promising a versatile and impactful tool for advancing CAR-T therapy. 1320. Examining the Reciprocal Effects of Natural Killer and Acute Myeloid Leukemia Cell Interactions on Immune Checkpoint Receptor Expression

Danielle G. Jones[1], Natalie Holl[1], Jun Choe[2], Ruyan Rahnama[1], Megan Zinsky[1], Arjun Modi[1], Challice Bonifant[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Baltimore, MD

Background: Recent developments have shown that engineered cell immunotherapies are a promising anti-cancer treatment option for hematopoietic malignancies, namely Acute Myeloid Leukemia (AML). The process of developing cell immunotherapies requires the expansion of a selected lymphocyte from donor peripheral mononuclear blood cells (PBMCs). We utilize Natural Killer (NK) cells with AML antigen-specific chimeric antigen receptors (CARs) to target and kill AML blasts *in vitro* and *in vivo*. NK cell activity is carefully mediated by a balance of signals integrated from activating and inhibitory receptors present on the NK cell surface. One group of these regulatory receptors is commonly referred to as the Poliovirus Receptor (PVR) family, which includes the inhibitory checkpoint molecule T cell immunoglobulin and ITIM domain (TIGIT). We are also interested in TIGIT's complementary activating receptor DNAM-1 present on NK cells, and the ligands that bind these checkpoint receptors on AML blasts: CD112 and CD155. Monoclonal antibody blockade of TIGIT is a promising strategy that has been pursued by numerous pharmaceutical companies to enhance effector cell function. Therefore, we endeavored to investigate the surface expression of these immune checkpoint receptors, competing activating receptors, and binding ligands using flow cytometry. This work provides insight into the dynamic receptor expression levels on NK cells and AML blasts in disease-relevant conditions and provides a basis for pursuing a CAR-NK cell inhibitory receptor modifications. **Methods:** We have designed and optimized fluorescent antibody staining panels to monitor relevant PVR family receptors on both AML blasts and NK cells. Molm-13, MV4-11, KG-1a, and OCI-AML3 AML cell lines were used. Qualitative histogram analysis was performed to confirm that NK cell and AML blast populations could be differentiated when the two sample types were mixed. Next, NK and AML cells were mixed at a 1:5 E:T ratio for 24 hours, then stained with our optimized NK and AML antibody panels. The resulting histogram and median fluorescence intensity (MFI) data was compared to that of NK and AML cells stained individually to measure differences in PVR receptor expression after interactions between effector and target cells. **Results:** NK and AML cells were resolvable when mixed at a 1:5 ratio with distinct populations of cells separated by CD123 or NKp46 expression. Flow cytometry data from 24-hour coculture samples indicated that while there are no significant changes in the percentage of TIGIT$^+$ NK cells (Figure 1A), there are significant decreases in the percentage of DNAM-1$^+$ NK cells across all four cell lines used for coculture when compared to NK cells alone ($p<0.0001$ vs NK alone, Figure 1B). **Conclusions:** We have successfully characterized the composition of NK cell populations in terms of TIGIT and DNAM-1 receptor levels when cocultured with four AML cell lines and found that there is a significance decrease in the DNAM-1$^+$:TIGIT$^+$ NK cell ratio. These results show that in the presence of AML blasts, NK cells are more likely to be inhibited via TIGIT than activated via DNAM-1. With this information, we intend to test TIGIT blockage using CAR-NK cells, with a hypothesis that CAR-NK cell function can be enhanced by preventing TIGIT inhibition. We believe this will ultimately both increase NK cell AML-targeted cytotoxicity and prevent NK cell exhaustion.

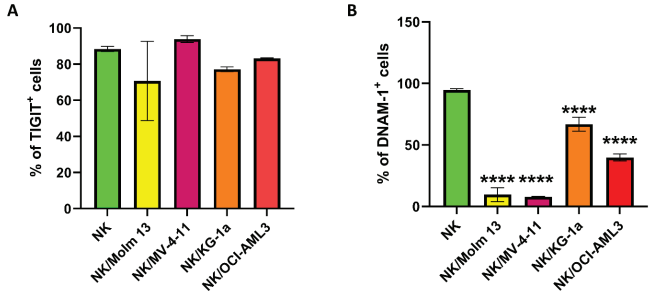

Figure 1. The effects of AML/NK coculture on TIGIT and DNAM-1 surface receptor expression

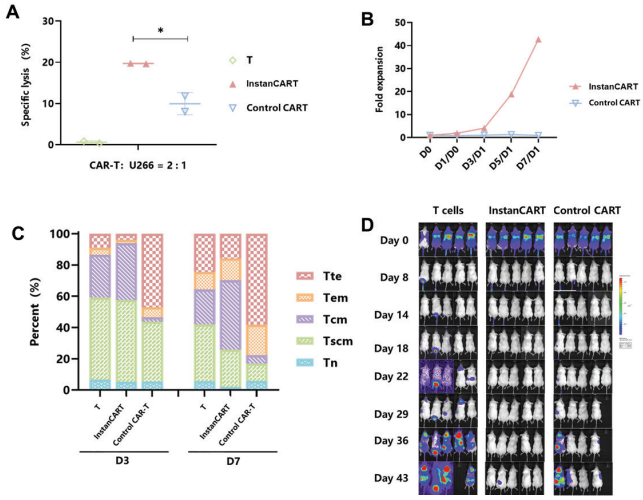


1321. A Rapid CAR-T Preparation Process InstanCART Improves Cell Stemness and Tumor-Killing Capabilities

Yujing Liu[1], Guanghua Liu[2], Yinkang Liu[1], Ting He[2], Xin'an Lu[1]

[1]Beijing Cygenta BioTechnology Co., Ltd, Beijing, China,[2]Beijing Imunopharm Technology Co., Ltd, Beijing, China

CAR-T therapy effectively targets refractory tumors, notably in hematological malignancies, by engineering patients' immune cells into Chimeric Antigen Receptor T-cells (CAR-T). These specialized cells aim to eliminate cancer cells upon reinfusion into the patient. Despite its efficacy, CAR-T therapy poses challenges, including a lengthy production cycle, individual variability, and complex manufacturing. The average timeline spans one to two weeks, with an extra week for quality release. Research has shown that extended *ex vivo* cultivation of T cells can compromise the presence of original cell subpopulations, including naive and stem cell memory T cells (Tscm) and central memory T cells (Tcm), in the final products of CAR-T cells. These subpopulations are closely linked to the therapy's therapeutic potential. To overcome the shortcomings of traditional CAR-T preparation, we produced InstanCART cells which preserves the stemness of T cells, do not require long-term *in vitro* culture. The production cycle can be completed in 2-3 days. Initially, T cells are enriched from the patient's leukocytes, cultured for 24 hours following lentiviral transfection for the expression of Chimeric Antigen Receptor. After collection and washing, the cells are formulated into the final product. InstanCART cells demonstrate increased CAR-T cell expansion potential with reduced exhaustion levels, and heightened anti-tumor activity. Compared to traditional CAR-T cell products, the InstanCART rapid production process allow for a substantial reduction in reinfusion dosage, holding the promise of providing patients with more effective and durable responses, enhancing long-term outcomes, and mitigating the risk of severe adverse events. In our

cytotoxicity experiments, we assessed the targeted killing efficiency of InstanCART cells in comparison to traditional CAR-T cells. The results reveal that InstanCART cells demonstrate specific cytotoxicity against BCMA-positive target cells (U266), showcasing a significantly elevated killing capacity in comparison to traditional CAR-T cells (Fig. A). Furthermore, when exposed to stimulation from BCMA-positive target cells, InstanCART cells exhibit a notably higher proliferation level than traditional CAR-T (Fig. B). Additionally, our investigation into the differentiation level of InstanCART cells affirms that the shorten *ex vivo* cultivation of CAR-T cells produces T cells with a reduced degree of differentiation, thereby significantly amplifying their effector functions (Fig. C). To further evaluate the therapeutic impact, we employed NCG mice to establish a multiple myeloma model through tail vein injection. The ensuing comparison of anti-tumor effects between InstanCART cells and traditional CAR-T cells, as illustrated in Fig. D, underscores that traditional CAR-T cells can inhibit the proliferation of tumor cells in mice. Moreover, a halved dosage of InstanCART cells significantly inhibits the proliferation of tumor cells in mice. This suggests that InstanCART cells wield potent tumor-inhibiting functions under reduced dosage conditions. Our initial data suggests that the current InstanCART rapid preparation process is proficient in generating low-differentiation CAR-T cells, showcasing favorable therapeutic efficacy and safety in both *in vitro* and *in vivo* experiments. The BCMA targeted InstanCART therapy, holds promising clinical prospects for effectively treating multiple myeloma.

Figure, A, Comparison of Cytotoxicity Levels between InstanCART and Traditional CAR-T (*, $P<0.05$). B, Comparison of expansion Levels between InstanCART and Traditional CAR-T. C, Comparison of T Cell Subtyping between InstanCART and Traditional CAR-T. D, InstanCART cells targeting BCMA significantly inhibit the growth of tumors in mice.

1322. Assessing the Influence of Non-Signaling Domains on Anti-TIM3 CAR T Cell Development for the Treatment of AML

Kristine Cate S. Pe[1], Sirirut Jewmoung[2], Ali Hosseini Rad S.M.[3], Koramit Suppipat[2,4], Supannikar Tawinwung[1,4]

[1]Department of Pharmacology and Physiology, Chulalongkorn University, Bangkok, Thailand,[2]Chulalongkorn Comprehensive Cancer Center, King Chulalongkorn Memorial Hospital, Bangkok, Thailand,[3]Kite Pharma, Santa Monica, CA,[4]Cellular Immunotherapy Research Unit, Chulalongkorn University, Bangkok, Thailand

TIM3 is overexpressed on AML cells and is absent in majority of normal hematopoietic cells. CAR T cells expressing the anti-TIM3 antigen-binding domain acquire specificity for AML. However, the effect of the non-signaling domain remains largely undefined with anti-TIM3 CAR. To investigate the effect of the spacer and transmembrane (TM) non-signaling domain, we generated TIM3-targeting CAR with CD8α spacer-CD8α TM (CD8/CD8) or IgG2-CH3 spacer-CD28 TM (CH3/CD28) bearing 4-1BB and CD3ζ endodomain. T cells transduced with CD8/CD8 yielded higher anti-TIM3 CAR positivity than with CH3/CD28 (CD8/CD8=82.8± 3.9 and CH3/CD28=36.7± 3, p=0.0001). The same phenomenon was observed even when the scFv was substituted with anti-CD19, CD8/CD8 construct exhibited higher CAR positivity than CH3/CD28. As TIM3 was expressed on activated T cells, we screened for its expression on CAR-T and determined the extent of fratricide by frequency of apoptotic cells. Compared with CH3/CD28, CD8/CD8 exhibited higher TIM3 expression and enhanced fratricide. Nonetheless, the absolute number of T cells in both constructs continuously expanded as fratricide was transient and CH3/CD28 proliferated more than CD8/CD8. Despite the significant difference in expression level, both constructs exhibited dose-dependent killing of $TIM3^+$ AML cell lines while sparing the $TIM3^-$ target cell line, wherein CD8/CD8 exhibited superior cytotoxic function. Together, our results demonstrate that non-signaling domain contributes to anti-TIM3 CAR T cell functionality. Anti-TIM3 CAR with CD8/CD8 construct has potential clinical advantages due to its higher CAR expression and anti-tumor activity. Therefore, this construct was used to further develop anti-TIM3 CAR with different costimulatory moiety to obtain the optimal CAR design.

1323. An Envelope-Modified Lentiviral Vector for Efficient Gene Delivery to Human Natural Killer Cells

Jing Huang

OBiO Tech, North Hollywood, CA

Natural Killer (NK) cells play a crucial role in tumor immunotherapy. The cytotoxicity of NK cells depends on a delicate balance between activated and inhibitory receptors, and it is not restricted by MHC. Allogeneic NK cell-based clinical therapies have demonstrated *in vivo* expansion without inducing graft-versus-host disease (GvHD). While Chimeric Antigen Receptor T cells (CAR-T) have shown remarkable success in hematologic tumors, CAR-NK holds tremendous potential for treating various tumors However, gene delivery for NK cells has posed a challenge. Reports indicate that BAEV-TR and BAVE-less pseudotyped lentiviruses effectively infect NK cells. Yet, we observed

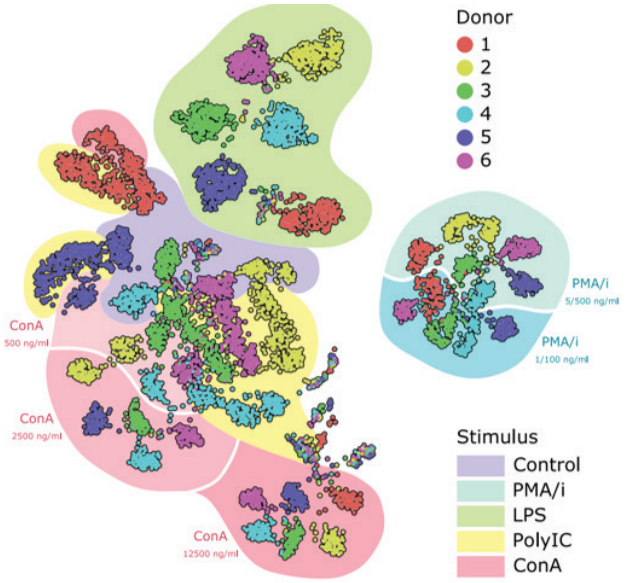
that the titers of transducible lentiviral particles were exceptionally low when packaged with these two mutated envelopes. To identify the most effective method for modifying human NK cells and achieving industrialization, we optimized viral envelopes to allow for the highest levels of transduction (up to 90%) and a significant increase in viral yield (titer up to 5E+06 TU/mL before concentration). Lentiviral virus-transduced primary human NK cells did not show significant alterations compared to untransduced NK cells in aspects such as receptors and markers expression, K562 tumor-killing activity, cell proliferation, etc. Transduction of NK cells with lentiviral vectors containing the Nectin4 CAR expression cassette selectively enhances the cytotoxicity of NK cells against Nectin4-expressing tumor cells. In conclusion, the envelope-modified lentiviral vector proves to be a potent tool for NK cell-mediated cancer immunotherapy.

1324. Assessing Individual Variability in Autologous CD19 CAR T Therapy with PBMC-Humanized Mice

Won Lee, Destanie Rose, James Keck, Jiwon Yang
The Jackson Laboratory, Sacramento, CA

Chimeric antigen receptor T-cell (CAR-T) therapy targeting CD19 represents a significant advancement in the treatment of hematological malignancies. However, its broader application is challenged by inter-patient variability in response and associated toxicities. This study leverages a peripheral blood mononuclear cell (PBMC)-humanized mouse model to capture individual variability in responses to CD19 CAR-T therapy, focusing on efficacy, cellular expansion, and cytokine profiles. Autologous CD19 CAR-T cells, engineered with a CD28 costimulatory domain and CD3z chain, were derived from three different human PBMC donors (A, B, C), exhibiting varying transduction rates of 92%, 52%, and 95%, respectively. This study was structured into two distinct experiments to comprehensively evaluate the therapy's efficacy and toxicity. In our first experiment, NSG™-MHC I/II double knock-out (DKO) mice were humanized with human PBMCs from Donors A, B, or C. Six days post humanization, we treated the mice autologous CAR-T cells. All three CAR-T preparations showed efficacy in eradicating CD19+ cells from the peripheral blood. Notably, CAR-T cell expansion varied among the donors and did not correspond with the transduction purity. Interestingly, Donor B, with the lowest CAR-T purity, showed comparable expansion to others, suggesting factors beyond purity influencing CAR-T behavior. Despite moderate weight loss observed in mice treated with Donor B's CAR-Ts, the anticipated correlation between cytokine profiles and CAR-T expansion was not straightforward. Elevated levels of cytokines typically associated with CAR-T expansion, such as IL-2, IL-6, IL-10, IFNγ, and TNFα, were not seen in Donor B's cohort. In the second experiment, we engrafted DKO mice with Raji-luc B cell lymphoma to increase CD19 targets. Seven days post tumor engraftment, the mice were humanized with PBMCs from Donors A, B, or C, followed by treatment with autologous CAR-T cells. Donor A's CAR-Ts led to the most efficient clearance of Raji-luc, as measured by IVIS bioluminescence imaging. Consistent with Experiment 1, Donor B's CAR-T cells showed the highest level of expansion. However, this did not correlate directly with treatment efficacy, adding complexity to the relationship between CAR-T expansion and therapeutic success. Serum cytokine profiling further illustrated this complexity, with Donor A's efficacious CAR-Ts inducing higher levels of key cytokines like Granzyme A, Granzyme B, IL-9, MIP-1A, and MIP-1B.This study underscores the PBMC-humanized mouse model's effectiveness in mirroring patient response variability in CD19 CAR-T therapy. Our analysis of CAR-T expansion, efficacy, and cytokine profiles sheds light on the mechanisms driving therapy variability. These insights can inform the refinement of CAR-T cell therapies, advancing personalized treatment approaches in hematological malignancies.

1325. Developing a First-in-Class Universal Allogeneic SNAP-CAR NK Cell Therapy



Carrie Stoltzman[1], Erika von Euw[1], Braxton Jamison[1], Emily Hsieh[1], Kevin Green[1], Lara Ionescu Silverman[2], Dan Yerace[2], Dave Mehalick[2], Colleen Delaney[1,2]
[1]Deverra Therapeutics, Seattle, WA,[2]Coeptis Therapeutics, Wexford, PA

Introduction: Natural killer (NK) cells can kill tumor cells without prior activation through their complement of activating and inhibitory surface molecules. Chimeric antigen receptor (CAR) expression by engineered NK cells can improve their innate anti-tumor functions by specifically activating NK cells in the presence of tumor antigen. Compared to autologous CAR therapies, allogeneic CAR NK cells can be generated and cryopreserved for future use, do not require HLA matching and do not cause graft versus host disease or cytokine release syndrome, offering the potential for a safer, more clinically accessible and cost effective cell therapy. Based on demonstrated successful use of a novel SNAP-CAR technology in T cells, we are developing a universal allogeneic SNAP-CAR NK cell. This first-in-class product replaces the extracellular antigen binding domain of a CAR with a SNAPtag enzyme that carries out a self-labeling reaction to covalently attach any antibody conjugated to a benzylguanine (BG) tag to create a functional antigen-specific CAR. **Methods & Results:** SNAP-CAR NK cells were generated from viral vector-transduced cord blood-derived CD34+ cells that were expanded and differentiated to NK cells using a proprietary *ex vivo* cell culture process that utilizes cell activation by a Notch ligand. SNAP-CAR NK cells were assessed for SNAP-CAR expression, NK cell phenotype, and *in vitro* anti-tumor cytotoxicity using BG-conjugated antibody. The SNAP-CAR NK cells displayed viability and phenotyping comparable to the untransduced control NK cells generated in parallel. Anti-tumor cytotoxicity against a CD20+ acute lymphoblastic leukemia (ALL) cell line was enhanced when SNAP-CAR NK cells were co-cultured with a BG-conjugated anti-CD20 antibody in an *in vitro* assay. **Conclusions:** Our off-the-shelf allogeneic NK cell generation platform pairs exquisitely with the highly versatile nature of the novel universal SNAP-CAR platform. Tumor targeting of the SNAP-CAR NK cell therapy can be modulated by the specificity and concentration of the BG-conjugated antibodies used, allowing for one bank of SNAP-CAR NK products to be used across multiple patients and multiple tumor types. Furthermore, for a single patient, multiparametric targeting of cancer can be achieved by infusing SNAP-CAR NK cells functionalized with multiple different antibodies, used concurrently or sequentially to target the tumor microenvironment and different antigens on the same tumor, to impede tumor escape resulting from variation or loss of tumor antigens (*e.g.*, patients who relapse after CD19 CAR T cell treatment due to tumor loss of CD19 antigen could receive follow-up treatment with CD20 and/or CD22 SNAP-CAR NK cells without additional risk of GvHD or CRS).

1326. nELISA High-Throughput Protein Profiling Captures Variability Across Cell Donors and Perturbations - Implications for Cell Therapy

Nathaniel Robichaud, Kevin Hernandez, Milad Dagher
Nomic Bio, Montreal, QC, Canada

The intra- and extra-cellular cues regulating cellular responses are complex, posing a significant challenge for cell engineering. Unfortunately, proteomics tools to capture cellular phenotypes compromise either content or throughput/cost, limiting their use. To overcome this issue, we developed the nELISA: a high-throughput miniaturized ELISA capable of quantifying hundreds of cytokines, chemokines, proteases, and growth factors, at 10x-reduced cost compared to previous tools. Here, we applied the nELISA to donor-derived cell models and demonstrated its ability to capture donor-specific and treatment-specific changes in the proteome. We ran the largest PBMC secretome screen to date, in which ~10,000 PBMC samples were profiled in 1 week, at a throughput of 1536 samples/day. Cells were treated with inflammatory stimuli, and a selected library of 80 recombinant cytokine perturbagens; 191 secreted proteins were profiled in all samples, resulting in ~2M datapoints. The broad nELISA content provided critical resolution power to distinguish between different cell donors, as well as between similar perturbagens, helping to select the most appropriate conditions. For example, IFN gamma was potently induced by >12 perturbagens: IL-23 had almost no impact other than to induce IFN gamma; in contrast, IL-15 also induced IL-1 beta, TNF alpha, CXCL9, CXCL10, and CCL5, whereas IFN beta impacted the expression of >20 other cytokines. Furthermore, the nELISA revealed that IL-1 Receptor antagonist shared all of the immunosuppressive effects of IFN beta, without the latter's pro-inflammatory effects, which can cause adverse events in patients receiving treatment for multiple sclerosis. These findings highlight the ability of the nELISA to capture a wide range of phenotypes across cell donors and perturbations, at a throughput and cost amenable to large-scale efforts. We will expand on these findings and discuss the applicability of the nELISA to selecting ideal cell donors to generate cell therapies, identifying ideal gene edits and culture conditions, as well as strategies for predicting response to therapy.

1327. CasPlus Effectively Prevents On-Target Chromosome Loss and Translocations in Multiplex Gene-Edited Human Primary T Cells

Qiaoyan Yang[1], Michelle Mai[1], Jonathan Abebe[1], Colin Konishi[1], Chengzu Long[2]
[1]NYU School of Medicine, New York, NY,[2]New York University, New York, NY

CRISPR-Cas9 mediated ex vivo T cell engineering enables precise and targeted modification to the T cell genome, facilitating enhanced functionality in autologous and allogenic T cell therapies. Despite these advancements, safety concerns persist regarding the potential complete or partial loss of targeted chromosome and translocations, especially in multiplex gene-edited t cells.Our previous work introduced the CasPlus gene editing platform which includes Cas9, guide RNA and engineered T4 DNA polymerase. This platform successfully alleviated on-target large deletions and chromosomal translocations in cultured HEK293T cells and iPSCs. To evaluate its translational potential, we conducted a comprehensive analysis of on-target large deletions, chromosome loss and translocations in human primary T cells induced by Cas9 and CasPlus editing, utilizing the same guide RNA pairs employed in ongoing clinical trials. Employing PacBio long-read sequencing, we discovered that CasPlus significantly mitigates on-target large deletions when components for Cas9 editing are delivered in the form of both mRNA and RNP. Additionally, through digital droplet PCR, we quantified the on-target chromosome loss, revealing a strong correlation between rates of chromosome loss measured by ddPCR and those estimated by PacBio long-read sequencing. Remarkably, our findings unveiled a negative correlation between rates of chromosome loss and the frequencies of insertions induced by distinct guide RNAs. Furthermore, we compared the translocations induced by the guide RNA pairs with lower rates of chromosome loss and the original ones deployed in the clinical trial. Guide RNA pairs with lower rates of chromosome loss also resulted in a reduced rate of translocations

between targeted chromosomes. The combination of CasPlus with guide RNA pairs exhibiting lower rates of chromosome loss demonstrated the lowest rate of translocations, suggesting that CasPlus can effectively prevent on-target chromosome loss and translocations in multiplex gene-edited human primary T cells.

1328. Revolutionizing Gene and Cell Therapy: The Power of Precision Mutant Libraries

Elaine Lou[1], Xing Gao[2], Andrew Tsao[1], Kevin Chen[2], Cedric Wu[1], Qingwei Meng[2], Jing Min[2]

[1]GenScript USA Inc., Piscataway, NJ,[2]GenScript Biotech Corporation, Nanjing, Nanjing, China

Variant libraries play a crucial role in the early-stage development of Gene and Cell Therapies (GCT). One key application is the modification of Adeno-Associated Virus (AAV) capsids to circumvent immune detection and improve targeting specific tissues. In CAR T-cell therapy, novel Chimeric Antigen Receptor (CAR) constructions are enhancing cell targeting and efficiency, with VHH DNA variant library screenings playing a significant role in improving affinity. Furthermore, the integration of artificial intelligence in computational design is revolutionizing the exploration of a large library of novel genetic sequences, thereby boosting the efficacy of gene and cell therapies. The conventional techniques for creating mutant libraries, reliant on degenerate oligonucleotides and error-prone PCR, often suffer from limited control over the codons introduced, and variants can incur significant codon bias and early termination. This results in a large library with over- or underrepresented variants and incomplete variants, causing a large screening effort on the researcher's part to ensure they are capturing the entire variation of the library. Our proprietary semiconductor-based electrochemical oligonucleotide synthesis technology, known for its high-throughput, precise, and accurate synthesis capabilities, allows customizable codon distribution at each mutated position, preventing the introduction of unwanted or stop codons and limiting codon frequency bias. This technology offers a uniform distribution of amino acids, reduces bias, and excludes stop codons, ensuring the generation of functional proteins. Moreover, its customizable nature facilitates targeted genetic investigations, thereby accelerating the creation of tailored, effective therapies. With approvals of groundbreaking therapies and the integration of artificial intelligence in genetic design, precision mutant libraries are not only enhancing current GCT research but also laying the foundation for a new era of sophisticated, efficacious gene and cell-based therapies.

1329. Next Generation Protein Characterization of CD19-CAR Signaling Cascades

Francisco Ramírez[1], G. Dalton Smedley[2], Charles Haitjema[1], Amrik Singh[3], David Hermanson[2], Chris Heger[1]

[1]Bio-Techne, San Jose, CA,[2]Bio-Techne, Minneapolis, MN,[3]Cell Signaling Technology, Danvers, MA

Chimeric antigen receptor (CAR)-T cell therapy is a revolutionary new pillar in cancer treatment with success in treating specific subsets of B cell leukemia, lymphoma, and multiple myeloma [1]. Much attention is focused on expanding CAR-T cell therapy to other hematologic malignancies and solid tumors. Central to engineering effective CAR-T cell therapies is a detailed understanding of the signaling cascades that regulate CAR-T cells, including trafficking and tumor infiltration, preventing antigen escape, resisting immunosuppressive responses, and ameliorating potentially fatal toxicity [1]. Detailed characterization of extracellular and intracellular signaling molecules is required, often with limited and complex sample types. To study CAR-T signaling, we leveraged a non-viral gene editing platform (TcBuster) to introduce a CD19-CAR into T-cells. Chemically selected cells were isolated and CAR surface expression was verified by flow cytometric analysis using an antibody raised against the peptide linker within the CAR scFv. We then stimulated the CAR-T cells with immobilized CD19 and implemented automated solutions to characterize IFN-γ secretion using automated ELISA (Simple Plex) and intracellular signaling events using a capillary immunoassay platform (Simple Western). The capillary immunoassay provided multiplex protein expression measurements of multiple signaling molecules, including phosphorylated and total protein isoforms, with specific molecular weight characterization, and required only 3 µL of lysate for analysis. Together, these data show the importance of understanding the delicate interplay between signaling molecules that regulate CAR-T function.

1331. CD33 Targeted gd T cells for Treatment of Acute Myeloid Leukemia

Justin C. Boucher[1], Anna L. Austin[1], Elena Kostenko[1], Kayla Reid[2], Mate Z. Nagy[1], Marco L. Davila[3], Jose A. Guevara-Patino[1], Nelli Bejanyan[2]

[1]Department of Immunology, Moffitt Cancer Center, Tampa, FL,[2]Department of Blood & Marrow Transplant and Cellular Immunotherapy, Moffitt Cancer Center, Tampa, FL,[3]Department of Medicine and Immunology, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Acute myeloid leukemia (AML) is the most common acute leukemia in adults. Allogeneic hematopoietic cell transplantation from healthy donor stem cells is the only curative therapy for most adults with AML who achieve remission with chemotherapy. However, in close to 40% of patients AML is either chemotherapy refractory or relapses after initial remission, leading to poor survival due to lack of effective treatment options. Prior reports suggest better survival with higher blood or marrow γδ T cell counts in patients with relapsed or refractory AML. However, γδ T cells are rare in the blood and functionally impaired in patients with malignancies. We previously reported an efficient expansion of an allogeneic healthy donor-derived γδ T cells to achieve cell doses sufficient for clinical use. Therefore, we hypothesized that incorporating a chimeric antigen receptor (CAR) into healthy donor γδ T cells would further enhance its efficacy. We used a CAR targeted against CD33 with 41BB co-stimulation and CD3ζ signaling domains in a retroviral vector. When we tested the cytotoxicity of these cells *in vitro* we found that γδ T cells transduced with the CAR had significantly enhanced killing compared to untransduced (UT) γδ T cells (**Figure 1A**). We then examined the effect of γδ CAR T cells on NSG mice given the AML tumor cell line MV411. We found a significant reduction of peripheral blood circulating AML cells at week 4 in the CAR treated group compared to the UT group. We also found that at week 7, 50% (4 out of 8) of mice in the CAR treated group survived, whereas in the UT

and tumor only groups only 12.5% (1 out of 8) survived (**Figure 1B**). This suggests treatment with γδ CAR T cells can reduce tumor burden and increase survival *in vivo*. We subsequently compared γδ CAR T cell and αβ CAR T cell *in vitro* killing. γδ CAR T cells had quicker and longer lasting cytotoxicity compared to αβ CAR T cells at lower effector to target ratios, suggesting that γδ CAR T cells may be more effective in higher stress environments. Additionally, both γδ CAR and UT T cells produced significantly higher levels of IL2 compared to αβ CAR T cells. In contrast, IL6, IFNγ, and TNFα were undetectable in the γδ CAR and UT T cells. This suggests that immunotherapy with γδ CAR T cells could potentially reduce toxicities such as cytokine release syndrome while retaining beneficial autocrine IL2 signaling. Together our data show that a CD33 directed CAR can enhance γδ T cell cytotoxicity against AML both *in vitro* and *in vivo*. This has potential to offer novel allogenic healthy donor derived γδ CAR T cell therapy to patients with relapsed and refractory AML.

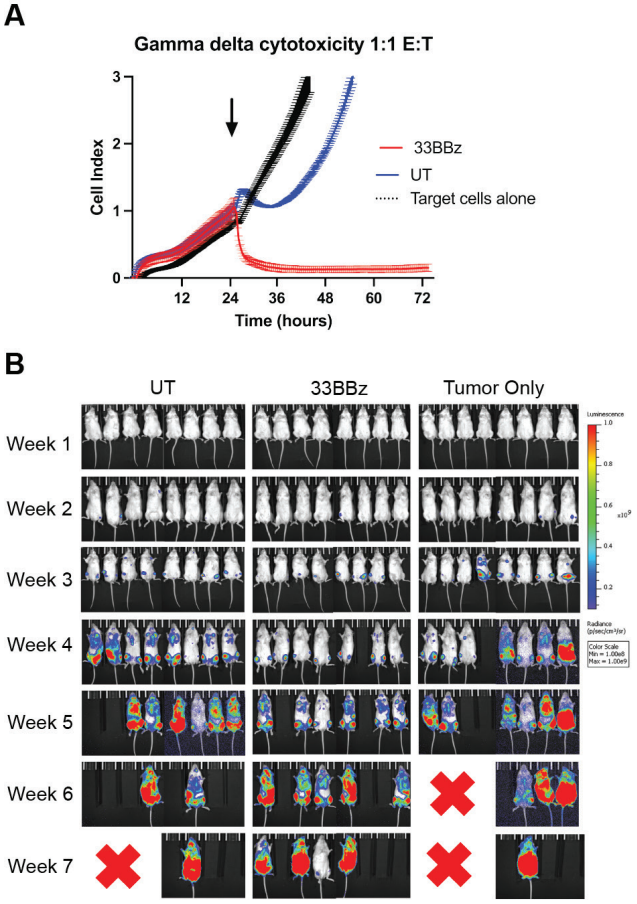

Figure 1. CAR enhances γδ T cell anti-tumor affect. **(A)** γδ CAR T cells (33BBz) were co-cultured with target cells expressing CD33 at a 1:1 effector to target (E:T) ratio. Arrow indicates when cells were added. **(B)** NSG mice were injected IV with $1x10^6$ AML tumor cell line MV411-FFL at week -1. UT or CAR γδ T cells were administered by IV at week 0. BLI was measured weekly. (N=8).

1332. Development of *In-Vitro* Potency Assays to Evaluate Early Activation, Granzyme B Secretion, and Cytotoxicity of CAR-T Cells

Jiu Jiang, Lisa Yu, Imelda Mema, Rachana Patel, Wayne Zhou, Sicco Popma, Bhoopathy Sid

Pharmaron (Exton) Lab Services LLC, Exton, PA

Purpose. The purpose of this study was to develop *in-vitro* potency assays for determining early activation and cytotoxicity of CAR-T cells using flow cytometry and measuring Granzyme B (GrB), a cytotoxic serine protease secreted by CAR-T cells, using ELISA. **Methods.** CAR-T cells recognizing the CD19 molecule on B cells were used as effector cells and Toledo cells from human B cell lymphoma were used as target cells. Toledo cells were incubated and re-suspended in complete medium, then plated in a 96-well round-bottom plate (5,000 cells/well). In parallel, a frozen vial containing anti-CD19 CAR-T cells was thawed and the cells were washed and re-suspended into the medium supplemented with rhIL-2. As effectors, the CAR-T cells were added to the wells in appropriate dilutions to obtain different effector-to-target (E: T) ratios (0.1:1, 1:1, 4:1, and 8:1). Negative-control wells contained the target cells with non-CAR-T cells. The cells were co-cultured at 37°C for 1 h, 2 h, 5 h, and 24 h, and supernatant was collected to measure GrB by ELISA. In addition, harvested co-cultures were stained with various antibodies for flow cytometric analysis determining early activation and cytotoxicity of the CAR-T cells at different times post co-culture. **Results.** Flow cytometry data showed that the percentage of tumor cells ($CD19^+$) was substantially lower when co-cultured with CAR-T cells at the 8:1 of E:T ratio for all time points. 77%, 91%, and 96% of tumor cells were killed at 24 h when E:T ratio was 1:1, 4:1, and 8:1, respectively. Significant upregulation of CD69, an early activation marker, was observed on the CAR-T cells at 5 h. Up to 70% of the CAR-T cells was activated when co-cultured for 24 h at 8:1 ratio while only marginal activation was observed in control T cells. Most remaining tumor cells were dead and/or apoptotic ($7\text{-}AAD^+$ and/or Annexin V^+) in the wells containing CAR-T cells. To investigate whether the expression of GrB, a cytotoxic molecule, was upregulated in the CAR-T cells, the supernatant of co-culture was examined using ELISA. GrB was detected at the earliest timepoint measured (1 h) in co-cultures containing CAR T cells. After co-culture for 24 h, the GrB level of the CAR-T cell group was approximately 20-fold higher than non-CAR-T cells at both 0.1:1 and 8:1 ratio. The data shows that GrB expression coincides with T cell activation and tumor cell death. Therefore, GrB may lend itself as a potency measure for CAR T cells. **Conclusions.** Early activation and a profound cytotoxic effect of CAR-T cells, coinciding with the secretion of GrB in co-cultures, was determined by flow cytometry and ELISA. Upregulation of CD69 and secretion of GrB demonstrate potential value as an *in-vitro* potency assay for CAR-T cells.

1333. Enhancing Transduction Efficiency and Efficacy of Non-Activated CAR T Cells by Modulating IFN1 Signaling

Joseph Durgin[1], Ashwin Sannecy[2], Andre Kelly[2], Roddy O'Connor[2], Saba Ghassemi[2]

[1]Department of Dermatology, University of Michigan, Ann Arbor, MI,[2]Center for Cellular Immunotherapies, University of Pennsylvania, Philadelphia, PA

Chimeric antigen receptor (CAR) T cells have demonstrated their efficacy in treating blood-based cancers. However, the durability of responses is often hindered by challenges related to long-term T-cell persistence and engraftment. The success of CAR T cell immunotherapy relies on the differentiation status and overall fitness of the CAR T cell product. Current protocols involve the activation and ex vivo expansion of patient T cells, however, this activation results in irreversible differentiation, compromising their therapeutic potency.Our recent work showed that employing a manufacturing protocol utilizing non-activated T-cells results in superior differentiation characteristics and reduced exhaustion, thereby promoting long-term tumor control. Despite these advantages, the use of non-activated T cells poses a significant challenge in CAR T manufacturing yield due to the high resistance of quiescent T cells to lentiviral infection.Quiescent T-cells initiate an IFN1-mediated innate response upon lentiviral vector transduction, which limits CAR T-cell transduction efficiency. Our data indicate that pre-treatment of non-activated T-cells with an IFN1-binding protein enhances CAR T-cell transduction efficiency and promotes a more naïve and central memory phenotype. We further evaluated the effect of sustained IFN1 blockade by constructing lentiviral transfer plasmids encoding both a CAR and a secreted anti-IFN1 binding protein. The anti-IFN1-secreting CAR T-cells showed greater transduction efficiency as well as enriched central memory differentiation and reduced TIM3 expression. They also exhibited enhanced cytolytic activity and cytokine production against target cells. In NOD-SCID γc−/− (NSG) mice bearing Nalm6 tumor xenografts, anti-IFN1-secreting CAR T-cells showed sustained persistence and anti-tumor control. These results suggested that the anti-IFN1 protein secretion enhances therapeutic activity against tumors employing sustained type I IFN signaling for immune escape.These studies represent a significant step toward enhancing T-cell fitness by countering anti-viral defenses triggered during manufacturing. Targeting the IFN1 response during non-activated CAR T-cell manufacturing offers a potential solution to improve transduction efficiency and enhance CAR T-cell functionality. Given the therapeutic promise of non-activated CAR-T cells, our findings have immediate translational relevance for broadening their appeal against cancer.

1334. Engineering Gate CAR-T for AML Using Non-Viral Delivery Methods

Rachel Bito, Samy Leon Jambon, Shawn Barman, Babak Moghimi

Cancer and Blood Disease Institute, Children's Hospital Los Angeles, Los Angeles, CA

Survival outcomes for pediatric acute myeloid leukemia (AML) lag significantly behind other pediatric leukemia and lymphomas. Given the unprecedented success of Chimeric Antigen Receptor T cells (CAR-T) for lymphoblastic leukemias, there is a dire need to develop AML-targeted CAR-T cells. However, its success has been limited due to the need for tumor-specific antigen targets in AML and the risk of off-tumor toxicities in the absence of such antigens. Recently, a novel combinatorial strategy using a synthetic Notch receptor called SynNotch has been developed. SynNotch gated CAR-T cells, designed to target a combination of antigens, are programmed to express CAR proteins in response to the presence of specific gated antigens. This logical circuit ensures safe and precise tumor targeting, significantly limiting the risk of off-tumor toxicities. Our team was the first to show clinically relevant application of SynNotch technology in murine models. We have further engineered gated CAR-T cells targeting the CD33-CD123 combination in AML using lentiviral-based engineering. Our preliminary work has demonstrated that these gated CAR-T cells are effective against AML cell lines and patient-derived xenografts in cell culture and in animal models. More importantly, these circuit CARs exhibit a superior T cell phenotype, characterized by a higher percentage of memory phenotype, enhanced metabolic state, and lower expression of exhaustion markers. Despite the advantages of these CAR-T cells over conventional ones, the complexity of engineering them, requiring large cargo and multiple lentiviral vectors, poses a barrier to the clinical translation of these novel immunotherapies. To address this issue, we have engineered these CAR-T cells using a non-viral PiggyBac transposon-based method aiming to facilitate the manufacturing of these novel treatments for AML. We demonstrate that CD123 CAR, expressed either constitutively or through a synthetic Notch receptor engineered using the PiggyBac system, was effective against the MOLM13 AML cell line both in vitro and in a mouse model of AML transplanted with MOLM13 cells. We have successfully engineered these gated CAR-T cells using a larger cargo incorporated into a single frame of the transposon cassette, which has streamlined the process of CAR-T cell selection. The implementation of non-viral methods to create complex CAR-T modules is novel and could significantly contribute to advancing future clinical trials more rapidly and at a lower cost. This approach could translate into improved access and equity of these life-changing treatments for all patients.

1335. Advancing Cancer Immunotherapy: Large-Scale Non-Viral Engineering and Feeder-Free Production of CAR-NK Cells

Deepak Kumar[1], Anna Liu[1], Erica Heipertz[2], Namritha Ravinder[3]

[1]Cell Biology, Thermo Fisher Scientific, Carlsbad, CA,[2]Thermo Fisher Scientific, Frederick, MD,[3]ThermoFisher Scientific, Carlsbad, CA

The use of engineered primary human natural killer (NK) cells holds great promise in immuno-oncology due to their demonstrated safety and their potent anti-tumor properties, especially in the case of solid tumors. Unlike primary T cells, NK cells do not rely on a matching human leukocyte antigen to function, reducing the risk of graft-versus-host diseases in allogeneic therapies. Gene delivery into NK cells is a crucial tool for studying NK cell biology and developing NK cell-based immunotherapies. However, efficient, safe, non-viral gene delivery methods for primary NK cells remain limited. To date, there is very limited published data demonstrating high-efficiency (>20%) non-viral gene knock-in for primary NK cells. In this study, we optimized a scalable, non-viral, closed-system gene delivery method for production of CAR-NK cells. To optimize the gene delivery protocol, we first investigated the effects of different electroporation parameters, including voltage, pulse length, and number of pulses, on cell viability and gene delivery efficiency. We then assessed the impact of various electroporation buffers and DNA concentrations on gene delivery efficiency and cell viability. Here, we present a fully non-viral workflow for achieving permanent knock-in of both a green fluorescent protein (GFP) and a chimeric antigen receptor (CAR) transgene in primary NK cells using the optimized electroporation protocol. We isolated PBMCs

using a closed counterflow centrifugation system followed by negative selection of CD56+ NK cells. Isolated NK cells were then expanded in feeder-free culture using CTS™ NK-Xpander™ Medium for 6 days before proceeding to gene engineering using CRISP/Cas9 RNP and relevant donor DNA delivered via electroporation. We conducted optimization of the electroporation conditions at a small scale (100 µl) using the Neon™ NxT Electroporation System, and successfully translated the optimized conditions to a clinically relevant scale using the CTS™ Xenon Electroporation System. Our optimized non-viral workflow achieves permanent transgene expression of GFP at the Rab11a locus in a single electroporation step by co-delivering a CRISPR-Cas9 RNP and a single-stranded DNA (ssDNA) template for homology-direct repair. We utilized this optimized workflow for non-viral permanent transgene expression of anti-meso3 CAR at the AAVS1 locus in primary NK cells. We also demonstrate the applicability of our electroporation optimizations for combined viral/non-viral workflows by performing non-viral knockout of the AAVS1 locus using electroporation followed by targeted viral knock-in of anti-meso3 CAR using an AAV6 virus. The genome edited NK cells were expanded after electroporation, maintaining high cell viability, and achieving clinically relevant levels of feeder-free cell expansion. To assess the impact of gene delivery on NK cell function, we performed functional cytotoxicity assays. We observed that gene delivery using the CTS™ Xenon Electroporation System did not impair the cytotoxicity of primary NK cells against target cells. The addition of anti-meso3 CAR was shown to enhance targeted killing compared to unmodified NK cells. In conclusion, this study presents closed automated cell processing and scalable, non-viral gene delivery methods for primary NK cells that enable efficient and permanent transgene expression without compromising NK cell viability or function. The ability to genetically modify primary NK cells will facilitate further studies on NK cell biology and enable the development of NK cell-based immunotherapies.

1336. Differential Susceptibility to Senescence in CART Cells Based on Co-Stimulatory Signaling

Ismail Can[1], Leo R. Sakemura[1], Claudia Manriquez Roman[1], Olivia Sirpilla[2], Carli Stewart[3], Kun Yun[3], Truc Huynh[1], James Girsch[3], Ekene Newton Ogbodo[1], Lionel Kankeu Fonkoua[1], Jennifer M. Feigin[3], Long Mai[1], Hong Xia[1], Brooke Kimball[1], Mehrdad Hefazi Torghabeh[4], Michael Ruff[1], Justin Boysen[1], Neil Kay[1], Elizabeth Siegler[1], Berke Alkan[5], Fatih Sezer[5], Atakan Ekiz[5], Saad Kenderian[1]

[1]Division of Hematology, Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]T Cell Engineering, Mayo Clinic, Rochester, MN,[4]Department of Oncology, Mayo Clinic, Rochester, MN,[5]Molecular Biology and Genetics, Izmir Institute of Technology, Izmir, Turkey

In chimeric antigen receptor T (CART) cell failure, the role of exhaustion has been studied extensively; however, the role of T cell senescence, another dysfunctional T cell fate, has remained unexplored. We developed an *in vitro* model for repeated CART cell activation and rest cycles, mimicking cancer relapse, to study the development of CART senescence. The resting period is essential to differentiate reversible exhaustion and irreversible senescence. Using CD19-targeted CART cells with costimulation via 4-1BB (BBζ) or CD28 (28ζ), we examined CART immunophenotype, cell cycle regulators, transcriptomic profile, and effector functions on days 0 (T cell), 8 (baseline CART), 15 and 22 (CART after one and two activation/rest cycles, respectively). Following an activation/rest cycle, T cell exhaustion markers CTLA4, LAG3, and PD1 returned to basal levels after an initial increase due to activation, while only TIM-3 levels remained elevated (BBζ; p=0.0090, 28ζ; p=0.0394). Despite the lack of an overt exhaustion immunophenotype, recurrent activation/rest cycles induce a state of dysfunction in BBζ and 28ζ *in vitro* and *in vivo*. Increased TIM-3 expression is associated with T cell senescence, which prompted us to further investigate the development of a senescence phenotype. We found elevated T cell senescence markers including p16 (BBζ; p=0.0103), p53 (BBζ; p=0.0248, 28ζ; p=0.0128), CD27 (BBζ; p=0.0080), and CD28 (BBζ; p=0.0327) in recurrently activated-rested CART cells. Overall, senescence-like phenotypes were observed more prominently in recurrently activated-rested BBζ than in 28ζ after one or two activation/rest cycles. Next, we evaluated the transcriptomic signature of recurrently activated-rested CART cells. Gene set enrichment analysis (GSEA) indicated enrichment of gene sets related to senescent T cells as well as senMayo, a novel gene set which is reported to be selectively enriched in senescing cells or tissues, in BBζ D15, but not in 28ζ D15, compared to T cell D0 or in BBζ D15 compared to 28ζ D15 (p=0.00014 and p=0.089, respectively). MYC-related pathways were found to be significantly enriched in recurrently activated/rested BBζ and depleted in 28ζ (p<0.1). Given these results, we induced senescence in CART cells using two alternative strategies: MYC activation (oncogene-induced senescence) and irradiation. Senescence induced by both methods impaired BBζ activity but improved 28ζ activity. Analysis with two independent patient data sets correlated the emergence of senescence with contradicting clinical outcomes to BBζ and 28ζ treatments. The presence of senescent 28ζ cells was associated with complete response in the clinic and longer disease-free survival (p=0.0029), while senescent BBζ cells were associated with non-response in the clinic (0.014). In summary, our study indicates that (i) CART cells are susceptible to a state of senescence, as demonstrated using three independent approaches (repeated activation/rest, irradiation, and MYC modulation), (ii) CART senescence is more prominent in BBζ-stimulated CART cells, and (iii) senescence is associated with worse outcomes following BBζ but not 28ζ treatment.

1337. Precision Biomaterials Enrich and Stimulate Long-Lived CD8+ CAR-T Cells for Supernumerary Expansion *Ex Vivo*

Xiao Huang[1], Yuanzhou Chen[2], Wendell Lim[2], Qizhi Tang[2], Tejal Desai[3]

[1]School of Biomedical Engineering, Drexel University, Philadelphia, PA,[2]University of California, San Francisco, San Francisco, CA,[3]School of Engineering, Brown University, Providence, RI

Chimeric Antigen Receptor (CAR) T cells have reshaped B-cell cancer treatment. However, tumor relapse remains a significant issue, mainly due to the limited post-infusion persistence. Persistence is an intrinsic feature of T cell differentiation, which can be modulated by biomaterials functionalized with precision immunomodulatory signals. Our previous research endeavors resulted in the development of a

DNA-scaffold platform capable of precision surface functionalization. Using microspheres made of biodegradable polymer PLGA (poly-(lactic-co-glycolic aid)) and decorated with controlled ratios of CAR-antigen (EGFR) to CD28 agonist antibody (a-CD28), we stimulated T cells engineered with 2nd-generation anti-EGFR CAR constructs. We identified an optimal ratio of antigen to a-CD28 antibody on microspheres that stimulated the best T cell proliferation for 4-1BB costimulatory (costim.) CAR T cells among 3 human donors (**Fig. 1A**). Importantly, repeated stimulations (every 8-10 days) with this optimal biomaterial formulation sustained continuous T cell proliferation *in vitro* for over 100 days, reaching an overall of ~10^12 folds of expansion (**Fig. 1B**). In comparison, CD28-costim. CAR-T cells did not show a difference of proliferation from various ratios of the two signals on microspheres during the first stimulation. However, T cells made from 2 out of 4 donors did require the optimally ratio-ed formulation for sustainable proliferation with repeated stimulations. Ultimately, we achieved a >100-day-continuous proliferation for both constructs *ex vivo* among >3 donors using precisely engineered biomaterials, whereas cancer cell (U87) stimulations led to cell apoptosis or dysfunction within 5 rounds of stimulation (**Fig. 1B**). Single-cell RNA sequencing shows a clear trend of clonal enrichment along the 100-day culture (**Fig. 1C**) for all tested donors with hallmarks of memory progenitor effector cells (MPEC). Although with extensive proliferation, cells did not show dramatically increased expression of the exhaustion markers (for both mRNA and protein data). Impressively, the massively expanded cells (~10^12 folds) throughout 8 rounds of stimulations retained their effector function from the *in vitro* tumor killing and cytokine secretion assays. Indeed, cells that underwent 3-5 rounds of stimulation showed enhanced effector function and mitochondria fitness compared to unstimulated cells (**Fig. 1D**). Whole-genome transcriptomic analysis 24 hours after the stimulation shows that biomaterials induce signaling that uncouple cell proliferation from excessive immune activation, compared to the cancer cell-mediated stimulation. The up-regulated signaling include DNA repair, mitochondria fitness, G1/S transition, and telomere maintenance. This data perfectly agrees with the phenotypes of massive proliferation, enhanced respiration capacity (by Seahorse assay), and temporally augmented telomerase activity (by TRAP assay). Our ongoing effort is to replicate these trends in CARs targeting different antigens and to test the in vivo anti-tumor efficacy of the expanded cells. This work can have a dramatic impact on our understanding of T cell signaling and fate decision, as well as shed new light on how to engineer cells for improved longevity.

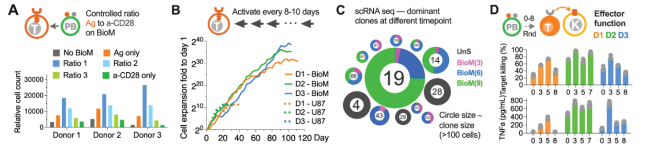

Figure 1. A) CAR-T cell proliferation 5 days after 1-round BioM stimulation. **B)** Expansion fold of T cells after repeated stimulations using BioM (Ratio 1) vs U87 cells. **C)** Distribution of dominant clones after 0 (UnS), 3, 6, 9 rounds of BioM-stimulation through single-cell RNA-seq based TCR repertoire analysis. Circle size of each clone is in scale with the clone size. **D)** Target killing and TNFa secretion of expanded CAR T cells when exposed to K562 cells for 2 days *in vitro* among 3 donors (D1-3).

Thursday Posters: Other Cellular and Regenerative Therapies

1338. Innovative Automation for iPSC Process in Cell Therapy Development: A Closed System Approach

Ranganatha R. Somasagara[1], Olga Cohen[1], Young Kim[1], Pushpalatha Cheluvappa[1], Carl Dargitz[2], Gregory B. Bonello[1], Namritha Ravinder[1]

[1]ThermoFisher Scientific, Carlsbad, CA,[2]Thermo Fisher Scientific, Carlsbad, CA

Induced pluripotent stem cells (iPSCs) provide a flexible platform for diverse clinical development that has incredible potential to address scalability issues and improve patient outcomes. iPSCs can be differentiated into various cell types, such as neurons, heart cells, or pancreatic cells, that can be transplanted into patients to replace damaged or diseased tissues. This approach has shown promise in preclinical and early clinical trials for conditions like spinal cord injury, heart disease, and diabetes. Allogenic cell therapy for cancer treatment has constantly been a developing field in the very recent years as iPSCs have drawn unique interest for the development of clinical manufacturing of CAR-NK and CAR-T cells. iPSC culture and differentiation involve multiple steps and require human intervention. To circumvent the drawbacks of human handling necessary during cell and gene therapy workflows, automation needs to be improved and there are currently limited automated, closed solutions available. he CTS™ Rotea cell processing system can minimize the human handling steps in multiple stages of iPSC process. It is a automated closed cell processing system that uses counterflow centrifugation technology that enables cell separation, washing, and concentration of different cell types. Utilization of instrumentation can eradicate manual effort, related mistakes, and time. In our current workflow, we cultured and expanded iPSC up to 4 billion cells in a 10-layer cell factory system similarly to clinical manufacturing scale for master bank cell preparation. iPSC manual process and harvest in 10-layer cell factory system is very labor intensive and prone to contamination. Utilizing of counterflow centrifugation system can minimize human intervention at multiple stages, including removal of media, washing of cells, addition of cell detachment media, collecting, concentrating iPSCs and delivery to collecting bags. Using this closed system, we can process and harvest large number of iPSCs in a single batch to create a master bank for cell therapy development. The iPSCs prepared using this method retains the pluripotency characteristics with good viability and expansion capability. In summary, using the closed counterflow centrifugation Rotea system reduces human error and minimizes the risk of contamination in large scale iPSC expansion and master banking. This system will be the best method to implement for iPSC workflow in cGMP-compliant clean room manufacturing environment.

1339. Evaluation of Flow Cytometry Utility in Hematopoietic Progenitor Cell Products for Patients with Multiple Myeloma Undergoing Stem Cell Collection

Sarah K. Grewal[1], Ayda Javanbakht[1], Marianne Yee[2], Jeanne Hendrickson[1], Edmund K. Waller[3], H. Cliff Sullivan[1]

[1]Department of Pathology and Laboratory Medicine, Emory University, Atlanta, GA,[2]Department of Pediatrics, Children's Healthcare of Atlanta, Atlanta, GA,[3]Department of Hematology and Medical Oncology, Emory University, Atlanta, GA

Introduction: Peripheral blood stem cell (PBSC) collection plays a pivotal role in the therapeutic paradigm for multiple myeloma (MM). While current regulatory requirements address essential components such as sterility, viability, and cell count, collection and processing practices among different institutions vary. For example, the evaluation of persistent disease is not mandated but some laboratories perform flow cytometry on human progenitor cell apheresis (HPCA) products. Herein, we aim to ascertain the clinical utility of this additional testing in ensuring the quality of PBSC collections for patients with MM. Methods: A retrospective review was undertaken of patients with MM who had autologous stem cell collections from October 2022 through January 2024. Flow cytometry results for HPCA products were unavailable for 4 patients and were excluded. Data extracted via chart review included flow cytometry results for HPCA products, as well as for pre-transplant and post-transplant bone marrow biopsies, and date of stem cell transplant, if applicable. Flow cytometry results were reported as a percentage of monotypic/clonal plasma cells identified in the specimen based on signed hematopathology reports of the leukemia/lymphoma panel using markers for CD19, CD27, CD38, CD45, CD56, CD81, CD117, CD138, KAPPA (cytoplasmic), and LAMBDA (cytoplasmic). Values were categorized as 0%, <1%, or >1%. The Fisher's Exact test executed using SAS v9.4 (Cary, NC) was used to compare results from the HPCA product and the pre-transplant flow result. Results: Of 354 patients with HPCA products, six (1.7%) had positive flow cytometry results, with all instances at <1%. Within the cohort, 109 patients (31%) had positive pre-transplant bone marrow biopsy results, with monotypic/clonal cell values ranging from <1% to 63%. On average, pre-transplant bone marrow biopsies were done 25 days before the date of collection (median 15), and 47 days before transplant (median 31). Out of 183 patients who had post-transplant data available, only 1 out of 6 positive HPCA cases had a result available, which showed no residual disease in the post-transplant bone marrow flow. Additionally, 21 cases (11.5%) displayed low levels (<1%) of monotypic/clonal cells in the post-transplant bone marrow biopsy, despite a negative HPCA product flow result. All positive HPCA products had positive pre-transplant flow results, while 69% of negative HPCA products had negative pre-transplant flow results (Table 1). Of note, none of the negative pre-transplant flow results were associated with a positive result for the HPCA product. Conclusions: These results highlight the infrequent occurrence of positive flow cytometry results for monotypic/clonal cells in HPCA products collected from MM patients undergoing stem cell collection. With less than 2% of patients demonstrating minimal residual disease in the HPCA product, flow cytometric evaluation would appear to represent test overutilization. Although the current study did not look at transplant outcomes, our findings prompt reconsideration of the clinical utility of routine flow cytometry during HPCA processing.

Table 1: Comparison of Pre-transplant and HPCA Product Flow Cytometry Results

	Pre-Transplant Flow Result		
HPCA Flow Result	**0%**	**<1%**	**≥1%**
0% (n=333)	230 (69%)	74 (22%)	29 (9%)
<1% (n=6)	0 (0%)	2 (33%)	4 (67%)

Fisher's Exact test: p<0.0001

1340. Off-the-Shelf *In Vitro* Expanded Peripheral Blood Stem Cells as a Source for Hematopoietic Stem/Progenitor Cell Transplant

Galaxy Gutierrez

Gift of Life Center for Cell and Gene Therapy, Boca Raton, FL

Timely transplant procurement is crucial for patients battling blood cancer since receiving a bone marrow stem cell transplant in the early stages of their disease significantly improves chances of survival. However, this timing remains a significant hurdle for patients in need, especially those of minority ethnic communities, as low availability of compatible donors and overwhelmed collection centers contribute to lengthy acquisition times. Optimistically, there is evidence that the *in vitro* expansion of hematopoietic stem cells (HSC) can be used to increase the restricted number of therapeutic cells in a transplant product. A single donation could potentially be multiplied to treat multiple patients. Having transplants readily available could reduce detrimental waiting time and directly improve patient outcomes. While there has been some documented success for expanding HSC sourced from umbilical cord blood, the greater challenge is achieving a sufficient dose of transplantable *in vitro* expanded HSC therapy from mobilized peripheral blood stem cells (mPBSC). To date, this has not been demonstrated. To contribute to this gap in knowledge we are investigating culturing mPBSC with small molecules from a library that targets key regulatory pathways involved in HSC self-renewal and differentiation. The aim of our project is to develop a cocktail of compounds that promote the *in vitro* expansion of mPBSC while maintaining stemness and therapeutic potential. This therapeutic potential is measured by assessing cell surface markers with flow cytometry for the presence of long term-HSC (LT-HSC), a subpopulation characterized by prolonged self-renewal and identified as the key to the success of bone marrow transplants. So far, we have preliminary results identifying two small molecules that expand LT-HSCs *in vitro* by affecting pathways that either arrest the cell cycle (Glycogen Synthase Kinase-3 inhibitor) or inhibit differentiation (Notch inhibitor). The milestones in our project will contribute to advancing the understanding of the mechanisms governing stem cell proliferation and the maintenance of stemness, ultimately paving the way for more refined and effective stem cell therapies.

1341. Optimizing Melanocyte Transplantation for Enhanced Vitiligo Treatment Outcomes

Sabrina Mai-Yi Fan[1,2], Wen-Jun Chen[1], Po-Hua Chen[3], Tzu-Ying Chen[1], Ming Yao[1,4], Sung-Jan Lin[1,2,3]

[1]Department of Medical Research, National Taiwan University Hospital, Taipei, Taiwan,[2]Research Center for Developmental Biology and Regenerative Medicine, National Taiwan University, Taipei, Taiwan,[3]Department of Dermatology, National Taiwan University Hospital, Taipei, Taiwan,[4]Division of Hematology, Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan

Vitiligo, a prevalent disorder characterized by pigment loss, often undergoes various non-invasive treatments, including local immunosuppression and ultraviolet light irradiation. Recently, the transplantation of cultured autologous melanocytes as a cell suspension has emerged as a promising therapeutic option. This study focused on obtaining residual skin specimens of approximately 1 to 2 cm^2 post-surgery, which were subsequently dissociated into single cells and cultured in different Melanocyte Culture Mediums to selectively expand melanocytes. The research revealed significant differences in melanocyte growth across various media, including variations in morphology, growth rate, melanocyte markers, and melanin production. Additionally, the study investigated the expression differences of TYR, TRP1, c-kit, and other markers in different passages of melanocytes under each culture medium. Moreover, this study sheds light on the potential for enhancing melanocyte engraftment effects through careful consideration of culture conditions. The observed variations in melanocyte behavior and repigmentation outcomes emphasize the critical importance of selecting an optimal culture medium for the expansion of melanocytes before transplantation. These findings provide valuable insights into refining protocols for clinical melanocyte transplantation, offering a promising avenue for improving the efficacy of pigmentation treatments. In conclusion, our study establishes a foundation for future research aimed at advancing the field of melanocyte transplantation and optimizing treatment outcomes for patients with vitiligo. By unraveling the complexities of melanocyte behavior in different culture conditions, this research paves the way for more targeted and effective vitiligo treatments, ultimately enhancing the quality of life for affected individuals.

1342. Generation of Universal Stem Cells

Masakazu Hamada[1], Wenhan Yu[1], Crystal Bottenfield[1], Gargi Roy[1], Su Mi Choi[1], Lijuan Du[1], Christina Schindler[1], Christine M. Kiefer[1], Susan D. Wilson[1], Stephen Ireland[1], Ryan Hicks[2], Natalie J. Tigue[3], Michael R. Doran[1], Yasuhiro Ikeda[1]

[1]AstraZeneca, Gaithersburg, MD,[2]AstraZeneca, Gaithersburg, Sweden,[3]Astrazeneca, Cambridge, United Kingdom

Preventing allograft rejection is a major design objective when developing off-the-shelf cell therapy products. Universal stem cells (USCs), or pluripotent stem cells with gene edits that render them hypoimmunogenic, are ideal precursors from which to manufacture allogeneic off-the-shelf cell therapies. Hypoimmunogenic off-the-shelf products will enable therapies to reach more patients faster, by contributing to process standardization that will improve product consistency and reduce manufacturing costs. Herein we describe the engineering of human USC clonal line with an integrated kill switch, and its characterization. We employed two rounds of simultaneous gene knock-out/knock-in to interrupt B2M and RFXAP expression and overexpress HLA-E, CD47 and a simeprevir-inducible Caspase 9-based kill switch. The USC maintained a normal karyotype, stably expressed pluripotency markers, HLA-E, CD47 and the kill switch, and differentiated into three germ layers as well as beating cardiomyocytes or hepatocytes. The USC was resistant to both allo-reactive T and NK cell killing *in vitro*, and kill switch function was validated in undifferentiated USCs, cardiomyocytes and *in vivo*. Our protocol provides a template for the engineering of USCs suitable for the manufacture of off-the-shelf cell therapy products, including an integrated kill switch.

1343. Primary Lung Exosomes Specifically Interact with Hematopoietic Stem Cells and Enhance Long Term *In Vivo* Engraftment Potential

Sanam Rezaei Benam[1], Samaneh Maleknia[1], Wang Xuepeng[2], Reuben Kapur[2,3], Reza Shahbazi[1,3,4]

[1]Hematology/Oncology Division, Department of Medicine, Indiana University School of Medicine, Indianapolis, IN,[2]Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN,[3]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN,[4]Brown Center for Immunotherapy, Indiana University School of Medicine, Indianapolis, IN

Hematopoietic stem and progenitor cells (HSPCs) are a critical population of cells responsible for maintaining the hematopoietic system throughout life. Despite their importance, the regulatory mechanisms controlling HSPC fate decisions, including self-renewal, proliferation, and differentiation, are not fully understood. Recently, exosomes, small membrane-bound vesicles secreted by cells, have emerged as important mediators of intercellular communication in various physiological and pathological processes [1]. Exosomes have been shown to regulate target cell function through the transfer of proteins, microRNAs, and other molecules. Our investigation into the communication between exosomes and HSPCs has yielded promising results, particularly in the context of LT-HSCs. LT-HSCs are a rare subpopulation of HSPCs that play a crucial role in maintaining the blood system over an individual's lifetime due to their unique capacity for self-renewal and differentiation, which is essential for the continuous production of all blood cells. The complex array of molecular mechanisms that govern LT-HSC maintenance, proliferation, and differentiation includes several molecular pathways such as the Wnt, Notch, JAK/STAT, PI3K/Akt, and BMP signaling pathways. Our study demonstrates that exosomes derived from healthy human primary lung (P. Lung) cells can directly interact with LT-HSCs, leading to an enhanced colony-forming potential and increased numbers of LT-HSCs. Flow cytometry analysis has confirmed that up to 80% of the exosome-positive populations exist within the LT-HSC population, compared to a lower interaction rate (5-10%) with MPP or CMP/GMP/MEP populations. Proteomics and miRNA sequencing were performed to identify potential molecules within the exosomes that play a key role in enhancing the stemness potential of HSPCs. Our in vivo data on NSG mice demonstrates that ex vivo treatment

of CD34+ HSPCs with P. Lung exosomes significantly enhances engraftment potential over a 28-week period. Analysis of different lineages reveals improved T cell, B cell, and myeloid cell development in mice engrafted with P. Lung exosome-treated HSPCs compared to untreated mock samples. To further validate these results, secondary transplantation was performed by retrieving cells from the mice bone marrow samples. The secondary transplantation results also confirm the high engraftment potential of P. Lung exosome-treated HSPCs, both in peripheral blood and bone marrow. In summary, our data reveal, for the first time in the literature, that P. Lung cells engage in cross-talk with HSPCs, demonstrating the significant impact of P. Lung exosomes on the modulation of stem cell behavior and engraftment potential.

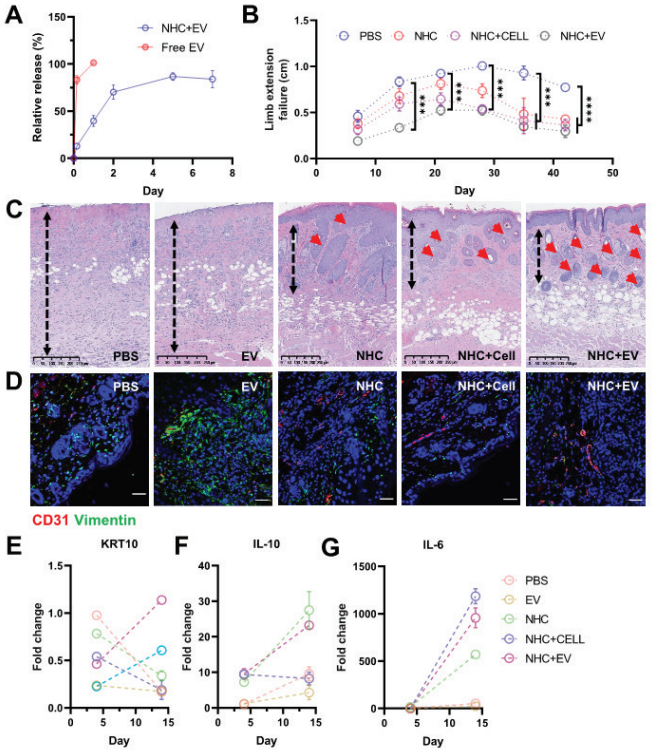
1344. Scalable Human IPSC-to-3D Bioprinting Pipeline: Successful Large-Scale Production Using Automated Bioreactor Systems

Rukmini Ladi[1], Debbie Ho[2], Stacey Lee[2], Jianyi Du[2], Jonathan Weiss[2], Tony Tam[2], Soham SInha[2], Danielle Klinger[3], Sean Devine[1], Art Hamfeldt[1], Hope Leng[2], Jessica Herrmann[2], Mengdi He[2], Lee Fradkin[2], Tze Kai Tan[2], David Standish[1], Peter Tomasello[1], Donald Traul[1], Noushin Dianat[4], Quentin Vicard[4], Kishore Katikireddy[1], Mark Skylar-Scott[2]

[1]Sartorius Stedim North America Inc, Bohemia, NY,[2]Stanford University, Stanford, CA, USA, Stanford, CA,[3]Sartorius Stedim North America Inc, Stanford, CA,[4]Sartorius Stedim France S.A.S, Aubagne, France

Human induced pluripotent stem cells (iPSCs) are pivotal in advancing tissue engineering, particularly for transplantation therapy and disease modeling. A sustainable approach to organ-scale tissue engineering demands the production of billions of human cells for bioprinting, especially wholly cellular bioinks. However, scalability challenges in conventional 2D cell culture methods, such as cost, space, and handling constraints, present significant hurdles. To address these issues, we optimized and developed a robust, scalable pipeline to produce iPSC aggregates (hAs) using an automated stirred-tank bioreactor system for bioprinting applications. Through a combination of Design of Experiments approach (MODDE® software) and multivariate data analysis, we identified an optimal culture condition from a dataset of 15 conditions with varied impeller speeds, seeding density, and use of polyvinyl alcohol. At the 250mL scale, we achieved a 23-fold cell expansion in 5 days, yielding 1 billion hiPSC hAs with optimal sizes and diameters. In terms of aggregate morphology, over 72% of hAs derived from SCVI-15, a versatile human iPSC line, and 90% of those from WTC-11, known for its genomic stability, had diameters ≤ 300 μm with an overall circularity of ≥ 0.73. Furthermore, pluripotency marker expression was maintained above 90% across three serial passages in SCVI-15 and WTC-11 cell lines. When scaled to a 1L stirred-tank bioreactor, the optimized parameters from the smaller scale remained effective. This successful scale-up to a 1L stirred-tank bioreactor resulted in ~20.4-fold cell expansion by day 4, yielding about 4 billion hiPSC hAs per vessel with >94% expression of pluripotency markers, while maintaining similar high cell density, viability, and circularity for both SCVI-15 and WTC-11 hiPSC cell lines. These pluripotent aggregates were subsequently differentiated into derivatives of the three germ layers, including cardiac, vascular, cortical, and intestinal organoids. The aggregates were successfully compacted into wholly cellular bioinks for rheological analysis and 3D bioprinting. The 3D bioprinted tissues exhibited high post-printing viability and the potential for vascular and neuronal differentiation, highlighting a promising pathway for billion cell-scale organ engineering. Our next objective is to further expand this process by implementing a 10L scale bioreactor system to enhance cell yield and process efficiency.



1345. Extracellular Vesicle-Incorporated Biostimulatory Matrix Prevents Radiation Dermatitis

Jiayuan Kong, Hexiang Feng, Kailei Ding, Kedar Krishnan, Sashank Reddy, Hai-Quan Mao

Johns Hopkins University, Baltimore, MD

State of Purpose: Radiotherapies have been a successful oncological treatment and widely conducted in clinical settings. However, around 95% of patients develop side effects associated with soft tissue damage after radiotherapy. These reactions often advance to chronic radiation dermatitis (RD).[1] Currently, there are no effective therapies to prevent or treat RD. There is an urgent need for standardized therapy. Here, we propose a nanofiber-hydrogel composite (NHC) matrix carrying adipose-derived stem cells (ADSCs) or ADSC-derived extracellular vesicles (EVs) to prevent the detrimental, chronic radiation-induced RD. We assessed the degrees of limb extension, hair loss, skin histology, fibroblast deposition, and inflammation-related gene expressions to evaluate the preventive outcomes. **Method**: The NHC matrix was generated according to our previous reports.[3] To assess the efficiency of preventing radiation fibrosis, B6 mice were treated with 30 Gy radiation to the left limb, and injected with NHC, EVs, NHC loaded with ADSCs, or NHC loaded with EVs, subcutaneously right after the radiation to mimic the prevention model of radiation fibrosis. Free EVs and PBS injection were used as controls. For NHC + EV group, the release of EVs was measured *in vitro* in PBS at 37°C. To evaluate the effect of fibrosis on tissue functions, limb extension was measured up to day 42. Skin histology was characterized by comparing the degree of inflammation and integrity of the skin. Fibroblast deposition was also investigated by immunostaining. Lastly, the expressions of three selected genes (KRT10, IL-10 and IL-6) were examined using qPCR. **Results**: Encapsulating EVs into NHC matrix extended EV retention from a few hours to around 5 days (**Fig. 1A**). For the *in vivo* study, a significant prevention of limb extension failure was observed in NHC groups starting on day 14. Moreover, NHC + EV group further enhanced preventive outcome (**Fig. 1B**). The H&E staining analysis suggests that compared to control groups, the NHC treatment with or ADSCs and EVs yielded lower dermal thickness, indicating reduced dermatitis responses. Moreover, NHC + EV showed robust hair follicle formation and preservation of native skin structure (**Fig. 1C**). The immunostaining for vimentin has similar trend as NHC groups showed lower numbers of fibroblasts from NHC containing groups (**Fig. 1D**). The qPCR assay showed that NHC + EV group had an increase of KRT10 and IL-10, indicating the regenerative responses at gene expression level (**Fig. 1E**, **F**). However, the IL-6 level was dramatically elevated in all NHC containing groups, especially in NHC + EV group

(~1000 fold; **Fig. 1G**). **Conclusion:** The ADSC- or EV-loaded NHC matrix allows for off-the-shelf therapy for radiation dermatitis. The stimulatory NHC matrix alone can reverse the detrimental effects of fibrosis, while the addition of ADSCs and EVs enhances the therapeutic effects. **References** 1. Berry, Charlotte E., et al. **Adv. Wound Care**, (2022). 2. Yao, Zhi-Cheng, et al. **Small**, 18.36 (2022): 2202309.

1346. FAST-STEM A Human Pluripotent Stem Cell Landing Pad System for Rapid Design-Build-Test-Learn Development of Human Cell Based Therapeutic Devices

Michael Garton

University of Toronto, Toronto, ON, Canada

Very recent clinical advances in stem cell derived tissue replacement have placed the possibility of human cell-based therapeutic devices firmly within reach. However, development of such devices has proven highly challenging, due to the need for generating stable cell lines for each design-build-test-learn engineering cycle. Current approaches to generating stable hiPSC lines are highly time-consuming and suffer from lack of control, poor integration efficiency, and limited functionality. Validation in clinically relevant stem cell derived tissues is also broadly lacking. We have developed an hiPSC landing pad platform called FAST-STEM (***F**acile **A**ccelerated **S**tem-cell **T**ransgene integration with **S**ynBio **T**unable **E**ngineering **M**odes*) that reduces the engineering time to 'differentiation ready' stem cell lines from several weeks to 6 days. Additional FAST-STEM innovations include: (i) rapid and highly efficient transgene integration; (ii) copy number control; (iii) simultaneous or consecutive integration of multiple gene cassettes; (iv) automatic landing pad reconstitution allowing unlimited consecutive transgene loading and (v) combinatorial library screen capability. In addition to this unique functional versatility, platform transportability and broad use case capability was confirmed by differentiation into eight different tissue types across nine different laboratories. This platform dramatically lowers the bar for integration of synthetic biology with regenerative medicine and paves the way for sophisticated human cell device development.

1347. Molecular Optimization of Transcription Factors and Vectors for High-Efficiency Generation of *In Vivo* Engraftable Motor Neurons

Nathan Wang, Katie Galloway

Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA

Replacement of damaged or diseased tissues and organs represents a major goal of cellular reprogramming. Potentially, autologous cell grafts generated from accessible cell donor populations may be used to regenerate and renew tissues and their function. However, low rates of direct conversion have limited the potential of reprogrammed cells for applications within the central nervous system (CNS) applications. While insight into the reprogramming process may guide new tools for reprogramming, the sparse and stochastic nature of reprogramming has obscured our understanding of how transcription factors drive cells to new identities. To address this challenge, we capitalized on our recently developed chemo-genetic cocktail that increases direct conversion to diverse neurons. Importantly, we first sought to reduce sources of extrinsic variation to resolve how individual transcription factors influence reprogramming outcomes. To this end, we tailored the transcription factor cocktail and minimized the number of viruses. In striking contrast to the prevalent assumption that optimal neuronal cocktails should drive early cell-cycle exit, our cocktail increases conversion to a post-mitotic identity and neuronal maturity by increasing the population of cells that undergo a period of rapid proliferation. By increasing the number of reprogramming events and titrating expression, we were able to identify transcription factor-specific correlations between expression and reprogramming events. Using these insights, we designed improved reprogramming cocktails for direct conversion of adult human fibroblasts to motor neurons and developed minimal vector systems that generate motor neuron grafts that can integrate with the murine central nervous system. With our two-vector system, we can generate induced motor neurons at scale (tens of millions of iMNs). Additionally, we achieve neurotrophic factor-free motor neuron reprogramming and show that our reprogrammed motor neurons survive in vivo grafting. As the in vivo environment may provide varying or limited neurotrophic support, our work highlights that cells can reprogram in the absence of neurotrophic support. Moreover, reprogrammed cells can be grafted following focal injury as needed for the replacement of damaged tissue, opening future studies for in vivo reprogramming and cellular therapies.

1348. Efficient and Reliable Measles Reprogramming Platform for the Generation of iPSC

Sarrianna Hoffer[1], Saksham Vashistha[1], Jessica Dade[1], Carter Caya[1], Brenna Sharp[1], Spencer Majerus[1], Qi Wang[1], Patricia Devaux[1,2]

[1]Department of Molecular Medicine, Mayo Clinic, Rochester, MN,[2]Mayo Graduate School, Rochester, MN

Previous studies from our lab have established the Measles virus (MeV) vector as an efficient and safe method for reprogramming somatic cells into induced pluripotent stem cells (iPSC). However, the efficiency was limited to 0.2%. Here, we present the next generation of the MeV reprogramming vector. The MV(O)(SK)(M) previously established by Rallabandi et al. was modified by substituting the P gene of the wild strain, MVPwt(O)(SK)(M). After validation of the four reprogramming factors OCT4, SOX2, KLF4, and c-MYC expression, and the propagation of the MVPwt(O)(SK)(M) vector, the reprogramming ability was analyzed in 6 adult human fibroblasts (AHF). Reprogramming was achieved at low multiplicity of transduction in 5 out of the 6 AHFs with average efficiency between 1.25-2.25%. Only one AHF was reprogrammed with a low efficiency (0.23%). At day 25 post-transduction, we isolated iPSC clones from each reprogramming. Following iPSC amplification, immunostaining was performed to confirm the induction of endogenous pluripotency-associated markers, SSEA-4, TRA-1-81, TRA-1-60, and NANOG. The iPSC pluripotency propensity was further confirmed by spontaneous and guided differentiation into three germ layers using immunostaining and confocal analysis. The rapid elimination of the vector from the iPSC at or before passage 5 was confirmed using qRT-PCR. Finally, we show the ability of the MeV-derived iPSC to differentiate into hematopoietic stem cells, pancreatic progenitor cells, neuronal progenitor cells, and terminal neurons. In conclusion, our study shows that the latest generation of MeV reprogramming vector is highly efficient and reproducibly reprograms adult human fibroblasts into iPSCs. Compared to other non-integrating reprogramming technologies, such as the Sendai system, MeV has a comparable to higher efficiency using a single vector, a lower multiplicity of transduction, and exhibits a faster vector elimination from iPSCs.

1349. High Throughput Multiomic Single Cell RNA Sequencing Revealing the Exosomal Communication with Long Term Hematopoietic Stem Cells

Samaneh Maleknia[1], Sanam Rezaei Benam[2], Xuepeng Wang[3], Reuben Kapur[3,4], Reza Shahbazi[1,4,5]

[1]Hematology/Oncology, Department of Medicine, Indiana University School of Medicine, Indianapolis, IN,[2]Hematology/Ocology, Department of Medicine, Indiana University School of Medicine, Indianapolis, IN,[3]Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN,[4]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN,[5]Brown Center for Immunotherapy, Indiana University School of Medicine, Indianapolis, IN

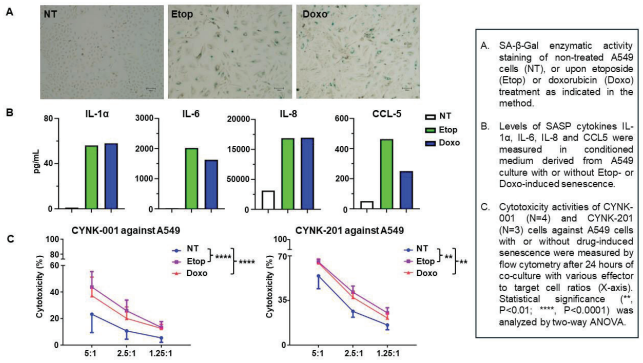
Hematopoietic Stem and Progenitor Cells (HSPCs) form a critical population in the human body responsible for the continuous replenishment of blood and immune cells. These multipotent cells reside in the bone marrow and have the remarkable ability to undergo self-renewal and differentiation, giving rise to a diverse array of blood cell lineages, including red blood cells, white blood cells, and platelets. HSPCs play a pivotal role in maintaining hematopoietic homeostasis throughout an individual's lifetime, ensuring the body's capacity to respond to various physiological demands and immune challenges. The intricate regulation of HSPC fate decisions, such as proliferation, self-renewal, and differentiation, involves a complex interplay of molecular pathways and signaling networks. Within the broader spectrum of HSPCs, Long-Term Hematopoietic Stem Cells (LT-HSCs) represent a rare subpopulation distinguished by their exceptional capacity for both self-renewal and differentiation [1]. LT-HSCs play a pivotal role in maintaining hematopoietic homeostasis over an individual's lifetime. The intricate regulation of LT-HSC behavior involves a complex network of molecular pathways, including Wnt, Notch, JAK/STAT, PI3K/Akt, and BMP signaling. Recently, we discovered distinctive populations of extracellular vesicles from the human primary lung (P. Lung) cells that significantly contribute to the homeostasis of LT-HSCs. Exosomes are small, membrane-bound extracellular vesicles secreted by cells, playing a pivotal role in intercellular communication. These nanosized structures carry a cargo of proteins, lipids, and nucleic acids, including microRNAs, reflecting the composition of their parent cells. We performed high throughput multiomics single-cell RNA sequencing to understand the potential effects of exosomal communication of P.Lung exosomes with both bone marrow-derived, and G-CSF mobilized peripheral blood HSPCs. We incubated P.Lung exosomes with CD34+ HSPCs for 48 h and performed CITEseq analysis using a full panel of antibodies defining the HSPC populations (CD34, CD38, CD90, CD45RA, CD49f). Our data show a significantly increased cell number and more defined LT-HSC cell type in P. Lung exosome-treated cells in comparison to untreated mock cells. We identified the upregulation of Krueppel-like factor 9 (KLF9) in LT-HSCs. KLF9 plays a key role in the TNF-alpha signaling pathway via NF-kB. This pathway is important in LT-HSC self-renewal, regulation of hematopoiesis, and maintenance of LT-HSCs. It is also important in keeping the balance between self-renewal and differentiation. Likewise, we identified significant upregulation of Nucleoporin 50 (NUP50) compared to the untreated mock sample. NUP50 is responsible for the regulation of the G2-M Checkpoint pathway which is critical in preventing uncontrolled proliferation or premature differentiation. At the same time, it contributes to the overall maintenance of the LT-HSC pool by ensuring the fidelity of the cell division process. In conclusion, we have identified multiple regulatory genes through our single-cell analysis of the exosomal communication with LT-HSCs. This is the first report revealing the intricate molecular pathways regulated by exosomes from human lung cells contributing to LT-HSC self-renewal and maintenance. **References** 1. Notta, F., et al. Science, 2016.

1350. Atelocollagen Supports Three Dimensional Culture of Human Induced Pluripotent Stem Cells

Yoshiki Nakashima, Masayoshi Tsukahara

Research and Development Center, CiRA Foundation, Kyoto, Japan

Currently, the standard approach for production of human induced pluripotent stem cells (hiPSCs) for clinical purposes is through use



of two-dimensional (2D) cultures, i.e. cultures in which the cells are attached to a substrate coated with scaffold material. Although this approach provides viable hiPSCs, the method does have some limitations as it does not lend itself to upscaling for mechanized cell production using culture dishes or for automated culture processes for industrialized mass production of clinical iPSCs. As autologous iPSC therapy requires a custom-made small-lot cell production line, the cell production method differs significantly from the existing processes for producing allogeneic iPSC stocks for clinical use. Specifically, mass culture to produce stock is no longer necessary; instead, a series of operations from iPSC production to induction of differentiation of therapeutic cells must be performed continuously. A 3D culture method using small, closed-cell manufacturing devices is suitable for autologous iPSC therapy. Use of such devices avoids the need to handle many patient-derived specimens in a single clean room; handling of cell cultures in an open system in a cell processing facility increases the risk of infection. We have screened a number of candidate materials for 3D culture of hiPSCs. One of the most promising of these is atelocollagen, a low-immunogenic derivative of type I collagen obtained by removing the N- and C-terminal telopeptide components. Atelocollagen has an atomic mass of 300 kDa and has a rod-like structure with a length of 300 nm and a diameter of 1.5 nm. It has been clinically applied in various settings, such as wound healing, as a bone cartilage substitute, and as a hemostatic agent. In the present report, we describe the characteristics and quality of hiPSCs cultured on atelocollagen. We also investigated the mechanism underlying their adhesion ability. In order to reduce the risk of rejection during cell therapy transplants, the ultimate goal is to generate iPSCs from the patient's own cells as this will enable the production of self-compatible differentiated cells that can be transplanted into the patient. Here, we sought to establish a cell manufacturing process using autologous iPSCs and focused on 3D cultures as these have the desirable characteristic of supporting automated culture. This information has enabled us to propose a potential cell manufacturing process using atelocollagen. In this study, atelocollagen beads were evaluated as a three-dimensional biomaterial to assist 3D culture in the establishment, expansion culture, and induced differentiation of iPSCs. It was found that iPSCs can be handled in a closed-cell device with the same ease as use of 2D culture when Laminin-511 is added to the medium. In conclusion, atelocollagen beads enable 3D culture of iPSCs, and the quality of the obtained cells is at the same level as those derived from 2D culture.

1351. Human Placental Hematopoietic Stem Cell Derived Natural Killer Cells Preferentially Eliminate Senescent Cells Derived from a Tumor Model

Li Li[1], Irene Raitman[2], Valentina Rousseva[2], Lin Kang[2], Adrian Kilcoyne[2], Robert Hariri[2], Yuechao Zhao[2]

[1]Celularity Inc, Florham Park, NJ,[2]Celularity Inc., Florham Park, NJ

Although natural killer (NK) cells play central roles in controlling senescent cells, whether they can be effectively eliminated by NK cell therapies remains unexplored. Celularity is developing human placental CD34+-derived, cryopreserved, off-the-shelf, allogeneic NK cell products non-modified (CYNK-001), or genetically modified to optimize persistence and efficacy (CYNK-201) for the treatment of tumors and age-related diseases. Here we report the cytotoxicity results of both CYNK-001 and CYNK-201 against senescent cells derived from a tumor model. CYNK-001 cells were generated from human placental CD34+ cells in the presence of cytokines. CYNK-201 cells were generated similarly but transduced with a lentivirus vector expressing soluble IL-15 and a high IgG binding affinity and protease cleavage resistant CD16 variant. For both NK cell products, the phenotype and transgene expression were validated. Senescence was induced in the non-small-cell lung carcinoma tumor cell line A549 with chemotherapy drugs etoposide or doxorubicin followed by a 6-day recovery period. Senescence was confirmed by β-galactosidase (SA-β-Gal) activity or protein expression, monitoring the secretion of senescence associated secretory phenotype (SASP) cytokines, and analyzing the expression of cell surface stress ligands in the treated and non-treated A549 tumor cells by flow cytometry. Cytotoxicity activity and inflammatory cytokine secretion of CYNK-001 and CYNK-201 against A549 cells with or without senescence induction was assessed by flow cytometry and multiplex Luminex analysis. CYNK-001 and CYNK-201 cells were generated from multiple placental CD34+ donors (n=4) with high CD56+/CD3- NK purity. CYNK-201 displayed IL-15 secretion and high ectopic expression of CD16. Both CYNK-001 and CYNK-201 showed robust expression of activation markers such as CD11a, CD226, NKp30 and NKG2D. By etoposide or doxorubicin treatment, A549 tumor cells not only presented the phenotypical β-Galactosidase enzymatic activity (Figure A) or protein expression, but also showed increased expression of stress ligands including CD58, MIC-A/B and ULBP-2/5/6, which are known to be recognized by NKG2D expressed on the NK cells. Chemo-treated A549 cells also had increased secretion of SASP cytokines IL-1α, IL-6, IL-8 and CCL-5 compared to non-treated A549 (Figure B). Functionally, both CYNK-001 and CYNK-201 cells demonstrated significantly enhanced cytotoxicity at 24h against A549 cells with chemo induced-senescence (Figure C). With CYNK-001, there was significantly increased cytolysis of etoposide or doxorubicin treated cells vs. cytolysis of control non-treated A549 cells. Similarly for CYNK-201, there was significantly increased killing of chemo-treated cells vs. non treated A549 cells. Consistently, significantly increased secretion of inflammatory cytokines GM-CSF, G-CSF, IFN-γ, and TNF-α was also observed following CYNK co-culture with chemo-induced senescent A549 cells compared to non-treated cells, further confirming the preferential senolysis. Our preclinical data indicates that CYNK cells could serve as potent and selective senolytic agent for age-related diseases and also following conventional cancer treatment, CYNK may improve overall therapeutic outcomes and delay disease recurrence. Further investigation of CYNK cells in this regard, including in vivo tests using animal models and clinical studies, is ongoing.

1352. Using Microtissues to Study Bone Marrow Stromal Cell Chondrogenesis

Michael Robert Doran[1], Kathryn Futrega[2]

[1]AstraZeneca, Gaithersburg, MD,[2]National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD

Arthritis is a serious health crisis, with approximately 20% of the US adult population suffering from some form of the disease. Strategies to extend cartilage function, and/or regenerate damaged cartilage, are needed to increase productivity and extend healthy lifespans. Bone marrow stromal cells (BMSC) have been touted as an ideal cell source from which to regenerate cartilage. However, despite BMSC chondrogenesis being first described over 25 years ago, generating functional chondrocytes from BMSC is not yet possible, and no BMSC-mediated cartilage repair therapies have been approved. BMSC chondrogenesis is typically studied in large diameter pellet or tissue models; such models suffer steep diffusion gradients, yielding radially heterogeneous cell and tissue output. We reason that this heterogeneous tissue readout obfuscates the biological intricacies of BMSC chondrogenesis, and has contributed, in part, to delayed progress. By contrast, small diameter microtissues have reduced diffusion gradients, yielding a relatively homogeneous cell and tissue readout. Herein, we review our exploration of BMSC biology using microtissues, summarizing critical insights not visible in commonly used tissue models. In 2010, we described the adaptation of a microwell cell culture platform to generate hundreds of uniformly sized small diameter microtissues, in place of single large diameter pellets. Using microtissue cultures we identified that a 2% oxygen atmosphere yielded radially homogeneous high-quality cartilage-like tissue, while 20% oxygen inhibited chondrogenesis, and that large diameter pellets yielded radially heterogenous tissue regardless of culture conditions. As we incrementally improved BMSC chondrogenesis, displacement or loss of sticky cartilage microtissues from microwells became problematic over 14 to 21-day cultures. In response, we invented the Microwell-mesh; the Microwell-mesh has a nylon mesh bonded over an array of microwells. The pores in the mesh are large enough to allow single cells to be centrifuged through the mesh and pelleted in microwells, but small enough to retain cells once they self-assemble into microtissues. The Microwell-mesh enables extended culture with no loss or displacement of microtissues. Since 1998 it has been presumed that *in vitro* BMSC chondrogenesis required 2-3 weeks of TGF-β1 stimulation; in 2021 we reported that, in fact, BMSC chondrogenesis is triggered by a single day of TGF-β1 stimulation, and that subsequent differentiation is driven by intrinsic signaling cascades. Many presume that chondrogenesis and hypertrophy are sequential processes, but our data revealed that these differentiation processes are intertwined, and both are initiated in BMSC following a single day of TGF-β1 stimulation. *BMP2* and *SP7* signaling is upregulated within hours of TGF-β1 stimulation, likely contributing to hypertrophic differentiation. We attempted to obstruct BMP signaling with a small molecule, and used gene engineering to silence *SP7* signaling. Both strategies dampened hypertrophy, but also compromised chondrogenesis, again suggesting that these processes are intertwined. We subsequently compared chondrogenesis in response to TGF-β1, GDF-5 or BMP-2 stimulation. TGF-β1 is the most potent, and the only growth factor for which brief stimulation triggers intrinsic differentiation cascades that progress independent of further growth factor stimulation. In totality, this body of work provides insights into BMSC chondrogenesis not discernable in the common large dimension tissue models embraced by the field. The microtissue provides a high resolution, homogenous readout that aids in the optimization of complex bioprocesses, such as BMSC chondrogenesis.

1353. Engraftment of Engineered Plasma Cells into Humanized Mice Shows for the Feasibility of Engineered Plasma Cell Therapies

Tyler Hill[1], Rene Yu-Hong Cheng[2], Anna Helmers[2], Andee Ott[2], Leah Homad[3], Greg Asher[2], Parnal Narvekar[2], Andrew Mcguire[3], David J. Rawlings[4], Richard G. James[2]

[1]Seattle Children's Research Institute - Seattle, Washington, Seattle, WA,[2]Seattle Children's Research Institute, Seattle, WA,[3]Fred Hutch, Seattle, WA,[4]University of Washington, Seattle, WA

Advances in genome-engineering have enabled the generation of engineered plasma cells (ePCs) that secrete large quantities of therapeutic proteins. However, *in vivo* modeling of human ePCs has largely been limited to short-term studies following adoptive transfer of ePCs into immunodeficient mouse models including immuno-deficient NOD.Cg-*Prkdc*^{scid} *Il2rg*^{tm1Wjl}/SzJ (NSG) mice. In this study, we tested the hypothesis that immunodeficient mice humanized by engraftment of syngeneic human CD34^{+} hematopoietic peripheral stem cells would better mimic the pharmacodynamics of human ePCs. ePCs engrafted more efficiently and in additional lymphoid compartments in mice engrafted with syngeneic CD34 cells (NSG-huCD34) than in control mice without. ePCs migrated to and localized long-term in the bone marrow and spleen while maintaining a mature plasma cell phenotype. Plasma cells engineered to express an anti-EBV antibody produced robust anti-EBV titers that lasted for at least 3 months. We used surface display to identify highly expressed antibody sequences, and found that SARS-CoV2-RBD297 was more highly expressed in B cells than AMMO1. Finally, we showed that humanized mice engrafted with ePCs expressing SARS-CoV2-RBD297 were capable of neutralizing SARS-CoV2 pseudovirus. Taken together, these data demonstrate that the presence of autologous human hematopoietic cells in NSG-huCD34 mice permit the establishment of a robust model for studying the in vivo biology of long-lived human ePCs.

1354. Identifying Metabolite Markers for Detection of Flaviviruses in Human Induced Pluripotent Stem Cells (hiPSCs)

Tahira Fatima[1], Aaron Scholl[2], Sandip De[2]

[1]FDA, Tumor Vaccine & Biotechnology Branch, Division of Cellular Therapy 2, Office of Cell Therapy and Human Tissues, Office of Therapeutic Products, Silver Spring, MD,[2]Tumor Vaccine & Biotechnology Branch, Division of Cellular Therapy 2, Office of Cell Therapy and Human Tissues, Office of Therapeutic Products, Silver Spring, MD

Introduction: Human cells, tissues and cellular and tissue-based products (HCT/Ps) are being evaluated for use as therapeutic agents. HCT/Ps are required to comply with the donor eligibility requirements as per 21CFR 1271. HCT/P donor testing and screening includes screening for Zika and testing and screening for West Nile viruses. Moreover, rising global temperatures and expanding insect vector populations have led to a surge in vector-borne diseases, including flaviviruses. So, a rapid, sensitive, and precise pan-flaviviral detection tool is imperative for testing donor cells and tissues. Objectives: 1. Compare the sensitivity, speed and specificity of metabolomics to the NATs and immunogenic detection assays. 2. Develop metabolite markers for detecting flaviviruses in hiPSCs. Methods: hiPSCs were infected with Dengue virus (DENV) - DENV3 and Zika virus (ZIKV)-MR766 strains. We assessed impact of viral infections on hiPSCs by examining cell viability, cytopathic effect (CPE), and viral load using immunofluorescence assay (IFA) and qRT-PCR. For metabolite extraction standardization, we analyzed 0.2, 0.8, 2, and 8 million control and infected cells using untargeted FIA-MS. Ions were annotated by matching their inferred mass with compounds in the Human Metabolome Database. We performed LC-MS of hiPSCs infected with both viruses at 0, 8, 24, 48 and 96 hpi to identify virus specific shift in metabolome and to confirm FIA-MS data. Raw data was normalized to the caffeine standard, and "differential metabolites" analysis was done using ANOVA. Results: We did not observe significant differences in cell viability and CPE in hiPSCs infected with DENV3 & ZIKV vs control. However, IFA and qRT-PCR results indicated higher virulence of ZIKV compared to DENV3. FIA-MS detected same number of annotated compounds in all tested samples concluding that 0.2 million cells are sufficient for extracting maximum number of metabolites. Downstream analysis of the FIA-MS data identified 5 differentially expressed compounds in infected samples at 24 hpi. LC-MS resulted in identification of 271 annotated metabolites including several unique metabolites in the mock, DENV and ZIKV infected samples. In addition, 15 metabolites were differentially expressed (fold change ≥2) upon either DENV or ZIKV infection. Further data analysis is under progress. Conclusions: We demonstrated that 'Metabolomics' is a reproducible, and sensitive method for detecting flaviviruses in infected cells. Our subsequent objective is to validate the 'specificity' of the identified metabolites for flaviviruses detection.

Thursday Posters: Vector Product Engineering, Development, and Manufacturing

1355. Revolutionizing mRNA Production: the Paradigm-Breaking Nfinty™ Continuous RNA system

Patrick Thiaville[1], José Castillo[2], Emilie Gateau[1]

[1]Exothera, Jumet, Belgium,[2]Univercells, Brussels, Belgium

The field of RNA manufacturing has witnessed significant progress in recent years, fueled by advancements in synthetic biology, enzymology, and process engineering. Our thorough technology and process development led to the deployment of the first available high-performance continuous RNA manufacturing system. Our predefined and standardized process does not require scale-up or process development and combined with our robotic equipment produces high quality RNA drug-substance (DS) compatible with therapeutics and vaccines. We performed > 250 IVT reactions using more than 45 different DNA constructs varying in length from 900 bases to > 4kb. The data demonstrates the process efficiency scales going from single milligram to multi-gram batches of mRNA. The process produced mRNA with > 85% integrity, > 90% capping efficiency, > 90% poly-A tail length. Also, the process produces very low impurities with < 130 ng/mg of dsRNA and < 1.2 ng/mg residual DNA while maintaining > 80 % product recovery. Finally, we will show how our production process enabled the implementation of a decentralized manufacturing sites to quickly produce mRNA for cell and gene therapies or vaccines at or near point of use. As a conclusion, by using this groundbreaking technology, pre-clinical or clinical development is already at the final scale, which accelerates process and product development and significantly speeds up the access of RNA therapies to patients.

1356. Rapid Optimisations for Cell and Gene Therapy Applications

Thomas M. Evans, Charles Moore-Kelly, Anurag G. Kulkarni, John O'Driscoll, Kyriacos A. Mitrophanous, Nicholas G. Clarkson, Andre Raposo

Oxford Biomedica (UK) Limited, Oxford, United Kingdom

The process of lentiviral vector production is complex and presents unique challenges. Optimal production is heavily dependent on the concentration and ratios of the plasmid DNA components contributing to the transfection process. Improving titres can determine whether a new gene therapy product is commercially viable. A considerable amount of research is aimed at establishing the best titre and one of the ways to do this is by ensuring optimal transfection ratios that can improve the productivity or recovery of upstream/downstream platform processes, respectively. This means that a multifactorial design approach is often required to address the biological complexity of the system and achieve optimised vector particle production. We have developed and optimised a cutting-edge digital and physical platform coupled with automated liquid handlers enabling: 1) Automated Design of Experiments (DoE) and multivariate systems optimisation; 2) High-throughput screening, including small molecules, siRNA, shRNA; 3) Machine Learning and Deep Learning Data Analysis; 4)

Robustness and Ruggedness Testing to Support Analytical Quality by Design (AQbD) Methods. Our platform routinely screens and models 5 to10 factors. We have proven capacity for modelling 100+ factors with execution of thousands of experimental runs in a single iteration. The new platform, High-throughput Optimisation Services (HtOS), has significantly reduced manual operator time, increased throughput while meeting high demand and with improvements in precision and robustness. We will describe the capabilities and present a Case Study where the new platform was used to successfully optimise the transient transfection plasmid ratios in upstream production of lentiviral vector.

1357. PKC Agonists as Small Molecule Inducing Agents for Enhancing Lentiviral Vector Production

Charles Moore-Kelly, Thomas M. Evans, Jordan Wright, Daniel C. Farley, Kyriacos A. Mitrophanous, Nicholas G. Clarkson, Andre Raposo

Oxford Biomedica (UK) Limited, Oxford, United Kingdom

Achieving high upstream lentiviral vector (LV) titres is fundamental to the development and manufacture of a commercially viable gene therapy product. Product titres can vary considerably with different therapeutic transgene sequences despite being produced in the same mammalian cell system. Implementing new technologies able to recover low titres or improve high titres further is invaluable. Induction is a key stage of the upstream LV production process that typically involves increasing the expression of LV genes in production cells with the histone deacetylase inhibitor, sodium butyrate. A series of recent screening experiments revealed that titres of LV products can be further increased by using an additional class of molecules known as PKC agonists alongside the induction step. Here, we describe how, through optimisation of dosing concentration and timing, LV titres can be enhanced 2- to 9-fold with PKC agonists prostratin and ingenol 3-angelate in a product-specific manner. Importantly, LV produced using PKC agonists have comparable or superior particle-to-infectivity ratios, and these PKC agonists are removed from the vector product following downstream processing. Furthermore, we demonstrate that PKC agonists act synergistically with an in-house technology based on LV RNA-targeted U1 snRNA to recover log-fold-increases in titre without detriment to product quality attributes particularly for large, multiple or complicated expression cassettes. Having established the benefits of introducing PKC agonists to our platform process and in our packaging/producer cell lines, we provide insight into the mechanisms by which these agonists are acting on production cells and their transfer to GMP production.

1358. Leveraging Automation in Analytical Analysis of Viral Vectors

Gareth McCathie, Gareth Price, Samuel Stockdale, Thomas M. Evans, Benni Juckes, John O'Driscoll, Kyriacos A. Mitrophanous, Nicholas G. Clarkson, Andre Raposo

Oxford Biomedica (UK) Limited, Oxford, United Kingdom

The commercial scale manufacture of lentiviral vectors (LV) presents unique problems in QC release testing. Many of the methods employed require days or weeks to complete often with multistep cell culture combined with quantitative analytical readouts. Lengthy protocols, operator-to-operator variability, and a heavy dependence on manual setup are common shortfalls. To successfully meet these challenges, further gains in throughput by enhancing processes and automating analytics are needed. Oxford Biomedica are at the forefront of developing technologies to address these issues. The Computer Aided Biology (CAB) Group design, implement and optimise lab-based robotics and digital tools to enable bench-scientists to work more efficiently, generate more robust data and reduce time-to-insight. We have leveraged automation to increase assay throughput, robustness, repeatability, reduce operator hands-on-time, and perform Design of Experiments (DoE) to identify optima at a speed that would be impossible using manual methods. Our automated systems were first introduced in Research laboratories and later in GMP-regulated environments, further increasing the return on investment. We will describe the evolution of our automated qPCR workflows as a case study - from initial concept, validation, continuous improvements, and lessons learnt. At the first stage, automated liquid handler methods were developed for the most heavily used qPCR standard operating procedures (SOPs) to allow batching of large numbers of samples into multiple assay plates in one run. At the second stage, we developed a single Universal qPCR method with expanded functionality to allow extensive adaptations to assay setup and combine multiple, completely independent assays in one run. This was achieved via the use of the familiar Excel front-end to translate user input into machine-readable instructions. These dynamic Worklists enable a single validated method to adapt to any qPCR assay parameters, thus expediting validation and minimising the burden of SOP updates and new method qualifications. Continuous improvements in assay robustness and error-handling (e.g. automated, traceable recovery of aborted assays) have further reduced QC paperwork and repeated experiments. At a time when lab automation devices and digital tools are rapidly becoming more varied and accessible than ever before we hope that presenting some of the issues that we have faced and the solutions that we have implemented will aid other teams looking to introduce automation in their own labs in the future.

1359. Tuned Silencing of HLA-I Expression in Allogeneic CAR T-Cells Strikes a Balance Between Immune Rejection by CD8 T-Cells and NK Cells

Marco Alessandrini, Antonija Šakić, Bénédicte Ponsard, Marine Mansuy, Vincent Blancheteau, Inès Lanz, Antoine Marteyn, Yasmine Genolet, Bryan Bourrat, Amelie Turc, Ophelie Cherpin, Sten Ilmjärv, Audrey Roussel-Gervais

Antion Biosciences, Geneva, Switzerland

Allogeneic chimeric antigen receptor (CAR) T-cell therapy offers a promising solution to overcome key challenges of autologous CAR T-cells, including high manufacturing costs and limited widespread adoption. Allogeneic CAR T-cells have the absolute need for removal of T-cell receptor (TCR) expression to mitigate the risk of graft vs host disease (GvHD). To enhance cellular persistence, knockout of HLA-I in CAR T-cells very efficiently allows bypassing of rejection by host CD8 T-cells; yet it provokes rejection by natural killer (NK) cells. To

overcome this, NK cell inhibitory molecules are also required for co-expression with the CAR. We have developed a proprietary microRNA (miRNA) gene silencing technology, which not only enables silencing of one or more target genes, but also "tunable" silencing of targets. When co-expressed with a CAR, our "miCAR" platform allows for highly efficient, multiplex engineering of next generation CAR T-cells. We sought to develop allogeneic anti-CD19 CAR (CAR19) T-cells with complete silencing of the TCR and tuned silencing of HLA-I with the intention of striking a balance between immune rejection by host CD8 T-cells and NK cells - without the need for co-expression of an NK cell inhibitory receptor. Primary T-cells were modified via lentiviral vector transduction of optimized miCAR19 gene constructs for tuned silencing of HLA-I, expanded in G-Rex cell culture plates, and purified by depletion of TCR-expressing cells. Produced miCAR T-cells were characterized by flow cytometric immunophenotyping, tumor cell cytotoxicity, loss of alloreactivity and mixed lymphocyte reactions (MLRs) with allogeneic CD8 T-cells and NK cells.Our data demonstrates engineering of distinctly pure miCAR19 T-cell products, all of which were completely silenced for TCR and with tuned silencing of HLA-I over a range of 70-95%. While CAR functionality was maintained in recursive cytotoxic assays against tumor cells, our novel allogeneic miCAR19 T-cells were non-alloreactive and remained largely protected from both CD8 T-cell and NK cell mediated cytotoxicity when HLA-I was silenced within a range of 80-90%. We therefore demonstrate key benefits of our technology platform, which not only facilitates multiplex engineering of fully functional allogeneic CAR T-cells, but also the ability to optimally tune down expression of molecules for optimal therapeutic benefit.

1360. Automating a Lentivirus Infectious Titer Assay (ITA)

Kristen Kellar, Sadik Canca, Meiling Miranda, Matt Troutman, James Richardson, Tim D. Culp, Philip R. Johnson

Interius BioTherapeutics, Philadelphia, PA

Lentiviral vector (LVV) potency, as measured by transduction efficiency, is a Critical Quality Attribute (CQA) that must be monitored for every LVV sample. At Interius, the *in vitro* potency of LVV samples is assessed in an infectious titer assay via the transduction of SupT1, a suspension T cell line, that serve as model CD7+ target cells. Transduction of target cells by the LVV, encoding a CAR20 protein, is detected through antibody staining of SupT1 cells using an anti-idiotype monoclonal antibody targeted to the scFv domain of the CAR20 protein using flow cytometry. LVV containing samples are serially diluted and added to a fixed amount of target cells in a 96 well plate format. The transduced cells are incubated for 7 days, with intermittent medium refresh, followed by live cell staining for CD7+ and CAR+. The transducing units (TU) per mL are calculated by assessing the CAR+ cells amongst total live SupT1 cells assuming a Poisson distribution of single cell infections in the range of 2 - 20%. The manual execution of the ITA method is a labor-intensive, multi-day process consisting of many discrete steps, followed by a long day of live cell staining and signal acquisition by flow cytometry. Standard 96 well plate reading flow cytometers are not well suited for high-throughput flow cytometry. To support the sample numbers required to develop multiple process development efforts simultaneously, a high throughput solution was required. To this end, we have developed a fully automated, multi-step method covering sample dilution, SupT1 transduction, medium refresh, moving from 96-well to 384-well plates, 384-well live cell staining and HT flow cytometry on a Sartorius iQue, followed by automated data reduction. Each of these discrete steps is designed to reduce hands-on time and eliminate operator to operator variability while providing the added benefits of increased throughput and speed. Importantly, the same assay framework can be utilized for different products and target cells with minor modifications.

1361. Evaluation of Residual Host Cell DNA Clearance and Sizing During Production of a Lentiviral Vector

Elaine M. Youngman, Meiling Miranda, Shanice Edwards, Thomas M. O'Malley, James C. Richardson, Tim C. Culp, Philip R. Johnson

Interius BioTherapeutics, Philadelphia, PA

Viral vector-based gene therapy drug products can contain residual DNA derived from the production cells. Production typically occurs in continuous cell lines with tumorigenic potential and residual host cell DNA carries a theoretical risk of oncogene transmission to recipient cells. This risk decreases as a function of reduced concentration and size of residual DNA fragments. It is therefore important to monitor residual host cell DNA concentration and size in gene therapy products. We have evaluated methods for quantitation of residual host cell DNA concentration and size during production of an engineered lentiviral vector manufactured in HEK293T cells and used those methods to compare the performance of two commercially available nucleases in downstream processing steps. We evaluated qPCR-based methods for quantitation of residual host cell DNA from multiple vendors, and multiple options were found to be accurate using the newly available ATCC/USP quantitative HEK293 genomic DNA reference standard. We find a substantial difference in performance between the two evaluated nucleases, DENARASE® and M-SAN HQ, across the downstream processing steps in our lentiviral production process, with material produced using M-SAN HQ having at least 10-fold lower residual DNA concentrations than the comparable material made with DENARASE®. To assess the size of residual DNA fragments, we developed a method based on universal linker ligation followed by PCR amplification (LiLi-PCR) and size analysis by capillary electrophoresis. The method accurately reports on the size distribution of mixed synthetic DNA fragments in the range of 50-1000 base pairs in concentrations ranging from 10 ng/uL to 0.5 ng/uL, with some bias against larger fragments at lower concentrations. Further, the method faithfully recapitulates the size distribution of a smear of genomic DNA fragments produced by enzymatic digestion. We will report on progress in evaluating whether available nucleases result in differing distributions of residual DNA fragment size after digestion and downstream processing.

1362. Efficient and Reliable Cell Separation Using Microbubbles for CAR-T Cell Manufacturing

Jason S. Ellis, Dominique N. Badea, Yifan Huang, Tiffany Snow, Jesse Chen, Jon Roussey, Chia Ku, Casey Wegner

Akadeum Life Sciences, Ann Arbor, MI

The chimeric antigen receptor-modified T cell (CAR-T) therapy has recently expanded. Despite several CAR-T products being approved and commercialized since 2017, CAR-T cell therapy still has several manufacturing challenges. Conventional CAR-T therapies are manufactured by collecting apheresis material (leukopaks) from a patient's blood, then modifying the isolated T cells from the apheresis material to express a cancer cell-specific CAR, and eventually infusing the CAR-T cells into a patient. Unfortunately, there are several challenges during the development of these therapies, including early exhaustion of the therapeutic cells, manual and laborious processes, and complex workflows. Akadeum's innovative microbubble technology can help shorten multiple CAR-T production steps to streamline the workflow. At the heart of the technology is the silica microbubble with an air-filled core. Utilizing the buoyant nature of these microbubbles has allowed Akadeum to develop a variety of kits for isolating desired cell populations. The microbubble's outer layer is composed of streptavidin. Cells are labeled with biotinylated-antibody cocktails, and the streptavidin-biotin bond allows the microbubbles to capture the labeled cell populations and lift them up to the top of the culture. This technology not only provides specificity in cell selection and isolation, but also significantly reduced processing time and a gentler process than magnetic selection methods. Akadeum's **Human T Cell Leukopak Isolation Kit - GMP** utilizes negative selection to remove unwanted cell populations from leukopak material. Isolated T cells are left untouched and can be used for cryopreservation for future research or immediate processing. Next, Akadeum's **Human T Cell Selection, Activation, and Expansion Kit - GMP (SAE)** uses a positive selection method to isolate T cells from PBMCs for immediate activation and expansion. The SAE kit not only provides over 95% purity but also allows 80-fold expansion of total cell counts, reduced PD-1 exhaustion marker, and increased CD69, CD25, and HLA-DR T-cell activation markers. Finally, Akadeum's newly launched **Human T Cell Depletion Kit - GMP** uses positive selection for the removal of CD3-expressing cells from genetically engineered CAR-T cell products.

1363. Lentiviral Production at the 50l Scale Using the Gibco CTS™ LV-Max™ Lentiviral Production System

Arjen van Den Berg[1], Paula Decario[2], Nils Williston[1], Jonathan Zmuda[1]

[1]Thermo Fisher Scientific, Frederick, MD,[2]Thermo Fisher Scientific, Logan, UT

As viral vector gene therapy processes reach the clinical and manufacturing stages, the ability to scale up these processes becomes crucial. Traditionally, Lentivirus (LV) has been produced using adherent 293T cell systems in the presence of fetal bovine serum (FBS). These systems have proven the be difficult and costly to scale up and the presence of the T-antigen as well as the use of animal serum are of regulatory concern. The Gibco™ CTS™ LV-Max Lentiviral Production System addresses these shortcomings by combining a 293F-derived suspension cell line, Viral Production Cells (VPC), adapted to growth in a chemically-defined media, a cationic lipid based transfection reagent and chemically defined LV production enhancers into a high titer transient production platform. In the present study we demonstrate scalability of the Gibco CTS LV-Max system at the 50 L scale producing an anti-CD19CAR-vector at a titer ≥1x10^8 TU per mL. We describe optimal conditions for growth and transfection of VPCs in Thermo Scientific™ Hyperforma™ 5:1 Single-Use Bioreactors as well as a scalable depth filtration train suitable for clarifying LVs produced in the LV-MAX system.

1364. Establishing Modified Adenovirus Serotype 35 Manufacturing Process Development

Toshihiko Okazaki

OSAKA University Hospital, Suita City, Japan

The development of gene therapy is progressing rapidly worldwide. In order to accelerate practical application, it is necessary to establish a system for providing high-quality, multi-item investigational drugs in small scale for clinical trials, which is different from commercial production. We are developing a novel adenovirus serotype-35 (Ad-35), to see if it could be useful as a vaccine (non-replicating vector) or oncolytic virus. So far GMP compliant manufacturing process of Ad-35 has not been established. This time, we challenged to establish Ad-35 vector manufacturing process development for the usage in the investigational clinical trial. Based on the pre-conditioning analysis of optimizing culture condition using the suspension HEK293 cell line with serum-free culture medium, initial seed virus prepared in flask culture was transferred to the shaking back-type of closed mass culture system. The virus suspension was prepared from the supernatant of the upstream 5 liter volume of Ad-35 vector-infected whole culture cells and further subjected to subsequent downstream virus purification and concentration steps. Subsequently, clarified harvest was subjected to fraction separation using ion exchange membrane chromatography to capture the target Ad-35 vector, and finally 50 mL of viral-contained fractions were collected. The virus fractions collected were subjected to the final steps of polishing and sterilization. Additional quality tests were confirmed, we finally could establish Ad-35 manufacturing process development.We were able to identify critical upstream and downstream process parameters. These findings will provide useful and important information for subsequent technology transfer aimed at establishing a scaled-up GMP-compliant virus production process.

1365. Comparison of Two Process Protocols for Allogeneic CART Production with Reduced Cost

Chunxia Lu

OBIO TECH, Shanghai, China

Introduction Autologous CD19 CAR-T cells have demonstrated outstanding efficacy in B-cell malignancy. CAR-T therapy mainly focuses on autologous T cells at present due to the restriction of MHC. However, autologous preparation of CAR-T cells has drawbacks in terms of manufacturing time, cost, feasibility and scalability that can

affect clinical outcome. In order to prepare off-the-shelf CAR-T cells, CRISPR/CAS9 technology was used to knock out TRAC and CD52 genes in donor T cells to avoid the potential GVHD and acquire resistance to anti-CD52 mAb based lymphodepletion after allogeneic T cell infusion. In this study, we report the allogeneic CAR-T cells production process using selected T cells and PBMC. **Methods and results** 2.1 Cell Banking, selection and stimulation T cells and PBMC were selected directly from apheresis for cell banking. One bag of T cells was thawed and then stimulated with TransAct or Dynabeads CD3/CD28 CTS. One bag of PBMC was thawed to isolate T cells and then stimulated with Dynabeads CD3/CD28 CTS. 2.2 Transduction and Electroporation Lentiviral transduction was performed in a serum-free activation and transduction system. The positive rate of CAR+ is more than 80%. After transduction, the T cells were gene edited by electroporation of CRISPR/Cas9 RNP complex to knock out TRAC and CD52. The maximum volume of electroporation is 20 ml with 2E+09 Cells. The knockout efficiency of double genes of TRAC and CD52 is more than 80%. 2.3 Cell expansion Perfusion culture process with Wave Cell Expansion System was used to expand T cells. The perfusion volume is up to 25 L with cell density ≥1E+7cells/mL and more than 90% cell viability, which generated more than 100 fold of T cell amplification. **Conclusion** Allogeneic CAR-T production process was developed by knockout TRAC and CD52 genes. Using two starting cell sources from T cell bank or PBMC bank, we demonstrated higher activated T cells with more than 60% recovery rate. Alternately, a low cost method was developed to use PBMC banks, but the activated T cells could be affected by the positive selection efficiency of PBMC.

1366. Personalized High-Throughput cGMP Manufacturing of Neoantigen-Based Plasmid DNA Cancer Vaccines

Ernst Boehm

Biomay, Vienna, Austria

Personalized medicine is an emerging therapeutic approach in cancer therapy, based on the unique genetic makeup of an individual tumor patient. One of the most rapidly advancing areas of application is an individualized cancer therapy where the mutational alterations of the patient's tumor cells - the individual profile of neoantigens - are evaluated. Based on the respective patient-specific neoantigen profile, a customized therapeutic cancer vaccine specific for that individual tumor patient is developed, manufactured and administered. Here we present our manufacturing platform, including a dedicated and specialized manufacturing facility for patient-specific plasmid DNA vaccines, which is operated under the conditions of current Good Manufacturing Practice (cGMP). More than 100 individual patient-specific DNA batches have been GMP-produced so far, to support a clinical trial for the treatment of different types of cancer. Manufacturing of individualized vaccines requires rapid turnaround times and robust processes across the complex supply chain, including tumor biopsy, identification of tumor-specific neoantigen biomarkers, vaccine design, generation of the patient-specific plasmid DNA starting material and manufacturing and quality control of the individualized drug substance and drug product. During the parallelized small-scale manufacturing process, a patient-specific *E. coli* cell bank is generated, which is then used in a fed-batch fermentation to propagate and produce the plasmid. After harvesting and alkaline lysis of the bacterial cell mass, the DNA plasmid is purified in a two-step chromatography process, formulated by ultra/diafiltration and finally aseptically filled. Key parameters of product quality, identity, purity and safety were characterized with a comprehensive set of analytical quality control assays. We will present our approaches to facility design, process optimization (e.g. DoE), quality control and quality parameter trending over a high number of batches. Considerations particularly crucial for personalized manufacturing will be made, e.g. a small footprint, rapid turnaround time and cost effectiveness. It could be shown that efficient GMP manufacturing of high-quality individualized tumor vaccines can be achieved within a short period of time, which is in the category of days to weeks rather than months.

1367. Design and Characterization of Next-Generation SMAR Nanovectors for Stable Cell Modification: Towards Safer Allogeneic and Autologous Adoptive CAR-T Cell Therapy

Toros Tasgin, Julia D. Peterson, Alice De Roia, Anna Hartley, Luisa Burger, Patrick Derigs, Richard P. Harbottle

German Cancer Research Centre (DKFZ), Heidelberg, Germany

Adoptive cell therapy (ACT) is one of the most prominent approaches to cancer immunotherapy and is attracting attention with recent promising clinical outcomes obtained in the treatment of melanoma and small cell lung cancer patients. The generation of CAR and TCR engineered T-cells allowed further advancement of the field by enabling off-the-shelf target specificities to peripheral T-cells, eliminating the need for isolation of tumor infiltrating lymphocytes (TILs). Moreover, the incorporation of induced Pluripotent Stem Cells (iPSCs) in cell engineering, coupled with subsequent differentiation into mature T-cells, has the potential to revolutionize ACT. This innovative approach offers an alternative means to generate a clinically significant quantity of CAR or TCR engineered T-cells, eliminating the necessity for stringent ex vivo T-cell expansion protocols that frequently result in T-cell exhaustion and diminished T-cell activity. Despite these advancements in ACT, conventional cell engineering strategies poses certain risks in clinical settings. Typically used integrating vectors can present inherent risks of genomic instability and genotoxicity and has recently led to the FDA warning of the risk of secondary malignancies. On the other hand, non-integrating systems, using viral replication-driving sequences such as Epstein-Barr Nuclear Antigen 1 (EBNA-1) or the SV40 large T antigen, are known to have transforming potential in the host cell. In this study, we address this limitation in current ACT protocols by refining and implementing a safer pipeline for engineering cells by utilizing an episomal DNA nanovector platform. Virus- -free S/MAR nanovectors are designed to adhere to the nuclear matrix, forming episomes that sustain stable transgene expression without genomic integration. Our findings demonstrate the efficiency of S/MAR vectors in introducing stable, and high level of CAR expression in transfected iPSCs and Jurkats, under both in selection-free and positive cell enrichment regimes. Additionally, our study aims to enhance episomal vector functionality, specifically focusing on matrix attachment stability and prolonged vector persistence within the transfected cell population. We have achieved this functional enhancement by designing and implementing a next-generation of S/MAR vectors with improved composition compared to our previously

described vectors. Results indicate that these vectors markedly improve vector persistence and transgene-positive cell population stability during long-term iPSC cultures, where transgene-positive cells are periodically enriched through Fluorescence-Activated Cell Sorting (FACS) Overall, the results of this study demonstrate the effectiveness and stability of S/MAR nanovectors for modifying iPSCs, providing a safer alternative to protocols that carry vector-mediated risks. Furthermore, we highlighted the potential for improving S/MAR vectors through a deeper understanding of the underlying mechanisms of S/MAR function. By gaining more insights into these mechanisms, it becomes possible to develop more clinically adapted and safer protocols for CAR-iPSC-T cell ACT by utilizing a more efficient S/MAR cell modification platform.

1368. Primary CD4 T-Cell Biofactory for Antigen-Inducible *In Situ* Synthesis of Engineered Proteins

Harikrishnan Radhakrishnan, Sherri Newmyer, Harold S. Javitz, Parijat Bhatnagar

Biosciences Division, SRI International, Menlo Park, CA

T-cell Biofactory is an engineered cell-based platform that assesses the disease burden and synthesizes calibrated amounts of complex protein-based biologics with desired properties at the disease site. This offers the potential to exert a broad range of functions without any dose misalignment, which otherwise causes side effects. Clinical translation of this technology has however been impeded by insufficient expression of the biologics from the T cell and manufacturing bottlenecks specific to the T-cell products. Compared to the pan T cells, the CD4 T cells offer to overcome these challenges due to their propensity for higher transduction, faster expansion, and a more productive transcription machinery. The results presented herein show that capitalizing on the CD4 T-cell biology, the CD4 T-cell Biofactory, compared to its CD8 counterpart, when configured with an appropriate chimeric antigen receptor (CAR), they achieve ~3X transduction efficiency of CD8 T cells, ~2X expansion rates, generating ~5X more biologic, and exhibit minimal cytolytic activity. Cumulatively, this address two main hurdles in the translation of cell-based drug delivery: scaling the production of engineered T cell *ex vivo* and generating sufficient biologics *in vivo*. When programmed to induce IFNβ upon engaging the target antigen, the CD4 T cells outperforms CD8 T cells, effectively suppressing cancer cell growth *in vitro* and *in vivo*. In summary, this platform enables precise targeting of disease sites with engineered protein-based therapeutics while minimizing healthy tissue exposure. Leveraging CD4 T cells extended persistence could enhance disease management by reducing drug administration frequency, addressing critical challenges in cell-based therapy.

1369. Lentiviral Vector Capture Using Anion-Exchange Chromatography: Removing an Industry Bottleneck through Rational Design

George Pamenter[1,2], Lee Davies[1], Carol Knevelman[1], James E. Miskin[1], Kyriacos Mitrophanous[1], Duygu Dikicioglu[2], Daniel G. Bracewell[2]

[1]Oxford Biomedica, Oxford, United Kingdom,[2]Department of Biochemical Engineering, University College London, London, United Kingdom

Lentiviral Vectors (LVs) have emerged as the preferred vector of choice for *ex vivo* modification of patient cells, particularly in Chimeric Antigen Receptor T-cell (CAR-T) therapies, with several products approved for commercial use. LV therapies hold immense potential for further application and future commercial success. However, challenges in manufacturing these therapeutics have resulted in a restricted global supply and limited early line use. As CAR-T developers endeavour to enhance therapy accessibility, efficacy, and safety, the demand for high-quality LV raw material is anticipated to rise. The manufacture of LV drug substance poses specific challenges arising from the large size and structural complexity of LVs. Downstream purification is particularly problematic and product recoveries of 15-25% are typical. Product capture primarily relies on charge-based separation using convective anion-exchange chromatography (AIEX) due to low cost and wide applicability across LV constructs. However, despite its near ubiquitous use across the industry, this purification step alone results in product losses of 60-85%, making AIEX a major bottleneck in the design of economical LV manufacturing processes. Despite its critical role in LV AIEX manufacture, widely variable AIEX performance is observed with little to no consensus on the optimal chromatographic configuration. This variability stems from a lack of focused research and a poor understanding of the complex LV-specific adsorption behaviours that result from the large size and structural complexity of LVs. The poor understanding of product loss mechanisms that underpin charge-based LV separation has led to a largely heuristic approach to process development. This highlights the need to further elucidate LV adsorption phenomena to pave the way for a more rational process development approach. In this work, we first identify the major product loss mechanisms driving poor recovery of LV on current commercial AIEX membrane adsorbents. Loss mechanisms such as entrapment and shear related damage are ruled out, with the importance of strong avidity effects that cause irreversible binding following prolonged adsorption periods highlighted. We further demonstrate the heterogeneous nature of LV binding and identify at least two binding subpopulations. The role of LV envelope structure in determining LV binding behaviour within these populations was explored, with the major LV envelope species responsible for binding identified. The role of thesespecies in driving time-dependent product loss mechanisms was theninvestigated, demonstrating that practicable improvements cannot be achievedusing current commercial adsorbents, thus advocating for an adsorbent redesign.The use of AIEX membrane prototypes developed specifically for LV purificationby Sartorius demonstrates high process recoveries are achieved in materialsdesigned for purpose. Finally, we highlight how we aim to enable *in silico* process development by applying the core understanding gathered to develop a mechanistic model of the AIEX process using the CADET Python package. LV-specific challenges are discussed such as the requirement for higher order binding isotherms, high-throughput analytical data and characterisation of non-conventional chromatography geometries.

1370. Improvements in Baseline Lentivirus Production Using Design of Experiment (DOE) Tool and Scale-Up in Bioreactors

Sonal Patel[1], John Mumira[1], Gregory Piscitello[1], Hiral Gami[1], Eva Fong[2], Joe S. Orlando[1], Scott Bahr[1]

[1]MilliporeSigma, Bedford, MA,[2]MilliporeSigma, Carlsbad, CA

Lentiviral vectors (LV) have gained popularity as modified gene therapy and gene delivery vehicles for treating a variety of acquired and inherited diseases. There is a growing demand for highly purified and concentrated viral vector products. To meet the market demands as research studies progress into pre-clinical and clinical phases, scalable manufacturing poses a big challenge. One of the areas that can help alleviate this challenge is optimization of transfection conditions to achieve higher viral titers. During lentivirus production processes using suspension-adapted HEK293T cells, 4 plasmids are complexed with a PEI-based cationic polymer and added to the cells at a specific cell density. Key factors for optimal transfection include transfection cell density, DNA to cationic polymer ratio, plasmid DNA molar ratio, transfection complex volume and transfection complex formation time. The work in this poster reflects the successful exploration of these factors using statistical software - JMP® and DOE approach, along with a new GFP transfer plasmid, to achieve higher lentivirus harvest titer. After obtaining optimal level for each factor, findings were confirmed in shaker flasks and scale-up was demonstrated in Mobius® 3 L and 50 L Single-Use Bioreactors.

Thursday Posters: Cell Therapy Product Engineering, Development, and Manufacturing

1371. Impact of Temperature Conditions on Cell Stability in Leukopaks During Shipping

Diana C. Chiluiza[1], Courtney Noah[2]

[1]Immune Cell Isolation, BioIVT, Watertown, MA,[2]Scientific Affairs, BioIVT, Westbury, NY

Human Peripheral Blood Mononuclear Cells (PBMCs) are critical components for cell and gene therapies (CGT) and regenerative medicine[1]. PBMCs are defined as a highly diverse heterogenous population of immune cells, which include lymphocytes such as CD4+ and CD8+ T cells, B cells, natural killer cells, monocytes which differentiate into macrophages and dendritic cells, and a small percentage of stem cells[2,3]. Leukopaks, sourced from leukapheresis, offer reduced variability as a single-donor origin for PBMCs. Proper storage and shipping conditions are important to ensure immune cell activation[4] as it plays a crucial role in the success of novel therapies. In this study, we investigated the impact of ambient and cold shipping conditions over time on white blood cells in leukopak products, focusing on cell concentrations, viability, and differential leukocyte counts (DLC). Study Design: Leukapheresis was performed on three healthy donors, and leukopaks were divided into aliquots stored at room temperature or 4°C to mimic shipping conditions. Viability, complete blood counts (CBC), and DLC were assessed daily for five days. Results: Viability of PBMCs remained stable for 72 hours in cold conditions but rapidly declined in ambient conditions (Fig. 1A). Lymphocyte to monocyte ratios (Lym/Mon) exhibited significant changes, with a notable increase in ambient conditions at 72 hours ($p<0.0001$, Fig. 1B). Total white blood cell counts were unaffected by time or temperature. Conclusions: Ambient shipping led to a significant drop in PBMC viability after 48 hours ($p=0.018$), suggesting it may not be ideal for prolonged transport. Lym/Mon ratios revealed distinct changes, indicating potential cellular effects. Cold shipping maintained PBMC viability and Lym/Mon ratios up to 72 hours, making it the recommended choice for extended shipping. Implications: The study supports the guarantee of cell product quality up to 72 hours when shipped in cold conditions, emphasizing the importance of optimal shipping conditions to prevent unexpected changes in leukopak cell populations and ensure successful research and therapy outcomes in the field of cell and gene therapy. Beyond 72 hours, the study suggests the need for further analysis of time and temperature impact on cellular functions. References: 1. Kobayashi, D. T. et al. 1372. Autologous CD19 CART Manufacturing from Whole Blood Collection for the Treatment of Autoimmune Disease

Vicki Stratton, Ashley Martynchuk, Yan Li, Jinmin Lee, Rebecca Dryer-Minnerly, Gwen Binder, Samik Basu, Chris Schmitt

Cabaletta Bio, Philadelphia, PA

Chimeric antigen receptor T (CART) cells targeting B-cells have been approved for treating various cancers and have now also demonstrated efficacy in refractory autoimmune diseases, including, but not limited to, systemic lupus erythematosus, myositis, systemic sclerosis, and myasthenia gravis. Despite the efficacy of CART cells in autoimmune disease and cancer, significant logistical barriers exist, limiting access

to patients. Access to apheresis centers is one of these barriers, as patients need to undergo leukapheresis to isolate T-cells for CART cell manufacture. To address this barrier and to improve the patient experience, we have developed a novel approach to isolate, transduce, and expand T-cells from whole blood collections. Studies were conducted to evaluate the isolation efficiency, determine the optimal blood volume(s), and characterize the immune phenotype of whole blood derived T-cells as compared to apheresis derived T-cells. T-cells isolated from whole blood collections were used to generate CD19 CART cells and compared against apheresis derived CD19 CART cells. These whole blood derived CD19 CART cells demonstrated comparable transduction efficiency, phenotype, cytolytic activity, and proliferative capacity as compared to apheresis derived CD19 CART cells. Taken together, our data support the ability of whole blood derived T cells for manufacturing CD19 CART cells which may alleviate some of the logistical burden to patients and enable broader access to CART cell therapies.

1373. Rethinking Transduction in Cell Manufacturing: Applying Functional Viral Titer (TU/mL) in Place of Multiplicity of Infection Improves Process Robustness

Gabriela Brumatti[1], Krystal Bridgeman[1], Seungyoul Oh[1], Jo Leen Lim[1], Ellen Otte[1], Andreas Gille[2]

[1]CSL, Melbourne, Australia,[2]CSL, Pasadena, CA

Introduction: Autologous CD34 positive hematopoietic stem and progenitor cells (HSPCs) can be genetically modified using lentivirus, making them an attractive target for gene therapy in the treatment of various genetic disorders and blood-borne diseases. One challenge in the development of such therapies is creating robust processes for a range of cellular product sizes based on variations in yield from mobilization and isolation (based on patient age, for example). The concept of multiplicity of infection (MOI) has been used to address this, where vector quantity scales with cell concentration based on protocols developed in the 1930s for T4 infection of *E. coli*. This concept (MOI) presumes that absorption of infectious particles is a dominant factor in transduction so that a constant ratio of particles to cells will achieve consistent transduction. However, this has never been systematically examined in the context of cell manufacturing for gene-therapies that use lentiviral vector (LVV) infection of HSPCs. These cells are substantially restricted and require high LVV concentrations for successful transduction. We hypothesized that considering diffusive limits in such a system and the number of LVV transducing units (TU) required for transduction, controlling LVV concentration (TU/mL) versus MOI (TU/cell) would improve the robustness of transduction processes independent of cell density. **Methods:** Human purified CD34 positive HSPCs isolated from GCS-F mobilized leukopaks, were transduced with two different lentiviral vectors encoding green fluorescence protein (GFP). Cells from 3 donors were plated at cell densities of 0.25, 0.5, 1, 2 and 4 x 10^6 cells per mL, followed by 24 h cytokine stimulation. LVV was added at different concentrations (0, 0.01, 0.1, 1 and 10 x 10^6 TU/mL) in the presence of transduction enhancers for 24 h. Cell viability and proliferation were determined by acridine orange/ propidium iodide or 7AAD staining, using the automated cell counter Cellaca MX and flow cytometry respectively, on days 3, 6, 9 and 13 post LVV addition. Transduction efficiency was determined at the same time-points through the detection of GFP expression by flow cytometry and quantification of vector copy number by ddPCR. **Results and Conclusion:** Transduction efficiency in HSPCs was LVV concentration dependent. Surprisingly, LVV potency on HSPCs strongly varied when expressed as MOI (TU/cell) but much less with LVV concentration as (TU/mL) (Figure 1). This finding is consistent with insignificant LVV adsorption to cells during the incubation. Moreover, high LVV concentrations did not impact on the viability or proliferation of HSPCs. Contrary to common practice, our data show that the use of MOI is an inadequate measure of LVV concentration for the transduction of HSPCs when varying cell densities. LVV concentration applied as TU/mL achieves robust HSPC transduction over the typical range of cell densities used in gene therapy cell manufacturing. Predictable transduction efficiency across a wide range of cell densities enables the use of automation when processing partial or pediatric cell products and allow significant savings of HSPCs in large scale manufacturing product development.

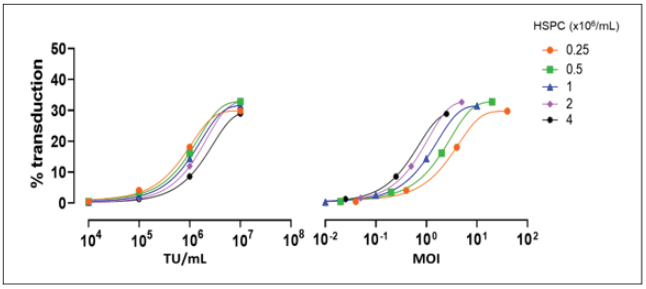

Figure 1. *LVV dosing by functional titer (TU/mL) versus MOI (TU/cell) improves robustness of HSPC transduction across cell densities.* Transduction was assessed as GFP-expressing cells by flow cytometry. Shown are the means of 2 donors. Error bars omitted for clarity.

1374. Establishing a Novel Reimbursement Strategy for Drugs Developed for "Angel" Ultra-Rare Disease Patients

Richard Horgan, Eric Faulkner

Cure Rare Disease, Woodbridge, CT

Our exponential advancement in genomics, systems biology, and cell and gene therapies have ushered in unprecedented opportunities to address devastating diseases at their core. One key group that has not had the opportunity to benefit from these novel therapy options are the majority of ultra-rare disease patients for which limited and often no therapeutic options exist. Around 70% of these diseases disproportionately impact pediatric patients. These patients and their caregivers have historically fallen through cracks in a US healthcare system never built for uncommon diseases. But viewed in the aggregate, patients with ultra-rare diseases constitute one of our largest US healthcare unmet needs - broader than focal, high-impact diseases like diabetes and many of the top cancer indications combined. Further, because our treatment development process in the US operates with a lens on individual diseases, many of these ultra-rare diseases do not rise to the level of commercial interest and thus will not be a target for potentially life-changing advanced therapy development. This sizable subset of rare disease patients with poor-to-no options have been dubbed "Angel" patients for purposes of this report. This research report intends to examine and layout a potential pathway for

offering these patients access to transformative cell and gene therapies. This report - available initially in interim form -methodologically involved targeted literature research, qualitative stakeholder research with providers, regulators, payers, patients and patient advocates and treatment manufacturers, as well as a quantitative multistakeholder survey en route to finalization. The concepts described herein are intended to serve as a foundation for multi-stakeholder dialogue and action needed to advance solutions for this often forgotten patient population with ultra-rare diseases. There are several key findings of this report, including the following: • Based on the numbers, the unmet need for rare and ultra-rare disease is cumulatively one of our most profound health challenges, with numbers of aggregate patients that rival or exceed many diseases considered the most high impact diseases of our time. • Across all dimensions of the Angel Treatment Pathway outlined in this report (i.e., **definition of "Angel" patients, evidence requirements, regulatory pathway, reimbursement pathway, and patient follow-up**), there *is* a foundation of precedent upon which to rapidly build and execute this pathway in the US - we would not need to start from scratch and solutions could be rapidly and broadly enacted. Despite this potential, it will take collective will and multi-stakeholder collaboration to action a replicable Angel Treatment Pathway in the US. This effort offers the most comprehensive, end-to-end view on addressing non-commercially applicable rare disease to date in the US, while acknowledging multiple areas where progress towards the goal of treating an aggregate rare disease population with profound and unaddressed unmet need. Our goal is offering up a fully fungible strawman and advancing dialogue and action towards pilots that can address the burden of rare disease in a scientifically sound, responsible, and life-changing manner, while taking into account the changes required beyond a model never built and infrequently adapted for niche populations.

1375. Developing a Novel Large-Scale Process for B Cell Therapy Manufacturing

Eileen Elliott, David Bengford, Kerri Somebang, Inosencio Casanova, Grant Li, Johnny Arenas, Robert Chang, Andy Rakestraw, Nallakkan Arvindan

Process Development, Walking Fish Therapeutics, South San Francisco, CA

Cell therapies have garnered much success as potent, versatile, and long-lived treatments for mostly oncological indications. Owing to advances in gene-editing, viral delivery, and large-scale culturing, B cells have emerged as new therapeutic modalities in the oncological, auto-immune, and rare disease spaces. B cells are particularly attractive cell-therapy because they are engraftable, long-lived, and have the potential to secrete high levels of biologic therapeutics. Walking Fish has developed a versatile, robust process to create multiple clinical doses of engraftable B cells engineered to secrete therapeutic levels of recombinant protein. In this report, Walking Fish describes a scalable, closed, GMP-compatible process to create its first B cell therapy WFX-001. This process uses the MaxCyte GtX™ together with CRISPR genome editing and AAV-based gene delivery to engineer B cells to secrete alpha-galactosidase (α-GAL) for the treatment of Fabry disease: a condition caused by poor α-GAL function. This autologous process edits Fabry-patient cells with functional α-GAL and then expands them to levels that are suitable for dosing. Walking Fish has adapted traditional and novel analytical tools to identify critical process parameters (CPPs) and critical quality attributes (CQAs) that contribute to engineering and manufacturing proficiency. Additionally, in vivo murine models illustrate the effectiveness of the WFX-001 therapy in secreting therapeutic levels of α-GAL and clearing the Gb3 intermediate that characterizes Fabry disease. As such, engineering B cells as live "factories" to deliver therapeutic cargo has become a reality.

1376. Importance of Clinical Trial Design on Therapy Commercial Access

Katie Moses, Jen Klarer

The Dedham Group, New York, NY

Background: In this abstract, we aim to share historical trends and expert analysis on how clinical trial design impacts market access and associated commercial dynamics manufacturers need to consider before pivotal clinical trials start. **Discussion:** Payers reference inclusion and exclusion clinical trial criteria to formulate coverage policies for cell and gene therapies. Once a payer has developed a coverage policy the criteria can be difficult to remove. To ensure appropriate access, manufacturers may wish to develop clinical trial inclusion and exclusion criteria with commercial management in mind. The goal of clinical trial criteria is to ensure controlled efficacy results for products, but this can inadvertently narrow patient populations and access for those products post-approval. For example, policy criteria of "no prior BCMA-targeted therapy" is relatively prevalent for multiple myeloma CAR-Ts, despite data supporting patient response greater than the control following BCMA exposure[1]. Now reaching 48% of commercial medical lives, this criteria can limit access particularly with the entrance of 5L+ BCMA-targeted bispecifics. On the gene therapy side, Zynteglo[2], clinical trial criteria included ineligibility for patients that have a known and available HLA-matched family donor[3]. This criterion, which has been widely used in commercial coverage policies covering 61% medical lives, indicates that if a donor is available, the patient must be evaluated for transplant prior to Zynteglo treatment. Although transplant is viewed as a functional cure, patients who undergo transplants can experience serious clinical complications, including morbidity and mortality (e.g., GvHD). The recently launched sickle cell disease gene therapies had similar clinical trial criteria, which will be important to watch in how payers manage the therapies[4]. Additionally, primarily in the gene therapy space, manufacturers have developed an innovative payment model to contract with payers. Such models need to be proactively planned during the clinical trial design phase to ensure the right endpoints are studied and available for outcomes-based agreements. Outcomes-based rebate models are one of the more commonly leveraged innovative payment models used to increase product access but can be challenging as outcomes are sometimes operationally difficult to measure. Manufacturers should consider clinical trial criteria that may be seen in claims processing or have ease of measurement to enhance the likelihood that payers will adopt these payment models and execute on them. **Methods:** Payer coverage for BCMA-targeted CAR-T therapies and Zynteglo was evaluated across ~93% Commercial medical lives to identify prevalence of respective clinical trial criteria in policies. **Conclusion:** Clinical trial design shapes the landscape of therapy access. Understanding how clinical trials criteria influence payer policies is crucial for ensuring appropriate patient access to innovative therapies. Strategically selecting control criteria, or proactively planning to mitigate potential

access risks associated with necessary control criteria, in pivotal clinical trials can avoid clinically inappropriate implications on commercial access. Therefore, as the field continues to evolve, proactive and thoughtful clinical trial design is key for manufacturers to overcome access challenges and advance patient care. **References:**[1]https://pubmed.ncbi.nlm.nih.gov/37558706/ [2:] https://www.fda.gov/media/161472/download [3]https://www.molinahealthcare.com/~/media/Molina/PublicWebsite/PDF/Common/Molina%20Clinical%20Policy/Zynteglo_betibeglogene%20autotemcel_R.pdf. 1377. Programmable Gene Silencing for Engineering Adaptable Cell Therapies

Vlad C. Seitan

Laverock Therapeutics Ltd, Stevenage, United Kingdom

Cell therapies are still facing considerable challenges relating to efficacy, safety, and cost. A significant proportion of these challenges can be tackled by genetically engineering therapeutic cells to become adaptable, so that they can respond to distinct cell state transitions and/or disease environments - such as the tumour microenvironment (TME). We have developed a new technology called Gene Editing-induced Gene Silencing (GEiGS) that enables programmable gene silencing, and thus allows the engineering of programmable therapeutic cells. GEiGS is a new way of harnessing the RNAi pathway that works by introducing specific gene edits within endogenous redundant miRNA genes, to redirect their silencing activity towards new desired targets. We have previously shown that this technology is able to effectively silence targets in human iPSCs in a tunable manner and with no detectable off-target effects. We now show that GEiGS activity can be programmed to silence target genes in a developmental- and cell state-specific manner, in a range of human cells including primary T cells, iPSC-derived macrophages and iPSC-derived pancreatic cells. By editing miRNAs that are differentially expressed in response to developmental and environmental cues, we show these dynamic changes can be leveraged to silence desired target genes in a programmable manner. This feature of the GEiGS technology allows the generation of adaptable cell therapies that can deploy their therapeutic activity 'at the right time, and in the right place'. We exemplify this through the design of GEiGS-engineered immune cells that are programmed to respond to the TME, and iPSC-derived hypoimmunogenic pancreatic cells with an improved safety profile.

1378. High-Throughput Characterization of Subvisible Particle Contamination in Cell and Gene Therapies

Karessa White

Halo Labs, Burlingame, CA

A key measure of biologic stability in cell and gene therapies are detecting and characterizing subvisible aggregates. The Aura+ is a high-throughput, low-volume approach that allows the detection of these subvisible aggregates by using a method called Backgrounded Membrane Imaging coupled with Fluorescence Membrane Microscopy. Here we demonstrate the complete characterization of subvisible aggregates and external particle impurities in a variety of cell and gene therapy products.

1379. Large-Scale Quantitative Live-Cell Tracking Using Label-Free Imaging of Individual iPSCs for Monitoring Pluripotency

Anthony J. Asmar, Zackery Benson, Michael Halter, Anne L. Plant

NIST, Gaithersburg, MD

The ability to quantitatively image induced pluripotent stem cells (iPSC) to monitor their state of pluripotency and differentiation in a non-invasive manner is important for establishing better metrics for pluripotency, and to assure consistency and efficiency in iPSC manufacturing. To address this, we have developed a label-free imaging and image analysis pipeline that allows tens of thousands of individual hiPSCs and their progeny to be segmented and tracked over multiple cell divisions using phase contrast microscopy. The AI model for this analysis is trained using automated segmentation of fluorescent nuclei. This also obviates the need for manual annotation and provides access to the large diversity of cells within an isogenic population and also allows for the development of a model in a minimal amount of time. The rapid imaging (all cells are interrogated every 2 minutes) allows detection of mitosing cells and tracking of their daughters with a high rate of accuracy. It has been frequently observed that each individual cell expresses its phenotype (e.g., expression of transcription factors, level of pluripotency, morphology, etc.) slightly differently that its neighboring cells. This distribution of observed phenotypes across a population seems to be indicative of the intracellular processes that produce the phenotype, and therefore can provide information about mechanistic aspects of regulatory networks. To demonstrate the usefulness of this knowledge to the expansion of pluripotent stem cell cultures, we are adapting our imaging and image analysis pipeline in order to interrogate different reporter stem cell lines. The cell lines produce fluorophores that report on the transcription factors relating to stem cell pluripotency. Quantitative optical imaging and AI-assisted image analysis of large numbers of individual live cells will allow quantification of the relative expression of single or multiple transcription factors within each cell. The presence of the reporter probe provides information that can used to inform models for the label-free identification of cell state. These data can provide a new metric that allows better characterization of the state of an expanding pluripotent or differentiating population of cells. These findings will help to establish the validity of this approach for use in hiPSC culture optimization and development.

1380. Optimization of Automated Selection and Lentiviral Vector Mediated Transduction of MSCs

Alessandra Gatti[1], Federica Mingotto[2], Paola Terreni[2], Ralitsa Arnaudova[2], Federico Lo Presti[2], Claudia Gentile[2], Nunzia Mangano[2], Fabio Ferrazzi[2], Giuliana Vallanti[2]

[1]AGC Biologics, Bresso, Italy,[2]Development, AGC Biologics, Bresso, Italy

Mesenchymal stem cells (MSCs) are adult stem cells that can be isolated from several adult tissues and are of great interest for the development of new MSC-based products in advanced therapies or regenerative medicine. They have a wide range of therapeutic applications and are a valuable tool to treat different pathologies. MSCs have traditionally

been isolated by manual flask-based methods based on their property of adherence to plastic. However, this classic approach includes many open handling steps that can be error prone and labor intensive. Automation has the potential to address these problems and so, aiming to an industrial translation of cell and gene therapies, we investigated Quantum cell expanssion system (Terumo BCT) for isolation and first cultivation passages of MSCs from unprocessed bone marrow (BM). The system is a hollow fiber bioreactor with a 2.1-m^2 surface area for cell growth and continuous medium perfusion. In addition, in the context of product early stage development, we demonstrated the feasibility of lentiviral vector-genetically modified MSCs production to generate cell-therapy-based drugs or for downstream application as exosomes production. Lentiviral vectors (LVV) are a platform to deliver and permanently express therapeutic genes and have displayed great potentiality in clinical trials.Here we present proof of concept results concerning the setting up of optimal MSCs transduction with a highly-purified VSV-G pseudotyped LVV encoding for GFP protein in order to obtain optimal genetic modification and process yield. Briefly, BM donor-derived MSCs were cultured in different chemically defined MSC-specific serum free media and seeded at different concentrations in tissue colture 2D supports. Transduction was performed at different timing up to 24 hours from seeding at MOI ranging from 20 to 50. Different conditions were tested and cells were maintained in culture up to fourteen days, thus obtaining optimal transduction efficiency (up to 80% GFP positive cells).

1381. Designing Instructional Materials for Synthetic Notch Receptor Activation in a 3D Context

Joanne C. Lee, Jonathan M. Brunger
Biomedical Engineering, Vanderbilt University, Nashville, TN

Introduction: To overcome tissue degradation and combat inflammation caused by injury, metabolic disorders, autoimmune diseases, and aging, regenerative engineers often leverage therapeutic cells *in situ* to deliver biologic factors, such as pro-inflammatory cytokine antagonists, or to engineer tissue substitutes. As adverse events can result from unreliable dosages of biologic factors and a lack of control over transplanted cell behaviors, it is extremely important to be able to precisely generate engineered, defined cell responses. In previous work, we have presented a 2D system leveraging synthetic biology tools to create a customizable platform where cells engage materials to overcome such limitations, termed MATRIX for material activated to render inducible expression. Here, we extend our platform to a 3D context for applicability in *in vivo* environments through implantation of the co-engineered cell and material system. **Materials and Methods:** Our system leverages the synthetic Notch (synNotch) receptor platform to program cellular responses to cues in their microenvironment. Like the native Notch receptor, synNotch is a juxtacrine receptor that regulates ligand-dependent transcriptional programs in cells. By exchanging Notch's extracellular domain with alternative recognition motifs and intracellular domain with synthetic transcription factors, we create synNotch receptors that produce user-specified sense/response behaviors. Since we can customize synNotch to drive expression of any transgene, we can tune defined cellular responses to selected orthogonal inputs, reducing crosstalk from native pathways. SynNotch, like native Notch, requires force on the order of piconewtons for activation. Thus, soluble monomeric ligands do not activate synNotch. We leveraged this feature to create biomaterials capable of capturing synNotch ligands, resulting in a privileged material:cell channel of communication, requiring co-localization of the engineered cell, the designer biomaterial, and the selected synNotch ligand. Here, we implemented our 3D platform to enable engineered cells to respond to GFP, a bioinert cue, and activate cells. **Results and Discussion:** Polystyrene scaffolds with fiber diameters of 150 microns and pores of 200 microns were functionalized with a nanobody for capturing GFP, termed GFP-TRAP. Mouse mesenchymal stem cells (mMSCs) engineered to produce secreted alkaline phosphatase (SEAP) and mCherry when activated were seeded across the functionalized scaffolds and then exposed to GFP in cell culture media over a period of 19 days. An increase in mCherry fluorescence and SEAP production as measured by a chemiluminescence assay was observed at the end of the culture period, demonstrating successful synNotch cell activation in a 3D context (Fig. 1A and Fig. 1B). **Conclusions:** Our system has the potential to be highly versatile with custom inputs and outputs through the customizability of synNotch. Our platform represents an innovative approach to co-engineer cells and biomaterials for increased cellular and spatiotemporal control, as the requirement for co-localization of all components gates responses spatially. Further work will test the platform's capabilities for regenerative functions, such as delivery of pro-inflammatory cytokine antagonists and cellular differentiation.

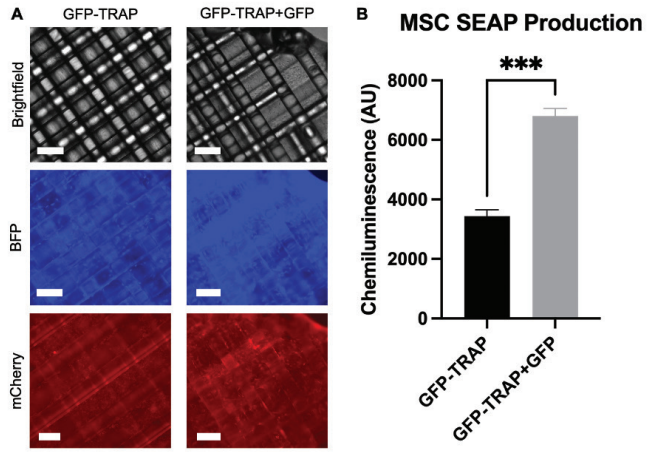

Fig. 1: A. SynNotch activation of mMSCs on functionalized GFP-TRAP scaffolds with and without GFP added as denoted by mCherry reporter fluorescence. Cells are constitutively BFP+, shown here for ease of visualization. Scale bar = 200 μm. B. SEAP production as measured by a chemiluminescence assay shows a significant increase in mMSCs exposed to GFP on functionalized GFP-TRAP scaffolds. (***p<0.001, Student's t-test).

1382. Novel Immortalized Human Bone Marrow Derived Mesenchymal Stem Cells Overcome Primary Cell Limitations

Nicholas Lee, Larisa Saari, Xiangshan Zhao, Fang Tian
ATCC, Gaithersburg, MD

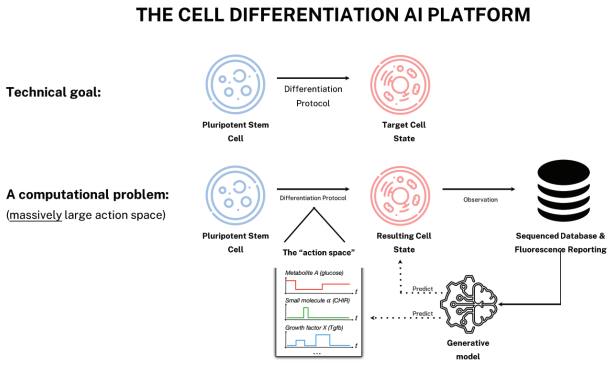
Mesenchymal stem cells (MSCs) are adult stem cells with the ability to differentiate into other types of cells. Additionally, MSCs can

modulate the immune response and promote tissue repair. Due to their properties, primary MSCs have a significant application potential in the treatment of various diseases. However, primary MSCs also have limitations such as limited life span, donor variability, source limitation, and heterogenicity. These limitations hinder the utilization of primary MSCs in preclinical applications. These constrains could be overcome with cell immortalization. Cell immortalization technology enables the establishment of new cell models that retain normal physiology, minimize cellular heterogeneity, and gain an indefinite lifespan. In this study, we generated a clonal cell line immortalized by stably expressing human telomerase reverse transcriptase (hTERT) gene in normal human primary bone marrow-derived mesenchymal stem cells (BM-MSCs). This immortalized cell line has been cultured for over 200 days and has continued to proliferate over 110 population doublings. The immortalized BM-MSCs exhibited normal karyotype and had a similar cell growth profile and cell doubling time as the parental primary cells. The immortalized BM-MSCs were positive for CD73, CD90, CD105, and negative for CD14, CD34, CD45. In this study, we also investigated the adipogenic, osteogenic, and chondrogenic differentiation abilities of these immortalized BM-MSCs. In summary, the immortalized BM-MSCs present a novel cell model that avoids the limitations of primary cells and can be used as a valuable tool for gene and cell therapy.

1383. Clinical Scale Genetic Engineering of MSCs with Complex Genetic Cargos

AJ Walters[1], Caleb Bashor[1], Scott D. Olson[2]

[1]Bioengineering, Rice University, Houston, TX,[2]University of Texas Health Science Center, Houston, TX



Mesenchymal stem/stromal cells (MSCs) are a widely studied cell type with potential therapeutic value. However, these cell therapies generally fail to show efficacy in large scale clinical trials. Genetic engineering represents an opportunity to augment cell therapies with novel mechanisms of action. Unfortunately, efforts to deploy genetic engineering in MSCs have been stymied by technical and logistical challenges that limits the manufacturing scale and size of DNA cargo. Through systematic optimization, we identified improved transfection and manufacturing conditions then produced genetically engineered MSCs (eMSCs) that meet clinical criteria. These eMSCs expand to a clinical scale product, maintain the growth kinetics, phenotype, and immunomodulatory properties of unmodified MSCs. This approach demonstrates comparable transfection outcomes to mRNA transfection with RNAiMAX, and resulted in a similar cell product to lentiviral transduction. We then installed DNA cargo greater than 15 kb, outside the typical capacity of lentivirus. To demonstrate the modularity and tunability of this approach, we installed an IL-10 transgene under multiple promoters. The multi-gene eMSCs expressing variable amounts of IL-10 proportionally decreased inflammation in myeloid cells. This demonstrated proof of concept that clinically-compatible eMSCs can be augmented with a user-defined transgene that introduces a novel and quantifiable mechanism of action. Importantly, this work enables the development of a new generation of MSC-based therapeutics.

1384. Somite-Derived Cells from Human Pluripotent Stem Cells for Cell Replacement Therapy

Kristy J. Brown, Lu Yan, Carl Morris, Cliff Tabin, Jonathan Rosenfeld, Allon Klein, Olivier Pourquie

Somite Therapeutics, Boston, MA

The delivery of cell replacement therapies requires producing cells of the appropriate identity and maturity, and to do so at scale while minimizing cellular byproducts, batch variability and cost during production. The search over protocol variations to optimally achieve these goals represents a considerable task that can be navigated efficiently using statistical learning approaches (artificial intelligence, or AI). A principled framework for AI-guided protocol optimization has been established. The initial focus of the framework is on optimizing somite-derived lineages for treating musculoskeletal and metabolic diseases. This will be applied towards large-scale production of differentiated muscular, dermal, tendon and skeletal (bones and cartilage) and brown fat tissues from human pluripotent stem cells (PSCs). The first proposed clinical indication is Duchenne muscular dystrophy (DMD), a rare X-linked genetic progressive muscle loss disease. Production of iPSC-derived muscle satellite stem cells (MSSCs) was optimized and their efficacy demonstrated through muscle force recovery in mice subjected to muscle injury. Additionally, iPSC-derived brown adipocytes capable of normalizing glycemia in a Type 1 diabetes mouse model has also been developed. The regenerative capacity of these somite derived cells, characterized by self-renewal and differentiation into mature functional tissues, positions them as promising therapies for long-term patient benefits and establishes a systematic framework for protocol optimization.

Thursday Posters: Pharmacology/ Toxicology Studies and Analytics/Assay Development

1385. Transduction Efficiency of rAAV8 Comparing Mouse and Non-Human Primate (NHP) Tissues Following Intravenous Administration

Nakyo Heo, Kentaro Konishi, Joshua Chang, Takeshi Sato, Megumi Adachi, Whitney Blankenberger, Marie Stark, Sam Sutton, Bala Medicherla, Damir Simic, Carlos Fonck

Astellas Gene Therapies, South San Francisco, CA

Introduction: Data from mouse and cynomolgus macaque studies were analyzed to investigate transduction efficiency following rAAV8 gene transfer. In the nonclinical development of AAV-based gene therapies, animal models of disease such as transgenic mice are typically used to investigate doses and vector exposures that are associated with efficacy. In contrast, species such as cynomolgus macaques are often utilized to investigate potential toxicity and biodistribution of the AAV vector. To the extent that non-clinical studies are used to select first-in-human doses, we were interested in any generalities or trends in terms of rAAV8 transduction patterns. We compared species, mouse versus cynomolgus macaque, and tissues, including skeletal muscle, heart and liver. The potential impact stemming from differences in DNA construct content and design was also assessed. The dependent variable in this analysis was vector copy number (VCN) measured in tissues. ***Materials and Methods:*** Four mouse and three non-human primate (NHP) studies across three gene therapy programs that utilized rAAV8 were selected to analyze VCN data from liver, heart, and quadriceps. These studies utilized the same methods to evaluate rAAV8 vector titers. rAAV8-treated animals received doses ranging between 1E12 and 8E14 vg/kg and included 202 mice and 39 NHPs. There were 241 liver samples, 193 quadriceps samples and 249 heart samples that included atria, ventricles and intraventricular septa. Body weights, animal age at the time of dosing or necropsy, and mouse genotype varied across studies. The VCN was measured in tissues by quantitative polymerase chain reaction (qPCR) or droplet digital PCR (ddPCR). The log-log linear regression between dose and VCN were analyzed on R and RStudio, assuming no differences between the bioanalytical methods utilized across the studies. ***Results and Discussion:*** The highest VCN levels were measured in the liver across all experiments which is consistent with several publications that investigated the ability of multiple capsid serotypes to transduce mammalian tissues. Heart showed slightly higher transduction efficiency compared to quadricep, while quadricep displayed the highest variability in terms of VCN measurements. Using tissue as an independent variable, dose-dependent increases in VCN were observed across species in all tissues, with 95%, 93% and 87% of the VCN values within 5-fold of the regression values in the heart, liver, and quadricep, respectively; indicating that the most consistent results were measured in the heart, with similar proportional increases across the two species in each tissue. There were no apparent differences due to construct design. The slope estimates were 0.96, 1.18, and 1.17, intercept of -11.2, -16.0, and -16.4, and r^2 of 0.77, 0.89, and 0.75, in liver, heart, and quadricep, respectively. When species was set as the independent variable, similar slope and intercept estimates in mouse heart (slope=1.23, intercept=-16.6) and NHP heart (slope=1.20, intercept=-16.4) were observed, suggesting that heart transduction is relatively more predictive when translating across species, compared to liver and quadricep. NHP showed slightly lower transduction in liver, and slightly higher transduction in quadricep compared to mice. There were no measurable differences in transduction efficiency across tissues or species when construct sequences were considered.

1386. Spatial Transcriptomics Decodes AAV2 and AAV9 Specific Signatures in the Mouse Liver

Bettina Amberg[1,2], Fabian Köchl[1], Nadine Kumpesa[1], Megana Prasad[1], Filip Bochner[3], Mar Hernández-Obiols[1], Michael B. Otteneder[1], Lucas Stalder[1], Björn Jacobsen[1], Sven Rottenberg[2], Alberto Valdeolivas[1], Petra C. Schwalie[1], Kerstin Hahn[1]

[1]Roche Pharma Research and Early Development, Pharmaceutical Sciences, Roche Innovation Center Basel, Basel, Switzerland,[2]Institute of Animal Pathology, University of Bern, Bern, Switzerland,[3]Department of Biosystems Science and Engineering, ETH Zurich, Basel, Switzerland

Introduction: Assessing the biodistribution of adeno-associated virus (AAV) gene therapy (GT) vectors and corresponding transcriptomic changes is invaluable to estimate the efficacy and safety of GT compounds. In this regard, spatial transcriptomics (ST) based on unbiased in situ capturing of the mRNA provides the unique opportunity to spatially map transgene expression and investigate vector or transgene-mediated responses. Moreover, the integration of ST and single-nucleus RNA sequencing (snRNA-seq) can reveal the distribution of numerous markers at nearly single-cell resolution, alongside mapping putative interactions and identification of cell communities. To validate this approach for AAV-based GT, we applied ST and snRNA-seq, to evaluate the serotype-inherent spatial biodistribution of AAV2 and AAV9 in the mouse liver. Methods: C57BL/6 mice (n=4 male/female per group) were intravenously injected with $5x10^{11}$ vg/kg of AAV2-CMV-EGFP, AAV9-CMV-EGFP or PBS. Frozen liver tissue was processed using the ST 10X Genomics Visium spatial gene expression and Chromium Single Cell 3' Reagent kits (v3.1 Chemistry Dual Index) for snRNA-seq. Spatial data were compared to EGFP in situ hybridization (ISH; RNAscope™, ACD) and immunohistochemistry (IHC) to assess the capturing of the AAV vectors. Results: Visium ST revealed spatial sex- and serotype-specific patterns, with periportal or pericentral accentuated transgene expression for AAV2 and AAV9, respectively. ST findings were in line with ISH, IHC and snRNA-seq results. The transcriptomic signatures in transduced liver zones included panlobular changes in the androgen and EGFR pathways, providing additional evidence for the relevance of both pathways for AAV2 and AAV9. We further used the spatial localization of the transgene to investigate its co-expression with receptor-encoding genes. This analysis identified known AAV entry factors such as the laminin receptor and syndecans as well as potential novel receptors. Conclusions: We demonstrate for the first time that AAV transgene levels and associated transcriptomic signatures can be robustly assessed using the commercially available 10X Genomics

Visium platform. This method can be extrapolated to other preclinical species and tissues and proves to be a valuable tool for GT development including efficacy and safety assessments.

1387. Transcriptomic Analysis of Vasculature Grown in 3D and 2D Platforms Helps Enable Complex *In Vitro* Model Selection in Pharma

Maryam Tarazkar, Monica Romero-Lopez, Chidubem Onyeagoro, Fjodor Melnikov, Kimberly Homan, Catrin Hasselgren

Genentech, South San Francisco, CA

Cell culture conditions can affect phenotypic and genotypic signatures of endothelial cells. 2D and transwell endothelial models have been widely used to study endothelial cell behavior and interactions. Vascular in vitro models are advancing in physiological complexity, yet few studies directly analyzed transcriptomic differences between endothelial cells cultured in 2D and 3D systems. Here, we compared the expression of key endothelial cell markers across various culturing platforms: 2D cultures (traditional cell culture plates and transwells), 3-lane Mimetas Organo-plate chips, and an in-house bioprinted 3D-Chip, aiming to provide foundational data to help drug development users select an endothelial model whose cellular function matches their need (e.g. effective drug transport or immune system regulation, etc). Bulk RNA-Seq data demonstrate the differences in gene expression profiles between 2D and 3D cultures. Specifically, the 3D-Chip generates a gene expression profile that is distinct from those observed in 2D cultures and/or Mimetas. It is known that endothelial cells exposed to various extracellular matrix (ECM), geometries, and flow patterns exhibit different gene expression pathways related to mechano-sensing, inflammatory, and endothelial cell damage markers. Here, we observed that the inflammation and endothelial activation pathways were downregulated in the 3D-Chip compared to other systems; suggesting that no-flow or bidirectional-flow contributes to the establishment of a more pro-inflammatory environment relative to the 3D-Chip culture. Our findings identified the value of 3D complex models compared to 2D cultures and highlighted the importance of considering specific culture conditions and their influence in cell behavior. This research provides an insight into the utilization of models by drug developers for internal decision-making and highlights the essential characteristics required for successful integration of new models into existing preclinical drug development pipelines. Specifically, it demonstrates how model-omics data generated across diverse vascular platforms assists users in selecting appropriate models for particular contexts of use.

1388. Qualification of a Preclinical to Phase I ELISpot Assay for AAV Immune Monitoring

Emma Kraus, Lauren Huffman, Hakan Cam, Sapna Varia, Victoria M. Velazquez

Analytical Sciences, AmplifyBio, West Jefferson, OH

The ability to identify cellular immune responses to advanced therapies, such as AAV gene therapy, is key in documenting their overall safety. The interferon-gamma (IFN-γ)-based Enzyme-Linked ImmunoSpot (ELISpot) assay is a robust and highly sensitive tool for this purpose. The goal of this study was to develop and qualify an IFN-γ ELISpot method suitable for identifying and enumerating AAV9-specific T cells in both non-human primates (NHPs) and in humans. The IFN-γ ELISpot was first evaluated by measuring human T cell responses to CMV in cryopreserved PBMCs, for: linearity, limit of detection (LOD), precision, specificity, and accuracy. When testing a PBMC input range of 0 to 1×10^6 PBMCs/well, the assay was determined to be linear ($R^2 \geq 0.95$), and the countable frequency of spot forming units (SFUs) were between 0 to 700 per well. To establish the LOD, human CMV "responder" PBMCs were supplemented with an increasing concentration of CD3-depleted cells from the same donor (non-responder cells) to artificially create a range of measurable CMV-specific T cell frequencies. The LOD was determined to be 11.2 SFU/million PBMCs, or 2.24 SFUs/well. To test precision, three CMV-responsive PBMC donors were tested over three different days by two independent operators. Intra-assay precision was determined to have a coefficient of variation percent (CV%) of 8.9-18.4% and inter-assay precision was 27.2-29.8% CV. These responses were deemed specific, as when human and NHP PBMCs were tested within the same assay for responses against human (hCMV, pp65) and cynomolgus CMV peptide sequences (CyCMV, UL55/UL83), each showed only a species-specific response. To address accuracy, the frequency of HLA-A2 CMV tetramer-positive cells, as identified using flow cytometry, was directly compared to the frequency of SFUs, as measured by the IFN-γ ELISpot assay. The two different methods were interchangeable, resulting in a Pearson's correlation coefficient of r=0.9. Finally, to assess suitability for use in preclinical safety (NHPs) and in phase I trials (humans), the assay was used to identify AAV9 specific T cell responses. A total of 20 (each) NHP and human PBMCs were tested. Responses were determined to be positive using an empirical method (positive = 2X background and ≥ 50 SFU/ 10^6 PBMCs). Positive stimulation controls included a CEFX peptide pool and mitogen PHA-L. The AAV9 peptides were a single pool of 182 peptides (15mers overlapping by 10, >95% purity). Responses were reproducibly detected in 2 of the 20 commercially purchased human PBMCs. Interestingly, while the NHP PBMCs did show responsivity to CyCMV peptides, confirming functional PBMCs, none of the animals responded to the AAV9 peptide pool. In summary, the qualification of this IFN-γ ELISpot method demonstrates its potential and suitability for use in both late-stage preclinical testing as well as in Phase I immune monitoring. Future directions will include further evaluation of PBMC stability and storage requirements, and continued monitoring of assay performance and suitability over time. We believe the IFN-γ ELISpot method, due to its sensitivity and reduced requirement for cells compared to other methods, will continue to be a useful immunological tool across discovery, preclinical and clinical applications.

1389. Safety of AMP-101 (AAV.Dok7) in Non-Human Primates

Patricio Sepulveda

Amplo Biotechnology, La Jolla, CA

Amplo is a late pre-clinical, gene therapy company, focused on diseases that affect the neuromuscular junction. AMP-101 (AAV-Dok7) was designed and optimised to express Dok-7 protein. AMP-101 has been successfully manufactured in suspension with projected COGS of ~$40,000 / patient. The product is efficacious in several disease mouse

models and safe in mice. We have performed a non GLP non-human primate study to assess the safety of AMP-101 that supports clinical translation.

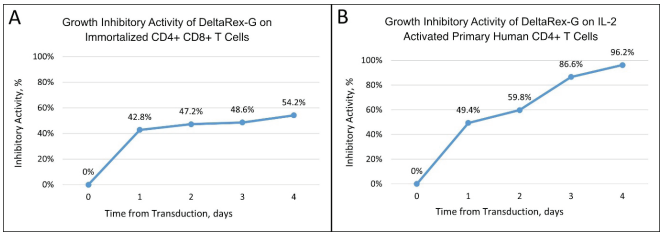
1390. Inline Variable Pathlength Chromatography Application for High Concentration Oligonucleotide Solutions

Teva Smith, Ramsey Shanbaky
Analytics, Repligen, Waltham, MA

With the increased focus on oligonucleotides within biopharmaceutical projects real-time measurements of product concentration can lead to increased efficiency within bioprocessing and manufacturing. A collaboration between C-tech/Repligen and Ionis Pharmaceuticals assessed the viability of inline measurement of oligonucleotide concentration during reverse phase chromatography. This incorporated a variable path length to measure highly concentrated anti-sense oligonucleotide (ASO) eluate. ASO's have become a group of interest in the field of oligonucleotide therapeutics due to successful implementation for diseases such as spinal muscular atrophy and hereditary transthyretin amyloidosis. Now many pharmaceuticals aim to assess the viability and capabilities of ASO's to combat diseases such as Alzheimer's disease, Parkinson's disease and other neurodegenerative diseases. The inline variable path length system ran at wavelength 260nm for a total of two elutions. The first run used a quick kinetic with auto pathlength adjustments to determine the optimal pathlength based on concentration of the eluate during elution. The second run used the optimal fixed pathlength range determined from the first run to maximize measurement frequency. The results were compared to traditional 1mm fixed path UV monitoring. With the 1mm fixed path, the absorbance of the eluted ASO solution is consistently out of the linear range of detection when using either the standard lambda max 260nm wavelength or the 295nm wavelength at which the operation was previously optimized. The test system successfully collected real-time concentration data, within the linear range of detection, at wavelength 260nm during both runs, despite the product solution reaching a peak concentration of 83.6mg/ml during elution. Real-time integration of the UV data from the first run with the auto pathlength setting estimated a collected product mass of 562g, while the results from the fixed pathlength range second run estimated a collected product mass of 526g. These values were compared to the determination of the product mass via an analytical HPLC method, which reported product masses of 506g and 511g, respectively. This represents a 11% (first run) and 2.9% (second run) difference. The project findings support the reliability of inline variable pathlength chromatography application to provide reliable data at target wavelength when compared to traditional fixed path chromatography for high concentration oligonucleotide solutions. The capabilities of inline variable pathlength UV monitoring found in this project provide a reliable alternative for biopharmaceutical laboratories looking to streamline manufacturing process eliminating the need to wait for in-process concentration result to proceed to downstream processing.

1391. Systemic Delivery of SGT-003 Microdystrophin Gene Therapy Using the Novel Capsid AAV-SLB101 Ameliorates Muscle Pathology and Rescues Muscle Function in the *mdx* Mouse Model of Duchenne Muscular Dystrophy

Jamie L. Marshall[1], Jessica Boehler[1], Prushti Bhavsar[1], Jennifer C. Gifford[1], Margaret Beatka[2], Hui Meng[2], Mariah Prom[2], Michael Lawlor[2], Jenny Marlowe[3]
[1]Solid Biosciences, Charlestown, MA,[2]Diverge Translational Science Laboratory, Milwaukee, WI,[3]Solid Biosciences, Cambridge, MA



Duchenne muscular dystrophy (DMD) is a rare, X-linked neuromuscular disease caused by mutations in the *DMD* gene that prevent the production of functional dystrophin protein. The lack of functional dystrophin protein results in severe, progressive muscle wasting and premature death. Solid Biosciences' next generation therapeutic gene therapy candidate SGT-003 utilizes a novel adeno-associated virus vector (AAV-SLB101) and contains a codon-optimized human microdystrophin transgene driven by the muscle-specific CK8 promoter. This unique microdystrophin transgene contains the R16/R17 nNOS binding domain that has been shown to be required for proper nNOS membrane localization and function, which is essential for increasing blood flow to the muscle during exercise to prevent damage that can occur due to functional ischemia. To test the efficacy of SGT-003, systemic injections were evaluated in *mdx* mice at escalating doses. Three months post-SGT-003 treatment, functional efficacy was observed at doses ≥ 6.0E12 vg/kg as measured by forelimb grip strength, EDL specific force production, and treadmill exhaustion. Microdystrophin and beta-sarcoglycan proteins, as well as nNOS enzymatic activity, were detected at the sarcolemma. Improvements in muscle pathology were also observed in response to microdystrophin expression. Overall, these data provided proof of concept for the use of SGT-003 in the treatment of DMD and supported initiation of a Phase I/II clinical study in boys with DMD.

1392. DeltaRex-G Inhibits Growth of Primary Human CD4+ and Immortalized Human CD4+CD8+ T Cells: A Potential Treatment Option for Parkinson's Disease

Erlinda M. Gordon[1], Nadezhda Omelchenko[2], Sant P. Chawla[3], Don A. Brigham[4], Rebecca A. Reed[4], Frederick L. Hall[4], Paul Chang[5], Paul Song[6], Bo Han[7]
[1]Neurodegenerative Disorders, Cancer Center of Southern California/Sarcoma Oncology Research Center and Aveni Foundation, Santa Monica, CA,[2]Cancer Center of Southern California, Santa Monica, CA,[3]Neurodegenerative Disorders, Sarcoma Oncology Center, Santa Monica, CA,[4]Neurodegenerative Disorders, Aveni Foundation, Santa Monica, CA,[5]Neurodegenerative Disorders, NKGen Biotech Inc., San Diego, CA,[6]Neurodegenerative Disorders, NKGen Biotech, Inc., Santa Ana, CA,[7]Tissue Engineering Lab, USC Keck School of Medicine, Los Angeles, CA

Background and Rationale: a-Synuclein, a key pathological component of Parkinson's disease, has been implicated in the activation of the innate and adaptive immune system. This immune activation includes

microgliosis, increased inflammatory cytokines, and the infiltration of T cells into the CNS. More recently, peripherally circulating CD4+ and CD8+ T cells derived from individuals with Parkinson's disease have been shown to produce Th1/Th2 cytokines in response to a-synuclein, suggesting there may be a chronic memory T cell response present in Parkinson's disease. In an animal model of Parkinson's disease, the authors found that T cell responses associated with a-synuclein pathology may be damaging to key areas of the CNS in Parkinson's disease and that targeting these T cell responses could be an avenue for disease modifying treatments (Williams et al., Brain, 2021). DeltaRex-G, an amphotropic retrovector displaying a pathology-targeted decapeptide and encoding a cytocidal *CCNG1* inhibitor gene, has shown clinical benefit and improved dose dependent overall survival in Phase 1 and Phase 2 clinical trials. DeltaRex-G is currently being studied in an FDA authorized expanded access program for an intermediate size population of pancreatic cancer, sarcoma and breast cancer. DeltaRex-G has also gained FDA emergency use authorization to treat severe COVID-19 by killing the activated immune cells that cause ARDS. Methods: To determine if DeltaRex-G, an amphotropic retrovector displaying a pathology-targeted decapeptide and encoding a cytocidal anti-cyclin G1 gene, would inhibit growth of immortalized (Jurkat) human CD4+ CD8+ T cells and IL-2 activated primary human CD4+ T cells in vitro, these cells were transduced with DeltaRex-G as previously described (Zhang et al., Plos Pathogens, 2010). Briefly, $5x10^3$ T cells were transduced with 300 ml DeltaRex-G vector/R10+polybrene or Control R10 + polybrene in 24-well plates, spun for 90 min at 1000 x g at 32°C, followed by incubation at 37°C for 4 hours. Fresh R10 was then added to transduced T cell cultures and further incubated at 37°C overnight. DeltaRex-G -induced growth inhibitory activity was then measured over 4 days post transduction. Results: Figure shows that DeltaRex-G progressively induced 54% inhibition of immortalized CD4+ CD8+ T cell growth (A) and 96% inhibition of IL-2 activated primary CD4+ T cell growth (B) over 4 days post transduction. Conclusion: DeltaRex-G inhibits growth of both immortalized CD4+ CD8+ expressing human T cells and IL-2 activated primary human CD4+ T cells *in vitro*, suggesting that DeltaRex-G has the potential of reducing T cell induced inflammation and neuronal damage in patients with Parkinson's disease.

1393. Assessment and Elimination of Pluripotent Cell Contamination in Stem Cells Derived Cell Therapy Products

Louise Delsing[1], Joana Ferreira[1], Isabelle Matthiesen[1], Märta Häll[2], Marcella Sini[1], Magnus Söderberg[1], Mick Fellows[1]

[1]Clinical Pharamcology and Safety Sciences, AstraZeneca, Mölndal, Sweden,[2]EarlyCVRM, AstraZeneca, Mölndal, Sweden

Stem cells have near limitless potential for use in cell therapy as they can be generated in large amounts and, in theory, differentiate to any cell type. However, in vitro differentiation is rarely 100% efficient and any remaining pluripotent cells could generate a teratoma, creating a significant safety concern and a major hurdle for clinical application. As such, contaminating pluripotent cells need to be identified and eliminated prior to clinical delivery. We describe a combination approach using marker evaluation (flow cytometry and qPCR), the high efficiency culture assay *in vitro* and *in vivo* tumorigenicity studies, to detect undifferentiated cells with high sensitivity. By comparing batches of stem cell-derived therapy product with different levels of pluripotent contamination, we translate how marker levels correlate with contamination of viable stem cells. In addition, we provide data to support the value of a bead based pluripotent cell contamination elimination method targeting a pluripotency marker protein, which ultimately produces a cell therapy product with a pluripotent contamination of less than 1 cell in a 1 million cell dose. We demonstrate the translatability and relevance of these methods to qualify release criteria setting for a stem cell-derived cell therapy product. Furthermore, we demonstrate that *in vitro* methods have superior sensitivity to standard *in vivo* tumorigenicity studies to detect pluripotent contamination, which should be considered in future safety assessment of cell therapy products to deliver more accurate predictions of clinical safety and reduced animal use in research.

1394. The Somatic Cell Genome Editing Consortium Toolkit

Melinda R. Dwinell[1], Jennifer Smith[1], Jeff De Pons[1], Jyothi Thota[1], Angela Lemke[2], Michael Grzybowski[1], Marek Tutaj[1], Monika Tutaj[1], Anne E. Kwitek[1], Aron M. Geurts[1]

[1]Physiology, Medical College of Wisconsin, Milwaukee, WI,[2]Physiology, Medical College of Wiscsonsin, Milwaukee, WI

The Somatic Cell Genome Editing (SCGE) Consortium Toolkit is a publicly available portal to provide access to data and resources generated by members of the SCGE Consortium. The focus of the first phase of the SCGE Consortium includes novel approaches for delivery of genome editing technologies with cell and tissue specificity, independent validation, and approaches to detect adverse effects of genome editing. The SCGE Toolkit has been developed to showcase the results from the SCGE projects and provide access to experimental details including tools, reagents, and protocols with the overarching goal of promoting collaborations and accelerating the use of the validated technologies to the broader scientific community. Data generated by the SCGE Consortium members have common elements, including genome editors, delivery technologies, and models in which these are tested, including large and small animals, and in vitro human biological systems. Metadata fields were identified and defined to standardize the data submission pipeline. The majority of the submissions to the SCGE Toolkit were from the delivery technology initiative and the small animal validation studies designed to provide second site validation of the primary results generated by the delivery projects. Where applicable, the validation studies are highlighted and linked to their respective delivery studies to allow users to discern similarities and differences between the studies and interpret the extent of independent validation. Public access to the submitted data

is through the SCGE Toolkit (https://scge.mcw.edu/toolkit/). Data is organized by SCGE initiative, experiments, and data types. Users can explore and visualize data using common interface components, including filtering functions, standardized structure, and sorting and download options. As submitted data is published, Toolkit data is linked to publications, providing access to the overarching goals of the studies and broader implications of the findings.

1395. Regional Limb Perfusion of AAV1 Gene Therapy Vectors Results in Robust Muscle Transgene Expression in Cynomolgus Macaque

Debora Pires Ferreira[1], Qiushi Tang[1], Darcy Reil[1], April Destefano[1], Janet Benson[2], Jane Lindborg[2], Alisha M. Gruntman[1], Terence R. Flotte[1]

[1]Gene Therapy, University of Massachusetts Chan Medical School, Worcester, MA,[2]Lovelace Biomedical, Albuquerque, NM

Alpha-1 antitrypsin (AAT) is the primary protease inhibitor in human serum, required to mainly protect the lungs from excessive proteolytic damage caused by neutrophil elastase during inflammation. Alpha-1 antitrypsin deficiency (AATD) is a genetic disorder caused by mutations in the *SERPINA1* gene, with the prevalent deficient variant (E342K mutant allele) leading to the PiZ phenotype. This phenotype is characterized by misfolded and polymerized AAT protein, causing hepatic accumulation and impaired plasma secretion, potentially contributing to liver (e.g., chronic hepatitis, cirrhosis) and lung diseases (e.g., COPD, bronchiectasis). As AATD is a monogenic condition with no cure or effective treatment, gene therapy has emerged as a definitive therapy for the disorder. We have previously shown that delivery to skeletal muscle using a venous limb perfusion approach resulted in similar, or higher, levels of serum AAT compared to intra-muscular (IM) injection. In order to bridge these results from the IM injection route used in our last clinical trial to a clinical trial using limb perfusion delivery, we performed a study with doses bracketing our previous clinical trial and comparing the manufacturing method used for the last trial (HSV co-transfection) to the planned method for future trials (triple transfection). We used two vectors packaged in adeno-associated virus serotype 1 (rAAV1), one carrying human AAT (rAAV1-CB-hAAT) that was manufactured using triple transfection and the other rhesus AAT (rAAV1-CB-rhAATmyc) that was used in our last study and manufacturing using HSV. These constructs were administered into the right pelvic limb of a non-human primate (cynomolgus macaque) using a venous regional limb perfusion method. The animals were divided into four groups, with two to three animals in each group that included both male and female members: Group 1 received vehicle (CTRL); Group 2 received rAAV1-CB-hAAT at a dose of 3E12 vg/kg; Group 3 was received rAAV1-CB-hAAT at a dose of 1.2E13 vg/kg; and Group 4 received with rAAV1-CB-rhAATmyc at a dose of 6E12 vg/kg. Our findings demonstrated that the rAAV1-CB-hAAT vector successfully transduces the skeletal muscle and produces relatively high M-AAT serum levels (300-400 μg/ml) (analyzed by ELISA and Western blot for hAAT or c-mycAAT) in a safe manner at both lower (3E12vg/kg) and higher (1.2E13 vg/kg) dosages. When comparing the transduction efficiency and safety profile of the rAAV1-CB-hAAT and rAAV1-CB-rhAATmyc vectors, there was no significant difference. The toxicity profile and potential for organ toxicity were examined through complete blood counts, platelet counts and serum chemistry, there was no evidence of toxicity. The rAAV1-CB-hAAT and rAAV1-CB-rhAATmyc vectors show potential as a viable option for skeletal muscle gene replacement therapy at high doses, particularly in cases of pre-existing liver conditions, offering a "liver-sparing" approach.

1396. Navigating Viral Safety: A Patient-Centric Approach to Biotherapeutic Development

Alysia Birkholz

Texcell - North America, Inc., Frederick, MD

Traditionally, safety assessments for biotherapeutics or drug products are conducted prior to human clinical trials, serving as a vital prerequisite for regulatory approval. Notably, the recently revised ICH Q5A, now R2/revision 2, stands out as a globally harmonized and influential Viral Safety document. This update brings attention to patients with less common or 'orphan diseases,' expanding its scope to encompass a more diverse patient population. The document also provides insights into addressing the imperative of viral testing at earlier stages of development. Alysia Birkholz, a patient and leader in the biotech industry, will share her unique perspective in a deeply personal narrative. She will delve into the significance of such safety testing and emphasize the criticality of early consideration in the development of manufacturing processes. Her story serves as a compelling call to action within the scientific community.

Thursday Posters: Molecular and Cellular Methods

1397. A Versatile Assay for Same-Section Spatial Visualization of Small RNA, mRNA, Exon Junction, Protein and Protein-Protein Interactions

Sonali A. Deshpande, Ge-Ah Kim, Manvir Sambhi, Julia Yu, Li-Chong Wang, Maithreyan Srinivasan

ACD-A Bio-Techne Brand, Newark, CA

Biologics and small molecule therapeutics have been the mainstay of treatment options despite only 0.05% of the human genome targeted by currently approved biologics and 85% of protein targets lack appropriate structural features for efficient small molecule binding and modulation (PMID: 19740696). RNA molecules such as antisense oligos (ASOs) and small interfering RNAs (siRNAs) expand the range of targets available for therapeutic intervention by directly binding to target RNA transcripts to modulate gene function. In addition, biological vector platforms are increasingly used to deliver payloads to either correct a gene function or engineer cell therapies *ex-vivo* or *in vivo*. All these studies require technologies to understand the biodistribution of the potential therapy in pre-clinical models and patient samples to ensure there are no off-target effects. To understand the biodistribution of cell and gene therapies (CGTs) and evaluate their safety and efficacy, we have developed a novel TSA based, protease-free, highly flexible

approach that integrates the ability to visualize miRNAs/ASOs/siRNAs, exon regions, mRNAs, proteins, and protein-protein interactions. The same-slide, 6-plex assay uses newly improved RNAscope chemistry with robust sensitivity of detection for exon junctions and point mutations while retaining the sensitivity and specificity for mRNA and small RNA targets. Here we present a proof-of-concept study to assess the impact of BRAF V600E mutation on miRNA, mRNA and protein targets in the MAPK signaling pathway. These targets enabled visualization and identification of different cell types in the tumor immune microenvironment (TIME). Co-expression of targets resulted in detection of specific tumor infiltrating immune cell populations and analysis of their activation states. The assay offers a powerful technique for multiomic analysis and accurate interrogation of complex tissues to obtain insights into novel biomarkers and therapeutic targets. In addition, the method can contextualize the biodistribution of CGTs with potential protein markers for cell types and further interrogate cell-cell/protein-protein interactions.

1398. RNA/Protein Multiomics Imaging Using RNAscope Technologies to Understand Nonclinical Biodistribution (BD) and Persistence of Gene Therapy (GT) Products

Sonali A. Deshpande, Anushka Dikshit, Manvir Sambhi, Li-Chong Wang, Maithreyan Srinivasan
ACD-A Bio-Techne Brand, Newark, CA

With over ten approved gene therapies and over 1500 ongoing GT clinical trials, the FDA has issued recommendations to generate nonclinical biodistribution (BD) data for "the evaluation and interpretation of nonclinical pharmacology and toxicology findings prior to initiation of human clinical trials". While several technologies to assess BD exist, RNA *in situ* hybridization is increasingly used to spatially visualize the delivered therapeutic, target gene, transgene and/or cell markers and complement information gathered from molecular technologies such as quantitative polymerase chain reaction (qPCR). Recently, RNAscope technologies have been widely used to co-detect the presence of vector and transgene expression as well as ASO/siRNAs and their intended mRNA targets. To enhance the information gained from these technologies and to satisfy FDA recommendations on understanding BD in the context of on and off-target cell types and tissues we have developed a novel codetection method that enables the detection protein targets along with of miRNAs/ASOs/siRNA and mRNAs. Built on the flagship RNAscope technology, the RNAscope Plus assay can detect 1 small RNA and 3 mRNA targets using TSA-based fluorescent readouts. Fixed, fresh frozen samples and formalin fixed paraffin embedded (FFPE) tissues are supported by manual and automated workflows using the Leica Bond Rx system. We have leveraged this technology to investigate spatial expression profile of miRNA and associated RNA targets across different tissue types and applications. We can also combine protein detection using a target antibody to visualize cell-type specific markers. This assay was used to demonstrate expression of miRNAs and target genes implicated in tumor initiation, progression, and angiogenesis. Expression of miR-205, associated tumor target genes such as *PTEN* and tumor suppressor *TP53* was visualized in head and neck cancer tumors. Downregulation of tumor-suppressor, *TP53* resulted in upregulation of miR-205 which downregulates *PTEN* expression. PanCK (protein) stained the tumor region in the tissue. This novel platform will enable researchers to visualize regulatory RNA simultaneously with target RNAs, protein, cell type and morphology markers in intact cells/tissues with single cell resolution. This technology can provide meaningful insights into disease pathology driven by miRNAs as well as assess biodistribution and efficacy of oligonucleotide therapeutics.

1399. Efficient Delivery of Lentiviral, DNA, and mRNA Reporter Gene Vectors in Human Colonic Organoids

Yanghao Fu[1,2], Mathieu Derouet[3,4], Samuel Asfaha[3,4], John Ronald[5]
[1]Medical Biophysics, University of Western Ontario, London, ON, Canada,[2]Robarts Research Institute – Imaging, London, ON, Canada,[3]Medicine, University of Western Ontario, London, ON, Canada,[4]Schulich School of Medicine & Dentistry, London, ON, Canada,[5]Medical Biophysics, The University of Western Ontario, London, ON, Canada

Introduction: Colorectal cancer (CRC) is a leading cause of cancer-related mortality, ranking second for men and third for women (Favoriti et al., JGO, 2019). Colonic organoids, developed from single colonic epithelial stem cells, effectively replicate the gut lining and are instrumental in studying human colonic physiology and diseases like CRC. These organoids offer significant advantages over small animal models, particularly in high-throughput screening of therapies and modeling human colon cancer progression (Yoo et al., WJG, 2019). To date, few laboratories have successfully modified organoids using transgene delivery methods using plasmids (Sato et al., Nat Prot, 2015) or lentiviral vectors (Spence et al., 2022). Given the transient and safe nature of mRNAs, exploring novel mRNA delivery into colonic organoids as a method of delivering gene editing systems is of significant interest. Our research focuses on comparing the efficiency of plasmids, lentiviruses, and mRNA gene delivery vectors for carrying a green fluorescent reporter gene into colonic organoids. **Methods:** We generated healthy human colonic organoid lines from patient-derived crypts, isolated and dissociated into single cells, then cultured in Matrigel. Plasmids and mRNA encoding green fluorescent protein (GFP) were delivered using electroporation, with rock inhibitor to reduce cell death during dissociation. Lentiviruses were mixed with dissociated organoids before embedding in Matrigel-coated wells, followed by fluorescence imaging at various time points post-delivery. Flow cytometry was used to assess delivery efficiency, and organoid growth was measured on the 7th day. Organoid establishment rates were tracked from day 1 to day 7. **Results:** Delivery efficiencies were approximately 80% for lentiviruses, 55% for DNA, and 85% for mRNA. Notably, mRNA delivery was significantly more efficient than plasmid-based methods ($p < 0.01$). Organoid growth post-delivery showed no significant differences across the groups, indicating the viability of all these methods for gene delivery. **Discussion:** This study underscores the versatility of gene delivery methods in colonic organoids, with lentiviral vectors enabling permanent gene integration and mRNA providing a safe, transient alternative for gene editing. The development of an efficient mRNA delivery system, reminiscent of its application in COVID-19 vaccines, represents a significant stride in CRC research, offering new avenues for modeling the disease and testing therapeutic

interventions. The differential permanence of gene expression by these vectors enriches the toolkit for genetic studies in colonic organoids, facilitating in-depth investigations of CRC onset and treatment efficacy.

1400. Mapping AAV Integrations Using Long-Read Sequencing (MAILR) to Solve the Structure of Complex AAV Integrations Associated with Genotoxicity

Eli J. Kaufman[1], Randy J. Chandler[2], Charles P. Venditti[2], Paul N. Valdmanis[1]

[1]Medicine (Medical Genetics), University of Washington, Seattle, WA,[2]National Institutes of Health, Bethesda, MD

Background: Recombinant AAV integration after gene therapy in preclinical models and clinical trials remains a critical determinant of long-term safety in patients. While considered a non-pathogenic virus, rAAV exposure can cause hepatocellular carcinoma (HCC) formation in mice (PMID: 28293963) and is associated with clonal expansion of transduced hepatocytes in hemophiliac dogs (PMID: 33199875). Additionally, the recent observations that integrated AAV vectors not only contribute to long term transgene expression in nonhuman primates but display complex rearrangements after integration (PMID: 37932420) further highlight the need to comprehensively investigate rAAV integration. Previous studies have largely relied upon LAM PCR, with primers anchored into the ITR, to amplify integration junctions, and the recovery of both 5′ and 3′ ends of integrated vectors has remained elusive and recalcitrant to chromosomal walking. **Methods:** To systematically evaluate rAAV integrations in an unbiased manner, we developed a pipeline that relies upon whole genome Nanopore long-read sequencing in an approach we designate as Mapping AAV Integrations using Long-Read sequencing (MAILR). DNA was obtained from from 21 mouse HCCs, many of which were associated with AAV integrations at the mouse *Rian* locus on chr12qF1 (PMID: 25607839). Samples were barcoded and then multiplexed and sequenced on a PromethION machine, yielding 72 million reads. We split the library into an initial flow cell for whole genome sequencing (achieving an N50 of 13.9kb) and two subsequent flow cells with alignment to an adaptive sampling file corresponding to regions of integration and the delivered AAV vector to enrich for integration reads. We used minimap2 for genome alignment, sniffles2 (v2.2) for calling insertions and deletions, and the MinKNOW integrated basecaller to query read methylation. **Results:** We successfully retrieved long reads that spanned both AAV integration junctions and the complete integrated sequence for 11/21 HCCs (52%), including several samples that failed LAM PCR based characterization. Each integration was unique, ranging from 255 to 4,545 bp, and was specific to the *Rian* locus on chr12qF1. However, within each tumor, AAV reads were homogenous and approached 50% of reads (1 of 2 chromosomes) at integration sites, suggesting clonality of the tumor sequence. All integrations contained promoter or enhancer elements, though only two contained the complete transgene. Importantly, we recovered several classes of integrations that would not be detected using conventional techniques, including one completely devoid of ITR sequence, another with a complex inversion event within the locus, and an integration coupled with a chromosomal translocation event between *Rian* and mouse chromosome 8. As Nanopore sequencing also permits methylation analysis, we determined that all integration-containing reads (43 total) were associated with DNA hypomethylation *in cis*, while the corresponding reads on the non-integrated allele were universally hypermethylated (46 reads). RNAseq confirmed that integration-associated DNA hypomethylation was associated with microRNA and RNA over-expression at the *Rian* locus. **Conclusions:** We demonstrate that our long-read sequencing and analysis pipeline, MAILR, is a cost-effective and sensitive approach to recover complex rAAV integration events associated with genotoxicity. MAILR addresses a critical gap in identifying potentially oncogenic rAAV integration events longitudinally across various organs both in preclinical models and in human subjects after gene therapy.

1401. Automated Analysis of High-Resolution Whole Genome Maps for Biodosimetry

Christopher J. Tompkins[1], Matthew McGowan[1], Douglas Brugge[2], Susan Bailey[3], Erin Cross[1], Aaron Datesman[4]

[1]KromaTiD, Longmont, CO,[2]University of Conneticut, Farmington, CT,[3]Colorado State University, Fort Colins, CO,[4]University of Virginia, Washington, DC

Understanding the relationship between a past exposure to radiation or cytotoxic compounds requires a highly sensitive measure of long-lasting DNA damage markers typically through a single cell cytogenetic test for structural variation. Historically, however, these cytogenetic biodosimetry assays have measured DNA damage in only a fraction of the genome or focused on individual classes of structural events, such as dicentric chromosomes. The dGH SCREEN assay developed by KromaTiD Inc. is whole genome cytogenetic test that uses ten million individual oligonucleotide hybridization produces targeting all the unique sequence in the genome. dGH produces high-resolution, single-cell whole genome maps of genomic rearrangements as small as 5Kb. Because of the unique nature of the dGH platform, dGH SCREEN is an unbiased measure of *all classes* of structural variants, including those involving orientation changes, such as inversions. Previous work with the SCREEN assay has demonstrated that this whole genome approach provides a higher sensitivity measure of structural variation and thus a more robust correlation of rates of structural variation with received dose. Inversions, in particular have proven to be more sensitive biodosimeters as they are more common and more stable than translocations. However, a critical limitation to the throughput of any single-cell cytogenetic assay is the labor involved in assessing the images of many individual genomes, labor that increases exponentially with the genomic coverage. For instance, in a typical unautomated cytogenetic analysis, the requirements of human scorers limit the number of single cell genomes analyzed to tens or hundreds and our human poweredl biodosimetry SCREEN assay is usually performed on only 50 single cell genomes. To address this limitation, which is most significant for low dose exposures with their corresponding rarer DNA damage events as well as for modified cells with low rates of off-target editing we have developed dGH SCREEN into a high-throughput automated cytogenetic DNA damage test. Using an efficient data pipeline combined with a well-trained AI, we are now measuring the long-lasting DNA markers of radiation exposure in a cohort exposed during and after the accidental Three Mile Island radiation release, analyzing tens, hundreds or even thousands of genomes with essentially no human image analysis labor. For the TMI cohort in particular, the extent and types of radiation released was not enough to explain the

reported clusters of cancers and other health effects downwind from the accident. Using AI SCREEN we are today providing the only method with the required sensitivity to understand the biological mechanisms of DNA damage after low dose exposures while at the same time, measure the true received dose of the exposed population. Finally, the method developed for measurement of historical radiation exposures is today being used to detect off-target DNA damage in batches of edited cells which occur at low frequency but provide similar long term cancer risk to patients receiving gene therapies.

1402. Genomic Integrity G-Banding for Cell and Gene Therapy Drug Product

Christopher J. Tompkins, Greg Husar, Matt McGowan, Michael Vernich

KromaTiD, Longmont, CO

T-Cell gene therapy drug products show great promise for treating refractory hematological diseases. However, when moving from an autologous to allogeneic treatment strategy, additional editing steps are required to prevent graft versus host disease and the edited cell population must be stimulated and expanded to produce batches large enough to treat multiple patients. Both the editing and the expansion are robust cellular processing steps, but they do create additional opportunities unwanted editing by-products, sub-clonal outgrowth, and/or genomic instability. To advance these novel gene therapies from R&D to the market while minimizing new risks to the patients, requires measurements of structural variation, sub-populations and markers of instability.G-banded Karyotyping is a classic cytogenetic method for imaging the structure of metaphase chromosomes typically applied to measure the high frequency structural variation associated with genetic diseases. While the resolution of G-banding is poor when compared to DNA hybridization based methods such as metaphase FISH or dGH, as a stain of secondary chromosome structure, G-Banding is an orthogonal and complementary approach to any measurement of DNA structure or sequence. As a metaphase chromosome "mapping" method, Single-cell g-banding karyotyping offers a direct visualization of individual chromosomes and the method is sufficient to detect large structural variations such as translocations or aneuploidy along with markers of instability such as complex rearrangements. When producing cell and gene therapy drug product from donor cells or cell lines, maintaining the integrity of the genome throughout editing and expansion is critical. Here we describe an adaption of classical G-Banding: **Genomic Integrity G-Banding** optimized for Cell and Gene therapy products. Rather than focused on high-frequency events driving genetic diseases, Genomic Integrity G-Banding uses larger numbers of cells (typically 100 or 200 rather than 20) to measure the low frequency events that occur during editing and expansion. This measurement is performed using a matched sample pair: the pre-editing donor or wild-type cells and the final drug product after editing and any required expansion. Genomic Integrity G-Banding is then a "before" and "after" comparison measuring the differences between edit associated structural variants and karyotypic variation from the baseline levels in donor cells. Importantly, the risk associated with instability or a specific variant is only related to the identity of the variant, not the source. Genomic Integrity G-Banding is a true, unbiased method and an equivalent measure of structural variation regardless of causation, whether that be an edit, impaired DNA damage repair capacity, or a variation contributed to the drug product from the donor cells themselves.

1403. dGH In-Site: An Assay System for the Simultaneous Single Cell Measurement of Edit Associated Structural Variation and Transgene Localization

Christopher J. Tompkins, Erin Cross, Stephen Gross

KromaTiD, Longmont, CO

Cell and Gene therapy products such as CAR-T or CAR-NK often require complex editing systems combining nuclease-based editing with insertion of one or more transgenes into the target genome. This complexity leads to additional opportunities for on- and off-target double-strand breaks which can mis-repair to form structural variants, such as inversions and translocations. Even in systems with highly specific targeted transgene insertions, there is the potential for off-target insertions at random or off-target editing loci within the genome.These number (and sometimes location) of the transgenes in these complex edited products can be measured on average by NGS or dPCR methods. However this averaging divorces structural variant and transgene data from any cellular context, making it impossible to observe co-localization of events or distribution of transgenes in a batch of edit cells; with only dPCR data, it is not possible to differentiate one cell with ten transgenes from two cells with five transgenes.This type of quantitation is best performed by a comprehensive, single cell method such as directional Genomic Hybridization™ (dGH™). dGH is a unique cytogenetic technique for mapping the structure and structural variation of individual genomes in single cells. Based on images of fluorescently labeled DNA probes designed to target specific loci and hybridized to metaphase chromosomes, dGH in-Site assays provide direct detection of structural variation, including DNA inversions, a common editing by-product. Combining this data with the number and location of transgene insertions however, is challenging due to the relatively small size of therapeutic CARs, often smaller than 2Kb. By combining advanced DNA probe design strategies that avoid homology, repetitive sequences and other sources of fluorescent signal noise with the unique sample preparation inherent in dGH, we have designed and qualified a single cell assay system for the simultaneous measurement of edit associated structural variation and transgene localization *in the same single cell*. Using a model transgene system we demonstrate the potential of this system for understanding the true structural heterogeneity in batches of edited cell products.

1404. A High Throughput, Multi-Plex, ddPCR-Based Platform for Cellular Kinetics and Biomarker Detection in Biofluid and Tissue Samples

Neha Sangewar, Jean-Pierre Minembe, Jing Mo, Hiroshi Sugimoto

Global DMPK, Takeda Pharmaceuticals (TBOS), Cambridge, MA

Droplet digital PCR (ddPCR) is a widely used platform for the detection and quantification of cell/gene therapy drugs, genetic mutations and disease biomarkers. It allows absolute quantification of target with high

accuracy and precision, and is compatible with various sample types. A typical ddPCR assay used in discovery and clinical research involves using FAM and HEX probes for detecting a target chimeric antigen receptor (CAR) gene for monitoring the CAR cells and a reference gene for normalization in blood samples. However, due to shared homology, the detection of CAR cells in mouse models xenografted with human tumors is challenging. Also, the CAR-specific 2-plex assay isn't designed for detecting un-transduced (UTD) control cells in the xenografted mouse model. Therefore, we applied a higher order of multi-plex using the QXOne ddPCR system where we developed a 4-plex assay for concurrently tracking CAR and UTD cells in the xenograft model. Using the same 4-plex assay format, we also designed an RT-ddPCR assay for detecting multiple target mRNA biomarkers in support of quantitative biomarker studies. Lastly, we developed a high throughput, automated, multi-plex assay workflow that we apply to rapidly bulk-analyze the *in vivo* study samples for CAR and biomarker quantification (Fig. 1). Hence, we are reporting here two case studies outlining the application of this multi-plex platform to generate cellular kinetics and genomic biomarker data. In the first study, we analyzed the blood samples from tumor xenografted mice that were dosed with either CAR cells, UTD cells or PBS using our 4-plex ddPCR assay. We successfully measured the proprietary CAR (FAM) and armoring (Cy5.5) constructs in CAR cell dosed mice. In the UTD group, UTD cells were detected using a human-specific gene (Cy5) whereas in PBS group, only the reference mouse- and human-specific gene (HEX) used for genomic DNA input normalization was detected. Our results demonstrate that our 4-plex assay allows simultaneous detection of CAR cells, armoring payload and UTD cells in *in vivo* samples which is highly crucial for the efficacy, toxicity and long term persistence analysis of the cell therapy product. In the second case study, we used the 4-plex one-step RT-ddPCR assay for mRNA quantification in the control non-human primate (NHP) biofluid and tissue samples. We observed that compared to the MetAP2 (HEX) and NONO (CY5) mRNA levels, the PIKfyve (FAM) mRNA levels were extremely low in NHP biofluid samples where PPP2R5C (Cy5.5) mRNA was used as housekeeping reference for normalization. In contrast, all three biomarkers were detected consistently in the tissue samples. Additionally, the developed 4-plex RT-ddPCR assay successfully detected these biomarkers, that are potential therapeutic targets for treating cancer such as glioblastoma (NONO and MetAP2) and B-cell lymphoma (PIKfyve), in control human tissue samples. So, our data shows that the 4-plex RT-ddPCR can be a valuable tool for supporting biomarker studies for drug target engagement and treatment prediction. Overall, we have designed a multi-plex genomic assay platform which is high throughput, automated, fast and adaptable across non-clinical and clinical studies.

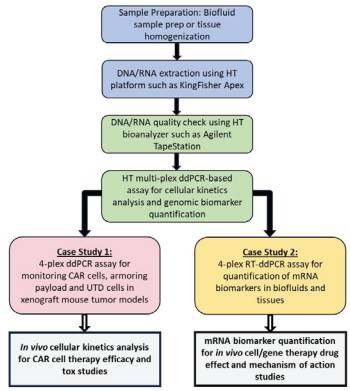


Figure 1. High throughput ddPCR-based multi-plex genomic assay workflow.

1405. Analyzing CAR T-Cell Genomes: Heterogeneity, Integration Patterns, and Safety Considerations

Maya Wright, Emily Caulfield, Dirk Kruit, Irina Sergeeva, Bergboer Judith, Georgios Georgiou, Nicole Hendriks, Ellen Stelloo

Cergentis, Utrecht, Netherlands

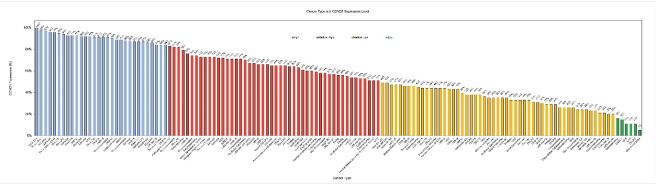
Chimeric Antigen Receptor (CAR) T-cell therapy has demonstrated substantial efficacy in hematological malignancies, yet concerns persist over the safety of viral and transposon-based vectors used for gene transduction due to the potential risk of insertional mutagenesis. This is not unprecedented, as the FDA has received reports of T-cell malignancies in patients who received treatment with CAR T-cell immunotherapies. Targeted Locus Amplification (TLA), an NGS technology based on proximity ligation, allows comprehensive genetic characterization of engineered CAR T-cells, focusing on the distribution of vector integrations and their proximity to cancer-related genes. Viable frozen retroviral transduced human T-cells were processed using Cergentis' TLA protocol. Genetic analysis, employing high-throughput sequencing, identified 1,078 different integration sites based on breakpoint sequences. The integration sites were distributed across all chromosomes in gene exons (5%), gene introns (48%) and within 1 kb upstream of genes (8%). Viral integration in gene exons occurred in 49 genes from which 11 were listed as cancer genes in the *NCG7.0 network of cancer genes*. While no integration site occurred more frequently than other sites, the sample exhibited significant heterogeneity; most of the integration sites were present in a limited number of reads with no overlap between the TLA data of 2 primer sets. Additional amplifications and/or sequencing could further illuminate integration patterns and sample heterogeneity. The sample's heterogeneity prohibited variant detection within the integrated provirus in individual integration sites but allowed analysis of abundant variants. In conclusion, TLA has proven valuable to identify integration sites, their distribution, and proximity to cancer-related genes. The occurrence of viral integrations within cancer-related genes emphasizes potential risks. A comprehensive understanding of CAR T-cell genetics is crucial for advancing these therapies safely and aligning them with stringent regulatory standards.

1406. Comparative Analysis of U937 and THP-1 Monocytic Cell Lines as Macrophage Models for Drug Discovery

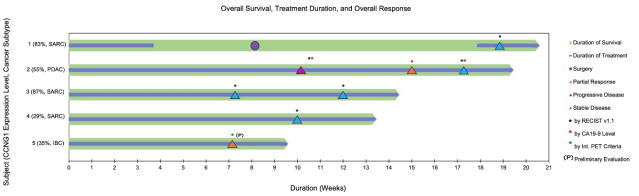
Shasha Li, Cindy Merino, Miguel Calero-Garcia, Mihee Kim

CSL Behring, Pasadena, CA

In drug discovery, high-throughput screening plays a pivotal role, especially in gene therapies. Robust and scalable cellular models are crucial for these endeavors, but challenges with primary monocytes and macrophages, such as donor variability and limited cell numbers, lead researchers to monocytic cell lines. This study thoroughly characterizes the responses of U937, and THP-1 cell lines after priming with phorbol 12-myristate 13-acetate (PMA) and exposure to polarizing stimuli. Differentiation into macrophage-like cells is induced using lipopolysaccharide (LPS), interleukin-4 (IL-4), or interferon-stimulating DNA (ISD). Evaluation includes immunophenotyping with 242 markers via flow cytometry, cytokine secretion profiling (16 cytokines) using the meso scale delivery platform (MSD), and interferon-stimulated gene (ISG) transcriptomic signatures via quantitative polymerase chain reaction (qPCR). Additionally, U937 and THP-1 cells show distinct transduction availabilities when transduced with lentiviral vectors. Despite differences from primary macrophages, these unbiased findings provide critical data for future drug screening assays using U937 and THP-1 cells, contributing insights to optimize gene therapy and drug discovery strategies.



Thursday Posters: Gene Therapy Trials - In Vivo Modification



1407. Deltarex-G Plus (Deltarex-G + FDA Approved Drug) Demonstrates Clinical Benefit in Advanced Chemoresistant Pancreatic Cancer, Sarcoma, and Breast Cancer (NCT04091295)

Samantha Jeffrey[1], Nadezhda Omelchenko[2], Vaishali Kumar[3], Rheanna Carter[4], Anmol Dia Agarwal[3], Rebecca A. Reed[1], Neal S. Chawla[3], Don A. Brigham[5], Ishrat Bhuiyan[3], William H. Isacoff[2], Michael A. Morse[6], William Swaney[7], Sant P. Chawla[8], Erlinda M. Gordon[1], Frederick L. Hall[5]

[1]Medical Oncology, Cancer Center of Southern California/Sarcoma Oncology Research Center and Aveni Foundation, Santa Monica, CA,[2]Medical Oncology, Cancer Center of Southern California, Santa Monica, CA,[3]Medical Oncology, Cancer Center of Southern California/Sarcoma Oncology Research Center, Santa Monica, CA,[4]Medical Oncology, BostonGene, Morgan Hill, CA,[5]Medical Oncology, Aveni Foundation, Santa Monica, CA,[6]Medical Oncology, Duke University Medical Center, Durham, NC,[7]Medical Oncology, Expression Therapeutics Inc., West Chester, OH,[8]Medical Oncology, Cancer Center of Southern California/Sarcoma Oncology Center, Santa Monica, CA

Background: Expanded access for DeltaRex-G, a tumor targeted retrovector encoding a CCNG1 inhibitor, is being studied for advanced cancers. **Methods:** CCNG1 expression levels in 137 tumors were assessed by RNA analysis. Nine cancer patients with known CCNG1 levels received DeltaRex-G with an FDA-approved drug (DeltaRex-G Plus) or as monotherapy. Overall survival, duration of treatment, and responses were evaluated. **Results:** Enhanced CCNG1 expression levels are depicted in Figure 1 by cancer type. Thirty (22%) tumors showed High CCNG1 expression, 48 (35%) showed Medium-High CCNG1 expression, 53 (39%) displayed Medium-Low CCNG1 expression, and six (4%) had Low CCNG1 expression. One hundred (73%) patients had metastatic disease, and 37 (27%) had localized disease. There was no correlation between CCNG1 expression and disease stage. Four patients with advanced pancreatic cancer, HR+Her2+ invasive breast cancer, triple negative breast cancer, and squamous cell carcinoma received DeltaRex-G between 2008 and 2021 and are alive 15, 3, 2.5, and 2.5 years from treatment initiation, respectively. Their tumors showed CCNG1 expression levels of 24%, 23%, 74%, and 40% respectively. One patient with pancreatic cancer and 2 patients with breast cancer enjoy sustained remission. Five patients are currently being treated with DeltaRex-G Plus: one patient with advanced breast cancer had a partial response, one patient with advanced pancreatic cancer and three patients with sarcoma had stable disease. All 5 patients had previously progressed with standard doses of chemotherapy. All patients are alive from 9 to 20 weeks since treatment initiation. Figure 2 illustrates the cancer type/CCNG1 expression level on the vertical axis and time from treatment initiation, duration of survival, and duration of treatment on the horizontal axis. No serious treatment-related adverse events have been reported. **Conclusions:** Taken together, the data shows that (1) 100% of 137 tumors tested have enhanced CCNG1 expression, further reinforcing the 2021 FDA-CBER authorization for use of DeltaRex-G Plus, and (2) DeltaRex-G Plus is a promising therapy for advanced pancreatic cancer, sarcoma, and breast cancer. Randomized Phase 2/3 studies are warranted to confirm the efficacy and safety of DeltaRex-G Plus.

1408. Preliminary Safety Results from the Ph1/2 Study of NGN-401, a Novel Regulated Gene Therapy for Rett Syndrome

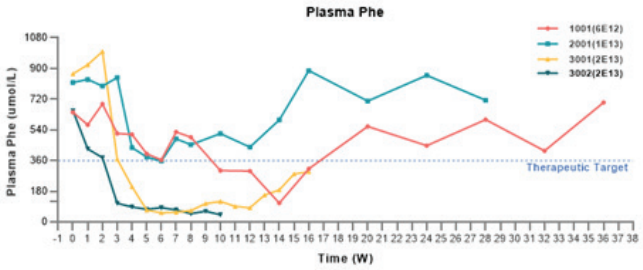
Bernhard Suter[1], David Lieberman[2], Sravan Jaggumantri[3], Cynthia Feng[3], Stuart Cobb[3], Julie Jordan[3]
[1]Departments of Pediatrics & Neurology, Texas Children's Hospital, Baylor College of Medicine, Houston, TX,[2]Department of Neurology, Boston Children's Hospital, Harvard Medical School, Boston, MA,[3]Neurogene Inc., New York, NY

Introduction: Rett syndrome (RTT) is an X-linked severe neurodevelopmental disorder of the nervous system caused by mutations in the *MECP2* gene that lead to deficiency of the methyl-CpG binding protein 2 (MeCP2). Conventional gene therapy approaches have not successfully advanced beyond preclinical development, as the MeCP2 levels required for efficacy are commonly associated with rapid onset toxicity, driven by the overexpression of MeCP2 in highly transduced cells. NGN-401, a recombinant AAV9 gene transfer therapy containing the full-length human *MECP2* gene, uses Neurogene's proprietary transgene regulation EXACT technology, designed to express a therapeutic level of MeCP2, while avoiding toxicity associated with overexpression in each transduced cell. Head-to-head biodistribution comparison of various routes of delivery for AAV9 demonstrated in non-human primates that intracerebroventricular (ICV) administration yields a 10-100x higher level of vector biodistribution to key areas of the brain that drive fundamental phenotypes in RTT relative to intrathecal lumbar administration. As a result, all nonclinical studies of NGN-401 were conducted using ICV to maximize its therapeutic potential in clinical studies. **Study Design:** NCT05898620 is an ongoing Phase 1/2 open-label study evaluating the safety, tolerability, and preliminary efficacy of NGN-401 in pediatric female subjects ages 4-10 years old with classic RTT, and Clinical Global Impression-Severity scores of 4-6. NGN-401 is delivered via ICV administration and prophylactic immunosuppression with corticosteroids is initiated at Day -1. Subjects in Cohort 1 receive a one-time total dose of 1E15 vector genomes. **Study Results:** The first three enrolled subjects were ages 7, 4 and 6 years at baseline, with a milder missense mutation in the first subject and mutations shown or predicted to be more severe in subjects two and three. Follow up data at the time of the abstract submission was approximately 6 months, 3 months, and 2 weeks for the three subjects. NGN-401 administration was generally well tolerated by all 3 subjects with no procedure-related adverse events. No clinical or laboratory signs or symptoms of MeCP2 overexpression (ie, no evidence of respiratory, gastrointestinal, or neurologic manifestations) have been observed in any subject post NGN-401 administration. Alltreatment-related adverse events have been mild (Grade 1). There has been oneGrade 1 ALT elevation and one Grade 1 AST elevation. All elevated liver enzyme levels have resolved or are resolving with corticosteroid administration. There have been no treatment-related serious adverse events. **Conclusions:** NGN-401 given via one-time ICV administration has been generally well tolerated, with an adverse event profile consistent with AAV9 administration. No clinical evidence of MeCP2 overexpression was observed in three pediatric female subjects with differing pathogenic mutations of classic RTT, including one predicted to result in residual MeCP2 function.

1409. Optogenetic Therapy UGX-201 for Patients Inflicted by Advanced Retinitis Pigmentosa: Interim Results of an Investigator Initiated Trial to Evaluate the Safety, Tolerability and Preliminary Efficacy at First Affiliated Hospital of Soochow University

Peirong Lu[1], Ziyue Song[1], Gaoqin Liu[1], Xiaohua Liu[2], Sijie Sun[2], Shanzhong Zhang[2,3], Li Li[2]
[1]The First Affiliated Hospital of Soochow University, Suzhou, China,[2]Ugenex Therapeutics Ltd.Co, Suzhou, China,[3]Otovia Therapeutics, Shanghai, China

Background: Retinitis pigmentosa (RP) is a genetic disorder characterized by progressive loss of vision due to degeneration of retinal photoreceptors. Optogenetic therapy represents a novel therapeutic approach, aiming to confer light sensitivity to retinal neurons which are normally light-insensitive. UGX-201 is an investigational optogenetic therapy designed to restore partial vision in advanced RP patients. It utilizes an adeno-associated virus (AAV) vector containing a gene of interest that expresses recombinant opsin upon transfection of retinal ganglion cells (RGCs), enabling them to perceive light and convert it to electrical signals. Methods: An open-label, single-arm investigator initiated trial (IIT) was conducted to evaluate the safety and efficacy of UGX-201 in advanced RP patients at the ophthalmology department of the First Affiliated Hospital of Soochow University, China. The trial was approved by the Science and Ethical Committee of the hospital. It planned to enroll two distinct cohorts: Cohort 1 included patients with extremely low visual acuity (Best-corrected visual acuity, BCVA<0.02) but with light perception, and Cohort 2 included patients without light perception, 6 patients each. Every patient signed an Informed Consent Form (ICF), underwent all necessary screening tests, and then received the investigational treatment. Following the treatment, the patients were followed for up to 52 weeks. The primary outcome measures of the study were focused on evaluating the safety of UGX-201, while the secondary outcome measures were aimed at assessing its efficacy. To date, enrollment has been completed for Cohort 1, with 6 patients, and has begun for Cohort 2, with 1 patient enrolled. Results: The interim results of the investigator-initiated trial evaluating the safety, tolerability, and preliminary efficacy of UGX-201 in advanced retinitis pigmentosa (RP) patients have shown promising outcomes. The safety profile of UGX-201 demonstrated favorable results, with no serious adverse events reported and all adverse events being of grade 1 seriousness. In terms of efficacy, the first patient in Cohort 1, barely able to see finger counting at 10cm at baseline, showed improvements in visual acuity, as evidenced by their performance on the Early Treatment Diabetic Retinopathy Study (EDTRS) chart, FrAct LogMAR and Full-field Stimulus threshold Testing (FST) results. The results suggest that UGX-201 optogenetic therapy has the potential to yield substantial improvements in visual function for patients with advanced RP, even for those with extremely low baseline visual acuity. Further data from the completion of follow-up for remaining patients in Cohort 1 and assessment of Cohort 2 will provide more comprehensive information on the safety and efficacy of UGX-201. Conclusion: Initial findings of this IIT indicate that UGX-201, the optogenetic therapy using the AAV vector to deliver and express recombinant opsin in RGCs, could be a safe and effective treatment for enhancing visual function in individuals with advanced RP, even those with extremely low baseline visual acuity.



More comprehensive data on the safety and efficacy of UGX-201 will be obtained upon completion of follow-up for the remaining patients in Cohort 1 and the full enrollment and assessment of Cohort 2.

1410. Safety and Efficacy of NGGT002 (rAAV8-hPAH) in Adults with Phenylketonuria (PKU): Results from an Investigator Initiated Study

Huan Zhou[1], Xiaoli Li[1], Gang Wang[2], Zhimin Shi[2], Yiting Liu[3], Guang Qu[2,3], Lixin Jiang[2,3], Hongju Wang[1]

[1]National Institute of Drug Clinical Trial, The First Affiliated Hospital of Bengbu Medical College, Bengbu, Anhui, China,[2]NGGT (Suzhou) Biotechnology Co., Ltd., Suzhou, Jiangsu, China,[3]NGGT, Inc, Walnut Creek, CA

Introduction: Phenylketonuria (PKU), also known as Phenylalanine hydroxylase (PAH) deficiency, is a rare autosomal recessive inherited disorder of phenylalanine (Phe) metabolism, most commonly caused by pathogenetic variants in the PAH gene. Hepatic PAH is responsible for the conversion of Phe to tyrosine (Tyr). Deficiency of PAH activity results in accumulation of Phe and lack of Tyr in the blood and brain, and subsequently abnormal brain development in childhood, psychiatric and cognitive problems in adults. The outcomes of current dietary restriction treatment are still suboptimal and pharmacological approaches have drawbacks. NGGT002 is an AAV8-based vector carrying the optimized expression cassette for human PAH (hPAH) and being investigated for treatment of PKU. Here, we present the safety and efficacy results of 4 adults with PKU who received a single intravenous (IV) infusion of NGGT002 in an investigator initiated trial (IIT). **Methods:** In the dose-exploring IIT study (NCT06061614), NGGT002 (rAAV8-hPAH) was administered at three ascending doses into adult PKU patients who had confirmed PAH mutations and displayed baseline serum Phe levels of ≥600 μmol/L. The primary endpoints included the incidence and severity of treatment-related side effects and the proportion of patients achieving a sustained blood Phe concentration of ≤360 μmol/L, the therapeutic goal, at 12,24,52 weeks after infusion. All participants will be followed for up to 5 years. **Results:** Four participants were enrolled in the study. As of the cut-off date (January 13, 2024), 1 participant dosed at 6.0×10^{12} vg/kg was followed up for 36 weeks, 1 at 1.0×10^{13} vg/kg for 26 weeks and 2 at 2.0×10^{13} vg/kg with 1 for 16 weeks and the other for 10 weeks. The most common treatment-related adverse events (AEs) reported in all subjects were transient and asymptomatic elevations in liver enzymes alanine aminotransferase (ALT) and aspartate aminotransferase (AST), which were well-managed by a tapering course of corticosteroid treatment. No severe liver dysfunction or long-term AEs on liver function was observed. All other AEs were identified as grade 1 or 2. All 4 subjects responded to NGGT002 treatment as demonstrated with a reduction in blood Phe level. 2 subjects dosed at 2.0×10^{13} vg/kg showed more rapid and significant decreases in blood Phe, reaching the normal level of ≤120 μmol/L. These subjects maintained a stable Phe level below the therapeutic goal of 360 μmol/L for at least 13 weeks as of data cut-off (Figure 1). **Conclusion:** A single infusion of NGGT002 gene therapy is well tolerated in adults with PKU. Encouraging evidence of significant and stable efficacy has been observed. These results support further clinical development of NGGT002. Patients in this study will continue to be followed. Updated efficacy and safety results will be reported.

1411. Long-Term Safety and Urea Cycle Function Following a Phase 1/2 Trial of DTX301 in Adults with Late-Onset Ornithine Transcarbamylase (OTC) Deficiency

Cary O. Harding[1], Tarekegn Geberhiwot[2], Maria Luz Couce[3], Nathalie Guffon[4], Wen-Hann Tan[5], Leticia Ceberio Hualde[6], Aneal Khan[7], Laura Konczal[8], Janet A. Thomas[9], Margo Sheck Breilyn[10], Lin Zhang[11], J Lawrence Merritt[11], Eric Crombez[11]

[1]Oregon Health & Science University, Portland, OR,[2]University of Birmingham, Birmingham, United Kingdom,[3]University of Santiago de Compostela, Santiago de Compostela, Spain,[4]Reference Centre in Inherited Metabolic Diseases, HCL, Lyon, France,[5]Boston Children's Hospital, Boston, MA,[6]Biocruces Bizkaia Health Research Institute, Cruces University Hospital, Barakaldo, Spain,[7]MAGic Clinic Ltd, Calgary, AB, Canada,[8]University Hospitals of Cleveland Medical Center, Cleveland, OH,[9]University of CO School of Medicine and the Children's Hospital Colorado, Aurora, CO,[10]Icahn School of Medicine at Mount Sinai, New York, NY,[11]Ultragenyx Pharmaceutical Inc, Novato, CA

Background: OTC deficiency is an X-linked urea cycle disorder that results in dysregulation of the urea cycle and a life-long risk of episodic hyperammonemia that can lead to coma, irreversible brain damage, and death. DTX301 is an AAV8 vector containing the OTC transgene that is being investigated for treatment of OTC deficiency. We report long-term safety follow up (LTFU) of 11 adults with late-onset OTC deficiency who received DTX301 in the Phase 1/2 trial (NCT02991144) with a focus on hepatotoxicity and urea cycle function. **Methods:** The initial Phase 1/2 study lasted 52 weeks; all participants are being followed for up to an additional 8 years. Patients received a single IV infusion of DTX301 on Day 1 ranging from $3.4x10^{12}$ to $1.7x10^{13}$ GC/kg. Patients in the last cohort received a prophylactic oral steroid taper. All patients received reactive oral steroids as needed. Data cutoff was 03 February 2023 for efficacy and 08 December 2023 for safety measures. **Results:** Patients have been followed for 2.5-6 years. No treatment-related serious AEs, dose-limiting toxicities, or infusion-related events have been reported. During the primary study, six patients experienced vector-induced hepatic effects, lasting from 20-168 days with peak ALT levels from ~1.5-6.0×ULN. All resolved following corticosteroid administration. During LTFU, three patients experienced mild ALT elevations and one patient experienced hyperammonemic crises (all considered unrelated to DTX301). Corticosteroids were generally well tolerated. Five patients had non-serious corticosteroid-related AEs. Most corticosteroid-related AEs

were mild (grade 1) AEs, though one patient had grade 3 AEs. Neither prophylactic nor reactive corticosteroids were associated with increased ammonia, hyperammonemia, or hyperammonemic crisis. The rate of ureagenesis improved over time, beginning at Week 6 and was sustained through long-term follow up. The overall mean (SD) rate of ureagenesis increased from 137 (88) μmol*h/kg at Baseline to 224 (178) at Week 52 (67% increase). Increases were sustained at least through Week 182 (the last time point with more than 1 patient), with a mean (SD) of 226 (92) μmol*h/kg (n=4, 79% increase). **Conclusions:** DTX301 continues to show a manageable safety profile. Expected vector-induced effects were treated by corticosteroids and resolved. Patients tolerated corticosteroid regimens without metabolic decompensation. Improvements in ureagenesis supports restoration of urea cycle activity and is encouraging evidence of durable efficacy. Patients in this study continue to be followed. The randomized, placebo-controlled Phase 3 trial (NCT05345171) is currently enrolling.

1412. Safety and Efficacy of Delandistrogene Moxeparvovec versus Placebo in Duchenne Muscular Dystrophy: Phase 3 EMBARK Primary Results

Jerry R. Mendell[1,2], Francesco Muntoni[3], Craig McDonald[4], Eugenio M. [1]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH,[2]The Ohio State University, Columbus, OH,[3]The Dubowitz Neuromuscular Centre, LONDON, United Kingdom,[4]UC Davis Health, Sacramento, CA,[5]Pediatric Neurology Institute, Catholic University and Nemo Pediatrico, Rome, Italy,[6]University of Rochester Medical Center, Rochester, NY,[7]Translational Medical Center, National Center of Neurology and Psychiatry,, Tokyo, Japan,[8]Department of Pediatrics, University of Florida,, Gainesville, FL,[9]Neuromuscular Unit, Neuropaediatrics Department, Hospital Sant Joan de Déu, Barcelona, Spain,[10]Children's Hospital of the King's Daughters, Norfolk, VA,[11]Department of Pediatric Neurology, Center for Neuromuscular Disorders in Children and Adolescents, University Clinic Essen, University of Duisburg-Essen, Essen, Germany,[12]Arkansas Children's Hospital, University of Arkansas for Medical Sciences, Little Rock, AR,[13]Department of Neurology, WUSTL, St. Louise, MO,[14]F. Hoffmann-La Roche Ltd, Basel, Switzerland,[15]Roche Products Ltd, Welwyn Garden City, United Kingdom,[16]Sarepta Therapeutics, Inc., Cambridge, MA

Introduction: Delandistrogene moxeparvovec, a rAAVrh74-based gene transfer therapy designed to address absent functional dystrophin by delivering a transgene encoding engineered micro-dystrophin, is approved in the USA, UAE, and Qatar for treatment of ambulatory pediatric patients aged 4 through 5 years with Duchenne muscular dystrophy (DMD) with a confirmed *DMD* gene mutation (as of Jan 2024).We report findings from Part 1 (Week 52) of the 2-part EMBARK trial(NCT05096221). **Methods:** Key inclusion criteria: Ambulatory males aged ≥4–<8 years with a confirmed *DMD* mutation within exons 18-79 (inclusive); North Star Ambulatory Assessment (NSAA) score >16 and <29 at screening; rAAVrh74 antibody titers<1:400; stable daily oral corticosteroid dose for ≥12 weeks pre-screening. Eligible patients received delandistrogene moxeparvovec (1.33×10^{14} vg/kg) or placebo. Primary endpoint was change from baseline to Week 52 in NSAA total score. **Results:** At Week 52 (N=125), the primary endpoint was not statistically significant—least-squares mean (SE) between-group difference for delandistrogene moxeparvovec (n=63) vs. placebo (n=61) was 0.65 (0.55) points (95% CI, −0.45,1.74; P=0.24). Between-group differences for time to rise (TTR), 10-meter walk/run(10MWR), stride velocity 95th centile (SV95C), and time to ascend 4 steps favored the treatment group with nominal significance (P<0.05). The most common treatment-related treatment-emergent adverse events (AEs) were vomiting (54.0%),nausea (31.7%), and decreased appetite (27.0%), with no AEs leading to study discontinuation or death. A prespecified global statistical test on a composite of functional endpoints (NSAA, TTR, 10MWR, SV95C, 100MWR, ascend 4 steps)indicated treatment benefit (P=0.004). **Conclusions:** Although EMBARK did not meet the primary endpoint, the totality of functional assessments indicated beneficial modification of disease trajectory. The safety profile was manageable and consistent with prior experience.

Thursday Posters: Cell Therapy and Cell-Based Gene Therapy Trials

1413. Consistency of Outcomes with Injectable Human Corneal Endothelial Cell Therapy Across Multiple Clinical Trials

Arnaud Lacoste

Aurion Biotech, Seattle, WA

Purpose: To compare the safety and efficacy outcomes of injectable human corneal endothelial cells from three clinical trials across different geographies in subjects with corneal edema secondary to endothelial dysfunction. **Methods**: Clinical trials conducted in Japan and El Salvador evaluated a single intracameral injection of human corneal endothelial cells in combination with ROCK inhibitor in subjects with corneal edema. Comparative retrospective analysis of outcomes was conducted between 65 subjects treated in the first-in-human investigator-initiated trial, 16 subjects treated in the exploratory IOTA trial, and 22 subjects treated in the Escalón trial. These clinical trials included multiple surgeons and subjects were followed for 12 months. **Results**: Similar safety and efficacy outcomes were observed in the Japan, IOTA and Escalón clinical trials. At 12 months, mean improvement in BCVA was 0.79 LogMAR, 1.00 LogMAR, and 0.66 LogMAR; mean CCT improved by 25%, 24%, and 19%, and percentage 3-line improvement in BCVA was 89%, 100% and 89% among each trial respectively. There were no treatment related systemic or ocular SAEs. **Conclusion**: A single intracameral injection of human corneal endothelial cells in combination with ROCK inhibitor was generally well tolerated and demonstrated comparable and repeatable efficacy outcomes out to 12 months as measured by BCVA and CCT in subjects

with corneal endothelial dysfunction across different geographies involving multiple surgeons. **Study Design**: *First-in-Human (Japan)* - Open Label; Investigator Initiated Trial (IIT)*IOTA Exploratory (El Salvador)* - Open Label; Sponsor Initiated; Proof of Concept*Escalón (El Salvador)* - Phase 1; Randomized; Masked. **Précis:** Retrospective analysis of three clinical trials was conducted to assess safety and efficacy of human corneal endothelial cells in subjects with corneal edema across different geographies. Safety outcomes measured by TEAEs were consistent across all clinical trials, with no treatment related systemic or ocular SAEs. Efficacy outcomes included both functional assessment (BCVA) and anatomical assessment (CCT), demonstrating consistent improvements in visual acuity and corneal edema. **Background Statement:** Corneal endothelial dysfunction is a progressive disorder causing visual impairment. To date, 130 subjects have received corneal endothelial cell therapy. A comparative analysis of these subjects was conducted across multiple clinical trials. About Arnaud Lacoste, MBA, PhD. As chief scientific officer of Aurion Biotech, Arnaud Lacoste leads the company's research and development of advanced cell therapies for ocular diseases. Previously, Arnaud spent 12 years at Novartis where he directed cell and gene therapy programs and built iPSC, CAR-T and ophthalmology cell therapy platforms. At Novartis, Arnaud and his team were responsible for advancing clinical candidates from early discovery to clinical stages. Prior to Novartis, Arnaud was the director of Rockefeller University's stem cell facility, and co-founder and chief scientific officer of Inseron, which developed genetic biomarkers for drug discovery and pathway profiling. Arnaud Lacoste holds an MBA from Boston University, a PhD in Life Sciences from the Université Pierre et Marie Curie (Paris VI), and an undergraduate degree from the University of Bordeaux.

1414. Deep Serological Profiling of Autoimmune Patients Treated with Anti-CD19 CAR-T Cells

Daniel Nunez[1], Darshil Patel[1], Jenell Volkov[1], Steven Wong[1], Dan Thompson[1], Zachary Vorndran[1], Georg Schett[2], Samik Basu[1]

[1]Cabaletta Bio, Philadelphia, PA,[2]Friedrich Alexander University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Erlangen, Germany

Anti-CD19 chimeric antigen receptor (CAR) T cell therapy is a ground-breaking emerging treatment modality for severe refractory systemic lupus erythematosus (SLE) and has shown early promise in other diseases, including myositis and systemic sclerosis. Initial clinical data demonstrate that adoptive transfer of anti-CD19 CAR-T cells induce a durable long-term remission in SLE patients. However, the mechanisms underlying remission are unclear. Our aim was to elucidate serological factors that are associated with responses in SLE, myositis, and systemic sclerosis patients following treatment with anti-CD19 CAR-T cells. Sera were collected from 8 SLE, 2 myositis, and 3 systemic sclerosis patients prior to and following anti-CD19 4-1BBz CAR-T cell therapy (1x106 CAR-T cells/kg following preconditioning with cyclophosphamide 1000 mg on day -3 and fludarabine 25 mg/m2/day on days -5 to -3 as described in Mackensen et al., Nat Med 2022). All patients had severe refractory disease prior to adoptive T cell transfer and were in remission off-therapy with up to 29 months of follow-up post-treatment. Sera were evaluated for 25 cytokines and chemokines by electro-chemiluminescence immunoassay (MSD). Sera were also evaluated for 17 SLE-associated antibodies, 28 myositis-associated antibodies, and 14 infectious disease-associated antibodies using a custom developed Luminex-based immunoassay. Serum levels of the inflammatory cytokines IL-10, IL-6 and TNFα were decreased in most patients post-anti-CD19 CAR-T cell infusion relative to pre-infusion. Levels of IL-7 and BAFF increased between 2 and 7 months post treatment. SLE associated antibodies decreased substantially in most patients following anti-CD19 CAR-T cell infusion. In one patient, SLE associated antibodies either remained stable or increased mildly despite resolution of clinical disease. Both myositis patients observed a decrease in Jo1-associated autoantibodies. Infectious disease associated antibodies typically remained stable or changed minimally following anti-CD19 CAR-T cell infusion. Together, these data suggest that anti-CD19 CAR-T cell therapy leads to the reduction of systemic inflammation and a drop in disease-associated antibodies without impacting pre-existing humoral immunity in a diverse set of autoimmune diseases. These studies support the continued exploration of anti-CD19 CAR-T cell therapy in autoimmune disease.

1415. FT819-102: Clinical Translation of Off-the-Shelf TCR-Less CD8ab+ Anti-CD19 CAR-T Cells for the Treatment of B Cell-Mediated Autoimmune Disorders

Lilly Wong[1], Amanda Sims[1], Alec Witty[1], Nick Brookhouser[1], Allison Aguilar[1], Christopher D'Angelo[2], Amitkumar Mehta[3], Umar Farooq[4], Anil Bagri[1], Rebecca Elstrom[1], Bahram Valamehr[1]

[1]Fate Therapeutics, Inc., San Diego, CA,[2]Division of Oncology and Hematology, University of Nebraska Medical Center, Omaha, NE,[3]Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, AL,[4]Division of Hematology, Oncology, Blood & Marrow Transplantation, University of Iowa Hospitals and Clinics, Iowa City, IA

Autoreactive B cells are key drivers of various autoimmune diseases such as systemic lupus erythematosus (SLE), lupus nephritis, rheumatoid arthritis (RA), and scleroderma. Management of autoimmune disease often includes prolong use of immune suppressants and B cell directed agents. Rituximab, an anti-CD20 antibody, has demonstrated the ability to deplete peripheral blood B cells. Despite this fact, the clinical efficacy of rituximab is limited and varies broadly among different autoimmune diseases due to incomplete clearance of autoreactive B cells in secondary lymphoid tissues. A single dose of autologous CD19-directed chimeric antigen receptor (CAR) T-cell therapy has shown results in sustained depletion of peripheral B cells and durable remission in refractory SLE patients (Mackensen, 2023). However, for CAR T-cell therapy to be a promising modality for the treatment of autoimmune diseases, several obstacles hampering its range of application including the challenge of controlling the T-cell product consistency, the inherent variability of manipulating a heterogenous cellular population and the inability to create the quantity of CAR T cells have to be overcome to support a wide patient base. FT819 is an off-the-shelf, anti-CD19 CAR T-cell product candidate derived from a renewable master iPSC line that may be ideal for broad patient access in the management of autoimmune diseases. The unique ability to mass produce uniform immune effector cells offers distinct advantages over patient- and donor-derived therapeutic approaches, enabling on-demand administration. FT819,

administered following lymphodepleting chemotherapy, appears safe and well tolerated with evidence of anti-tumor activity, including complete responses in aggressive lymphomas with no ICANS or GVHD, and low incidence of CRS (Mehta, 2022; NCT04629729). Here, we present preclinical and translational data that supports the development of FT819 in B cell-mediated autoimmune disorders. Preclinically, FT819 co-cultured with PBMCs from five heathy donors demonstrated potent and specific CD19+ B cell killing in an in vitro cytotoxicity assay. Similarly, PBMCs derived from SLE and RA patients exhibited durable elimination of CD19+ B cells in the same assay. Biodistribution studies in immunodeficient mice illustrated the ability of FT819 to be well distributed throughout the mouse, including in tertiary tissues that are implicated in autoimmune diseases, such as bone marrow and spleen. As further evidence of the translatability of FT819 to autoimmune disorders, in the Phase 1 lymphoma study (NCT04629729), blood and tumor samples were obtained from patients and evaluated for FT819 mediated B cell effects by flow cytometry and IHC. After FT819 infusion,peripheral blood CD19+ B cells were undetectable in patients with sustainedsuppression at the end of the treatment cycle, Day 29. Importantly, B cell depletion was also observed in lymph node biopsies illustrating the ability of FT819 to reach secondary tissues. Recovery of B cells in the periphery occurred 1-3 months after the treatment cycle. Based on itsestablished clinical and translational profile in B-cell lymphoma, coupled withpreclinical data in CD19-mediated autoimmunity, FT819 may be an idealoff-the-shelf cell therapy with the potential to reset the immune system ofpatients with autoimmune diseases.

1416. Preliminary Safety Data of a Phase 1/2 Clinical Trial to Support the Use of High Dose Intrathecal AAV9/AP4M1 for the Treatment of Patients with SPG50 Disease

Souad Messahel[1], Xin Chen[2], Terry Pirovolakis[1], Sydney Cooper[2], Andrea Boitnott[2], Kalayarasan Srinivasan[2], Alagar Muthukumar[2], Keith Gottlieb[1], Darius Ebrahimi Fakhari[3], Steven J. Gray[2], James Dowling[4], Susan Iannaccone[2]

[1]Elpida Therapeutics SPC, Los Angeles, CA,[2]UT Southwestern Medical Center, Dallas, TX,[3]Boston Children's Hospital, Boston, MA,[4]Hospital for Sick Children, Toronto, ON, Canada

Hereditary Spastic Paraplegia Type 50 (SPG50) is a rare, childhood-onset autosomal-recessive disease caused by bi-allelic loss-of-function variants in the *AP4M1* gene, which impacts adaptor protein complex 4 function. This results in a progressive neurological syndrome characterized by progressive spastic paraplegia, global developmental delay, secondary microcephaly and seizures, with onset typically in early childhood. The majority of children become non-ambulatory and full-time wheelchair users. We present preliminary safety data of four subjects, up to 24 months post treatment in a phase 1/2 clinical trial using targeted gene replacement of the AP4M1 gene across the CNS. No deleterious immune responses have been noted, and the treatment has been well tolerated across all 4 subjects. There has been no evidence of DRG toxicity and nerve conduction has been shown to be stable following gene transfer. Our recombinant vector is designed to achieve life-long expression of AP4M1 and broad CNS transgene distribution. Our approach utilizes early intervention and higher intrathecal AAV doses than are used in most other intrathecal AAV clinical trials. Doses given to 3 subjects aged 3-5 years were $1x10^{15}$ vg (total dose per patient), and $4x10^{14}$ vg to a 5-month-old presymptomatic infant. APM41 treatment is challenging as it does not benefit from cross correction or amenable to enzyme replacement therapy. We speculate that the self-complementary design of the vector contributes to its potential efficacy, and the relatively modest strength UsP promoter contributes to its safety. Immune management was designed to allow inclusion of both CRIM(-) and CRIM(+) patients, also thought to be contributing to the overall safety of patients. Interim data from the trial, including efficacy outcomes, will be presented.

1417. Hurdles in Cell and Gene Therapy Trials: Interpreting Clinical Holds Between January 2020 to January 2024

Harishwar Venkatesh, Eunjoo Pacifici

Department of Regulatory and Quality Sciences, University of Southern California, Los Angeles, CA

Clinical development of cell and gene therapy trials contain added layers of intricacy compared to small molecule drugs, making them increasingly more demanding and costly. The characteristics of these therapies also render them particularly vulnerable to clinical holds, which typically last an average of 6.2 months, causing substantial hindrances to the advancement of clinical trials. Examining the nature of clinical holds could provide helpful insights into common pitfalls that could help researchers improve the conduct of clinical studies associated with cell and gene therapies. The objective of this study was to investigate cell and gene therapy trials in order to identify challenges and risk mitigation strategies and, ultimately, streamline the clinical trial process. A comprehensive analysis of clinical holds, FDA warning letters, and relevant literature from January 2020 to January 2024 was conducted to identify factors contributing to challenges in conducting cell and gene therapy trials. In four years, press releases and public disclosure statements from over 75 biotechnology and pharmaceutical companies were observed, revealing a total of 94 publicly disclosed clinical holds. An emphasis was placed on identifying preventable causes of clinical holds. Among all the clinical holds, 43% belonged to therapies treating oncological conditions, while 18% belonged to neurological conditions, 14% to genetic conditions, 10% to blood-related conditions, and 9% to infectious conditions. The remaining therapies treated a variety of unique conditions. Additionally, 69 of the 94 therapies were classified as biologics, the remainder being various small-molecule drugs. Across the period studied, the number of holds each year varied, ranging from 17 to 28. Forty of the clinical holds resulted from varying grade adverse events, the remaining 54 holds had causes ranging from insufficient preclinical data to manufacturing concerns. Results indicate that clinical holds have remained consistent over the last four years. The actions taken by the Food and Drug Administration (FDA) in response to these novel therapies may reflect a cautious approach aimed at prioritizing the safety of trial subjects. While adverse events are inevitable, a thorough understanding of expectations and compliance with regulations while submitting an Investigative New Drug Application (IND) may reduce the likelihood of a therapy being placed on a clinical hold.

1418. Targeting Infections Post Alternative-Donor Hematopoietic Cell Transplantation with Pathogen-Specific T Cells

Anastasia Papadopoulou[1], Ioannis Kyriakou[1], Zoe Boussiou[1], George Karavalakis[1], Chrysa Pantazi[1], Ioanna Vallianou[1], Maria Giannaki[1], Fani Stavridou[1], Maria Liga[2], Ioulia Mavrikou[1], Kiriakos Koukoulias[1], Apostolia Papalexandri[1], Fotini Kika[1], Eleftheria Sagiadinou[2], Ioannis Batsis[1], Alexandros Spyridonidis[2], Ioanna Sakellari[1], Evangelia Yannaki[1]

[1]George Papanikolaou Hospital, Thessaloniki, Greece,[2]University Hospital of Patras, Patra, Greece

The rising trend in alternative-donor hematopoietic cell transplantation (HCT) has brought out an increasing incidence of opportunistic infections. Adoptive immunotherapy with pathogen-specific T cells (pSTs) holds promise as it targets precisely the infected cells circumventing the systemic toxicity of traditional drug therapies, is less prone to resistance and provides a long-lasting immune memory. We here present combined results from two phase I/II studies evaluating the safety and efficacy of trivalent-pSTs targeting cytomegalovirus (CMV), Epstein Barr virus (EBV), and BK virus (BKV) and pentavalent-pSTs targeting additionally, adenovirus (AdV) and Aspergillus fumigatus (AF). GMP-grade pSTs were developed from donor blood mononuclear cells, stimulated with pepmixes of EBV (LMP2/EBNA1/BZLF1), AdV (Hexon/Penton), CMV (pp65/IE1), BKV (Large-T/VP1) and AF (Gel1/SHMT/Crf1) antigens. After 10 days in culture, the cells reached a 7fold increase resulting in a mean cell count of 222±30x10^6 cells. Expanded pSTs were predominantly CD3+ (93.2%) with balanced distribution of CD4+ (50.9±3%) and CD8+ (41.7±3%) subsets and displayed central (40.4±4%) and effector (43.5±4%) memory markers. Patients, excluding those with graft-versus-host disease (GvHD) requiring >0.5mg/kg methylprednisolone, received a single infusion of pSTs (2x10^7 cells/m^2) to control post-HCT infections from the targeted pathogens. In total, 29 patients received pSTs for single (CMV=8/ EBV=6/ BKV=6), double (BKV+EBV=3/ BKV+CMV=2/ EBV+CMV=1) or triple infection (CMV+EBV+BKV=3). Infusions were well-tolerated, with no related toxicity or GvHD occurrence/ exacerbation. 29 patients post haplo- (n=27) or volunteer unrelated-donor (n=2) HCT, received pSTs for CMV, EBV and BKV infections. Out of a total 41 infections at infusion, including 21 viral diseases (BKV cystitis/nephropathy, CMV gastritis/colitis/pneumonia, EBV colitis/encephalitis/PTLD), 35 (85.4%) showed complete response, 5 (12.2%) partial and 1 (2.4%) no response. In the latter case, a patient with triple infection, received a dual-specificity (EBV & BKV) product from a CMV-negative donor and controlled all infections except CMV. Importantly, 16/41 infections including one EBV-PTLD case and 3 BKV cases previously unresponsive to standard treatment, were successfully resolved with minimal (9/41) or no (7/41) antiviral medication. Clinical and viral load responses coincided with circulating pST expansion. Over 6 months post infusion, 17/29 patients experienced 22 new viral reactivations from which, 11 were controlled by the expanded pSTs, requiring minimal or no use of antiviral drugs. The other 11 reactivations occurred mostly in patients with relapse or increased immunosuppression at reactivation (7/9) and required pharmaceutical intervention or/and a second pST infusion (5/9). Nine of these 11 reactivations, including one EBV-PTLD case, were completely resolved, one responded partially, and a single CMV reactivation persisted due to ongoing immunosuppression. In summary, pSTs can serve as a powerful, sustainable, and safe alternative therapy for opportunistic infections post-allo-HCT, significantly reducing or even eliminating the need for drug therapy by effectively managing both current and future reactivations. Clinical Trial Registry: EudraCT2020-004725-23, NCT05471661/ EudraCT2014-004817-98.

Friday Posters: AAV Vectors - Virology and Vectorology

1419. Strategies for Large-Scale Plasmid DNA Complexation and Delivery to Support Commercial-Scale AAV Production

Kenneth W. Thompson[1], Collin Rasmussen[1], Natalie Miller[1], Siva Sai Krishna Dasa[1], Emily Jackson-Holmes[2], Chao Yan Liu[1], Jonathan Zmuda[1]

[1]Thermo Fisher Scientific, Frederick, MD,[2]Thermo Fisher Scientific, Carlsbad, CA

While AAV gene therapy has entered the commercial landscape, achieving scalable and robust manufacturing processes for consistent high-quality and high-yield AAV production remains a challenge. To address these shortcomings, we developed the Gibco™ CTS™ AAV-MAX Helper-Free AAV Production System, an all-in-one, chemically defined, suspension based AAV production system that allows for scalable, high-titer production of AAV viral vectors in a non-293T cell lineage. Recently, we developed processes for AAV production in single-use stirred tank reactors up to the 1000L production scale. During this work, we identified two critical aspects of the workflow required to ensure consistent, high titer, and high quality AAV production: 1) the health of the cells at the time of transfection, and 2) efficient and consistent complexation and delivery of plasmid DNA at large volumes. Because GMP-grade plasmid DNA can account for >50% of the entire cost of a clinical or commercial-grade production run, an in depth understanding of the critical parameters of this process is of the utmost importance to minimize production risks. In the present study, we utilized dye-based studies as well as actual large-scale (50-100L) complexation reactions to identify the critical parameters enabling efficient and consistent complexing of plasmid DNA and transfection reagent in bioprocessing bags and stirred tank mixers as well as strategies for delivery into large scale reactor vessels. For bioprocessing bags, the parameters evaluated included headspace, rocking angle and speed, orientation of the bag on the rocker, mixing time, complexation volume and pump flow rates. For stirred tank mixers, parameters tested were mixing time and top vs. bottom addition of components to the reactor as well as power input. The data presented indicate the key aspects of large-scale plasmid DNA complexation and delivery critical for clinical and commercial scale AAV processes. We rank a hierarchy of factors that should be evaluated and controlled to provide maximum consistency in AAV production at large scales using the Gibco™ CTS™ AAV-MAX Production System.

1420. Optimization of Transient rAAV Production via HEK293 Cell Line Generation, Clone Selection and Production Process

Ulrike Jung[1], Yi-hsuan Huang[1], Sven Mathias[1], Pia Brinkert[2], Kathrin Teschner[3], Sandra Klausing[3], Suneetha Nunna[4], Magda Tomala[4], Stefano Boi[1], Kristin Thiele[1]

[1]Sartorius Stedim Cellca GmbH, Ulm, Germany,[2]Sartorius Xell GmbH, Schloß Holte-Stukenbrock, Germany,[3]Sartorius Xell GmbH, Bielefeld, Germany,[4]Sartorius Stedim Biotech GmbH, Göttingen, Germany

Recombinant adeno-associated viruses (rAAV) are currently the predominant viral vector for *in vivo* gene therapy in clinical studies. The initial phase of therapy development focuses on increasing the yield of rAAV. This process commonly involves transient transfection in HEK293 cells. An essential component of this step is therefore the development of a HEK cell line that generates highly potent doses of viral vectors and the optimization of the production process. Commonly a proprietary cell line is used, and a pre-existing set of plasmids fine-tuned for the plasmid ratio and amount per cell, using a specific growth medium. In some cases, feeds are also tested. We've developed a single cell cloning approach that allows automated high throughput screening of 400 clones for rAAV productivity (vg/L and TU/L). While yield is highly dependent on the medium, feeds and plasmid ratios, we show that even the impact of the plasmid system varies greatly depending on cell clone or pool or even culture conditions. Accordingly, optimization of the setup and selection of the best combination of parameters is a highly complex task and requires a high throughput approach for best results.

1421. High-Fidelity Maintenance of Heterologous DNA Sequences Stably Integrated in Recombinant Baculovirus Under Repeated Amplification Conditions

Chingyi Ho, Platon Selemenakis, Moeed Ahmad, Favour Malumi, Min Chen, Haifeng Chen

Virovek, Inc., Houston, TX

The baculovirus expression system has been widely used in biopharmaceutical industries for the production of various proteins, including vaccines, therapeutic proteins, enzymes, viral-like particles (VLPs) and adenovirus associated virus (AAV) vectors. However, baculovirus harboring heterologous DNA sequences is genetically unstable and productivity is lost after a series of amplifications or passages in insect cells due to the accumulation of defective interfering particles (DIPs) and loss of the heterologous DNA sequences. A new method of maintaining foreign DNA sequences stably integrated in the recombinant baculovirus (rBV) despite of repeated amplifications or passaging is urgently needed. We discovered that the genetic stability of rBV was dramatically increased by linking a drug resistant gene expression cassette to the heterologous DNA sequence(s) and adding drug selection despite repeated amplifications. After the rBVs were generated without plaque purification, they were used to infect fresh Sf9 cells overnight and then selection drug was added. After 3 to 4 days of infection in the presence of selection drug, specific rBV to total rBV ratio was determined with QPCR method using primer sets corresponding to the heterologous DNA sequence and to the wild type baculovirus DNA sequence (gp64). The results indicate that the heterologous DNA sequences were quickly deleted after several passages without drug selection, whereas the rBV retained the heterologous DNA sequences stably integrated even after passaging 10 times in the Sf9 cells under drug selection conditions. The results clearly demonstrate that under selection pressure, the recombinant AAV genome and the Rep and Cap expression cassettes were maintained stably in the rBV despite repeated amplifications even without plaque purification. We used passage 1 and passage 10 rBVs respectively for AAV productions and compared their AAV yields. The QPCR titer results indicate that at least 1.25E+14 vg purified AAV vectors were obtained from one liter of passage 10 rBV infected Sf9 cells. SDS-PAGE and agarose electrophoresis analyses indicate that AAV vectors produced by the passage 10 rBVs had the same VP1/VP2/VP3 ratio and DNA genome size as those produced by the passage 1 rBVs. Further experiments to analyze the AAV infectivity, sequence the AAV genome and the Rep-Cap regions are undergoing. This high-fidelity method of maintaining heterologous DNA sequences stably integrated in the rBVs should pave the way to commercial scale biologics manufacturing without compromising the productivity and integrity of the products.

1422. A Highly Efficient PCR-Based Approach to Isolate Novel Naturally-Occurring AAVs

Emanuela Pone[1,2], Antonella Ferrara[2], Elena Marrocco[2], Arjun Padmanabhan[2], Vittoria Iovino[1], Zoltán Zádori[3], Ivana Trapani[2,4], Alberto Auricchio[2]

[1]Department of Translational Medicine, Federico II University, Napoli, Italy,[2]Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli (NA), Italy,[3]Institute for Veterinary Medical Research,, Centre for Agricultural Research, Hungarian Academy of Sciences, Budapest, Hungary,[4]Department of Advanced Biomedicine,, Federico II University, Napoli, Italy

Adeno-associated virus (AAV) vectors, renowned for their exceptional efficacy and safety, stand as the leading platform for in vivo therapy. To uncover new AAV variants with distinctive biological features, PCR-based amplification of AAV capsid sequences from biological samples has been mostly focused on short variable regions of the Cap gene (here called Dg PCR for diagnostic PCR).Here we describe an efficient PCR-based method that amplifies in a single step the entire Cap coding sequence (here called Full PCR) thus allowing to identify novel variants with differences across the whole capsid which we used to screen a collection of porcine liver samples. Using the traditional Dg PCR which targets two/three hypervariable regions (VRs) in the CAP gene, 36% (n=98/273) of liver samples were found to contain AAV sequences. Amino acid sequence alignment of these fragments revealed 7 novel AAV variants among the positive AAV samples. When the liver samples were analyzed with Full-PCR, 25% (n=69/273) of all samples were positive for AAV presence, however 17 of them were novel variants (including the 7 identified by DgPCR) based on aminoacid differences across the whole CAP and not limited to the hypervariable regions. All 17 variant CAP sequences were vectorized resulting in high titer AAV vector preps. We conclude that Full PCR is more effective than Dg PCR for the identification of novel AAV variants from biological samples allowing to isolate in a single step the whole CAP sequence for further rapid vectorization.

1424. Orientation of Plasmid Origin of Replication and Its Impact on Inverted Terminal Repeat Stability

Syam Pillai[1], Judy Jan[1], Alexei Saveliev[2], Ying Chen[2], John Bowen[1], Brian Tomkowicz[3]

[1]Plasmid Operations, SK pharmteco - US, King of Prussia, PA,[2]Next Generation Sequencing, SK pharmteco - US, King of Prussia, PA,[3]Viral Vector Research & Development, SK pharmteco - US, King of Prussia, PA

The observations that Adeno-associated virus 2 (AAV2) could be rescued and replicated from pro-viral plasmids and that the *cis* oriented AAV ITRs were the only sequences essential for rescue, replication, and packaging of viral genomes underscores the importance of these DNA sequences for successful vector manufacturing. AAV2 ITRs are unique nucleotide sequences that support cross-packaging of *cis*-plasmids across all AAV natural or engineered serotypes. These GC-rich segments of DNA are ~145 nucleotides long, with the first 125 palindromic nucleotides able to form a T-shaped hairpin structure, which flanks the entire AAV genome and provides critical recognition sequences that are required for directing the AAV Rep and host cell proteins to replicate and encapsidate the viral DNA into pre-assembled AAV capsids. We sought to address the impact of the plasmid Ori orientation and its proximity to ITR on the stability of both ss- and scAAV ITR-containg plasmids. Towards that end, we employed short-read Illumina MiSeq Next-Generation Sequencing technology to identify the mutation frequency across multiple plasmid propagation conditions. Our results indicate that across the different bacterial strains tested (DH5α & Stbl3), culture media (LB, TB & proprietary media), propagation temperature (30°C vs 37°C), or colony size (small vs large), the predominant variable that directly impacted ITR stability was the orientation of the Ori in plasmid constructs. When the orientation of the Ori was adjacent to scAAV ITRs, significant deletions were detected in the proximal ITR, resulting in complete proximal ITR deletion in 33% of clones in the condition using Stbl3 at 37°C. However, all other conditions resulted in a 22 bp B loop deletion in the same scAAV ITR in 6.41 to 91.63% of alleles. For ssAAV ITR plasmids, the B loop deletions and C loop deletions were observed in 7.21 to 50.53% and 6.15 to 18.55% of alleles, respectively, across the treatments. When the Ori was orientated in the direction opposite the ITR, separated by the antibiotic resistance cassette, no significant deletions were detected in either the left or right ITR. Moreover, no deletions were observed in the distal ITR, regardless of Ori orientation. These results provide significant insight into plasmid ITR stability to ensure high quality plasmids and viral vectors for AAV-based gene therapies.

1425. A Comparison Study of Orthoganol Assays, Mass Photometry, SV-AUC, Absorbance, ELISA and dPCR to Estimate Empty Full AAV Particles

Srivanya Tummala, Khan Umaer, Ngan Trinh, Kelly Geosits, Marguerite Campbell, Brian Tomkowicz

Viral Vector Research & Development, SK pharmteco - US, King of Prussia, PA

Mass photometry is a relatively new analytical technology that can measure the mass of individual AAVs in solution. The method uses light-based interference microscopy to determine quality attributes of AAV samples, including empty/full/partial capsid ratios, sample purity, aggregation, and titer. To date, the gold standard for measuring these attributes has been Sedimentation Velocity - Analytical Unltra-Centrifugation (SV-AUC), a technique which uses the buoyant density between particles of various sizes in a heterogenous mixture. While SV-AUC offers unparalleled resolution of various AAV particles (empty/full/partial/overfilled) in a mixture, it is a laborious technique that requires extensive expertise to execute both from an assay set-up and data interpretation perspective. To ensure that robust process parameters are being met, in process sample testing during vector manufacturing needs to be timely, cost effective, and easily achieved, yet still be reliable in providing accurate information. Towards that end, we compared several commonly employed analytical techniques used in the determination of empty/full capsids: ELISA (dPCR VG/ELISA VP), Stunner (dPCR VG/Stunner VP), Absorbance (A_{260}/A_{280} ratio), SV-AUC, and Mass Photometry. Our results indicate that on purified AAV particle, A_{260}/A_{280}, SV-AUC, and mass photometry equally predict similar % Full AAV particles. On the contrary, we found that ELISA-based methods were inadequate and equally were not accurate in % full estimations. Employing Absorbance and mass photometry methods for particle characterization are simple methods that require very little training yet offer outstanding resolution and accuracy. These metrics for assay performance are highly desirable in large scale manufacturing where test sample quantities and volume require the need for significant speed and cost-savings.

1426. Assessing the Impact of Adeno-Associated Virus Production, Residual DNA Packaging, and Potency Between ms-DNA vs Plasmid DNA Formats

Khan Umaer[1], Srivanya Tummala[1], Ying Chen[2], Alexei Saveliev[2], Roderick Slavcev[3], Alvaro Amorrortu[3], Nafiseh Nafissi[3], Brian Tomkowicz[1]

[1]Viral Vector Research & Development, SK pharmteco - US, King of Prussia, PA,[2]Next Generation Sequencing, SK pharmteco - US, King of Prussia, PA,[3]Mediphage Bioceuticals, Inc., Toronto, ON, Canada

Ministring DNA (msDNA™) is a novel, non-viral gene therapy technology that forms a linear, covalently closed (LCC) DNA vector containing only the region of interest. For AAV production, this includes the Gene-of-interest, Rep2Cap, and pHelper sequences. Unlike conventional plasmid-based systems, msDNA™ format is completely devoid of backbone sequences that are undesirable contaminants in cell and gene therapy products. Hence, the msDNA™ format confers a selective advantage for viral vector and mRNA-production platforms. Herein, we comprehensively examined AAV viral vectors produced using conventional pDNA vs LCC ministring DNA formats. Our results demonstrate that AAV vectors produced using msDNA™ showed a considerable reduction in aberrant backbone DNA incorporation by Next-gen sequencing, improved full particle yields, as well as increased *in vitro*- and *in vivo*-based potency. Because msDNA™ has a strong safety profile due to the absence of immunogenic sequences, comes with an in-built safety switch that prevents undesired chromosomal integration, and is easy to manufacture, this platform provides an attractive alternative for improved safety for gene therapy products.

1427. Topoisomerase Poisons Alter AAV Transduction and Integration Targeting

Aradhana Kasimsetty[1], Young Hwang[1], John K. Everett[1], Alexander G. McFarland[1], Aoife M. Roche[1], Denise E. Sabatino[2,3], Frederic D. Bushman[1]

[1]Department of Microbiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[2]The Raymond G. Perelman Center for Cellular and Molecular Therapeutics, The Children's Hospital of Philadelphia, Philadelphia, PA,[3]Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Introduction: Adeno-associated virus (AAV) vectors are a promising but sometimes inefficient transgene delivery system, motivating the development of small molecule modulators to improve efficiency and reduce vector dose. Some of these modulators are associated with DNA damage response (DDR), which has been implicated in AAV viral replication and in some cases, AAV integration. Integration events can result in genotoxicity but can also promote vector persistence in dividing cells. One category of small molecule modulators is topoisomerase poisons, which are reported to increase production from vector transgenes in short-term transduction experiments. Topoisomerase poisons stabilize topoisomerase complexes post DNA cleavage, freezing single-strand (Topoisomerase I poisons) or double-strand (Topoisomerase II) DNA breaks. Thus, we investigated the effects of multiple topoisomerase poisons on AAV transduction and integration. **Methods:** We evaluated the transduction effect of three topoisomerase poisons, camptothecin, doxorubicin, and etoposide, in several cell models. We demonstrated dose-dependent and cell line-dependent increases in transgene expression for an AAV-GFP vector. Transduction and transgene persistence were monitored by measuring GFP fluorescence. We then isolated DNA for integration site analysis (ISA). We selectively amplified AAV integrants with ITR-primed, sonication-based, ligation-mediated PCR. Amplified integrants were sequenced with Illumina short-read sequencing. Integration sites (IS) were mapped with the AAVengeR software pipeline. Integration frequency and clonality were quantified by sonicated fragment lengths and unique molecular identifiers (UMIs). Simulated random matched controls were used to compare IS distributions to distributions of selected histone markers and transcription factors associated with topoisomerase binding. **Results:** Both dividing and induced non-dividing cell lines demonstrated an increase in GFP expression in response to all three drugs, with primary cell lines having higher tolerability for the drugs and greater transgene expression. While all three drugs showed an increase in expression at early time points, as reported previously, longer-term time points showed that the samples treated with the topoisomerase I poison camptothecin did not show increased transduction, while samples treated with topoisomerase II poisons doxorubicin and etoposide retained higher transgene expression compared to controls. ISA results showed similar levels of IS frequency across the control and camptothecin-treated cells, whereas the doxorubicin and etoposide-treated cells demonstrated increased integration frequencies, up to 4-fold higher than baseline. Preliminary integration distribution mapping supports a change in IS distribution with an increased association with topoisomerase binding sites in type II topoisomerase poisoned cells. **Conclusions:** ISA of cells treated with topoisomerase poisons indicate that these small molecules can influence both AAV transduction and integration. While DDR likely contributes broadly to an increase in early transgene expression, the variation in integration effects between camptothecin and doxorubicin/etoposide implies that the nature of the DNA damage protein targeted plays a role in promoting and targeting integration. This study demonstrates that small molecules may be used to redirect AAV integration targeting. These effects should be considered when evaluating modulators for enhancing AAV transgene expression.

1428. Structural Insights into Porcine Adeno-Associated Viruses

Austin Nelson, Mario Mietzsch, Paul Chipman, Julia Eby, Robert McKenna

University of Florida, Gainesville, FL

Current clinical trials using adeno-associated virus (AAV) vectors exclusively rely on capsids derived from primate origin. However, pre-existing neutralizing antibodies in a large percentage of the human population, from prior exposure to naturally circulating AAVs, can lead to vector inactivation and loss of treatment efficacy for many of the primate AAVs. Advances in DNA sequencing technologies have led to the discovery of AAVs from a wide range of non-primate animals including numerous isolates from pigs (AAVpo.1 - AAVpo.8). The capsid amino acid sequence identity of these viruses can vary by up to 50% to the primate AAV serotypes. In this study, the capsids of AAVpo.1 and -po.6 were selected for structural characterization due to their low viral protein (VP)1 sequence identity compared to AAV2, AAV4 and AAV5, as well as to one another. The porcine AAV vectors were produced using the standard triple transfection system of HEK293 cells utilizing the AAV2 rep gene to package AAV2-ITR vector genomes. The resulting vectors were purified by Iodixanol density gradient ultracentrifugation, revealing the typical incorporation of VP1, VP2, and VP3 into the AAV capsids. Here we present the capsid structures of AAVpo.1 and AAVpo.6 determined by cryo-electron microscopy. As the porcine AAVs have been described to infect human cells, and AAVpo.6 being able to cross the blood brain barrier (BBB), structural comparisons to the existing AAV capsids structures, including those of AAV9 and AAVrh.10, will be conducted. These comparisons will aid in the identification of potential receptor utilized by these capsids. Furthermore, the reactivity to human antibodies will be analyzed to determine the value of porcine AAV capsids as alternatives to the AAV vectors currently used in clinical trials.

1429. The AAVone Single-Plasmid AAV Production System Effectively Generates Large-Size AAV Vectors in Suspension HEK 293 Cells with Bioreactor System

Pauline Schorter[1], Huan Hu[2], Zhen Shi[2], Elisa Berera[1], Julie Regnery[1], Yuling Dai[2], Rongze Yang[2], Yuyan Wang[2], Leming Wang[2], Jiarui Liang[2], Daozhan Yu[2], Quentin Bazot[1], Qizhao Wang[2]

[1]ABL, Lyon, France,[2]AAVnerGene Inc., Rockville, MD

We have recently introduced AAVone, a novel, single-plasmid AAV production system. This streamlined system incorporates the Ad helper genes (E2A, E4orf6, and VA RNA), AAV helper genes (rep and cap) and the AAV vector genome into one compact plasmid, named

pAAVone, which has a 13 kb backbone plus the AAV genome. By simply transfecting host cells with the pAAVone plasmid, efficient AAV vector production is achieved. We previously reported that AAVone shows a 2 to 4-fold increase in AAV yield compared to the traditional triple plasmid system for a payload size of 2.2 kb or 2.8 kb. To test the effectiveness of the AAVone system for packaging larger AAV vectors, we created pAAVone constructs with varying AAV genome sizes from 2.2 kb to 4.7 kb with plasmid sizes from 15.2 kb to 17.7 kb which encodes enhanced green fluorescence protein (EGFP). The AAVone system efficiently packages AAV9 vectors with these varying genome sizes in suspension cells. In suspension HEK 293T cell culture using flasks, the yield for 4.4 kb AAV9 vectors was approximately 2.27e12 vg/ml, a ~38% reduction compared to the 3.72e12 vg/ml yield with 2.2 kb genomes. The yields for 4.6 kb and 4.7 kb AAV9 vectors were around 2e12 vg/ml. Using suspension HEK 293 cells in flasks, we achieved over 1e12 vg/ml crude titer with both FectoVIR-AAV and Transporter 5 as transfection reagents, with Transporter 5 yielding higher crude and full particle ratios in the AAVone system. A decrease in productivity of 28% was noted when comparing a 4.4kb payload to a 2.2kb genome. In suspension HEK 293 cells cultured in Ambr250 bioreactors, the crude AAV9 reaches 1.34e12 vg/ml of genome titer(dPCR) and 5.56e12 vp/ml capsid titer (Elisa) for 2.2 kb genomes. AAV9 particles produced with 2.2kb payload are 38.8% full, either with 1 copy (29.4%) or 2 copies (9.4%) of genomes, as measured by mass photometry. Packaging efficiency test for construct with 4.4kb payload size in HEK293 cells cultured in a bioreactor is ongoing and is expected to reach ~1e12 vg/ml based on observations made in flask cultures. In conclusion, while larger AAV genomes lead to a slight decrease in overall genome titer, the productivity for those larger payload size is significantly higher than triple plasmid system with the same payload size. The AAVone system remains highly effective in producing large-size AAV vectors.

1430. The AAVone Single-Plasmid System Efficiently Generates High-Quality AAV Vectors

Yu Liu[1], Yuyan Wang[1], Rongze Yang[1], Yuling Dai[1], Zhen Shi[1], Leming Wang[1], Cuiping Chen[1], Haniya Zaidi[1], Jiarui Liang[1], Ngoc Tam Tran[2,3], Daozhan Yu[1], Phillip WL Tai[2,3], Qizhao Wang[1]

[1]AAVnerGene Inc., Rockville, MD,[2]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[3]Department of Microbiology and Physiological Systems, UMass Chan Medical School, Worcester, MA

We previously developed an all-in-one, single-plasmid AAV production system, named AAVone. In this system, the Ad helper genes (*E2A*, *E4orf6*, and *VA RNA*), AAV helper genes (*rep* and *cap*), and the AAV vector genome are consolidated into a single compact plasmid. The pAAVone plasmid design, has a 13-kb 'backbone' (obligate plasmid sequences required for AAV production), which is significantly larger than AAV's packaging capacity. With this system, an AAV vector can be efficiently generated by simply transfecting the corresponding pAAVone plasmid into host cells. We show that AAVone has a two- to four-fold increase in AAV productivity compared to what is achieved by the original triple plasmid system. A comparative analysis revealed that AAV vectors produced by different systems exhibited similar AAV capsids, genome content, and in vitro infectivity. The integrity of the AAV genome payload in AAV vector is a critical quality attribute for clinical applications. By leveraging the capabilities of single molecule, real-time (SMRT) sequencing, we are able to analyze AAV genomes at the single molecule level. The pAAVone-AAV2-*CMV-EGFP* plasmid used in AAVone system and pAAV-*CMV-EGFP* plasmid used in the triple plasmid system have the same 2,730 bp AAV-*CMV-EGFP* genome, and harbor a 130-bp L-ITR(15 bp shorter than the wtITR) and a 119-bp R-ITR[PT1] (an extra 11 bp deletion in the C arm). AAV genomes from the two systems have nearly the same genomic read-length profiles, showing a major 2,771 nt peak, which is the intact AAV genome size harboring two 145 nt intact ITRs(2730 nt+15 nt*2+11 nt). *The* majority of ITRs in the vectors produced by either systems are 140-150 bp in length at both the L-ITR and R-ITR, and displayed similar flip:flop ratios. The presence of ITRs missing 11 bp of the C arm, constituted only about 1.5% of the total reads, implying that the deletion was largely repaired during vector genome replication. Despite their similarities, we observed some intriguing phenomena between the AAV vectors produced by AAVone and triple plasmid systems. The AAVone system's AAV vectors exhibited a slightly higher percentage of the intact AAV genome, a notably higher read coverage at the sequences close to R-ITR, fewer non-ITR truncations, and lower percentage of snap-back genomes. Taken together, our data support the notion that vectors produced by AAVone have nearly identical capsid and genome components compared to vectors produced by triple plasmid transfection; and they perform equally well. These similarities underscore the efficacy and reliability of the AAVone system as a promising alternative for AAV vector production, with potential benefits, such as increased intact genomes, reduced non-ITR truncations, improved vector genome homogeneity, which all contribute to improved vector quality and therapeutic potential for gene therapy applications.

1431. Impurities Analyses of AAV Vectors Produced by the Novel AAVone Single-Plasmid AAV Production System

Yuyan Wang[1], Yu Liu[1], Yuling Dai[1], Zhen Shi[1], Rongze Yang[1], Leming Wang[1], Cuiping Chen[1], Haniya Zaidi[1], Jiarui Liang[1], Ngoc Tam Tran[2,3], Daozhan Yu[1], Phillip WL Tai[2,3], Qizhao Wang[1]

[1]AAVnerGene Inc., Rockville, MD,[2]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[3]Department of Microbiology and Physiological Systems, UMass Chan Medical School, Worcester, MA

We previously developed an all-in-one, single-plasmid AAV production system, named AAVone. In this system, the Ad helper genes (*E2A*, *E4orf6*, and *VA RNA*), AAV helper genes (*rep* and *cap*), and the AAV vector genome are consolidated into a single compact plasmid. The pAAVone plasmid design has a 13-kb 'backbone' (*i.e.*, obligate plasmid sequences not meant to be packaged into the AAV vector), which is significantly larger than the AAV packaging capacity. In this system, an AAV vector can be efficiently generated by simply transfecting the corresponding pAAVone plasmid into host cells. The platform shows a two- to four-fold increase in AAV productivity compared to what is achieved by the original triple plasmid system. Residual input plasmid DNA is one potential concern with the AAVone system, as it harbors the *rep*, *cap*, *E2A*, *E4orf6*, *VA RNA* and AAV genomes in one plasmid. To address this concern, we employed single molecule, real-time (SMRT) sequencing to thoroughly examine potential impurities originating from the AAVone plasmid system. First, we confirmed that the two

ITRs are the primary *cis* elements responsible for AAV packaging, as the majority of the reads are mapped to sequences between the ITRs. Second, we found that the frequency of detecting backbone sequences located outside of the ITRs are primarily determined by their proximity to the elements. In other words, sequences in close proximity to the ITRs typically exhibit higher read coverages, whereas those situated further away, tend to have lower read coverages. Third, we observed an asymmetrical distribution of impurities for both AAV vectors produced by AAVone and triple-plasmid systems. A higher abundance of reads was found mapping closer to the left (L)-ITR than mapping to the right (R)-ITR. Within the AAVone system, the three most prominent contaminating elements were those associated with *VA RNA* (located near the L-ITR), followed by the *cap* (0.48%, positioned near the L-ITR), and the bacterial backbone (0.34%, situated near the R-ITR). In contrast to the AAVone system, the predominant contaminants in the triple plasmid systems were the bacterial backbone of pGOI. Analysis of genomic contamination within the AAVone system reveals that a substantial portion of these contaminants comprised of sequences containing ITRs. For example, a majority of VA RNA sequences (99.47%) appear to be contiguous with the GOI. Likewise, a considerable proportion of *cap* sequences (93.28%) and bacterial backbone sequences (94.61%) also contained the GOI, suggesting that they are composite sequences consisting of the GOI and the *cap* or bacterial backbone regions. Overall, there were no notable differences in host cell (hc) DNA contaminants among the AAV vectors produced by the AAVone and triple plasmid systems, each showing approximately 3% of the total sequences. In summary, SMRT sequencing of vectors generated by the AAVone platform demonstrated significantly lower levels of bacterial DNA contaminants and antibiotic resistance genes, comparable levels of *rep*, *E2*, and *E4* contaminants, but a substantial increase in *VA RNA* and *cap*, compared with the triple plasmid system. Despite this shift in the nature of contaminants, the overall total genomic contamination in the AAVone system does not exhibit a general increase in undesired genomic contaminants, and may even show a decrease in frequency. This underscores the effective management of total genomic contaminants by the AAVone system, a critical factor in ensuring the production of high-quality and safe AAV vectors.

1432. Optimization of AAVone system to Further Increase AAV Packaging Efficiency and Reduce Impurities

Zhen Shi, Yuling Dai, Yuyan Wang, Yu Liu, Rongze Yang, Cuiping Chen, Leming Wang, Haniya Zaidi, Daozhan Yu, Qizhao Wang

AAVnerGene Inc., Rockville, MD

Our previously developed single-plasmid AAV production system, AAVone, offers streamlined AAV vector generation via transfection of a single compact plasmid into host cells. In this system, the Ad helper genes (E2A, E4orf6, and VA RNA), AAV helper genes (rep and cap), and the AAV vector genome are consolidated into a single compact plasmid, pAAVone, which has a 13-kb 'backbone'. In this system, replacing the ATG start codon with ACG for Rep expression resulted in decreased AAV production, highlighting the importance of efficient translation initiation. Conversely, incorporating a more potent intron donor significantly boosted AAV yields by enhancing splicing efficiency intron between P40 promoter and Cap ORF. Moreover, a novel P5 promoter, P5I, was developed to drive Rep expression, which demonstrated the capability to enhance AAV packaging efficiency by 40% when compared to original AAV2 P5 promoter. Notably, while the dual P5 design(P5-Rep-Cap-P5) in the triple plasmid system enhanced AAV packaging efficiency, excision of the additional P5 after Cap from pAAVone revealed its dispensability for AAV packaging. Additionally, our research also found that VA RNA II is non-essential for AAV production, unlike the crucial role played by VA RNA I. Intriguingly, removing the additional P5IEE and VA RNA II resulted in a 36% increase in AAVone system productivity. We observed the asymmetrical distribution of plasmid related impurities in AAVone system with the primary dual P5 design, which showed higher abundance in the sequences closer to L-ITR compared with R-ITR. We hypothesize that the presence of the additional P5 after Cap might be contributing to this phenomenon, as its functional similarity to ITRs. Elimination of the additional P5 and VA RNAII not only increase AAV productivity, but also reduced plasmid related impurities closed to L-ITR, making the impurities are almost equal for the sequences out of L-ITR and R-ITR. These results demonstrated the potential for further optimizing the AAVone system design to enhance both packaging efficiency and reduce plasmid related impurities.

1434. Genome Length Dissection: A Comparative Analysis of AAV Variants for Enhanced Gene Delivery Efficiency

[1]J&J, Brisbane, CA,[2]J&J, Spring House, PA

Adeno-associated virus (AAV) is a small, non-enveloped virus with a single-stranded DNA, measuring approximately 25 nm in size. The wild-type AAV genome spans about 4.7 kb and relies on a helper virus for replication. Although the packaging capacity of AAV vectors is typically thought to be under 5 kb, some research has indicated successful delivery of larger transgenes. Nevertheless, subsequent investigations have revealed incomplete assembly of particles in such vectors. To enhance the understanding of how transgene size affects AAV packaging and quality, AAV transgenes of 7 different sizes (from 3.1 to 5.1 kb) were packaged into AAV1 serotype in HEK293 suspension cells by triple transfection. Transgenes were constructed with the CAG promoter driving eGFP expression and non-coding stuffer sequences of various lengths. Downstream purification using affinity chromatography and anion-exchange chromatography (AEX) was performed for all samples, and a thorough analysis was conducted to assess vector purity, integrity, and the percentage of fully assembled capsids. No significant differences in AAV titers were observed for transgenes below 4.8 kb, however a slightly decreased genome titers were observed for vectors above 5 kb. The transgene size had no effect on VP ratios by SDS-PAGE gel, however transgenes above 4.8 kb showed a truncated or smaller genome size as observed on an alkaline gel. TEM-based analysis remains qualitative and was used to monitor capsid aggregation and non-AAV protein contamination. Neither were observed in any of the vectors with different genome length.

Additionally, 3 of the 4 orthogonal methods used for determining full percentage indicate a significant decrease in the percentage of full capsid above 4.7 kb, and a consequent increase in partially packaged capsids as observed by AUC. These results were reasserted by NGS AAV content analysis where the encapsulated AAV genome fraction was consistently above 90% in all the samples from 3.1 to 5.1 kb lengths. However, the percentage of particles carrying the full-length payload dropped slightly then significantly at 4.8 and 5 kb, respectively. In conclusion, we demonstrated here that overpacking AAV beyond 4.7 kb led to decrease in fully packaged capsid and full-length payload.

1435. Early Characterization of Research-Grade AAV6 Productions Allows for Manufacturing Alignment During Candidate Nomination

Amira D. Rghei, Shona Robinson, Lisa Santry, James Fasano, Jay Cai, Daniel Kennedy, Theresa Dao, Omar Matalka, Azam Hassaninasab, Will Arnold, Adriana Geldart, Debaditya Bhattacharya, Bojiao Yin, Mercedes Segura, Stacie Seidel, Cherylene Plewa
ElevateBio, Waltham, MA

Adeno-associated virus (AAV) is the most popular vector in the gene therapy space, with extensive applications for treatment and cure of monogenic disorders. There are currently hundreds of active clinical trials for recombinant AAV (rAAV) therapeutics, and a handful of EMA and FDA-approved modalities. Though there have been large strides in the gene therapy field, effective characterization (primarily packaging efficiency and manufacturability) prior to larger scale-up of rAAV vectors remains an ever-evolving challenge in the industry. These larger scale process development (PD) efforts can include costly and labor-intensive optimization of production, purification, and post-purification processes. Unfortunately, the characteristics of the final scaled-up products may not match with material used for the initial R&D candidate characterization, resulting in longer and more tedious pre-clinical development timelines to reconcile the differences. There is a clear need for early and well-defined characterization of therapeutic candidates at the R&D level that aligns with production, purification, and characterization methods across both upstream and downstream PD platforms. Here we describe a process to streamline our lead therapeutic candidate selection process for research and development (R&D)-grade rAAV6 vectors, using a high throughput workflow preceding large scale-up efforts. Four AAV vectors expressing therapeutically relevant transgenes, with genomes between 4.1-4.7kb in length, were packaged in AAV6 using our R&D scaled-down method. A series of analytics were used to characterize R&D material and larger scaled-up material, including vg titers (ddPCR), viral protein ratios (Maurice, automated capillary electrophoresis system), % full analysis (Mass photometry and analytical ultracentrifugation), followed by 3rd Generation Sequencing. These results show that our R&D grade vectors had crude titers >1e11 vector genomes (vg)/mL, as well as >30% full by Mass photometry and AUC. When compared to PD 2L bioreactor scaled-up AAV material, purified by AKTA (high performance liquid chromatography) chromatography, the R&D and PD material were demonstrated to have comparable characteristics. This early characterization of rAAV6 candidates has allowed for faster, and more efficient testing of multiple construct designs, and cost-efficient movement towards manufacturing of lead therapeutic candidates from our R&D to PD team.

1436. Characterization of Residual Contaminants in AAV Vectors Leveraging Long-Read Sequencing

Kiran Adhikari[1], Bob Bruccoleri[2], Serena Dollive[1]
[1]Oxford Biomedica (US) LLC, Bedford, MA,[2]Congenomics, LLC, Glastonbury, CT

An ideal Adeno-associated virus (AAV) vector would consist of a full-length construct packaged within the capsid. However, existing vectors are not 100% pure as they contain residual contaminants. The types and amount of these residuals can vary between vector production conditions and vector genomes. Proper characterization of residuals is important to make the AAV vectors more reliable and safer. Here, we have developed an assay to characterize the residuals present in the vector sample by taking advantage of PacBio long-read sequencing. With the sequencing reads capable of spanning the whole length of the genes, we were able to quantify the amount of residual antibiotic resistance genes, Adenovirus genes E1, E2A, and E4 as well as Rep and Cap present on the vector sample. We were also able to characterize whether these genes are full length or partial. This method could help improve product quality by more robustly characterizing residual contaminants.

1437. An Improved Helper Plasmid Containing E2a and E4 Gene Deletions Results in Increased AAV Productivity

Laura van Liehout, Stacy Ota, Eli Wiberg, Annie Adusei, Katrina Costa-Grant, Marissa Stanvick, Ify Iwuchukwu, Diane Golebiowski, Jin Yin
Oxford Biomedica, Bedford, MA

Adeno-associated virus (AAV) vector production typically involves transfection of an adenovirus helper plasmid to provide the helper genes E2a, E4 and VA RNA, which are required for AAV replication and gene expression. These helper plasmids tend to be large and can be difficult to manufacture, leading to higher costs at GMP scale. We sought to reduce the size of our helper plasmid by introducing deletions into the E2a and E4 genes as they represent the majority of the plasmid sequence. Within the E2a gene, there is approximately 3 kb between the E2a promoter and the start codon. Five different E2a deletions were made in this region ranging from 0.5-2.0 kb. The three largest deletions failed to produce comparable vector genome (VG) titers to the control. Both the 0.5 kb and 0.9 kb E2a deletions demonstrated comparable productivity to the control helper plasmid, therefore we selected the larger 0.9 kb deletion for additional studies. The E4 gene is composed of at least six open reading frames (ORF) of which E4ORF6 is thought to be critical. Three E4 deletions were tested; the first removed 1.2 kb (ORFs 1-3), the second removed 1.5 kb (ORFs 1-4) and the third removed 2.0 kb (ORFs 1-4, 6/7). All three constructs kept ORF6 intact. Each of the E4 deletions generated comparable VG productivity to the control helper. There was an advantage to keeping both ORF6 and ORF6/7 intact, therefore we selected the 1.5 kb E4

deletion for follow up. In combination with removal of 1 kb from the plasmid backbone, the size of the deletion helper plasmids was reduced from 12 kb to 10 kb for the E2a deletion and 9.5 kb for the E4 deletion. We also evaluated a combination of the E2a and E4 deletions resulting in a plasmid 8.5 kb in size. Interestingly, the E4 deletion and E2a+E4 deletion helper plasmids both resulted in VG and capsid productivity that was 2-3X higher than the control helper. The E2a deletion alone did not result in any increases and appears inconsequential. Using RT-qPCR, Rep and Cap transcripts increased in the E4 deletion and E2a+ E4 deletion helpers, which is also supported by an increase in Rep and Cap protein by western blot. The E2a deletion alone did not show an increase in Rep and Cap transcripts or protein. RT-qPCR analysis for E2a transcripts shows minimal impact from any helper deletion including the E2a deletion, suggesting that this particular E2a deletion does not impact E2a expression. However, E4orf6 RT-qPCR indicates there is a reduction in ORF6 transcripts with the E4 deletion and E2a+E4 deletion helpers but not with the E2a deletion. This could suggest that the optimal expression level of E4ORF6 is lower than what is generated from an intact E4 gene and that lower E4ORF6 levels allow for enhanced Rep and Cap expression, leading to higher VG and capsid productivity. The E2a+E4 deletion helper has resulted in increased productivity for a number of capsid serotypes including AAV2, AAV5, AAV6, AAV8 and AAV9 and across five genomes with multiple promoters and transgenes ranging from 2.3-4.2 kb. Finally, the increase in E2a+E4 deletion helper productivity has been observed for both pOXB dual and traditional triple transfection, demonstrating the wide-ranging utility of this improved helper plasmid for various AAV applications.

1438. Impact of Sample Treatment on DNA Length Distribution Analysis by Duplex ddPCR

Marina Magerl, Felicia Thoennissen, Sophie Beer, Rebecca Feiner, Sonya Schermann, Markus Hoerer, Sabine Geiger

Ascend, Planegg-Martinsried, Germany

Introduction Recombinant adeno-associated virus (rAAV)-encapsidated plasmid impurities are an undesirable byproduct of vector manufacturing consisting of heterogeneous non-vector genome fragments of DNA arising from the production plasmids. Horizontal gene transfer of manufacturing plasmid-derived resistance genes might be a potential risk when they are packaged as full-length genes. Thus, regulatory authorities require thorough characterization of these DNA impurities. We developed a novel duplex ddPCR method for assessing the length distribution of encapsidated nptII (kanamycin resistance) gene fragments. Here we describe how typical sample treatments used to disrupt virus capsids prior to droplet formation can impact fragment length analysis performed by duplex ddPCR. **Methods** To assess full-length nptII gene species, two duplex ddPCR approaches were developed. In the first one, two primer-probe sets with different fluorophores positioned 795 bp apart were used so that droplets positive for both fluorophores indicate full-length sequences. However, this approach carries the risk of overestimating full-length DNA species if two smaller nptII gene fragments are co-packaged in the same rAAV capsid, creating double-positive droplets. Thus, a second approach was developed using two primer-probe sets with different fluorophores spanning approximately 400 bp fragments at each side of the gene, minimizing the risk of false-positive full-length results (Figure 1). Sample treatments typically performed to reduce re-annealing of plus and minus rAAV strands after capsid disruption such as the use different buffers and heat treatments were tested in both methods. Additionally, the impact of mechanical processing (e.g. vortex mixing) on nptII length distribution analysis was assessed. Acceptance criteria for the assays included recovery of >90% of a linearized plasmid control, confirmation of dilutional linearity for plasmid controls and samples, and coefficients of variation <15% for replicate measurements. **Results** Plasmid and rAAV samples which were not subjected to a specific treatment prior to ddPCR showed the expected results, while a dramatic decrease in full-length species was observed for samples which were treated with heat for 30 minutes. The impact on DNA integrity seemed to be time-dependent since heat treatment for shorter time periods caused less fragmentation. Interestingly, samples subjected to mechanical manipulation (vortexing) for different amounts of time did not show any signs of DNA fragmentation. **Conclusion** While the first method described here (using two primer/probe sets positioned 795 bp apart) might lead to an overestimation of full-length nptII impurities due to co-packaging of two smaller gene fragments in one capsid, the second approach we developed (using primer/probe sets spanning approximately 400 bp at each side of the gene) can be considered fit for the purpose of assessing full-length nptII gene fragments in rAAV batches. However, care must be taken during sample treatment since commonly used methods such as heat treatment can quickly result in fragmentation of DNA, leading to an underestimation of full-length impurity species. Separation of intact capsids into droplets prior to heat disruption ensures that DNA fragments are distributed into individual droplets in one piece.

Figure 1. Schematic representation of the assay principle of duplex ddPCRs for nptII

1439. Impact of the Genome Length of Adeno-Associated Viral Vectors on Yield and Quality Parameters

Rupert Derler, Martina Ohme, Elisabeth Schweigert, Florian Dunker, Kathrin Breunig, Florian Sonntag, Markus Hoerer, Andreas Schulze

Ascend, Planegg, Germany

Wild-type adeno-associated virus (AAV) contains a single-stranded DNA genome with a length of approximately 4.7 kb. Yet even packaging of close-to wildtype sized transgene cassettes can lead to lower yields compared to smaller transgene cassettes. Production of rAAV with vector genomes in the range of the wild-type genome length is therefore challenging concerning vector yields and quality parameters. We have developed a robust modular suspension platform process based on our proprietary HEK293 cell line and split two plasmid system, that is optimized towards yield at best possible quality with full scalability. The platform has already provided successful manufacturing of several distinct capsids. We continue to expand our data to underline the platform's universal application across both natural and engineered

capsids. We present here the impact of a wild-type genome length cassette (4.7 kb) in comparison to a medium-size vector genome (approx. 3.0 kb) in context of AAV9 produced using our suspension platform process. We analyzed yield and quality parameters that are known to be strongly impacted by the design and choice of the biological starting materials and the upstream process. A panel of analytical methods was applied to enable a comprehensive and detailed comparison of many different attributes. Vector genome and capsid yields in a comparable range were observed independent of the vector genome length. Increased levels of mispackaged plasmid- and host cell DNA-derived sequences were detected for the wild-type genome length in comparison to the medium-size vector genome using the same process parameters for both setups. Integrity of all vector genomes was demonstrated by alkaline gel electrophoresis. Our results demonstrate the applicability of our suspension platform rAAV9 production process for challenging vector genome lengths at the rAAV packaging limit. We continuously invest in further CMC innovation to optimize yield and quality for all relevant genome lengths across capsids.

1440. Development of a Water-Based Hypotonic Cell Lysis Method for AAV Vector Production

Sujit Pujhari, Ronald Smithwick

Pharmacology, Physiology and Neuroscience, School of Medicine, University of South Carolina, Columbia, SC

Gene therapy has emerged as a promising approach for treating genetic diseases, and adeno-associated viral (AAV) vectors have gained widespread use due to their safety and efficacy. More than 200 gene therapy trials using rAAV vectors are currently underway or completed in the USA. rAAVs are produced in human embryonic kidney cells (HEK293T) and, more recently, using insect cells (sf9 cells). AAV being a cell-associated virus, the cells must be lysed to purify. Commonly used methods of cell lysis, including freeze-thaw (FT), sonication, or chemical lysis, are time-consuming and expensive. Therefore, new methods are needed to purify AAV to ensure readily accessible, cost-effective, and safe AAV treatment. To overcome this obstacle, this study has developed a novel water-based hypotonic (WH) method for AAV production that is faster, simpler, and more cost-effective than the traditional freeze-thaw (FT) water lysis method. This study used the AAV6 serotype expressing GFP visual marker protein. The quality of AAV6 expressing GFP produced using the WH-lysis method was comparable to those produced using the FT-lysis method. Furthermore, the transduction efficiency of virus preparations by measuring GFP expression in HEK293T, Huh7.5, Cos-1, and Vero cells and found that the WH-lysis method outperformed the FT-lysis method. Overall, this proof of concept study demonstrates that the WH-lysis method is a fast, convenient, and effective method for producing high-quality AAV vectors for various gene therapy applications. The use of this method could significantly reduce the cost and time required for AAV vector production, making gene therapy more accessible and affordable to patients.

1441. Development of a Single Clonal Suspension Cell Line PCS3.0 for High Yield AAV Production

Xin Swanson[1], Longxiang Sheng[1], Paul Li[2], Ye Bu[1], Yunyi Chen[1], Weixiao Huang[1], Zexin Zhou[1], Liying Yang[1]

[1]PackGene Biotech INC, Houston, TX,[2]PackGene Biotech, Worcester, MA

Cell substrates are among the most crucial raw materials in the AAV manufacturing process. The monoclonal characteristics of HEK293 cell lines mitigate genetic heterogeneity among cell pools, enabling stable and efficient AAV production using triple-plasmid transfection. To generate highly homogeneous monoclonal cells, we utilized a Dispencell in-situ cell dispenser for single-cell sorting of the parental HEK293 cell pool, and D0 cells were imaged using CloneSelect Imager for assurance of clonality. Sorted single cells were cultured, expanded, and screened by AAV production yield and Population Doubling Time (PDT). The promising high-yield candidate clone underwent a series of gradient-decreasing serum cultures to obtain suspension cell clones. To enhance AAV productivity stability, suspension cell clones underwent two rounds of single-cell sorting and screening based on the triple-plasmid transfection platform. The top clone with the highest AAV productivity was selected and confirmed as the PCS3.0 cell line, with a systematic characterization of growth curve, PDT, and metabolic dynamics during AAV production. PCS3.0 cells were assessed with a production test on different AAV serotypes, including AAV2, AAV5, AAV8, and AAV9, using a therapeutic Gene of Interest (GOI) on shake flask and 3 L stirred bioreactor scales, showing stable production capacity with lysate genome titer ranging from 1E+11 vg/mL to 5E+11 vg/mL. Host cell DNA (HCD) and empty capsid ratio in DS were further evaluated. HCD can be controlled below 100 ng/E+13 vg, and the empty capsid ratio can be controlled below 10%. In conclusion, we successfully constructed a suspension single clone cell line, PCS3.0, enabling high AAV production capacity, stability, and quality, providing strong support for industrial-scale AAV manufacture in IND/BLA applications.

Friday Posters: AAV Vectors - Capsid Engineering

1442. Rationally Designed Chimeric AAV Capsids Demonstrate Enhanced Muscle Transduction and Reduced Liver Tropism in Both Rodents and Non-Human Primates

Paul Li[1], Yue Pan[1], Yujian Zhong[2], Youwei Zhang[2], Zhiyong Dai[2], Huan Chen[2], Keqin Tan[2], Rui Duan[3], Min Guan[4], Ye Bu[2]

[1]PackGene Biotech, Worcester, MA,[2]PackGene Biotech, Houston, TX,[3]South China Normal University, Guangzhou, China,[4]Chinese Academy of Sciences, Shenzhen, Guandong, China

The recombinant adeno-associated viral (rAAV) vector stands out as a pivotal technique within the gene delivery arsenal. However, its potential clinical application remains restricted by insufficient target

transduction and undesirable side effects, notably liver toxicity. To address these limitations, we employed sequential evolution of the AAV capsid via a robust pipeline, which starts with a direct comparative analysis of pre-selected AAV capsids screened from a high-throughput library and ends with functional validations in both rodents and NHP models. First and foremost, we rationally designed three chimeric capsids: AAV.Zero1, AAV.Zero2, and AAV.Zero3, which were verified to dramatically narrow down their tropisms in multiple major organs, especially in the liver. Further modification confirmed AAV.Zero3, a good choice of myotropic capsid backbone for a peptide-displaying mutant called AAV.eM5, exhibits superior efficiency and specificity in the musculature, including skeletal muscle and the heart, following systematic delivery cross-species. This holds great potential for muscle-related gene therapy. We envision that AAV.Zero1 and AAV.Zero3 are universal backbones that may not only be useful in targeting muscles but also be broadly applied to other organs or cells with specific peptide insertions. Moreover, our comprehensive serotype screening methodology (π-Icosa) is compatible with any capsids, targets, and species, and will thus facilitate and accelerate the development of optimal AAV vectors for human gene therapy.

1443. Novel Insertion Peptide AAV Capsids Exhibit Enhanced Transduction in Muscle and Ocular Tissue Across Different Serotypes

Trailokyanath Panigrahi[1], Ruchita Selot[1], Ashish Khaparde[1], Veluchamy A. Barathi[2], Arkasubhra Ghosh[1]

[1]GROW Research Laboratory, Narayana Netralaya Foundation, Bangalore, India,[2]Translational Pre-Clinical Model Platform, Singapore Eye Research Institute, Singapore, Singapore

Despite the success of recombinant AAV (Adeno-associated viral vectors) across numerous clinical trials, many studies have documented sub-optimal results with various AAV serotypes. This challenge has spurred development of capsids with enhanced efficiency, employing diverse strategies such as site-directed mutagenesis, rational design, directed evolution, and insertion of RGD peptides identified from a library-based approach. Here, we have developed a set of new insertion peptide containing AAV capsids incorporating RGD peptides (7-mer RGD integrin binding sequence, AAV-TIP) selected via rational design from pre-existing information regarding sequence affinity to integrin subsets expressed on human cells and compared that with a published, best performing RGD sequence (7-mer RGD containing sequence AAV-CIP). Further, since comparative studies on insertion of the peptides across different serotypes and application in tissue types are lacking, we tested three distinct clinically applicable serotypes (AAV2, AAV8, AAV9) in muscle and retina. The capsid sequences from AAV2, AAV8 and AAV9 were used for insertion of two different RGD peptides at positions 588, 589 and 589 respectively. The novel capsids were packaged by standard triple transfection method followed by purification via affinity chromatography. Subretinal and intramuscular injections were administered into 6-week-old C57BL/6J male mice at 6x10^8vg/eye and 1x10^9vg/TA muscle respectively. Six weeks post injection, muscle tissues were analysed for GFP expression using imaging, Q-PCR, and immunoblotting. Retinal structural changes and spread of GFP expression across all groups were assessed weekly by funduscopy, FFA and PS-OCT imaging. The viral genome quantification for wild-type and mutant vectors ranged from 7.04x10^11vgc/mL to 5.2x10^12 vgc/mL. In HEK293T cells and differentiated myotubes, AAV9-TIP.GFP and AAV9-CIP.GFP transduction exhibited higher expression levels compared to AAV9-WT.GFP (~20-fold, $p<0.05$ and 14-fold, $p<0.05$ respectively). Expression from AAV2 mutants was similarly high compared to AAV2-WT, but AAV8 mutants showed a lesser difference with AAV8-WT compared to other serotypes. This suggests that novel AAV-TIP peptide improves transduction at par with comparator. Analysis of GFP expression in mouse muscle revealed approximately >25-fold ($p<0.05$) higher expression from both AAV9-CIP.GFP and AAV9-TIP.GFP compared to AAV9-WT. Although AAV2 transduction overall was very low in muscles, we observed 3-fold ($p=0.051$) increase in GFP gene expression with AAV2-TIP and no significant change with AAV2-CIP. Interestingly, in muscle tissues, we observed much lower fold differences between AAV8-WT and AAV8 mutants compared to AAV9, which requires further validation. Subretinal injection of AAV9-TIP.GFP demonstrated early onset of expression and widespread distribution of GFP, showing ~10-fold increase in expression from both mutants across all serotypes compared to its wild-type ($p<0.05$ when comparing mutants with respective WT). Subtle differences in patterns of expression between TIP and CIP mutants were seen specific to the tissues type and serotypes were observed. However, AAV9-TIP vectors showed the highest overall transduction in retina as well as muscle. Interestingly in retina, both AAV2 CIP and TIP showed significantly higher expression than WT ($p<0.05$). The mouse in vivo data demonstrates significant superiority of new TIP vectors in the context of all three serotypes and non-inferiority to comparator CIP. We anticipate that these novel capsids will help improve AAV vector performance in clinical studies and reduce vector dosage.

1444. Selection and Characterization of AAV Capsids with Improved Tropism for Ocular Tissues in NHP

Bingfu Jiang, Dianyang Chen, Lumei Xiao, Huimin Kong, Peilu Li, Bing Wu, Hao Luo, Jinxin Deng, Zheng Luo, Yue Zhang, Shurong Zuo, Yanjun Shen, Hui Liu, Carol Huang, Jay Hou, Yanqun Shu

Skyline Therapeutics, Cambridge, MA

Adeno-associated virus (AAV) is considered as the most attractive vector for therapeutic gene delivery, AAV2 and AAV2 derived capsids have proven especially useful for vector construction for treating ocular disease. Intravitreal injection (IVI) is a simple and promising delivery route, but it often fails to achieve desired efficacy owing to inferior efficiency of vector to cross retina inter limiting membrane (ILM). To obtain capsids with high efficiency across ILM and improve tropism for the cells in retina, AAV2 based capsid library screening was carried out in non-human primates (NHP). Several capsids with significantly increased transduction for retinal cells were attained from the screening, and after packaging GFP and luciferase reporter transgene into a group of selected capsids, we thoroughly characterized them in NHP. The individual vector was injected via IVI into the animals and the vector genome copy numbers, transgene mRNA levels and expressed protein levels were measured using qPCR, RT-qPCR and luciferase assay. Retina wholemount and immunohistochemistry was also performed to detect which type of cells in the retina were transduced 3 weeks post injection. Our results indicated that most

of the novel vectors outperformed the benchmark wildtype AAV2 in biodistribution and transduction of retinal cells. Genome copy numbers were correlated with reporter gene expression well. In addition, the selected novel capsids showed notably higher levels of staining for retinal cells compared to wildtype AAV2. All the data suggested that the identified capsids gained biochemical properties that enabled them to cross ILM and penetrated different layers in the retina to effectively transduce the cells. We further evaluated the capsids in rodent via IVI injection, the results were consistent with that from NHP. All in all, the data indicates that the promising novel AAV2 capsid variants can be used to efficiently target retina; the vectors generated with the novel capsids can be potentially used in gene therapy for the treatment of a variety of human ocular diseases.

1445. AI-Aided AAV Capsids Design for Efficient Retina Transduction in NHP

Shuyuan Chen, Xiaodong Pang, Changpeng Wan, Zhongwan Li, Weiwei Wu, Runyuan Zhang, Xing Lan, Guanlin Li, Zhenhua Wu, Shaoyong Li, Guo-jie Ye
Exegenesis Bio Inc., Lower Gwynedd, PA

The success of adeno-associated virus (AAV) vector-based gene therapy depends on efficient delivery of the vector to the target cells. Most ocular diseases are due to the impairment of the development or function of photoreceptors, and/or cells of the RPE. Delivery of genes to these and other retinal cells presents a challenge because of the physical barriers of the retina. While subretinal administration provides the most direct access to photoreceptors and the RPE, it is more invasive, with a risk of damage to the retinal tissue. Intravitreal (IVT) injection is a safe, non-surgical procedure and have been widely used for delivery of protein therapeutics to treat common retinal diseases. Thus, more effective IVT delivery of AAV-based gene therapeutic products for retina is an unmet need for ocular gene therapies. Here, we reported two novel AAV capsids (AVT260 and AVT239) engineered with our AI-aided AAVarta® platform. In NHP, the efficiency of retina transduction of AVT239 and AVT260 delivered by intravitreal injection are 307-fold and 119-fold higher than that of AAV2, and 5-fold and 2- folds higher than AAV2.7m8, an intravitreal benchmark AAV capsid, respectively. The screening process relies on the next generation sequencing (NGS) of the target mRNA recovered from the retina and driven by a photoreceptor-specific promoter. Data obtained from each round of screening in NHP was used to train our regression models which will direct the design of AAV capsid library of next generation. After AAVarta® enrichment ranking analysis, 95% of top 100 capsid variants were shown to originate from our AI platform. Selected candidates were individually produced for validation with GFP or mCherry as reporter genes. Several variants exhibited widespread and high-level retinal transduction in NHP. Especially, both AVT260 and AVT239 showed significantly better transduction efficiency in the retina over AAV2.7m8 in Cynomolgus macaque (*Macaca fascicularis*). These results demonstrate that our designed variants with high efficiency in retinal transduction offer promise for IVT retinal gene therapies and how we can employ the AI power in capsid design.

1446. Criticality of Manufacturability Assessment in Supporting Discovery of Novel AAV3B and AAV8 Variants

Amanda Zhang, Azadeh Bazarchi, Bonnie Wu, Nadia Gantt, Thuy Bui, Ayda Mayer, Craig Malzahn
REGENXBIO Inc., Rockville, MD

Our institution has been undertaking the effort to engineer capsids for improved transduction efficiency and minimized off-target effects for certain routes of administration. To achieve this goal, we developed a directed evolution platform NAVIGATE (Novel AAV Vector Intelligent Guided Adaptation Through Evolution) for new capsid discovery, and this is accomplished by generating diverse libraries with randomized 7-mer peptide insertions in the AAV VR-IV and VR-VIII surface loop regions. For one of the projects, we applied NAVIGATE to AAV8 and AAV3B capsid optimization in the context of suprachoroidal space (SCS) delivery to ocular tissues. During library screening phase, we used various high-throughput techniques for material generation, such as transfecting with enhanced plasmid ratio or purifying mixed AAV variants using ultracentrifugation technology, which resulted in production of ~300 runs and >10000 peptide variants. The AAV library material produced went through multiple rounds of selection and the biological activity data generated showed differences in folds of improvement for these novel capsids over the AAV8 and AAV3B parental controls. Subsequently, a panel of variants were selected at 0.25L production scale for preliminary manufacturability assessment. Manufacturability assessment is crucial in helping to identify the suitability of a therapeutic molecule, to evaluate its fitness to a platform, and to reduce the process development effort due to unexpected results. For the initial manufacturability screening study, we used an in-house developed high throughput chromatography technology that can simultaneously purify 12 runs, at both the capturing and polishing chromatography steps. We were able to quickly observe the process differences between these novel SCS capsids. While the harvest titers, analyzed by digital droplet PCR (ddPCR), were all acceptable, there is a ~2.5 fold difference between the lowest and highest harvest titers for this panel of tested variants. The purification steps also demonstrated differences in the step yields and elution patterns for certain AAV8 and AAV3B variants. The polishing steps showed that the AAV8 variants all eluted earlier and that AAV3B variants all eluted later when compared to AAV8 and AAV3B controls. We further narrowed down the more promising novel SCS capsids to produce at 10L scale for a more complete manufacturability assessment, and the process profiles matched that of the smaller scale high throughput screening. The final produced material all had similar product qualities based on capsid purity, genome integrity, and percentage of full capsids present in solution, but the thermos-stability testing showed major differences, up to ~30°C, in melting temperatures. This information in combination with earlier biological activity data helped to determine the desirable capsids for further NHP studies. In summary, via our high throughput toolbox we ensured optimal production efficiency to provide material for our NHP studies, while swiftly discovering the potential process and product differences to better understand manufacturability for these variants. This has aided in selecting the novel SCS capsids that have optimal biological activity profiles but also possess the desirable manufacturability attributes, thus saving time, cost, and effort related to potential product redesigning.

1447. Grafting of an Enhanced VP1u Region onto Multiple Serotypes of AAV to Boost Baseline Transduction of Vectors for Gene Therapy

Mengtian Cui, Jackson McGowan, Jialing Yang Liang, Xiupeng Chen, Mitchell Yip, Suk Namkung, Tapan Sharma, Fang Zhang, Thomas Leland, Dan Wang, Jun Xie, Guangping Gao, Phillip Tai
UMass Chan Medical School, Worcester, MA

Adeno-associated virus (AAV) vectors are currently the most utilized viral vehicle for gene therapy. AAV capsid engineering efforts to boost transduction and safety have been in high demand. We have discovered an AAV2 capsid modality within the VP1 unique (VP1u) region, which has been named "MC1". The VP1u sequence is located at the N-terminus of the VP1 protein and initially resides within the lumen of the capsid. The region is then hypothesized to be externalized during its conformational change in late-endosomal/lysosomal compartments. VP1u is believed to participate in endosomal escape and trans-Golgi network (TGN) trafficking steps. We have shown that the MC1 modification AAV2 (AAV2.MC1) outperforms the gold-standard retinotropic capsid AAV2.7m8 for mouse retinal transduction following intravitreal (IVT) injection. AAV2.MC1 showed wider transduction of the retina in cynomolgus macaques than achieved by AAV2 following IVT administration. Interestingly, AAV2.MC1 externalizes its VP1u region at lower temperatures than AAV2 (45-50 °C versus 55 °C) as revealed by dot blot assays using a VP1u epitope-targeting antibody (A1). Using an intact capsid-specific antibody (A20), we found that AAV2.MC1 exhibited an overall higher thermostability than that of AAV2 (70-72 °C versus 68 °C), which was consistent between vectors packaged with either single-stranded or self-complementary genomes. These phenomena are also assessed by differential scanning fluorimetry (DSF). These findings reveal a role for the VP1u region in impacting AAV stability. Further studies in this regard are in process. Since VP1u is conserved among different AAV serotypes and shares similar functional domains with other parvoviruses, we hypothesized that the MC1 modality can increase the transduction efficiencies of other serotypes when grafted onto other capsid variants. Grafting MC1 onto AAV.7m8 further boosts its transduction. Unexpectedly, different serotypes showed distinct tolerances for the MC1 graft (*i.e.*, do not compromise vector packaging/production). AAV8, and AAV9 tolerated the graft, but only when purified by iodixanol gradient ultracentrifugation. Purification by CsCl gradient ultracentrifugation for these capsids caused >10-fold reduction in titers. Since CsCl purification requires higher centrifugation speeds compared with iodixanol purification, we hypothesize that the MC1 graft onto AAV8 and AAV9 may lower their stabilities. In contrast, AAV3b tolerated the MC1 graft, likely because of the high conservation between AAV2 and AAV3b. We have found that the MC1 graft increases AAV3b transduction *in vitro* and AAV1 transduction of mouse muscle. Grafting of MC1 onto AAV8 (AAV8.MC1) showed a two-fold greater transduction of mouse liver than achieved by grafting wildtype AAV2 VP1u onto AAV8. Grafting of MC1 onto AAV1, AAV5, AAV9, and subsequent *in vivo* testing is ongoing. Our results show that both AAV stability and transduction can be significantly impacted by VP1u, a domain that has largely remained unexplored by AAV capsid engineering efforts. G.G. and P.T. are corresponding authors.

1448. Intravitreal Delivery of an AAV2-Based and Cell-Penetrating Peptide Grafted Novel Capsid Produces Enhanced Panretinal and Photoreceptor Transduction with Reduced Inflammation

Jianghui Wang, Mengtian Cui, Hao Liu, Dan Wang, Phillip WL Tai, Guangping Gao
UMass Chan Medical School, Worcester, MA

Inherited retinal diseases (IRDs) are attractive therapeutic targets at the forefront of recombinant Adeno-associated virus (rAAV)-based gene therapy. The rapid development in this field has resulted in the first gene therapy product approved by FDA, Luxturna. To efficiently transduce the major target cells in IRDs, photoreceptors, rAAV needs to be administered via invasive subretinal injection. Due to the clinical and technical limitations of the subretinal injection, this approach entails an invasive procedure and only achieves local therapeutic effects and significantly reduces the efficiency of gene therapy. Thus, increasing efforts are dedicated to engineering novel capsids that enable rAAV penetrating to photoreceptors following intravitreal (IVT) injection. In this study, we aimed to graft cell-penetrating peptides onto AAV2 capsid and select resulting capsids for enhanced penetrating capability through vitreous space and retinal structures. To this end, we designed a moderately diverse capsid library with over 1000 cell-penetrating peptides (CPP) at various length (3-42 mer) inserted at position N587 of AAV2 VP3. The resulting AAV2 library were intravitreally injected in mice, and mRNA were subsequently prepared from retina and RPE complex one week post-IVT, followed by Next Generation Sequencing to examine the abundance of each capsid variant in the tissues. One CPP candidate, tentatively named as CPP1, was selected after one round of selection based on its highest enrichment in the retina at the transcriptional level. To validate our engineering strategy, we produced a single-stranded AAV2.CPP1.EGFP (ssAAV2.CPP1) and dosed mice by IVT injection ($2x10^9$ vgs/eye) along with AAV2 (ssAAV2) and 7m8 (ss7m8), an engineered AAV2 variant capable of transducing photoreceptor efficiently via IVT. Our preliminary data revealed that ssAAV2.CPP1 resulted in more robust (>2-fold) panretinal transduction than both ssAAV2 and ss7m8. Moreover, compared to the other two vectors, ssAAV2.CPP1 demonstrated enhanced GFP expression in all inner retinal cell types. Most importantly, ssAAV2.CPP1 exhibited 7- and 2.4-fold increase in photoreceptor transduction compared to ssAAV2 and ss7m8, respectively. As rAAV-induced immune responses and inflammation are major barriers in ocular gene therapy, we examined the expression of several inflammatory cytokines at mRNA levels in the eyes of the mice treated with different rAAV. We found that ss7m8 is prone to increased expression of these inflammatory cytokines, particularly Interleukin 6 (IL-6), while ssAAV2.CPP1 generates significantly lower IL-6 expression compared to ss7m8. Furthermore, there were significantly fewer microglial cells, a local immune cell type, identified in the inner plexiform of the mouse retina receiving ssAAV2.CPP1 compared to those receiving ss7m8. Altogether, our preliminary data suggest that our CPP-engrafting

capsid engineering strategy can potentially generate novel capsids that outperform 7m8 capsid in retinal transduction in both inner retinal cells and photoreceptors with reduced inflammation, potentially expanding our toolbox for retinal gene therapy applications through IVT. Given the restricted rounds of selection in this pilot study, further evolution and examination of this library are underway. J-H.W., M.C. and H.L. are considered as co-firstauthors.

1449. Engineering Novel AAV Capsids through Directed Evolution of the VP1u Region

Mengtian Cui, Jiang-Hui Wang, Jackson McGowan, Mitchell Yip, Phillip WL Tai, Guangping Gao
UMass Chan Medical School, Worcester, MA

Adeno-associated virus (AAV)-based vectors are currently the most used viral vectors for clinical gene therapy. As the number of clinical gene therapy trials has increased, there is a strong demand for safe and effective capsids with specific tropism profiles. To this end, we previously discovered two natural AAV2 variants isolated from human tissues that showed strong transduction of mouse and NHP retinas following intravitreal (IVT) injections. Interestingly, these variants only differ from AAV2 in the VP1 unique (VP1u) region, a poorly investigated sequence at the N-terminus of the VP1 protein. These findings hint at the potential for engineering capsids at the VP1u region. As the majority of capsid engineering is made in VP3, we hope to expand rational design efforts through identifying positive VP1u mutations that can likewise enhance transduction. However, sparse knowledge of VP1u limits our confidence in rationally modifying the region. To overcome this issue, we employed a directed evolution, a proven approach to assist the identification of tissue-tropic and highly efficient capsids, at the VP1u region. We randomly introduced mutations into the entire VP1u by error-prone PCR, followed by NGS analysis to estimate variant diversity and enrichment. In the first round of the AAV2 VP1u library, 4.93E5 unique capsids (approximately 95.5% variants and 0.5% AAV2) were identified, and the library was intravitreally injected in mice, followed by mRNA preparation from the retina and RPE complex one-week post-injection. The VP1u variants were amplified and packaged into a second AAV library consisting of 4.2E5 unique capsids (approximately 85% variants and 15% AAV2). Following the injection of this library, the unique capsid variants found in the tissue were reduced to 5.4E4. The enrichment score (ES) from the 2nd round of screening indicates the relative tissue abundance of each capsid normalized to library gDNA. Based on this ES metric, there were 10 candidates found to outperform AAV2. Interestingly, the top candidates differed from the AAV2 VP1u sequence by single amino acid mutations located in poorly described regions. A third round of screening will be performed to further enrich the leading candidates.To validate our engineering strategy, we selected one of the ten aforementioned candidates, named v113, to evaluate the potential of these capsids. This variant was individually packaged with an *Egfp* expression cassette and then evaluated by IVT injection in mice. v113 was found to transduce the mouse retina with two-fold greater efficiency than AAV2. It showed a relatively better photoreceptor transduction. These preliminary results demonstrated the potential of AAV VP1u library screening as a means of identifying effective capsids. This exploration has encouraged us to individually evaluate more highly enriched candidates following additional rounds of selection. Moreover, the knowledge gained from this work may provide invaluable insights into the AAV field and enable us to better characterize the under-researched functional domain of VP1u, expanding our capsid engineering approaches. **M.C., J-H.W. are considered as co-first authors.**

1450. SNAC: Single-Nuclei Atlas of Capsid Distribution for AAV Capsid Selection for Ocular Gene Therapies

Eugenia Lyashenko[1], Rachna Manek[1], Yinyin Huang[2], Jeremy Huang[2], Margaret Hennessy[1], Michael Ryan[1], Jasmine Bloom[1], Tess Torregrosa[1], Pavitra Ramachandran[1], Andre Kurlovs[2], Virginia Savova[2], Giorgio Gaglia[2], Sourav R. Choudhury[1]
[1]Genomic Medicine Unit (GMU), Sanofi, Waltham, MA,[2]Precision Medicine Computational Biology (PMCB), Sanofi, Cambridge, MA

Neurodegenerative ocular diseases lead to irreversible loss of vision and affect up to 300 million people worldwide. Because the eye is a relatively small and contained anatomical structure, AAVs can be delivered locally. Therefore, ophthalmic gene therapy can potentially avoid systemic immune responses and provide therapeutic benefit at low capsid doses, making ophthalmology an excellent candidate for the gene therapy approach. Recent advances in genome-wide association studies (GWAS) and single cell sequencing have allowed the genetic targets of disease to be mapped to specific cell populations. However, cell-type specific gene therapies for ocular indications are not yet available due to lack of cell-type specific capsids to deliver the therapies. To address this unmet need in gene therapy, we have developed a novel methodology, SNAC (Single-Nuclei Atlas of Capsid Distribution), to screen and select AAV capsids targeting specific cell-type populations in NHP retinas by generating a single-cell resolution transduction profile of a library of 24 natural AAV capsids. First, we manufactured and injected the pooled GFP-encoding capsids into NHP eyes via intravitreal route of administration. From nuclei isolated from peripheral and central/macula regions, we generated and deeply sequenced transcriptomic and GFP barcode libraries. Using these sequences, we matched the transcriptomes of individual nuclei to the list of GFP barcodes contained in the injected library. Next, using CellBridge (a software package pipeline published by Sanofi) and data- and literature- derived marker gene sets from NHP and human retinal studies, we identified major cell types and quantified individual AAV capsid transduction profiles of specific cell populations. As a result, we detected all major retina cell types specifically, photoreceptors (rods and codes), bipolar cells, amacrine cells, horizontal cells, retinal ganglion cells (RGCs) and non-neuronal subtypes (Muller glia, microglia, astrocytes, endothelial cells, pericytes). We validated the internal consistency of the data by comparing the cell type proportions from different regions (peripheral compared to macula) to benchmark retinal cell type proportions from the literature. Finally, we quantified the percentage of AAV transduced cells by cell type, finding that AAV2, AAV6, and AAV1 are the top three capsids transducing RGCs, amacrine cells, horizontal cells, and Muller glia. This confirms previous observations that AAV2, the current AAV capsid of choice for ocular gene therapies in the clinic, transduces the eye at high levels. To validate these findings, we conducted bulk RNAseq of retinal samples from the same animals and found that the ranking of capsids detected by SNAC

agrees with that from bulk RNA sequencing of the entire tissue. In conclusion, we have developed SNAC, a method which allows screening barcoded AAV libraries to detect cell-type specific transduction in tissues. We demonstrated and validated this method on a library of 24 known natural AAV capsids in NHP retinas for ocular gene therapy indications. SNAC now can be applied for high-throughput single-cell resolution profiling of retina transductions by kilo-scale AAV libraries. In the future, this methodology can be applied to other tissues where precise cell-type specific targeting of AAV capsids is needed.

1451. Development of Mutant AAV-DJ Capsids with Better Transduction Efficiency for Local and Systemic Delivery

Ozgun Firat Duzenli[1], Zhang Lianwen[2], Kah-Whye Peng[2], George Aslanidi[1]

[1]The Hormel Institute, University of Minnesota, Austin, MN,[2]Mayo Clinic, Rochester, MN

The success of desired therapeutic benefit with AAV vectors requires the use of high vector doses which inevitably increase the risk of dose associated adverse events such as host immune response and liver toxicity. Therefore, it is critical to develop novel AAV vectors which are able to deliver therapeutic genome load at lower doses. To this end we produced several capsid-optimized AAV.DJ vectors with point mutation of critical amino acid residues to obtain novel vectors with improved transduction efficiency. These mutations included: N664V located in HI loop and involved in virus escape from the endosome; I648V and T710I reduce binding affinity for neutralizing antibodies; G506R and Y707C are glycan-binding residues which can reduce undesired liver accumulation while maintaining broad biodistribution; T493V, Y706F, and Y732F, which are proven to improve intracellular trafficking of AAV vectors. We also combined several single mutations to test the advantages of the synergetic effect of targeting multiple mechanisms of AAV life cycle and host interactions. These double mutants include T493V+N664V, G506R+Y707C, and Y706F+Y732F. The packaging plasmids encoding mutant capsids were generated by site-directed PCR by using the plasmid encoding wtAAV.DJ as a template. A single-stranded DNA cassette encoding firefly luciferase - yellow fluorescent fusion protein under the chicken β-actin promoter was packaged to each single and double mutant AAV.DJ and compared with wtAAV.DJ. The packaging efficiency of the most capsid-mutants was 2-3 times lower than wtAAV.DJ, while vectors harboring the mutations Y707C and G506R+Y707C were packaged with about 1-log lower titer. We further evaluated the transduction efficiency of the wt and mutant AAV.DJ vectors in HEK293 cells by using *in vitro* luciferase assay. AAV vectors were used at different MOI consisting of 2.000, 5.000, and 10.000 vg/cell. The bioluminescence signal was measured 48 hours post-infection. We observed that the mutants N664V, I648V, and Y732F showed 3-6 fold superior transduction compared to the wt AAV.DJ capsid, while infectivity of all double mutants was similar to wtAAV.DJ. To test the *in vivo* bioactivity of wt- and mutant AAV.DJ vectors, six- to ten-week-old male C57BL6 mice were intramuscularly injected with $1x10^9$ vg/mice with AAV vectors. Expression was monitored weekly with IVIS Lumina S5 Imaging System for two weeks. Consistent with *in vitro* results the *in vivo* luciferase assay showed that only AAV.DJ-N664V mutants have superior *in vivo* activity compared to wtAAV.DJ vector and all other capsid compositions displayed similar or lower transduction. We are currently testing capsid-modified AAV.DJ vector activity by non-invasive *in vivo* imaging technique with a sodium iodide symporter (NIS) from minke whale (*Balaenoptera acutorostrata scammoni*) for precise tracking of vectors spread and tissue transduction. Our results might lead to the development of superior AAV vectors for local and systemic administration by manipulating critical regions of viral capsids. **Acknowledgments:** This project is supported by FDA/CBER R01FD007483 funding.

1452. Evaluation of Cross-Species Expression Across Four Species and Cellular Tropism of VCAP-102, an Engineered Blood-Brain Barrier-Penetrating AAV Derived Capsid from TRACER Platform Screens

Hamza Khalid[1], Anupriya Kulkarni[1], Munachiso Egbuchulam[1], Alexandra Tsolias[1], Amy Bruce[1], Rong Zhao[1], Tyler Moyer[2], Nilesh Pande[1], Chanchal Sadhu[1], Mathieu E. Nonnenmacher[2]

The blood-brain barrier (BBB) prevents therapies from engaging targets within the central nervous system (CNS) resulting in the use of invasive delivery methods of adeno-associated virus (AAV) vectors. The TRACER (Tropism Redirection of AAV by Cell-type-specific Expression of RNA) platform has enabled the generation of engineered AAV variants that have greater BBB crossing efficiency and liver detargeting compared to parental AAV capsids using intravenous (IV) administration. Previously, we have shown that VCAP-102 was superior to AAV9 in crossing the BBB after IV administration and had widespread CNS transduction and expression in Cynomolgus macaques. To evaluate the efficacy of VCAP-102 for preclinical studies in rodents and show potential translatability into humans, we performed VCAP-102 biodistribution and transgene expression studies after IV administration in mice, marmosets, African Green Monkeys (AGM), and Cynomolgus macaques. We observed higher biodistribution and widespread transgene expression of VCAP-102 in all the tested species as compared to AAV9. Further, using immunofluorescent staining, we confirmed that VCAP-102 mediated transgene expression in both neurons and astrocytes in the cortex of mice, AGM, and Cynomolgus macaques. Our data confirm that VCAP-102 is superior to AAV9 in crossing the BBB across multiple species after IV administration, thus suggesting that VCAP-102 can be used for preclinical studies and may be useful for CNS-targeting indications.

1453. GUAAVA: Generation of Ultra-Manufacturable Adeno-Associated Viruses by Artificial Intelligence

Jason Wu[1], Yumeng Cao[2], Yu Qiu[2], Tess Torregrosa[1], Margaret Hennessy[1], Michael Ryan[1], Mehmet Takar[1], Eugenia Lyashenko[1], Sourav R. Choudhury[1]

[1]Sanofi, Waltham, MA,[2]Sanofi, Cambridge, MA

Gene therapy is transforming human health by addressing rare diseases with single dose-administration of therapeutic adeno-

associated viral (AAV) vectors. However, the exorbitant financial cost of these treatments limits widespread adoption of gene therapies. Manufacturing cost is a major contributor to Cost of Goods Sold (COGS) for genomic medicines. Improving manufacturability of AAV capsids can lead to the reduction of COGS for AAV-based gene therapies, therefore allowing for increased patient accessibility to gene-therapy products. Taking advantage of recent advancements in artificial intelligence (AI) and falling costs of DNA synthesis, we applied machine learning (ML) methodologies to rationally design super-manufacturable AAV capsids. Here, we developed a generative AI framework, GUAAVA (Generation of Ultra-manufacturable Adeno-Associated Viruses by Artificial Intelligence), to derive high manufacturability AAV mutant sequences. First, we developed a state-of-the art ML model to predict the manufacturability of AAV capsid mutants based on the amino acid sequence of the capsid monomer, viral capsid protein 1 (VP1). This model is trained on capsid fitness data of AAV2 VP1 single point mutants and embeds sequences in the space of a massive protein language model. Then, using the predictive ML model as an oracle, we built a generative framework, GUAAVA, that focuses on exploring the sequence space around wild-type AAV2 sequence. Finally, we validated the GUAAVA model experimentally by comparing the manufacturability of the *in-silico* designed sequences to a set of randomly generated AAV2 mutants. To do this, we synthesized a pool of viral capsids encoding GUAAVA-generated sequences and randomly generated AAV2 mutants and measured relative production of each viral capsid by NGS in a pooled library. We found that the manufacturability of the best GUAAVA-generated capsid is more than 1000-fold that of parental AAV2 capsid. Furthermore, when we ranked individually packaged capsids by manufacturability, we found that GUAAVA-generated capsids accounted for the top 20 capsids. In addition, we show that the top individually packaged GUAAVA-generated capsids have x200 fold higher production than wild-type AAV2 in a titer assay. In summary, we have established GUAAVA, a generative AI-based platform and used it to improve the manufacturability of AAV capsids which can increase the economic viability of AAV gene therapies. This generative model framework is extensible; with proper training data, it can apply to other critical features of AAV gene therapies, such as immunogenicity or tissue tropism, bringing AAV-based genomic medicines to a wider patient population.

1454. High Throughput Production, Purification and Screening Pipelines for AAV Capsid Variants

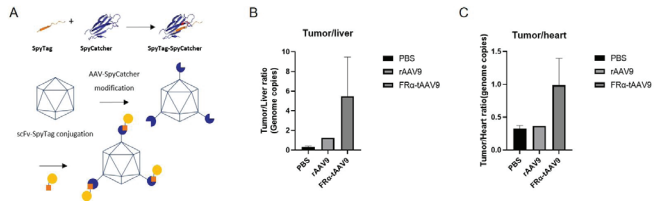
[1]Ginkgo Bioworks, Boston, MA,[2]Ginkgo Bioworks, Cambridge, MA

The Adeno-associated virus (AAV) field has advanced tremendously over the past 60 years and the virus has quickly become a preferred vehicle for in vivo gene therapies. Novel capsid development via engineering and high-throughput screening has demonstrated the value of isolating variants more highly specific to specific target indications and applications. Existing approaches range from shuffling of the entire capsid sequence to randomization of discrete, functional regions of the AAV's surface variable loops, producing millions of capsid sequences requiring downselection. Ginkgo Bioworks is building high-throughput, arrayed transfection and purification pipelines that allow for the construction of large libraries of pre-selected capsids for in vivo and in vitro applications.Here we developed and evaluated automated AAV triple transfection workflows at 100uL, 500uL, and 1mL plate scale formats to produce 100-1000 combinations of different AAVs with modified capsids and barcoded ITR payloads in an arrayed format. Cell lysates were pooled before being subjected to density gradient centrifugation, size-exclusion or affinity chromatography (AAVX) purification workflows. These barcoded AAV capsids variant libraries were then characterized via amplicon sequencing after purification as well as after administration in vivo to study biodistribution. Alternatively, cell lysates were processed in arrayed workflows where individual well lysates were not pooled and instead subjected individually to high throughput IMCS tip- or magnetic bead- based AAVX purification. These arrayed libraries were then deployed in high-throughput, singleplex, in vitro applications. Both pooled and arrayed approaches yielded sufficient vectors for downstream applications. The flexibility of using this dual approach allows the interrogation of a pooled library of constructs in vivo or evaluation of arrayed individual constructs using high throughput screening platforms in vitro to pre-select vectors with desired preclinical phenotypes.

1455. Nanobody-Mediated Retargeting of a Modified AAV Enhances Distinct and Highly Specific Transduction of Tumor Tissues

Olaniyi Olarewaju[1], Franziska Held[1], Pamela Curtis[2], Cynthia Kenny[2], Tadas Panavas[2], Udo Maier[1], Francois du Plessis[1]

[1]AAV Gene Therapy Group, Research Beyond Borders, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riß, Germany,[2]Biotherapeutics Discovery, Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT



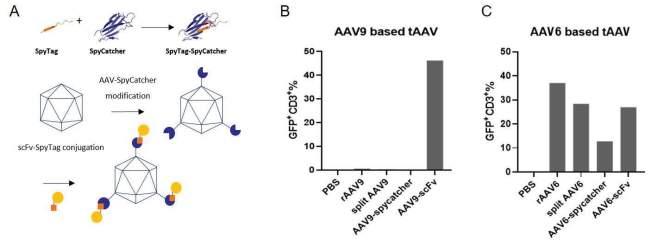
Background: Despite the recent clinical and commercial successes of adeno-associated virus (AAV)-based gene therapies, the platform is still poorly explored for targeted delivery of therapeutic agents to tumor cells, due to the refractiveness of tumor cells to AAV transduction. In this study, we harnessed a nanobody (VHH) in combination with AAVs by engineering a capsid-surface modified AAV decorated with a single domain antibody, VHH. The aim was to establish a proof-of-concept by targeting the fibroblast activating protein (FAP) which is a distinctly expressed cell surface receptor in tumor stroma and fibrotic tissues, but rarely expressed in normal tissues. Thus, creating a versatile AAV vector platform for targeting tumor cells. **Methods**: An α-FAP VHH (α-FAP-VHH) was displayed on the capsid surface of an AAV2 vector with the HSPG-binding motif ablated ($AAV2^{KO}$). To display approximately 1-5 copies of the VHHs per capsid, the VP1 start codon was mutated on the AAV2 Rep2/Cap2 plasmid ensuring only the production of Rep proteins, VP2 and VP3 capsid proteins respectively. The VP1 capsid protein was then supplied in *trans* on an additional plasmid with the nanobody integrated at the GH2/GH3 loop of the modified VP1. The modified $AAV2^{KO}$ displaying α-FAP-VHHs were packaged with the nanoluciferase (NLuc) transgene. The generated AAV was functionally validated for specific targeting of

human FAP receptor (huFAP) expressing cells *in vitro* in a human FAP receptor-expressing HT1080 fibrosarcoma cell line (HT1080-huFAP), as well as a HT1080-huFAP cell-derived xenograft (CDx) mouse model. **Results**: Our *in vitro* data shows that the AAV2^{KO}_α-FAP-VHH vector selectively transduces HT1080-huFAP cells very efficiently (23 to 80-fold) compared to the negative control non-huFAP expressing HT1080 cells. Moreover, the activity of AAV2^{KO}_α-FAP-VHH can be competitively inhibited by blocking the FAP-receptor on the HT1080-huFAP cells by an α-FAP antibody, indicating a specific and direct interaction of the vector with the FAP receptor via the integrated VHH. Following our *in* vitro experiments, the HT1080-huFAP cells were engrafted in NXG immunodeficient mice to generate a CDx huFAP expressing mouse tumor model. Transduction of the HT1080-huFAP CDx mice with AAV2^{KO}_α-FAP-VHH resulted in an enhanced transduction (>6-fold) of HT1080-huFAP tumors compared to wild-type (WT) AAV2, combined with a strong detargeting (=10-fold) of AAV2^{KO}_α-FAP-VHH from the liver compared to WT AAV2. To broaden the versatility of such a high-fidelity platform, which is hugely necessitated due to the limited nanobody repertoire, a high throughput yeast display library screen was performed to identify novel α-FAP nanobodies. We successfully identified and characterized several novel α-FAP nanobody candidates with binding affinities to FAP ranging between 0.1 nM to >100 nM. These new VHH binders will be used to further investigate the epitope and affinity influence for antibody based AAV targeting. **Conclusion**: This study offers a new opportunity for exploring the application of AAVs as a veritable vehicle for highly selective delivery of therapeutic agents to the tumor stroma. Furthermore, we utilized an adaptable high throughput yeast display library screening platform for the identification of novel single domain antibodies for the functionalization of AAV capsids. Beyond tumor targeting, this platform is applicable for selective delivery of AAVs to specific target cells or tissues of interest. This can help overcome the challenges posed by AAVs broad tropism, which often lead to the need for high vector dose administration to achieve therapeutic level of transgene expression in target tissues.

1456. The Development of Tumor Targeting AAV

Lei Zhao, Chuyuan Chen
Cure Genetics, SuZhou, China

Introduction: Cancer immunotherapy requires many modalities such as mono-clone antibody, oncolytic virus, immune agonist cytokine, chimeric antigen receptor immune cell, antibody-drug conjugate, tumor vaccine, etc. based on different MOAs (mechanism of action) and drug targets. The new modality, novel MOA and promising combination will give more solutions for clinical requirements. Cytokine armored oncolytic virus is one of the valuable therapy which designed both to lyse tumor cells by oncolytic virus and to regulate immune responses by secreting of cytokines. However, the high immunogenicity of oncolytic virus requires intratumoral (IT) administration and multiple dosing, somehow limited the application in clinical trials. Here, we developed a tumor targeted AAV vector (t-AAV) which delivered specific cytokine to solid tumor. This new modality can 1) use intravenous (IV) administration instead of IT; 2) secrete pro-inflammatory cytokine in tumor microenvironment (TME) to reduce the side effect from systemic administration of cytokine; 3) long-term treatment by single dose of AAV. This t-AAV is engineered from wtAAV which carried SpyCatcher modified VP1 in site of 453. This viral particle was then conjugated with SpyTag modified tumor cell targeting scFv (anti folate receptor alpha, FOLR1 or FRα) (Fig. A). This t-AAV (AAV9 based) infected human SKOV3 cell line (FRα+) with appx. 15-20% infection rate while rAAV9 only represented less than 5%. Biodistribution study also confirm that t-AAV can specific target solid tumor in compare with rAAV9. Results and Discussion: AAV9 and AAV6 are selected as basic AAV serotype for SpyCatcher engineering. The plasmid of VP1 has been isolated from Rep-Cap plasmid for protein engineering. The SpyCatcher003 (variant of SpyCatcher) was inserted in the site of 453 of VP1 with the replacement of 453-459. The titer after 4-plasmid AAV packaging and purification is comparable with triple-plasmid packaging of rAAV9. The viral vector was then conjugated with SpyTag003 (variant of SpyTag) modified anti-FRα scFv. The conjugation yield is very high and the ratio of VP1 and VP2 is 1:1 before and after conjugation. The transduction activity after conjugation of t-AAV is monitored by infection of SKOV3 cell line. The AAV9 based T-AAV has 15-20% infection in different MOIs activity while rAAV9 only has less than 5% infection. The in vivo biodistribution of t-AAV has been tested in mice. In compare with rAAV9, t-AAV represents strong solid tumor targeting effect while also showed liver and heart tropism in mice (Fig. B-C.). This result indiates the potential IV administration of t-AAV. The secretion of cytokine was studied in both SKOV3 and MC38 (both with FRα+) cell lines. Both cell lines represent very good IL-12 secretion with maximum 200-600 pg/mL. Conclusions: Tumor targeted AAV (t-AAV) based on AAV9 serotype represents high target cell selectivity in vitro and in vivo. The delivery and expression of cytokine with t-AAV has been also confirmed in vitro. It is a potential vector for cancer immune therapy.



1457. The Development of T Cell Targeting AAV

Lei Zhao, Yongji Jiang
Cure Genetics, SuZhou, China

Introduction: Chimeric Antigen Receptor T-Cell (CAR-T) is one of most potent therapy in hematological cancer treatment. However, the disadvantage of the autologous cell therapy, non-off-the-shelf productivity and the potential risk of new cancers after treatment with CAR-T therapies limited its application. Although the allogeneic cell therapy offers advantages over the autologous counterpart, it still remains the new cancer risk from gene integration by transduction of CAR with lentivirus (LV) or retrovirus (RV). Nowadays, in vivo CAR-T, which directly dose the vector with CAR gene to patient, is developed as another option with allogeneic cell therapy. The vectors such as LV, adenovirus (AD), lipid nanoparticle (LNP), virus like particle (VLP) etc. had been developed for T cell targeting properties. Here, we developed a T cell targeting adeno-associated virus (T-AAV) vector for in vivo CAR-T therapy. The T-AAV is engineered from wtAAV which

carried SpyCatcher modified VP1 in site of 453. This viral particle was then conjugated with SpyTag modified T cell targeting scFv (Fig. A). This T-AAV (AAV9 based) infected human T cell in hPBMC with appx. 40-50% infection rate while rAAV9 only represented less than 1% (Fig. B-C). This T-AAV is potentially in vivo CAR-T vector without the risk of genome integration. It also generates the long-term gene expression in T cell compare with RNA technologies. Results and Discussion: AAV9 and AAV6 are selected as basic AAV serotype for SpyCatcher engineering. The plasmid of VP1 has been isolated from Rep-Cap plasmid for protein engineering. The SpyCatcher003 (variant of SpyCatcher) was inserted in the site of 453 of VP1 with the replacement of 453-459. The titer after 4-plasmid AAV packaging and purification is comparable with triple-plasmid packaging of rAAV9. The viral vector was then conjugated with SpyTag003 (variant of SpyTag) modified anti-CD3 scFv (OKT3). The conjugation yield is very high and the ratio of VP1 and VP2 is 1:1 before and after conjugation. The binding affinity of T-AAV and CD3 has been confirmed by ELISA, T-AAV represented appx. 5-10 folds increased affinity than recombinant scFv which correlated with number of scFv (VP1) in one T-AAV nano-particle. The transduction activity conjugation of T-AAV is monitored by infection of hPBMC. The infection of CD3+ T cell has been used for criteria of T-AAV activity. The AAV9 based T-AAV has 45% infection activity while rAAV9 only has less than 1% infection. However, AAV6 based T-AAV does not improve the T cell specificity in compare with rAAV6. Thus, AAV9 based T-AAV has been chosen as the vector for in vivo CAR-T therapy. The in vivo biodistribution of T-AAV has been tested in mice. In compare with rAAV9, T-AAV also showed liver tropism in mice but with appx. 10-fold lower infection activity. This result represents the potentially safety profile with T-AAV. Conclusions: T-AAV based on AAV9 serotype represents high T cell selectivity in vitro assay and reduced liver tropism than rAAV9 in mice. It is a potential vector for in vivo CAR-T or other T cell therapies.

1458. T-Lymphocyte Specific *In Vivo* Gene Delivery with CD8-Targeted AAV2 and AAV6

Muhammed Burak Demircan[1], Luca Zinser[1], Alex Michels[1], Mar Guaza-Lasheras[1], Fabian John[1], Samuel Arthur Theuerkauf[1], Dorothee Günther[1,2], Dirk Grimm[3], Petr Chlanda[4], Frederic B. Thalheimer[1], Christian J. Buchholz[1,5]

[1]Molecular Biotechnology and Gene Therapy, Paul-Ehrlich-Institut, Langen, Germany,[2]Molecular Biotechnology and Gene Therapy, Ernst Strüngmann Institute for Neuroscience in Cooperation with Max Planck Society, Frankfurt Am Main, Germany,[3]Heidelberg University Hospital, Heidelberg, Germany,[4]Department of Infectious Diseases/Virology, Medical Faculty, University of Heidelberg, BioQuant, Heidelberg, Germany,[5]Frankfurt Cancer Institute, Goethe University, Frankfurt am Main, Germany

A major challenge for *in vivo* gene therapy is the development of vectors capable of mediating highly selective gene transfer specifically into therapy-relevant cells. Among these, subtypes of T lymphocytes, particularly CD8+ T cells, represent a highly relevant target cell population not only in patients, but also in mice to address basic immunological research questions. Among various strategies, receptor-targeted approaches emerge as ideal for specifically targeting CD8+ T cells. Here we present DARPin-targeted AAVs (DART-AAVs), a second-generation receptor-targeted AAV, exhibiting improved DARPin display specific for human and murine CD8. The insertion of DARPins into the GH2-GH3 loop of viral protein 1 (VP1) in both AAV2 and AAV6 resulted in high selectivity for CD8-positive T cells, while maintaining robust gene delivery efficiency. Cryo-electron tomography enabled imaging of DARPins protruding from particle surfaces. Importantly, the capsid core structure was unaltered from that of the parent capsid core at a resolution of 3.3 Angstrom. In complex primary cell mixtures, i.e. in donor blood and in mice, CD8-targeted AAVs were by far superior to unmodified AAV2 and AAV6 in terms of selectivity, target cell viability and gene transfer rates. *In vivo*, up to 40% of activated CD8+ T cells were hit upon a single vector injection into humanized mice. By inserting a murine CD8-specific DARPin into the GH2-GH3 loop of the AAV2 VP1, we achieved >99% gene transfer selectivity on CD8+ murine splenocytes, however, the gene transfer rates were low under the non-activated conditions. Remarkably, after *in vivo* conditioning of mice with T cell-activating compounds (anti-CD3/IL2 complex), gene transfer rates dramatically increased, leading to up to 20% transduction of CD8+ T cells in murine blood with a single vector injection into immunocompetent mice. In all settings, selectivity for CD8+ T cells was close to absolute with exceptional detargeting from liver. These findings demonstrate that the capsid insertion of DARPins enables highly selective and efficient gene transfer into both mouse and human T lymphocytes. Consequently, the CD8-AAVs described in this study broaden the array of strategies available for immunological research and enhance the scope of *in vivo* gene therapy options.

1459. Mucin-Type *O*-Glycosylation in Viral Protein 2 Indirectly Affects the Transduction Efficiency of Recombinant Adeno-Associated Virus Serotype 6

Yuki Yamaguchi[1], Kentaro Ishii[1], Sachiko Koizumi[2,3], Hiroaki Sakaue[4], Takahiro Maruno[1,5], Mitsuko Fukuhara[1,5], Risa Shibuya[1], Yasuo Tsunaka[1], Aoba Matsushita[1], Karin Bandoh[1], Tetsuo Torisu[1], Chie Murata-Kishimoto[2], Azusa Tomioka[4], Saho Mizukado[4], Hiroyuki Kaji[6], Yuji Kashiwakura[7,8], Tsukasa Ohmori[7,8], Atsushi Kuno[4], Susumu Uchiyama[1]

[1]Graduate School of Engineering, Osaka University, Osaka, Japan,[2]GlycoTechnica Ltd., Yokohama, Japan,[3]Precision System Science Co. Ltd., Chiba, Japan,[4]Cellular and Molecular Biotechnology Research Institute, National Institute of Advanced Industrial Science and Technology, Ibaraki, Japan,[5]U-Medico Inc., Osaka, Japan,[6]Institute for Glyco-core Research (iGCORE), Nagoya University, Aichi, Japan,[7]Department of Biochemistry, Jichi Medical University School of Medicine, Tochigi, Japan,[8]Center for Gene Therapy Research, Jichi Medical University, Tochigi, Japan

Recombinant adeno-associated viruses (rAAVs) are promising vehicles for target genes in gene therapy. Glycosylation of biopharmaceuticals is known to influence on their safety and efficacy, and rAAV capsids may undergo glycosylation as post-trans modification during manufacturing process. Some previous studies reported glycosylation of rAAVs; however, the types of glycan that attach to rAAVs are still controversial. In this study, we extensively studied on rAAV serotype 6 (rAAV6) to explore whether rAAV is glycosylated, and if so, what types of glycans are actually attached to the capsid. For deep and precise characterization, we attempted to isolate the glycosylated rAAV6 particles. After testing more than 20 lectins, the fractionation of rAAV6 using *Agaricus bisporus* agglutinin (ABA), which is one of the *O*-glycan-recognizing lectins successfully captured the rAAV6 particles which accounted for only 1% of total particles. LC-MS/MS analysis for those fractions AAV6 was modified with two types of *O*-glycans: the mucin-type glycans, *O*-GalNAc (Tn-antigen) and mono- and di-sialylated Galβ1-3GalNAc (T-antigen) with at S156, T162, T194, and T201 in viral protein (VP)2, and *O*-GlcNAc at T242 in VP3. Interestingly, mucin-type glycans in VP2 were only observed in by ABA-bound particles, whereas *O*-GlcNAc in VP3 was only detected in ABA-unbound particles. Considering the reported three-dimensional structure of rAAV6, the *O*-GlcNAc at T242 in VP3 region is located at inner side of the capsid, whereas although the structure of VP1 and VP2 has not been elucidated, mucin-type *O*-glycan clusters at in VP2 should be located at the position which is accessible by ABA. Physicochemical and biological analyses were performed for the fractionated rAAV6 to reveal the impact of the mucin-type *O*-glycosylation on particle size distributions, VP ratio, in vivo and in vitro transduction efficiencies. Surprisingly, the mucin-type *O*-glycosylated rAAV6 particles encapsidated full-length genome and showed significantly lower VP1 ratio than rAAV6 without mucin-type *O*-glycans, resulting in lower transduction efficacy both in vitro and in vivo.In summary, rAAV6 contains 1% of ABA-bound particles, namely mucin-type *O*-glycosylated rAAV6 particles with lower VP1 ratio which resulted in reduced transduction efficiency than that of rAAV6 without mucin-type *O*-glycans, suggesting that mucin-type *O*-glycosylation of rAAV indirectly influence on transduction efficiency. This report provides us the conclusively proof that rAAV is *O*-glycosylated and in-depth insights of glycosylation for rAAV-based therapeutics.

1460. Computational Design and Validation of Extended Rigid Hairpins on the Surface of AAV

Samantha A. Yost[1], Sigmund Tejada[1], Elad Firnberg[1], Emre Firlar[2], Olivier F. Danos[1], Ye Liu[1], Andrew C. Mercer[1], Jason T. Kaelber[2]

[1]Research and Early Development, REGENXBIO, Inc., Rockville, MD,[2]CryoEM & Nanoimaging Facility, Institute for Quantitative Biomedicine, Rutgers, The State University of New Jersey, Piscataway, NJ

Adeno-associated virus (AAV) capsid variants with enhanced gene transfer utility are highly sought after. Flexible loops in variable region eight (VR-VIII) and more recently VR-IV have been used as targets for capsid engineering by peptide library insertion but appear to be limited to small peptides and may interfere with the native folding and function of capsid (VP) proteins. Larger proteins have been successfully incorporated with varying degrees of success by using very long, flexible linkers, fusion with the N-terminus of VP2, or as an additional covalently linked moiety; however, these methods can raise concerns about manufacturability, homogeneity, and batch-to-batch variability. Here we present computationally designed, rigid linkers in VR-VIII to create a stabilized hairpin that protrudes from the capsid surface. We hypothesize that these would function as an extended hinge, allowing for larger insertions without compromising VP folding and increasing ligand accessibility. Hairpin constructs were initially based on a tryptophan zipper motif or streptococcal protein G hairpin before applying hallucination methods to refine sequences within the context of AAV9. An additional mutation of Q590 to proline, a conserved residue found in several other serotypes in the adjacent position in structural alignments (e.g. AAV8 P593), was included in some constructs to increase stability. All six stable hairpin design constructs packaged AAV genome successfully by ddPCR evaluation with titers ranging from 38-105% of wild type AAV9. Structures were evaluated for three constructs via cryo-electron microscopy to confirm the predicted conformation and support further refinement. Previously described muscle targeting peptides incorporated at the end of a hairpin loop were tested in differentiated human myoblasts to verify transduction capabilities via reporter protein expression. Myoblasts transduced with AAV9 displaying a stable hairpin and the inserted peptide exhibited 300-fold higher fluorescence intensity from expressed tdTomato over cells treated with wild type AAV9. Insertion of larger targeting moieties such as 16kDa designed ankyrin repeat proteins (DARPins) with inclusion of a stabilized hairpin provided a 3-fold improvement in transduction of cells expressing the DARPin target over GS linker. We hypothesize that the utility of these hairpin linkers may extend to other AAVs, and further evaluation is ongoing.

1461. mRNA Enrichment Enables High-Throughput Directed Evolution for AAV Capsids

Sigmund K. S. Tejada, Sungyeon Cho, April R. Giles, Samantha A. Yost, Andrew C. Mercer, Xu Wang, Ye Liu, Elad Firnberg

REGENXBIO Inc., Rockville, MD

AAV capsid library studies ranging from pools of <100 individually barcoded capsids up to large libraries containing >10^8 variants can suffer from high data noise and variability due to poor sampling of barcoded transcripts measured with Next Generation Sequencing (NGS). Reliable NGS data from transduced tissue is dependent on measuring large numbers of transcripts to reduce library sampling biases. The NAVIGATE (Novel AAV Vector Intelligent Guided Adaptation Through Evolution) platform overcomes this potential problem by including an mRNA enrichment process using magnetic poly-dT oligo beads to capture mRNA from extracted total RNA or directly from the transduced tissue lysates without a separate RNA extraction step. This technology, when paired with the automatic high-throughput Apex purification system (ThermoFisher), and subsequent use of a one-step RT-PCR kit can accelerate the tissue-to-NGS processing to one day instead of several days. This methodology was optimized to be used in multiple non-human primate (NHP) tissues including retina, muscle, liver, and brain. The NAVIGATE platform was first employed to discover improved muscle capsids by harvesting tissues three weeks post-intravenous administration of AAV libraries in NHPs. During early platform development, traditional column

RNA extraction and RT-PCR was done on skeletal and cardiac tissues that resulted in no amplification of library transcripts; by comparison, mRNA enrichment after pooling the same tissue types provided robust amplification and sequencing of high library diversity providing highly enriched AAV variants on the target tissue. NAVIGATE was also used to identify ocular capsids that would improve retina transduction post-suprachoroidal space (SCS) administration. To determine on which template capsid to build a peptide insertion library and select for improved-retina transduction post-SCS delivery, a pool of 118 diverse capsids packaged with a barcoded CAG.eGFP transgene was administered to NHPs at a dose of 7.2E11 genome copies per eye via SCS administration. Retina was collected and total RNA was extracted and processed, resulting in poor PCR amplification of the library target sequence, low-quality NGS reads, and detection of only 73 out of 118 barcodes with an average standard deviation of 0.016. In contrast, performing mRNA enrichment provided strong amplification of library target sequence, high-quality NGS reads, and detection of 99 out of the 118 barcodes with an average standard deviation of 0.008. The mRNA-enriched dataset identified AAV3B and AAV8 as potent SCS capsids which could be used as backbones for further directed evolution. The mRNA enrichment workflow, and subsequent mRNA DIRECT workflow developed for high throughput processing, provides high-quality mRNA transcript recovery and robust library of NGS data for evaluating AAV library in various NHP tissues.

1462. Evaluating Antibody Binding Affinities to AAV by Charge Detection Mass Spectrometry

Lohra Mickelle Miller[1], Junping Zhang[2], Benjamin E. Draper[1], Weidong Xiao[2], Roland W. Herzog[3], Klaus-Ingmar Pfrepper[4], Martin Jarrold[1]

[1]Megadalton Solutions, Bloomington, IN,[2]Indiana University, Indianapolis, IN,[3]IU School of Medicine, Indianapolis, IN,[4]PROGEN, Heidelberg, Germany

Recombinant adeno-associated virus (rAAV) is a non-pathogenic virus that has shown great success as a gene therapy vector. However, the interaction of the viral vector with host antibodies can result in neutralization and reduced transduction efficiency. The techniques that can be used to characterize interactions between rAAV and antibodies are ensemble methods that are limited in their ability to determine stoichiometry. Charge detection mass spectrometry (CD-MS) is a single particle technique that is routinely used to resolve and quantify empty, partial, and full AAV particles. Here, CD-MS is used to determine the stoichiometry of ligand binding, using AAV8 capsids as a test system with murine monoclonal antibody ADK8. Both the intact antibody (mAb) and fragment antibodies (Fabs) were investigated. With intact mAbs, the number of bound antibodies increased with increasing mAb concentration but did not reach saturation. Instead, the capsids agglutinated forming dimer, trimer and tetramer complexes that were directly observed by CD-MS. Fc depleted $F(ab')_2$ fragment antibodies also did not saturate and showed increased agglutination compared to the intact mAbs. On the other hand, increasing Fab concentration led to saturation at around 60 Fabs bound per AAV8 capsid, confirming expectations that there are 60 sites available for Fab binding. For all ligands the CD-MS mass measurement allowed for the distribution of bound species to be quantified as a function of initial ligand concentration. Binding curves were determined for Fab binding to AAV8. The results showed strong positive cooperativity, where the binding affinity increased substantially with Fab coverage. While this work focuses on AAV8 and ADK8, the method is robust and can be used to characterize the binding of any ligand to any serotype of interest.

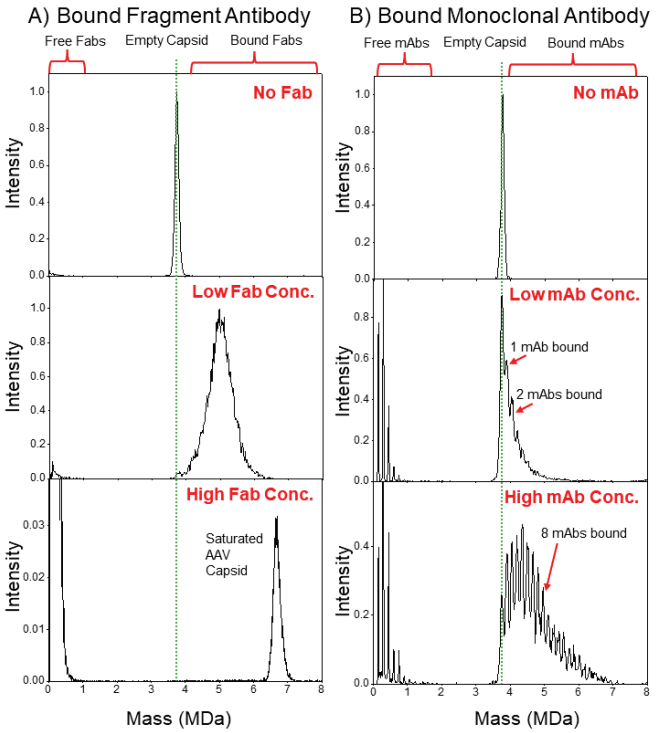


Figure 1. AAV8 empty capsid bound to fragment antibodies until saturation. B) AAV8 empty capsid bound to monoclonal antibodies at two mAb concentrations.

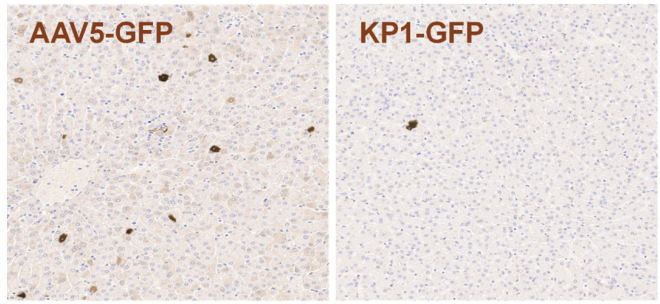
1463. Characterization of Adeno-Associated Virus Capsids by a Novel Capillary Isoelectric Focusing-Based Fractionation Method and Charge-Detection Mass Spectrometry

Jiaqi Wu[1], Benjamin E. Draper[2], Chris Heger[1]

[1]Bio-Techne, San Jose, CA,[2]Megadalton Solutions, Bloomington, IN

Adeno-associated viruses (AAVs) are small, non-pathogenic, ssDNA packaging viruses that have become widely used for gene therapy [1]. AAVs are comprised of three capsid proteins (VP1, VP2, and VP3) that form a 60-mer capsid in an approximately 50:5:5 VP3:VP2:VP1 ratio [2]. In addition to possessing different molecular weights, these proteins exhibit charge heterogeneity from both sequence differences and post-translational modifications [3]. Charge heterogeneity is also conferred to the intact capsid. The charge heterogeneity of the intact capsid is influenced by ssDNA packaged in the particles [4], random incorporation of VP subunits [5], and post-translational modifications of the capsid proteins, for example, deamidation of VPs [3]. Imaged capillary isoelectric focusing (icIEF) [6] is a powerful tool for protein charge heterogeneity characterization. We have reported that AAVs exhibit charge heterogeneity that can be observed using imaged cIEF (icIEF) [7,8]. A new CE instrument was recently released (MauriceFlex™, Bio-Techne) that can fractionate protein charge variants



for downstream analysis and is expected to provide a clearer insight into these charge variants. Here we show for the first time, a seamless workflow to fractionate intact AAV capsids with comprehensive downstream analysis using both capillary electrophoresis and charge detection mass spectrometry (CD-MS). CD-MS measures the mass of intact AAV particles to characterize capsid protein average viral protein ratio and DNA packaging heterogeneity. [9,10] Through this analysis, we demonstrate that not only do we fractionate intact particles, but we can isolate subpopulations based on various features of the virus including capsid ratio, content status, and post-translational modifications. 1464. AAV KP1 Efficiently Transduces Human Cell Lines *In Vitro* and Mouse Liver but Not Non-Human Primate Liver After Intravenous Injection

Zhong-Dong Shi, Hongbin Xu

Frontera Therapeutics, Bedford, MA

To date, seven AAV gene therapy drugs have been approved including Glybera (2012), Luxturna (2017), Zolgensma (2019), Upstaza (2022), Roctavian (2022), Hemgenix (2022), and ELEVIDYS (2023). Despite the remarkable achievements, limited tissue transduction has prevented AAV from broader application expansion. To realize the full potential of AAV vectors, a lot of work has been focused on improving cell transduction by modifying the capsids or screening for novel capsids. However, oftentimes novel capsid variants screened from in vitro cell models or mouse models cannot be translated to human patients. NHPs are the closest animal models to humans regarding genetics, physiology, and behavior, and have been frequently used to evaluate novel capsids in recent years. The goal of this study was to evaluate whether a novel AAV capsid, KP1, is better than AAV5 for liver targeting. KP1 capsid was identified by directed evolution in human pancreatic islets in vitro and has been shown to transduce both mouse and human hepatocytes very efficiently in mice with humanized livers (Pekrun et al., 2019). To evaluate whether KP1 is a better liver-targeting capsid than AAV5, we compared transduction efficiencies of the bac/Sf9 system-produced AAV KP1 and AAV5 in cultured cells, in mice and NHPs (African green monkeys). For in vitro cell and NHP studies, the transgene for both KP1 and AAV5 is CBA-GFP (PA091, scAAV); for mouse study, the transgene is HLP-FVIII-SQ (PA103, ssAAV). In vitro, at MOI = 1E4, the KP1-GFP vector transduced 94.6% of 293T cells while AAV5-GFP transduced 9.02% of 293T cells; when transduced a human hepatoma cell line Huh-7 at MOI = 1E4, the transduction efficiencies were 80.3% and 0.26% for KP1 and AAV5, respectively. In wild-type mice, ~150% of human FVIII-SQ antigen was detected at 4 weeks post-injection of 5E12 vg/kg of KP1-PA103, to get a similar level of human FVIII-SQ antigen expression from AAV5-PA103, the dose had to be at 6E13 vg/kg, while 2E13 vg/kg of AAV5-PA103 only produced ~50% of FVIII-SQ. The data suggest that KP1 is much more potent than AAV5 when targeting mouse liver. Lastly, we compared KP1 and AAV5 in NHPs by systemically injecting 4E12 vg/kg of two AAV-GFP vectors in African green monkeys and collected animal tissues 4 weeks after injection. The bioassay data showed that NHPs injected with the KP1-GFP vector had much lower GFP expression in the liver based on IHC staining compared to animals injected with the AAV5-GFP vector. Vector genome quantification showed that AAV5 and KP1 have ~4.43E6 and ~3.06E5 copies/ug DNA in the liver, respectively. GFP expression levels in the liver correlated well with the vector genome data. In summary, KP1 capsid transduces exceptionally well in both human cell lines in vitro and mice liver. However, it shows very poor liver targeting in NHPs (African green monkey) compared to AAV5 capsid when injected intravenously. Our observation is consistent with other reported studies in rhesus and cynomolgus monkeys (Pekrun et al., 2022; Catalyst Biosciences, 2020). The underlying cause of low transduction in NHP liver remains to be understood and whether KP1 can efficiently transduce human hepatocytes in human patients remains unknown.

Representative GFP IHC staining shows significantly higher and broader GFP protein expression in the African green monkey liver injected with AAV5-GFP than KP1-GFP. Brown staining and blue staining are GFP protein and nucleus, respectively.

1465. Expanding the Serotype Frontier: Design of Synthetic AAV Capsids with Artificial Intelligence

Sam Sinai, David Brookes, Jeffrey Chan, Alex Mijalis, Alex Kern, Neha Prasad, Theodore Sternlieb, Farhan Damani, Kathy S. Lin, Jamie Kwasnieski, Adrian Veres, Eric Kelsic

Dyno Therapeutics, Watertown, MA

As a substantial percentage of human sera neutralize naturally circulating Adeno-associated viruses (AAVs), patients can find themselves ineligible to receive life-saving gene therapies due to previous capsid exposure. One conceptual approach to remedy these concerns is to leverage natural sequence diversity to reduce the likelihood of recognition by the immune system. However, the number of naturally occuring AAV capsids is limited and the process of discovering and characterizing new natural serotypes with clinically relevant properties is slow. In contrast, there are more possible AAV sequences than atoms in the observable universe. Hence, novel synthetic serotypes can provide an evergreen source of diversity that may address the critical concern of pre-existing immunity to gene delivery vectors. The catalog of known serotypes is a survey of

naturally occurring Dependoparvoviruses among host species, derived from sequencing human and vertebrate viromes. These canonical AAV serotypes (between 6 to 345 mutations apart) have seeded directed evolution campaigns where recombinant capsids with a low number of new mutations are optimized for better clinical properties, without drastic changes to the original sequence. However, new source serotypes with relevant in vivo delivery properties are now less frequently being discovered-in other words, for a decade or more the serotype frontier has been mostly stable. The advancement of machine learning and artificial intelligence (AI) in recent years opens a new route to expanding the AAV serotype repertoire. Key developments, such as highly-accurate protein structure prediction, structure to sequence methods, and data-driven generative models of function, have made it possible to design increasingly complex proteins while maintaining control over their structure and function. However AAV capsids are multi-domain proteins that perform several functions, which are far more challenging to engineer than the protein design tasks these AI methods have been validated on (typically single-domain, single-function, and under 250 amino acids). Here we show that it is possible to design families of capsids that are far away in sequence space from the closest serotype without getting closer to any other known serotypes. That is, by applying and adapting the AI techniques (mentioned above) in tandem, we generate a type of diversity that is impossible to create by natural recombination or DNA reshuffling. We show that these methods are capable of introducing many novel mutations in highly-conserved and easily destabilized regions. For instance, with a single experiment we successfully introduce 45 edits to a largely buried and mutation-sensitive segment of AAV9, changing more than half of the residues of an integral architectural part of the VP monomer. We also generate 4 distinct families of capsids with mutations in different structural segments, ranging between 37- 50 mutations to the AAV9 backbone. Testing high-edit distance variants for in-vitro transduction efficiency on HEK293 cells, we also observe up to 60-fold improvements over AAV9. We prove that the combination of current cutting-edge AI tools can push the frontier of sequence diversification beyond available natural diversity while maintaining or even improving upon productivity and in-vitro transduction efficiency. Our results anticipate a fertile ground for development of novel serotypes, far beyond those found by natural or in-lab evolution.

1466. AAV(Lung)s: A Class of Lung Tropism AAV Capsids with Improved Specificity and Transduction Efficiency

Bing Wang, Cheng Xu, Yu Liu, Yuyan Wang, Leming Wang, Zhen Shi, Daozhan Yu, Qizhao Wang
AAVnerGene Inc., Rockville, MD

Developing a lung-specific AAV (Adeno-Associated Virus) capsid is a significant focus in gene therapy, particularly for treating lung-related diseases such as cystic fibrosis, chronic obstructive pulmonary disease, and genetic disorders affecting the lungs. Different AAV serotypes (AAV2, AAV5, AAV9) and engineering variants (AAV6.2FF, AAV2H22, AAV2.5T and AAV9.452sub.LUNG1) have been reported to transduce in lung cells, organoids, and tissues with different animal models. With our ATHENA I platform, we confirmed the AAV9 performs better than other AAV variants at RNA level in the lung of C57B6 mice after systematically injection. However, AAV9 demonstrates significant transduction in the heart, kidney, brain, and liver tissues as well, indicating that it is not a lung-specific capsid. Interestingly, while AAV9 exhibits high expression in the lung, it simultaneously shows a low DNA copy number in the same tissue. Following the results from the ATHENA I evaluation, we systematically designed a series of AAV variants, which we have named AAV(lung)s. Our preliminary findings consistently show that certain AAV(lung)s achieve an approximately 500-fold increase in DNA accumulation in the lung compared to AAV9. AAV(lung)s demonstrated similar RNA levels compared with AAV9, but has 10-100 folds higher than AAV2.5T and AAV2H22. Significantly, AAV(lung)s exhibit high RNA expression exclusively in lung tissues, with negligible expression in other organs. Additionally, the DNA levels of AAV(lung)s are markedly lower in the brain, heart, and kidneys, compared with AAV9. Overall, we have developed a series of AAV capsids specific to mouse lungs, which will be beneficial for future lung gene therapy applications. Further research will focus on evaluating the efficiency and specificity of these findings in non-human primates.

1467. Exploring the Inner Capsid of the Parvoviridae Family with Multiscale Computational Techniques

Heather A. Noriega[1], Bing Wang[2], Qizhao Wang[2], Daozhan Yu[2], Xiang Simon Wang[1]
[1]Artificial Intelligence and Drug Discovery Core Laboratory for District of Columbia Center for AIDS Research (DC CFAR), Department of Pharmaceutical Sciences, College of Pharmacy, Howard University, Washington, DC,[2]AAVnerGene Inc., Rockville, MD

The Parvoviridae family, particularly adeno-associated viruses (AAVs), plays a significant role in the field of gene therapy and gene delivery. Parvoviridae viruses are characterized by their small size and structurally complex capsids. These capsids are made up of protein subunits that form a tight, geometrically precise arrangement. Understanding this structure at a detailed level is crucial for insights into how these viruses infect cells and how they can be adapted for gene delivery. The external surface is responsible for the initial interaction with the host cell and has recently received much attention in structure research. However, little is known about the inner capsid structures. The inner capsid structure is vital for several functions, including the stability of the virus, its ability to infect host cells, and the packaging of its genetic material. This investigation utilizes AlphaFold2, a deep-learning-based program to build accurate 3-D structures of Parvoviridae viral proteins including both capsids and the inner region. With pLDDT (≥70), pTM (≥0.7), PAE, and RMSD (<1) scores, our structures were found to be sound and accurate. The capsids were assembled using a fit-to-map method that resulted in high scores of ≥0.7 and subjected through a wide range of algorithms to analyze the structural-based (i.e., secondary structures, SASA, etc.), sequence-based (i.e. composition, transition, distribution, etc.), and physiochemical properties (hydrophobicity, polarity, charge, etc.). With them, we were able to generate over 2000 protein descriptors. These data, with additional inputs from Cryo-EM studies (VIPER database) and X-ray structures (Protein Data Bank, PDB), were used to create a machine learning model in which the Random Forest algorithm was applied with 10-fold cross-validation. We succeeded to predict the package capacity of Parvoviridae viruses and stoichiometric assemblies with a high F1 score of 0.923. Further

usage and experimental validation are underway. The outcome of this research would be critical in overcoming the package limitation of Parvoviridae viruses and thus can offer significant contributions to therapeutic gene delivery.

1468. Deployment of a Large Language Models to Design an AAV Capsid Targeting HER2

Chenrui Xu[1], Zhehao Xiong[2], Zhaoren He[1], Hui Li[2], Liang Gao[1], Zhongshan Cai[3], Li Zhao[3], Qingzhou Ji[3], Ziyao Xu[1], Vicky Qu[1], Le Song[1], Per Greisen[4], Fernando Garces[4]

[1]BioMap, Beijing, China,[2]BioMap, Suzhou, China,[3]Porton Advanced Solution Ltd., Suzhou, China,[4]BioMap, Palo Alto, CA

Introduction: With the advent of AlphaFold2, machine learning (ML)-based protein design gained in popularity. Much of that is been tested in the antibody space ranging from the de novo discovery of new binders to developability. However, these artificial intelligence (AI) task models can also be trained to successfully design sequences for other AI protein modalities including the adeno-associated virus (AAV). AAVs are small and non-enveloped virus that has the capability to deliver DNA to specific cells through protein engineering, indicating it's potential applications in gene therapy. For example, AAV2 has been authorized to treat Retinal Dystrophies caused by gene deficiency. Although there are examples of AAV design/engineering using classical directed evolution methods, such approaches are often time and resource consuming as it often relies on trial and error. Therefore, ML methods can reduce both cost and project timelines markedly, while predicting success. However, most ML-guided methods rely on prior training with experimental data, which can limit this effort altogether. **Methods:** Here we introduce a novel AAV capsid design diagram, which leverages the power of BioMap's cutting-edge foundation AI models and performs highly efficient design in a zero-shot manner. To demonstrate this method, we chose the case of the insertion of a binding motif that recognizes the tumor associate antigen (TAA) HER2. BioMap's proprietary large foundation model xTrimoPGLM, pre-trained on 1.6 billion protein sequences, ensures that AI designed AAV-HER2 capsids retain desirable characteristics including folding and expression similar to native AAV capsid. The whole design steps are finished within BioMap's multi-objective optimization (MOO) platform, which executes task models and performs iterative optimization. The AI designed library (9×10^4) was then tested for viral viability, binding and tropism using a cohort of mice bearing HER2 expressing tumor. **Results:** Initial NGS results showed that AI designed variants displayed higher viability rate when compared with those from random mutagenesis (control). Moreover, in vitro pull-down and the in-vivo experiments revealed that top variants demonstrate suitable HER2 binding and HER2-positive tumor tropism. **Conclusions:** Altogether, BioMap's AI approach achieved faster timelines and higher hit rate, suggesting a potential approach for inserting a variety of TAAs, but not limited to, into AAV capsids.

[1]BioMap, Beijing, China,[2]Porton Advanced Solution Ltd., Suzhou, China,[3]BioMap, Palo Alto, CA

Introduction: Machine learning (ML) techniques are revolutionizing our capacity to develop and refine proteins with enhanced and desired traits and functionalities. However, the majority of ML techniques rely on prior model training, using extensive experimental data, thus potentially limiting their overall application. Protein large language models (LLM) have emerged as powerful tools for extracting biological insights from protein sequences. Here, we developed and fine-tuned a framework based on a large-scale pre-trained language model, xTrimoPGLM (xTrimo Protein General Language Model). This framework exhibits robust transfer and generalization capabilities across various protein attributes. **Methods:** We have constructed an integrated workflow that adapted the xTrimoPGLM parameters using Low-Rank Adaptation (LoRA), and incorporated a multi-objective fusion network head for diverse predictive tasks. This workflow strategically balances the learning strengths of the model with its ability to generalize across different protein attributes. **Results:** In this work, we have successfully developed a new task model, the xTrimoAAV, and finetuned it with a folding stability dataset that enables the successful prediction of the adeno-associated virus (AAV) viability. Indeed, the model demonstrated a significant correlation 0.53 across various AAV serotypes (AAV5/AVV9) and mutation range. Moreover, by further finetuning it with known AAV experimental labelled data, the xTrimoAAV model's predictive correlation on an independent mutation dataset was enhanced to a value of 0.73. **Conclusions:** Here, the xTrimoAAV model has demonstrated outstanding performance in predicting the AAV viability. Therefore, the generalizability across different attributes supports the deployment of LLMs for the design of the next generation therapeutics such as the AAV. **Figure 1.** Pearson correlations on different task levels of Porton experimental datasets. See Table 1 for the complete set of correlations.

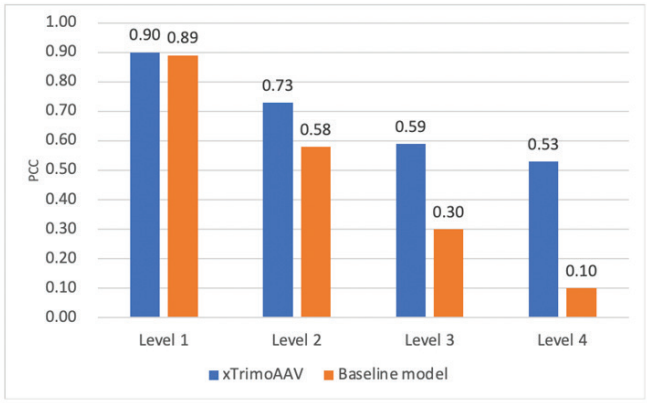

Table1. The performance of xTrimoAAV and Baseline Model on different task levels of Porton experimental datasets. **Task level**: classifications based on the difficulty level of tasks, the higher the level, the more difficult the task. **Task info**: description of task level. **Mutation info**: data mutation details e.g. AAV5 376-378 means using serotype AA5 with mutation range from 376 to 378. **PCC:** Pearson Correlation Coefficient. **Baseline Model**: xTrimoPGLM + linear regression head.

Friday Posters: AAV Vectors - Preclinical and Proof-of-Concept In Vivo Studies

1470. Screening of Novel Liver-Directed Enhancers Using Pooled, Barcoded AAVs

Aditya Saxena, Yahui Lan, Perry Evans, Laura Pereira, Sean M. Armour, Daniel M. Cohen

Spark Therapeutics, Philadelphia, PA

Efficient, predictable, and safe AAV-based gene therapy relies on the delivery of expression cassettes to on-target cells through the combination of capsid tropism and promoter/enhancer cell-type specificity. Here we describe a pooled AAV approach for *in vivo* screening of cis-regulatory elements encoding hepatocyte-specific gene expression. Enhancer sequences were paired with a short hepatocyte-specific promoter with or without the inclusion of 5' UTRs. We tested different barcoding strategies and found that a 12 nucleotide random barcode can reproducibly report on promoter activity measured by next-generation RNA sequencing. Additionally, we performed a dose escalation study to understand the relationship between AAV dosage, promoter strength, as well as UMI recovery from total RNA. Based on RNA/DNA ratio, we observed enhancer-promoter pairs varying in strength by ~1000 fold, with high reproducibility between biological replicates and doses (Pearson's correlation >= 0.9). Interestingly, we identified several short liver-specific enhancers with comparable potency to ApoE-hAAT. Validation of single enhancer candidates is currently underway. Our results demonstrate the success of pooled AAV screening for selection of liver-directed cis-regulatory elements and will help enable the identification of novel, compact transcriptional units with improved potential for gene therapy, especially when paired with large payloads.

1471. A Rapid Low-Cost Method for Producing Adeno-Associated Viral Vectors Suitable for Transducing Rodent Neurons *In Vitro* and *In Vivo*

Doug B. Howard[1], Reinis Svarcbahs[2], Lana N. Gore[1], Brandon K. Harvey[2], Christopher T. Richie[1]

[1]Genetic Engineering and Viral Vector Core, National Institute on Drug Abuse, Baltimore, MD,[2]National Institute on Drug Abuse, Baltimore, MD

The use of adeno-associated viral (AAV) vectors for delivery of genetic information into the mammalian CNS remains popular, but producing in vivo-compatible vectors requires significant upfront investment (e.g., time, effort, and equipment). To address this need, we have developed a modified protocol for AAV production that does not require large capital equipment (ultracentrifugation or chromatography machines) and still produces AAV in quantities that are sufficient for testing prototypes in the rodent brain. The protocol uses a transfection-based packaging method followed by centrifugal filtration and concentration to produce a crude preparation of AAV. This "small scale" AAV production protocol has been used to successfully generate several AAV serotypes including AAV1, AAV9, AAV-DJ, and rAAV2-retro indicating the process is serotype-independent. These vectors also transduce primary rat cortical neurons in vitro. Intrastriatal injection of AAV1 or AAV9 serotyped vectors expressing EF1a-GFP-KASH into Long Evans rats demonstrated that our small scale AAV preparations produce transgene expression and inflammation patterns that are similar to those derived from injections with identical AAV vectors purified by affinity column chromatography. Overall, we describe a small-scale AAV packaging protocol that allows for an efficient means of producing multiple vectors in parallel and makes it possible to test multiple AAV prototypes (e.g., variant guide RNAs for CRISPR) simultaneously with reduced investment of resources.

1472. Development of an AAV9-Based Gene Therapy for Dermatosparaxis Ehlers-Danlos Syndrome

Abby W. McElroy[1], Jillian Gallagher[2], Toloo Taghian[2], Erin F. Hall[3], Hector R. Benatti[1], Elizabeth Parsley[4], Laura Dupont[5], Miguel Sena-Esteves[2], Alain C. M. A. Colige[5], Heather L. Gray-Edwards[2]

[1]Horae Gene Therapy Center, UMASS Chan Medical School, Worcester, MA,[2]UMass Chan Medical School, Worcester, MA,[3]UMASS Chan Medical School, Worcester, MA,[4]Cummings School of Veterinary Medicine at Tufts University, North Grafton, MA,[5]Laboratory of Connective Tissues Biology, University of Liège, Liège, Belgium

Ehlers-Danlos syndrome (dEDS) is an autosomal recessive connective tissue disorder occurring in humans, cattle, sheep, dogs, and cats. Patients present with severe skin fragility and redundant skin, spontaneous bleeding and bruising, and visceral fragility with hemorrhage. To date, there is no definitive treatment any type of EDS. This disorder is caused by a loss of function mutation in ADAMTS2 leading to impaired extracellular cleavage of the N-terminal-propeptide of type I procollagen by the procollagen N-proteinase enzyme. This results in collagen fibrils with aberrant morphology and lower tensile strength. This form of EDS is amendable to AAV gene therapy, because 1) it is caused by a loss of function of a secreted protein (ADAMTS2), 2) it is encoded by a 3.6kb cDNA, and 3) since ADAMTS2 is expressed ubiquitously throughout the body and the procollagen targeted by ADAMTS2 does not have any known function, we hypothesized that global secretion of ADAMTS2 will be efficacious in treating this form of EDS. Since ADAMTS2 functions extracellularly, our strategy is liver and skeletal muscle directed AAV gene transfer and systemic secretion of ADAMTS2 to affected tissues. Four AAV9 vectors were designed and packaged: 1) encodes for a wildtype signal peptide and codon optimized ADAMTS2 cDNA 2) encodes for an enhanced signal peptide (sp7Δ8) and a codon optimized ADAMTS2 with an HA tag at the c-terminus of the cDNA 3) a codon optimized ADAMTS2 cDNA with an HA tag located at the C-terminus of the cDNA or 4) in the middle of the cDNA. Vectors were first tested in wild type mice for expression and/or toxicity (n=4 WT 6-week-old C57BL/6 mice per group). Mice were treated via intravenous tail vein injection at a dose of 1E12 vg/mouse and were sacrificed 1-month later. No adverse clinical outcomes were observed. Tissues appeared grossly normal at necropsy. Histopathology of skin, aorta, quadriceps femoris, lung, liver, and kidney were normal. Transmission electron microscopy of the skin and aorta were unremarkable. Western blot demonstrated increased expression of an active cleavage form of ADAMTS2 plus the HA tag at approximately 75 kDa for the vector utilizing the wildtype signal peptide and with the HA tag on the C-terminus of the cDNA. Other bands were observed at approximately 45 kDa and 20 kDa, representing other cleavage products of ADAMTS2. Vector biodistribution was performed in liver, kidney, skeletal muscle, heart, aorta, and skin. A knockout ADAMTS2 mouse model was used for further therapeutic development. Two cohorts of mice were injected by intravenous tail vein injection at a dose of 1E12 vg/mouse at 8-weeks of age with three vectors containing an HA tag in the middle of the cDNA and a wild type signal peptide (n=9), an HA tag at the C-terminus of the cDNA and an enhanced signal peptide for increased secretion from liver and skeletal muscle (n=8), and a wild type signal peptide and no HA tag (n=8). Wild type untreated controls (n=7) and untreated ADAMTS_KO mice (n=4) were also evaluated. Mice were sacrificed at either 8 months or 6 months post injection. Post-mortem assessments are underway and include electron microscopy for the pathognomonic hieroglyphic collagen, histology, vector biodistribution and western blotting. In conclusion, this study outlines the development of a liver and skeletal muscle directed AAV gene therapy as a treatment for dEDS.

1473. Evaluating Tissue Specific Promoters Using Adeno-Associated Virus Based Gene Therapy

Nicole Zielinska[1], Yanlong Pei[1], Erin L. Howard[1], Brenna A. Y. Stevens[1], Melanie M. Goens[1], Elena S. B. Campbell[1], Madison E. Hughes[1], Dinghai Zheng[2], Benjamin Gordon[2], Alec Nielsen[2], Jeff Caswell[1], Luis G. Arroyo[3], Raja R. Srinivas[2], Sarah K. Wootton[1]

[1]University of Guelph, Guelph, ON, Canada,[2]Asimov, Boston, MA,[3]Clinical Studies, Ontario Vetrinary College, Guelph, ON, Canada

Background: With the rapid expansion and adoption of gene therapies, ensuring safety and addressing adverse events have become key considerations for drug product development in the gene therapy space. Many recombinant adeno-associated virus gene therapy platforms continue to use highly active promoters to drive the expression of exogenous therapeutic transgenes. Although these ubiquitous promoters are well-established and confer strong transgene expression, they present several disadvantages including off-target transgene expression which may cause compromised cell viability, inflammation, and toxicity. For instance, many gene therapy approaches have been limited by off target liver transduction, which negatively impacts drug bioavailability, therapeutic effectiveness, and increases the likelihood of adverse effects. To address these concerns, our approach involves computational mining and engineering techniques to develop a variety of tissue-specific promoters. These promoters aim to promote high level transgene expression in a specific tissue while limiting expression in any off-target tissues that are susceptible to adverse events or may increase immunogenicity of the vector. By selecting an appropriate AAV serotype and pairing it with a tissue-specific promoter, we have shown persistent transgene expression in intended tissues, and de-targeting unwanted tissues including the liver. **Methods**: Here, we use vectors AAV6.2FF, a novel triple mutant, and AAV9 to express the reporter gene human placental alkaline phosphatase (AP). This enabled the evaluation of vector biodistribution and specificity driven by tissue-specific promoters predicted and designed using Asimov's proprietary algorithm. These human promoters were identified and mined using available genetic databases, to drive expression in either the cardiac tissue or skeletal muscle thus minimizing liver transduction. AAV vectors were administered to C57BL/6 mice (n=4) using PBS as a negative control and AAV6.2FF or AAV9 with ubiquitous promoter CASI expressing AP as a positive control. Mice were transduced with $1x10^{11}$ vector genomes (vg) via intraperitoneal (IP) or intramuscular (IM) injection. Mice were euthanized 21 days post-administration and all major organs harvested and stained for AP reporter gene expression. Tissues were grossly imaged and AP activity assays were used to quantify AP expression per tissue. Histologic analysis was performed to identify the cell types where the promoters were active. **Results:** When evaluating a series of putatively cardiac- and muscle-

specific promoters, we identified three noteworthy candidates that operated as predicted by the algorithm. Denoted by number, promoters 5965 and 5970 showed precise cardiac specificity when administered via IP by either AAV6.2FF-AP or AAV9-AP vectors. Promoter 5972 showed excellent transduction in skeletal muscle when delivered by AAV6.2FF-AP via IM administration. AP assays confirmed low to undetectable AP expression in the brain, liver, nasal cavity, pancreas, spleen, and trachea as well as the heart and skeletal muscle depending on which promoter was evaluated. **Conclusions:** AAV6.2FF or AAV9 in conjunction with computationally derived promoters can efficiently transduce the cardiac and skeletal muscle while minimizing off target effects. Additionally, these promoters can achieve expression levels comparable to ubiquitous promoters all while de-targeting the liver, potentially enhancing the safety of AAV gene therapies across a variety of applications, including therapeutic interventions and advancements in biotechnology.

1474. Engineering a Targeted and Safe Bone Anabolic Gene Therapy to Treat Osteoporosis in Alveolar Bone Loss

Chujiao Lin[1], Yeon-Suk Yang[1], Jun Xie[2], Guangping Gao[2], Jae-hyuck Shim[2]

[1]UMass Medical School, Worcester, MA,[2]UMass Chan Medical School, Worcester, MA

Alveolar bone loss in elderly populations is highly prevalent and increases the risk of tooth loss, gum disease susceptibility, and facial deformity. Unfortunately, there are very limited treatment options available. Here, we developed a bone-targeted gene therapy that reverses alveolar bone loss in patients with osteoporosis by targeting the adaptor protein Schnurri-3 (SHN3). SHN3 is a promising therapeutic target for alveolar bone regeneration, because SHN3 expression is elevated in human and mouse mandible tissues with osteoporosis while deletion of SHN3 in mice greatly increases alveolar bone and tooth dentin mass. We used a bone-targeted recombinant adeno-associated virus (rAAV) carrying an artificial microRNA (miRNA) that silences SHN3 expression to restore alveolar bone loss in mouse models of both postmenopausal and senile osteoporosis by enhancing WNT signaling and osteoblast function. Additionally, rAAV-mediated silencing of SHN3 enhanced bone and collagen formation of human skeletal organoids in xenograft mice. Finally, rAAV expression was tightly controlled in the mandible via liver- and heart-specific miRNA-mediated repression or via a vibration-inducible mechanism. Collectively, our results demonstrate the clinical potential of bone anabolic gene therapy to treat alveolar bone loss in osteoporosis.

1475. *In Situ* Injection and Transduction of Human Limbal Stem Cells Using Adeno-Associated Viruses

Hyeck Soo Son[1], Albert S. Jun[2], James W. Foster[2], Wei Wang[2], Yassine Daoud[2], Gerd U. Auffarth[1], Madhuparna Roy[2]

[1]University of Heidelberg, Heidelberg, Germany,[2]Wilmer Eye Institute, Baltimore, MD

Purpose: Inherited corneal dystrophies may cause severe visual impairment. While phototherapeutic keratectomy or corneal transplantations may provide symptomatic relief, the procedures are associated with high infection and recurrence rates. Gene therapies may provide an alternative and a potentially permanent treatment. Adeno-associated viruses (AAVs) have emerged as the vectors of choice for ocular gene therapy thanks to their established safety profile. This study aimed to evaluate the efficacy of *in situ* adeno-associated virus (AAV)-mediated gene delivery into the human corneal limbal region via targeted sub-limbal injection technique. **Methods:** Human cadaveric corneal tissues were fixed on an artificial anterior chamber. Feasibility of sub-limbal injection technique was tested using trypan blue and black India ink. An eGFP encoding AAV DJ was injected into sub-limbal region. After AAV injection, corneal tissues were incubated in air-lift culture and prepared for immunohistochemical analysis. Cell survivial and expression of eGFP, stem cell markers (p63α and cytokeratin 19), and differentiation marker cytokeratin 3 (KRT3) were evaluated using confocal microscopy. **Results:** Both trypan blue and black India ink stained and were retained sub-limbally establishing specificity of the injection technique. Immunohistochemical analysis of corneas injected with AAV DJ-eGFP indicated that AAV-transduced cells in the limbal region co-express eGFP, p63α, and KRT19 and that these transduced cells were capable of differentiating to KRT3 postitive corneal epithelial cells. **Conclusions:** Our sub-limbal injection technique can target cells in the human limbus in a reproducible and efficient manner. Thus, we demonstrate that in situ injection of corneal limbus may provide a feasible mode of genetic therapy for corneal disorders with an epithelial etiology.

1476. Preclinical Development of SENS-501 as a Treatment for the Autosomal Recessive Non-Syndromic Deafness 9 (DFNB9) Using an Adeno Associated Vector-Based Gene Therapy

Rafik Boudra[1], Guillaume Olivier[1], Christophe Tran Van Ba[1], Lise Barrot[1], Julie Duron Dos Reis[1], Pierre Rambeau[1], Charlene Vaux[1], Sandra Pierredon[1], Anais Pages[1], Pauline Liaudet[1], Audrey Broussy[1], Anne-Gabrielle Harrus[1], Selma Dadak[1], Laura Gallot[1], Geraldine Petit[1], Jerome Nevoux[2], Ghizlene Lahlou[3], Natalie Loundon[4], Christine Le Bec[1], Emilie Bousquet[1], Marie-Jose Lecomte[2], Said Safieddine[1], Christine Petit[5], Arnaud Giese[1], Laurent Desire[1]

[1]Sensorion, Montpellier, France,[2]Genetics and Physiology of Hearing Laboratory, Institut de l'Audition/Pasteur, Paris, France,[3]Institut de l'Audition, Institut Pasteur, INSERM, Université de Paris, Paris, France,[4]Hopital Necker-Enfants Malades, Paris, France,[5]Institut de l'Audition/ Institut Pasteur, Paris, France

Congenital sensorineural defects heavily impact patients' life and their ability to communicate with others. Among this vast family of communicating disorders, non-syndromic autosomal recessive deafness 9 (DFNB9) is one of the most common form of congenital deafness, accounting for up to 8% of cases. This severe-to-profound auditory neuropathy is caused by biallelic loss of function in the OTOFERLIN gene (OTOF), which encodes for a calcium sensor protein involved in neurotransmitter release at presynaptic level between inner

sensory hair cells (IHC) and spiral ganglion neurons. So far, the only medical solution is cochlear implantation, which improves hearing to some degree, but still has a lot of limitations. To address this unmet medical need, we developed SENS-501, a dual-AAV (adeno associated virus) hybrid approach using two different recombinant vectors each containing one half of the OTOF cDNA. This strategy was tested on congenitally deaf DFNB9 mutant mice by injecting SENS-501 in the inner ear through the round window membrane. Hearing improvement was evaluated with multiple auditory and behavioral tests. Auditory brainstem response (ABR) recordings showed significant lowering of the thresholds along the auditive spectrum after intra-cochlear injection, with durable (one year) improvement of hearing in a dose-responsive manner. A startle reflex behavior test was performed to confirm the ability of treated DFNB9 mutant mice to integrate sound similarly to wild-type mice. We were able to detect restoration of their startle reflex ability when exposed to randomized sudden loud noises. We also evaluated vestibular function of treated mice by analyzing their exploratory behavior in an open-field arena. Data indicated that our approach did not show any significant increase in circling behavior when compared to control mice. We performed a similar set of experiments in non-human primates (NHP) after SENS-501 intracochlear injections using a surgical approach and our proprietary medical delivery device approved for clinical trial. Surgery and SENS-501 injection did not affect ABR thresholds, similar to what was observed in mice. Immunohistochemistry experiments were performed in both mice and NHP, demonstrating effective recombination and selective expression in IHCs of the full-length therapeutic protein and its flag-tagged counterpart. A 3-month GLP toxicology and biodistribution study following a single intra-cochlear injection was conducted in NHP with two doses of SENS-501. Biodistribution data indicated that the vast majority of the vectors remained in the inner ear. SENS-501 shedding in fluids showed a limited dissemination of the vectors with decreasing levels over time. The two doses of SENS-501 were well tolerated and no clinical or adverse SENS-501-related effects in the inner ear or outside the inner ear tissue in any evaluation -including immunology- were found. Altogether, our nonclinical pharmacology, safety, biodistribution, and two ongoing natural history studies support the clinical development of SENS-501 and the initiation of our phase I/II clinical trial first half of 2024.

1477. Enhanced Long-Term Efficacy of an AAV8-DX88-HSA Vector for Treating Hereditary Angioedema

Weimin Guo[1], Yufeng Guo[1], Shuai Ji[1], Shengmei Wen[1], Yiting Liu[2], Guang Qu[1,2], Lixin Jiang[1,2]

[1]NGGT (Suzhou) Biotechnology Co., Ltd., Suzhou, Jiangsu, China,[2]NGGT, Inc, Walnut Creek, CA

Introduction: Hereditary angioedema (HAE) is a rare autosomal dominant disease. HAE patients experience recurrent episodes of edema (swelling) in the hands, feet, face, intestinal wall, and airway. Airway swelling is particularly dangerous and can lead to death by asphyxiation. Attack may start since childhood and, in severe cases, with weekly episodes. HAE mainly is caused by mutations in the SERPING1 gene that result in the dysfunction of its encoded protein C1 inhibitor (C1-INH), the main inhibitor of the complement and the kallikrein-kinin pathways. Defected C1-INH increases activity of plasma Kallikrein (pKal), which in turns cleaves high molecular weight kininogen (HMWK) to form bradykinin. Bradykinin binds B2 receptors on the vascular endothelium, triggering vasodilation and increased vascular permeability. DX88 is a potent and specific inhibitor of pKal with a very short half-life which limits its effects on suppressing angioedema. Long-term expression of DX88 through AAV-based liver-directed gene therapy could be a valuable approach to treat HAE. **Methods/Results:** We developed an rAAV8-based vector to express DX88-HSA fusion protein (AAV8- DX88-HSA). In vitro, purified DX88-HSA protein produced from transfected 293F cells inhibited pKal activity in either human or monkey serum activated by 20 μg/mL Dextran sulfate (DXS), approximately at an IC(50) value of 250 nM. Sequence-optimized vectors resulted in a 10-fold increase in DX88-HSA expression level compared to WT sequence in mice. AAV8-DX88-HSA stably expressed fusion protein for at least 24 weeks following a single injection at 5E11 vg/kg. The expression level reached 2000 nM in mouse serum, 8 folds higher than the concentration required to sufficiently inhibit pKal in human or monkey serum. Next, we generated a mouse model expressing human pKal to evaluate the efficacy of AAV8-DX88-HAS in vivo. In the mouse model, the expression level of human pKal was 1.5-fold of normal human serum. The concentration of the downstream HMWK was significantly reduced compared to that in WT mice, consistent with a higher activity of pKal due to its overexpression. Following AAV8-DX88-HSA treatment, there were an increase in HMWK level and a marked decrease in pKal activity, suggestive of the active inhibitory effect of DX88 mediated by the vector. An concomitant suppression of vascular permeability was observed. **Conclusions:** In vitro and in vivo data demonstrated that AAV8-DX88-HSA robustly inhibited pKal activity. A single injection of the vector stably expressed DX88-HSA for at least 24 weeks in mice. These results support further development of expressing DX88 fusion protein mediated by AAV as a potential approach to treat HAE.

1478. Exploring Gene Complementation Therapy on Dysmyelination and Neurodegeneration in a Murine Model of Free Sialic Acid Storage Disorder

Mahin Shaimonti Hossain[1], Petcharat Leoyklang[1], Marya S. Sabir[1,2], Mary Hackbarth[3], Laura Pollard[4], Marjan Huizing[1], William A. Gahl[1], May Christine Malicdan[1]

[1]Human Biochemical Genetics Section, National Institutes of Health, Bethesda, MD,[2]University of Oxford, Oxford, United Kingdom,[3]University of Maryland School of Medicine, Baltimore, MD,[4]Biochemical Genetics Laboratory, Greenwood Genetics Center, Greenwood, SC

Introduction: Free Sialic Acid Storage Disorder (FSASD) is a rare, lysosomalstorage disorder resulting from bi-allelic variants in *SLC17A5*. Thisgene encodes sialin, a lysosomal transmembrane protein responsible fortransporting sialic acid (SA) from lysosomes to the cytosol. In additionto coarse facial features, developmental delay, organomegaly, and elevatedurinary free sialic acid, the disorder results in progressiveneurodegeneration, characterized by ataxia, spasticity, hypotonia, and profoundCNS hypomyelination. There is currently no FDA approved treatment and thepathophysiology of the disorder's

neurodegeneration and myelinationdeficits remains enigmatic. In the present study, we explore *SLC17A5* genecomplementation as a potential therapeutic strategy in mouse embryonicfibroblasts (MEFs) derived from a novel mouse model of FSASD and establishgrounds for further in vivo investigations in these mice.Methods: We generated a novel *Slc17a5*^{R39C}knock-in mouse model with the most common p.Arg39Cys (R39C) mutation seenin human patients and characterized the biochemical, histological, andneurobehavioral phenotype. To explore gene complementation, we firsttransfected *Slc17a5*^{R39C} mouse embryonic fibroblasts (MEFs)with GFP-tagged human *SLC17A5* (hSLC17A5). We then delivered thehSLC17A5 or eGFP open reading frame in an AAV vector intravenously to mice atPostnatal Day 2 (PND2); these AAV vectors were driven by the hSYN1promoter. At 6- and 12-weeks post treatment, we collected biological tissuesand fluids to perform biochemical, histological, and immunofluorescent assays. Results: The *Slc17a5*^{R39C} micerecapitulated several features of the human disease, including progressiveataxia, impaired performance on a battery of neurobehavioral tests, increasedurinary free sialic acid, and impaired egress of alkyne-labeled SA fromlysosomes. Early developmental studies revealed that *Slc17a5*^{R39C} miceexhibit decreased myelination, significant white matter astrogliosis, andPurkinje cell loss over time. Purkinje cell vacuolization precededdegeneration, which was progressive from Postnatal Day 21.Transfection of *GFP-hSLC17A5* in *Slc17a5*^{R39C}MEFs increased incorporation of alkyne-labeled SA in cells, suggestingsome recovery of sialin-mediated release of alkyne-labeled SA from lysosomes.Widespread CNS tropism of AAV containing eGFP, except for glial cells, wasconfirmed by immunofluorescence. While *Slc17a5*^{R39C} miceinjected with AAV-*hSLC17A5* showed increased retention ofPurkinje cells, these cells were vacuolated in appearance and there was minimalrecovery of myelination when compared to saline-treated counterparts.Furthermore, AAV-*hSLC17A5* treatment did not correct free sialicacid levels in biological fluids or tissues. Overall, these resultsindicate the need for local CNS delivery and/or the use of a promoter that caneffectively target glial cells.Conclusion: Our study interrogatesthe feasibility for *SLC17A5* gene complementation for FSASD. Ourfindings define key cellular targets in the pathogenesis and progression ofdisease, critical for future preclinical studies and development of noveltherapeutic strategies, and emphasize the role of glial cells such asastrocytes, oligodendrocytes, and microglia in the pathobiology of thedisorder. These results underscore the intricacy of developing genetherapy for neurodegenerative lysosomal storage disorders and pave the way forfuture studies to optimize therapeutic gene delivery to the CNS.

1479. AAV Mediated Therapy for Hereditary Spastic Paraplegia Caused by Mutations in *SPTSSA*

Ashley Glover[1], Yi Gong[1], April Qian[1], Natalie Golovanov[1], Kenneth Gable[2], Casey A. Maguire[1], Teresa Dunn[2], Florian Eichler[1]

[1]Department of Neurology, Massachusetts General Hospital, Boston, MA,[2]Department of Biochemistry and Molecular Biology, Uniformed Services University of the Health Sciences, Bethesda, MD

Sphingolipids (SLs) are lipid molecules that play essential structural and signaling functions in eukaryotes. Aberrant SL metabolism has been linked to many neurological diseases, including neuronal lysosomal storage diseases, Creutzfeldt-Jakob disease, Alzheimer's disease, and Parkinson's disease. Serine palmitoyltransferase complex (SPT) mediates the first and rate-limiting step in the de novo sphingolipid biosynthetic pathway. The larger subunits SPTLC1 and SPTLC2/SPTLC3 together form the catalytic core with a smaller third subunit either SPTSSA (small subunit A) or SPTSSB (small subunit B) propelling the catalytic efficiency and providing substrate specificity for the fatty acyl-CoA substrates. Recently, a de novo variant (p.Thr51Ile, SPTSSA^{T51I}) in SPTSSA was discovered in two female children with stagnant neurodevelopment, who both showed substantially elevated levels of several SLs. To further investigate the pathophysiology of this monogenetic disease and to explore therapeutic approaches, we developed a mouse model using CRISPR technology, assessed the sphingolipid biochemistry and performed systematic behavioral phenotyping. While the *Sptssa*$^{T51I/+}$ had only a mild phenotype up to 5 month of age, biochemical analysis did reveal elevated SL levels. Surprisingly, supplementation with 10% L-serine at 2 months of age continuously for a 2-3-month duration further increased SL levels and worsened the hind limb clasping behavior at 5months of age. Notably, mixed glial cells extracted from *Sptssa*$^{T51I/+}$ mice showed remarkable elevation of SLs and AAV9-sc-CBA-SPTSSA treatment led to robust SPTSSA protein expression and subsequently significant reduction of SL in a dose dependent manner. AAV9-sc-CBA SPTSSA delivery by retroorbital injection was able to transduce the brain and spinal cord evenly and, in a dose dependent manner. In conclusion, serine supplementation in *Sptssa*$^{T51I/+}$ mice aggravated the biochemical and motor phenotype and mimicked the patient clinical features. Our preliminary data in mixed glia cells warrant further in vivo assessment of AAV mediated gene therapy to restore the dynamic regulation of SPT and to prevent abnormal hindlimb clasping in our *SptssaT51I/+* mouse model.

1480. Intra-Articular Delivery of an AAV-Anti-TNF-α Vector Alleviates the Progress of Arthritis in a RA Mouse Model

Shuang Luo[1], Qing Xie[1,2], Qingwei Li[1], Qiang Zheng[1,2]

[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, China,[2]Sichuan Provincial Key Laboratory of Innovative Biomedicine, Chengdu, China

Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by erosive arthritis, which occurs at any age, with a peak incidence between 30 and 50 years of age. The pathological feature includes chronic inflammation in the synovial membrane, formation of vascular opacities and destruction of cartilage and bone in the joints, leading to joint deformity and loss of function eventually. Anti-TNF-α such as Adalimumab, Etanercept and Golimumab are commonly used medication drugs, which are administrated by intra-articular injection directly into the articular cavity, the operation is normally conducted at a frequency of 1 to 4 doses per month depending on the severity of the symptom, causing great inconvenience to the patients and compromised compliance. Therefore, a non-invasive, low-frequency medication for treating rheumatoid arthritis is urgently needed. AAV-mediated gene therapy is considered a treatment strategy involving a single administration with long-term effectiveness, holding immense potential in the treatment of RA. To develop a gene therapy approach, an AAV8 vector harbouring a transgene expressing the anti-TNF-α (KH656) was created in this study. The potency of this vector for the

treatment of RA in a type II collagen-induced RA mouse model was explored. In this study, the KH656 was injected into the mice's ankle joint at a dose of 1E11vg/joint; Animals injected with Adalimumab (8 mg/kg, bi-week) were used as the benchmark. The disease progress/severity is determined by the following indicators: (1) the paw thickness and articular damage clinical scores; (2) cartilage damage; (3) inflammatory cytokines and the infiltration of M1/M2 macrophages; (4) chondrocyte damage, osteoclast damage, osteoprotegerin and osteoclast differentiation factors.The paw thickness and the clinical score of the animals were measured first. The disease animals showed swollen paws, with an average thickness of 3.42±0.42 mm, and a clinical score of 5.21±1.58 at day-48. In the benchmark group, the treatment of Adalimumab alleviated the symptoms of animals by reducing the paw thickness and clinical score to 3.11±0.44 mm, 4.00±1.17 respectively. Notably, the KH656 alleviated the paw swollen with a thickness of 2.92±0.1 mm and a clinical score of 2.43±1.24 on average, which is superior to the Adalimumab group in terms of therapeutic efficacy. The biomarkers of the therapeutic effect were detected after the treatment. The M1 macrophage infiltration and the secretion of the inflammatory factors including IL-1β, IL-6 and TNF-α were inhibited in all treated animals' joint fluid, and the KH656 group showed a stronger inhibitory effect than the Adalimumb group. The animals' joint tissues were subjected to immunohistochemical analysis as well. Compared with the Adalimumab group, KH656-treated animals had a less inflammatory response, slighter chondrocyte and osteoclast damage, lower M1/M2 macrophages ratio, lower levels of osteoprotegerin, osteoclast differentiation factor and fewer apoptotic cells.In summary, Intra-articular delivery of KH656 was found to be capable of protecting articular cartilage, inhibiting synovial inflammation, alleviating arthrophlogosis and restoring normal joint functions in mice. In light of these promising preclinical observations, future NHP studies and clinical trials using the anti-TNF-α-based AAV gene therapy are expected to show substantial benefits to human RA patients.

1481. Utilizing Recombinant AAV and Liposome-Liquid Droplet Form for Improving Osteoarthritis Treatment

Hyeonjee Seo, Kye Il Joo

Ewha Womans University, Seoul, Korea, Republic of

Osteoarthritis(OA) is a common joint disease, but it is still difficult to treat due to a lack of disease-modifying therapy. The impaired articular cartilage possesses limited inherent healing capabilities, necessitating alternative approaches like cartilage reconstruction. This research aims to utilize recombinant AAV (rAAV), genetically engineered with cloned proteins, as a therapeutic intervention. AAV is a comparatively safe viral vector, and its modified form, tailored for gene therapy, transforms into a tool for delivering specific genes to the body to address diseases. This rAAV is anticipated to be introduced into the joint to facilitate the differentiation of resident stem cells, thereby aiding in tissue repair. To this end, we propose a novel liquid droplet-based biomaterial platform to enable precise spatiotemporal administration of rAAV for the efficient treatment of osteoarthritis. Lipo-coa, incorporating liposomes into the existing coacervate, demonstrates an enhanced capacity to adeptly navigate and adhere to narrow crevices. Additionally, it exhibits effective lubrication along the shear reaction boundaries, fostering anticipation for more efficacious treatment and drug delivery.

1482. Transduction Efficiency of Nine Myotropic AAV Variants in a Human Skeletal Muscle Xenograft Model

Matthew James Burke[1], Jin Han[1], Xiufang Pan[1], Yongping Yue[1], Keqing Zhang[1], Lei Jin[2,3,4], Jun Li[2,3,4], Shi-Jie Chen[2,3,4], Dongsheng Duan[1,5,6,7]

[1]Department of Molecular Microbiology and Immunology, University of Missouri, Columbia, MO,[2]Department of Physics, University of Missouri, Columbia, MO,[3]Department of Biochemistry, University of Missouri, Columbia, MO,[4]Institute for Data Science and Informatics, University of Missouri, Columbia, MO,[5]Department of Biomedical, Biological & Chemical Engineering, University of Missouri, Columbia, MO,[6]Department of Neurology, University of Missouri, Columbia, MO,[7]Department of Biomedical Sciences, University of Missouri, Columbia, MO

Myotropic AAV variants hold promise to treat inherited neuromuscular diseases such as Duchenne muscular dystrophy (DMD). Several bioengineered AAV capsid variants recently demonstrated superior muscle transduction in mice and nonhuman primates. Many of these capsids contain a surface-exposed RGD motif. Despite promising results, their performance in human skeletal muscle is unknown. To address this, we used a human muscle xenograft model to compare six RGD-motif capsids with three AAV capsids that are currently in use in clinical trials (AAV8, AAV9, and AAVrh74). Fully regenerated muscle grafts were established in immune-deficient NSG mice using skeletal muscle from adult human donors. To evaluate the efficiency of gene delivery and gene expression in the same animal, we utilized a novel exonic barcode system. This system allows for detection of each barcoded vector genome and mRNA transcript using conventional qPCR techniques. Barcoded but otherwise identical reporter AAV genomes expressing EGFP driven by the ubiquitous CAG promoter were packaged in each of the nine capsids. Viral titers of each vector were determined by barcode-specific qPCR. A cocktail containing equal ratios of each AAV variant was delivered to host mice by intravenous injection at two doses (3E+12 vg/kg/AAV, n=6 and 1E+13 vg/kg/AAV, n=5). At one-month post-injection, we collected tissues and evaluated graft regeneration by immunofluorescence staining and morphometric analysis. We then used TaqMan qPCR assays unique to the DNA and mRNA barcodes to evaluate vector genome and transcript copy numbers in the human muscle graft, mouse tibialis anterior muscle, and mouse liver. Our preliminary results indicate differential transduction and transgene expression between AAV variants in human muscle and mouse tissues. The full data set will be presented at the Annual Meeting.

1483. Microdystrophin Configuration Optimization for Duchenne Muscular Dystrophy Gene Therapy

Xiufang Pan[1], Nalinda B. Wasala[1], Lakmini P. Wasala[1], Chady H. Hakim[1], Yongping Yue[1], Keqing Zhang[1], Matthew J Burke[1], Dongsheng Duan[1,2,3,4]

[1]Department of Molecular Microbiology and Immunology, School of Medicine, University of Missouri, Columbia, MO,[2]Department of Biomedical Sciences, Department of Biomedical Sciences, College of Veterinary Medicine, University of Missouri, Columbia, MO,[3]Department of Neurology, School of Medicine, University of Missouri, Columbia, MO,[4]Department of Chemical and Biomedical Engineering, College of Engineering, University of Missouri, Columbia, MO

Duchenne muscular dystrophy (DMD) is a lethal muscle-wasting disease caused by the null mutations in the *DMD* gene. This results in the loss of the sarcolemmal stabilizing protein dystrophin. Dystrophin is one of the largest proteins. The dystrophin coding sequence exceeds the packaging capacity of the adeno-associated virus vector (AAV), the only viral vector capable of efficient bodywide muscle gene delivery. Systemic microdystrophin gene therapy aims to replace the missing dystrophin protein with a highly abbreviated form of dystrophin. Several microdystrophin constructs are currently in clinical trials, and one has received accelerated approval from the FDA to treat 4 to 5-year-old patients. The full-length dystrophin protein has four hinges in the rod domain. Two hinges flank the rod domain, and the other two are in the middle of the rod domain. Some clinical trial microdystrophins contain a centrally located hinge while others do not. To determine the functional implication of the central hinge, we engineered two microdystrophin constructs; one contains a centrally located hinge, while the other does not. The microdystrophin cassettes were packaged in AAV9 and delivered to 2.5-m-old mdx mice via the tail vein at 4e14 vg/kg. Microdystrophin expression, muscle histology, grip force, and muscle force were examined when mice were 6 -7 months old. Both constructs yielded saturated expression in skeletal muscle and the heart. Both constructs resulted in similar histological improvements and equivalent grip strength and muscle-specific force. However, the construct without the central hinge was more effective in protecting against eccentric contraction-induced force drop. Our data suggest that fine-tuning microdystrophin configuration is a promising strategy to improve DMD gene replacement therapy (Supported by NINDS, NIH).

1484. A Proof-of-Concept AAV Gene Replacement Therapy for GNE Myopathy in a Knock-in Mouse Model

Katherine E. Koczwara[1], Petcharat Leoyklang[2], Angela Lek[3], Alec DeSimone[1], Shushu Huang[1], Vincent Ho[1], Qi Zhang[1], Justin Cohen[1], Kaiyue Ma[1], Stella Mitrani-Rosenbaum[4], Marjan Huizing[2], Monkol Lek[1]

[1]Yale University, New Haven, CT,[2]NHGRI, NIH, Bethesda, MD,[3]MDA, Chicago, IL,[4]Hadassah-Hebrew University of Jerusalem, Jerusalem, Israel

Rationale: GNE myopathy is a rare, autosomal recessive disease, leading to progressive skeletal muscle atrophy and weakness in the limbs. Myopathy occurs due to pathogenic mutations in the *GNE* gene, resulting in reduced enzymatic activity of the GNE protein, a bifunctional enzyme involved in the sialic acid biosynthesis pathway. To date, over 250 pathogenic mutations in *GNE* have been reported, making mutation correction a poor therapeutic approach. While oral supplementation of N-acetyl-D-mannosamine (ManNAc), the substance produced by GNE within the sialic acid biosynthesis pathway, may be a viable therapeutic strategy, its efficacy in treating GNE myopathy patients is still being evaluated (NCT04231266). Alternatively, delivery of a fully functional *GNE* gene to muscle tissue should restore proper GNE function, regardless of the particular pathogenic mutation. AAV-based gene delivery has proven successful for the treatment of other genetic neuromuscular diseases, and the relatively small size of the *GNE* coding sequence (<2.2kb) make this approach an attractive treatment strategy for GNE myopathy. Study Design: In this study we designed, optimized, and evaluated the efficacy of a gene replacement therapy for GNE myopathy. A library of AAV vectors was developed and evaluated *in vitro* for GNE expression due to: (1) the promoter used; (2) the inclusion of an intron; (3) the GNE isoform; and (4) the position and type of protein tag. Following selection of an optimal vector, two high expressing constructs were packaged into AAV9 particles, and a dose and biodistribution study was performed in C57BL/6 wildtype mice to determine the safety and efficiency of GNE expression across a variety of tissues. Lastly, the efficacy of gene replacement therapy was evaluated in a knock-in mouse model of GNE myopathy. In brief, both AAV9 and AAVmyo2 serotypes were utilized to treat 6-8 week-old mice with constructs that express the *GNE* coding sequence under control of muscle-specific promoters. At 12 weeks post-injection, several outcome measures were determined, including (1) the effects of gene replacement therapy on muscle hyposialylation, (2) the biodistribution of viral genomes depending on AAV serotype used, and (3) GNE protein expression across a variety of tissues. Results/Conclusions: *In vitro* optimization demonstrated that the CK8e-SV40-*hGNE1*-V5 and MCK-SV40-*hGNE1* constructs resulted in high *GNE* transcript and GNE protein expression in myoblasts. The AAV9 dose and biodistribution study in C57BL/6 mice indicated robust, dose-dependent transcript and GNE protein expression across a variety of muscle tissues at 8 weeks post-injection. While the effects of GNE gene replacement therapy on muscle hyposialylation in a mouse model of GNE myopathy are still being investigated, preliminary results of this study indicate a high dose (3e14 vg/kg) of AAVmyo2-MCK-SV40-*hGNE1* led to strong exogenous GNE protein expression in skeletal muscle. Additionally, the use of the AAVmyo2 serotype resulted in significantly decreased liver targeting of the viral vector compared to AAV9, while exhibiting increased skeletal muscle targeting. This proof-of-concept study provides key insights into the optimal muscle-specific promoter, dose, and AAV serotype to be used within the context of GNE myopathy. In-progress and future work investigating the effects of AAV therapy on muscle hyposialylation and other disease-relevant phenotypes will be important in determining the efficacy and minimum required dose for a successful gene replacement therapy.

1485. Expression of Large and Highly Functional Dystrophins Using Split Inteins and Myotropic AAV Vectors

Hichem Tasfaout[1], Christine L. Halbert[1], James M. Allen[2], McMillen Tim[1], Stephen D. Hauschka[1], Dirk Grimm[3], Michael Regnier[1], Jeffrey S. Chamberlain[1]

[1]University of Washington, Seattle, WA,[2]University of Washington School of Medicine, Seattle, WA,[3]Heidelberg University Hospital, Heidelberg, Germany

Gene replacement using Adeno-associated viral (AAV) vectors is a promising therapeutic approach for many diseases. However, this therapeutic modality is challenged by the packaging capacity of AAVs (~4.7 kb), limiting its application for disorders involving large coding sequences, such as Duchenne muscular dystrophy, with a 14 kb mRNA. Here, we developed a novel method for expressing large dystrophins by utilizing the protein *trans*-splicing mechanism mediated by split inteins. We identified several split intein pairs that efficiently join two or three fragments to generate a large midi-dystrophin or the full-length protein. We show that delivery of two or three AAVs into dystrophic mice results in robust expression of large dystrophins and significant physiological improvements compared with micro-dystrophins. Moreover, using the potent myotropic AAVMYO and strong muscle-specific expression cassette CK8e, we demonstrate that low total doses ($2x10^{13}$ vg/kg) are sufficient to express large dystrophins in striated muscles bodywide with significant physiological corrections in young or very old *mdx*^{4cv} dystrophic mice. Our data support the feasibility of this approach *in vivo* and show a clear functional superiority of large dystrophins over micro-dystrophins that are being tested in clinical trials. This novel method could benefit many patients with Duchenne or Becker muscular dystrophy regardless of genotype and, if not complicated by immune responses to intein polypeptides, could be adapted to numerous other disorders caused by mutations in large genes exceeding the carrying capacity of AAV.

1486. Control of Cardiotoxicity Related to AAV Gene Transfer

Isabelle Richard, Ariane Biquand, Evelyne Gicquel, Jérôme Poupiot, Anthony Brureau

GENETHON, Evry, France

Gene delivery technologies based on adeno-associated virus vectors (AAV) have yielded promising results for the treatment of monogenic diseases, leading in recent cases to marketing authorization in Europe and US. However, preclinical studies and clinical trials have highlighted that infusing high vector doses can induce cytotoxicity in a number of organs, leading in a few cases to the death of the patient. We investigated the consequences on the heart of administration of high doses of AAV vectors expressing 3 different transgenes corresponding to muscular dystrophies: a form of microdystrophin for Duchenne Muscular Dystrophy, the human full-length SGCG cDNA for γ-sarcoglycanopathies and the human full-length FKRP cDNA for FKRP deficiencies. We observed in all these cases the possibility of cardiotoxicity with high doses injection whereas no abnormality was present in the skeletal muscle. Dissection of the mechanisms at stake revealed activation of different molecular cascades due to supraphysiological transgene expression in the heart and leading to cardiomyocyte death. Preventing transgene expression in heart through the use of a cardiac specific microRNA or a heart detargeting promoter was shown to prevent the appearance of such cardiotoxicity. Overall, our data highlighted a specific sensitivity of the heart to transgene expression, in particular compared to skeletal muscle, suggesting the importance to regulate finely the expression of transgene in this organ in any gene therapy approach. The manuscript presenting this work is ready for submission.

1487. U7snRNA-Mediated Exon 17 Skipping in Duchenne Muscular Dystrophy

Liubov V. Gushchina[1], Gabrielle Dufresne[2], Ezgi Saylam[2], Adrienne Bradley[2], Natalie Rohan[2], Allison Lowery[2], Hui Lin[2], Nicolas Wein[2], Kevin M. Flanigan[2]

[1]Center for Gene Therapy, The Ohio State University and Nationwide Children's Hospital RI, Columbus, OH,[2]Center for Gene Therapy, Nationwide Children's Hospital RI, Columbus, OH

Duchenne muscular dystrophy (DMD) is a severe genetic disease affecting approximately 1 in 5,200 live male births and characterized by progressive muscle weakness, leading to premature death due to cardiac and respiratory failure. DMD is caused by mutations that disturb the open reading frame (ORF) of the dystrophin gene leading to loss of the dystrophin-glycoprotein complex. Currently approved and experimental gene therapies have resulted in expression of multiple internally deleted, partially functional dystrophin isoforms, the efficacy and durability of which are still limited. An alternative and most effective strategy to induce exon skipping is to incorporate antisense oligonucleotides (ASOs) into U7 small nuclear RNA (U7snRNA) and deliver them using adeno-associated virus (AAV). This approach has already demonstrated long-term potential to restore either full-length dystrophin or a highly functional N-terminal truncated protein in Dup2 mice and patients with exon 2 duplication mutations (NCT04240314). Here, we examined the therapeutic potential of rAAV.U7snRNA-mediated therapy to correct disrupted ORF in DMD patients carrying variable exon 17 skip-amenable deletions. We designed several AAV vectors and tested them *in vitro* and *in vivo*. Two DMD patient-derived cell lines—Immortalized tet-inducible-MyoD fibroblasts (FM cells)—carrying exon 17 amenable deletions were treated with rAAV.U7snRNA vectors at four different doses and then differentiated them for 8-14 days. Both cell lines revealed robust exon 17 skipping in a dose-dependent manner. Semi-quantitative analysis of RT-PCR gel images also confirmed the presence of In-frame (IF) dystrophin mRNA transcripts in both cell lines. To confirm exon 17 exclusion *in vivo*, all three vectors were tested using a novel DMD mouse model carrying an out-of-frame (OOF) deletion of exons 18-41. Del18-41 mice were intramuscularly injected into both the left and right sides of the tibialis anterior (TA) and gastrocnemius (Gast) muscles. Animals were euthanized 4 weeks after vectors administration, and tissues were collected for analysis. RT-PCR analysis revealed exclusion of exon 17 for two of the three target sequences in both TA and Gast muscles, resulting in dystrophin protein levels of 0.9-5.2% detected by Western blotting. Overall, we clearly demonstrate that rAAV.U7snRNA-mediated therapy is a powerful therapeutic tool that can benefit nearly 5.5% of all DMD patients carrying amenable mutations (duplication and deletion) flanking exon 17.

1488. AAV9 Mediated Dars2 Gene Therapy Prevents Neurodegeneration in Two Mouse Models of LBSL

Ines L. Garofolo[1], Yajie Liang[2], Miroslaw Janowski[2], Piotr Walczak[2], Ali Fatemi[1,3], Christina L Nemeth[1,3]

[1]Moser Center for Leukodystrophies at Kennedy Krieger, Kennedy Krieger Institute, Baltimore, MD,[2]Department of Diagnostic Radiology and Nuclear Medicine, University of Maryland, Baltimore, Baltimore, MD,[3]Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD

Leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL) is a rare white matter disease caused by mutations in the mitochondrial aspartyl-tRNA synthetase (mt-AspRS, or *DARS2*) gene, which is important for the synthesis of proteins in mitochondria. Abnormalities within cerebral white matter, brainstem, and spinal cord are observed in all patients' MRI; however, a large phenotypic spectrum exists. Previously, we have shown that *Dars2* deletion from CamkII alpha excitatory neurons results in a severe and slowly progressive phenotype emerging at 22 weeks old, consisting of significant cortical atrophy and ventricular enlargement (Nemeth et al., 2019). More recently, we have generated mice with *Dars2* deletions in Advillin-expressing cells, or sensory neurons of the dorsal root ganglia. *Dars2*/Advillin deletion mice display severe ataxic behavior starting at as young as p14, eventually leading to death by 6 weeks. As LBSL patients primarily experience symptoms associated with ataxia, disordered gait, and white matter abnormalities, these models provide a representation of disease phenotype for the further study of disease mechanism, cell-type specific effects, and therapeutic efficacy. Our current focus in therapeutic testing within these mouse models is via treatment with an Adeno-Associated Viral (AAV) vector, serotype 9, containing a human *DARS2* plasmid. Our hope is to improve the biochemical and phenotypic deficiencies in our models by way of intracerebroventricular (ICV) or intrathecal (IT) injection of the AAV9 vector. At 8 weeks of age, and prior to onset of symptoms, *Dars2*/CamKIIα mice were treated with a single *DARS2*-AAV9 via ICV injection. Open field analysis was performed at baseline and every 2 weeks following treatment until mice were sacrificed at 32 weeks. Behavior data indicated a positive effect of the therapy to decrease excitatory behavior and prevent cortical atrophy (figure 1). *In situ* hybridization detected presence of human *DARS2* in neuronal cells, suggesting that cell uptake of human *DARS2* has therapeutic effects in mice. On or around p6, *DARS2*-AAV9 was administered via IT injection to *Dars2*/Advillin mice. On p35, gait was assessed in wild-type, *Dars2*/Advillin knock-out mice, and AAV9 treated knock-out mice. Preliminary results indicate improvements to spasticity through a normalization of base of support measures, a significant reduction of weight loss, and improved life span. Together, these data suggest that gene delivery via AAV9 reduces the phenotypic burden of *Dars2* deletion in two different mouse models. Ongoing studies are currently addressing biodistribution and toxicity of the *DARS2* vector.

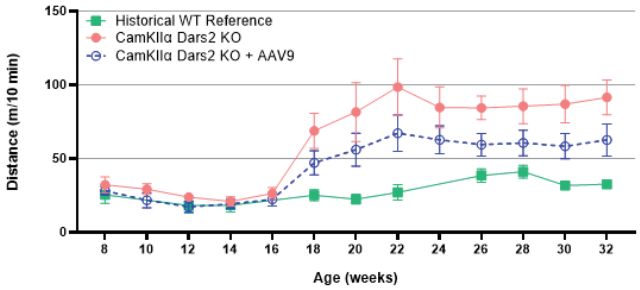

Figure 1. Intracerebroventricular injection of AAV9 decreased excitatory behavior in *Dars2*/CamKIIα KO mice.

1489. Highly Effective Expression of Full-Length Dysferlin Protein in Bla/J Mouse Muscle After Systemic MyoAAV Administration

Danielle Velez, Chady H. Hakim, Ana Maria Manso, Graham Salmun, Stephanie Landeros, Mark Fielden, Sharif Tabebordbar

Kate Therapeutics, San Diego, CA

Dysferlinopathy (LGMD2B/R2) is a genetic muscle disease caused by mutations in the *DYSF* gene resulting in the absence of dysferlin, a membrane protein involved in muscle membrane repair (membrane patch). Dysferlin deficiency compromises sarcolemmal integrity, leading to progressive muscle degeneration. Gene replacement therapy is a promising therapeutic strategy for dysferlinopathy. However, the dysferlin coding sequence (~6.2 kb) exceeds the packing capacity of a single AAV. Dual AAV strategies have been proposed as a strategy to overcome this hurdle and allow expression of full-length dysferlin. However, production of full-length dysferlin with conventional dual AAV strategies is often inefficient, because it requires delivery of vector genomes from both AAVs into the same nucleus in muscle fibers, and because the efficiency of homologous recombination in post-mitotic cells is low. To address this, we used an alternative dual AAV strategy utilizing split protein inteins to express full-length dysferlin. In this strategy, two segments of the dysferlin protein are expressed individually and the full length protein is generated by protein splicing in the muscle fiber cytoplasm. We tested multiple split inteins *in vitro*, and identified a lead dual AAV candidate containing a split intein that results in high efficiency of protein splicing and full length dysferlin protein production in myotubes. Systemic delivery of dual MyoAAVs for the lead candidate in Bla/J mice at low dose resulted in physiological or supraphysiological full-length dysferlin expression in multiple skeletal muscles. Immunofluorescence analysis showed widespread dysferlin expression across most muscle fibers, which provided protection against strain injury in Bla/J muscles.Our results provide evidence for the feasibility of a dual AAV strategy utilizing split protein inteins for effective expression of full-length dysferlin protein in dystrophic muscle following low-dose systemic MyoAAV administration.

1490. Cell-Type Specific Enhancer AAVs for the Treatment of Motor Deficits in Parkinson's Disease

Ananya Chowdhury, Alex Fraser, Max Departee, Alex C. Hughes, John K. Mich, Yemeserach Bishaw, Bryan B. Gore, Emily A. Kussick, Naz Taskin, Victoria Omstead, Nathaly Munoz, Ximena Opitz-Araya, Refugio Martinez, Kathryn Gudsnuk, Boaz P. Levi, Ed S. Lein, Jonathan T. Ting, Tanya L. Daigle

Human Cell Types, Allen Institute for Brain Science, Seattle, WA

Gene therapy has the potential to provide long-term clinical benefits for debilitating human disorders of the central nervous system (CNS) and the body. Among others, human clinical trials are in progress to test gene therapies for the treatment of Parkinson's disease (PD), a debilitating neurodegenerative disease impacting the brain's dopaminergic system. These trials showed promising results using AAV2 to drive the expression of human aromatic l-amino acid decarboxylase (hAADC)—a rate-limiting enzyme in dopamine synthesis—under the control of a ubiquitous promoter (CMV). However, this required a bilateral, intraoperative MRI-guided putaminal infusion, which is expensive as well as highly invasive, and prone to technical issues. The ability to deliver the therapeutic cargo via a non-invasive route of administration like the intravenous (IV) method would be a huge step forward in the field of gene therapy. To achieve that, we need to ensure they cross the blood-brain barrier (BBB) and show strong and widespread transduction in the brain while minimizing off-target effects in non-diseased cells of the brain, sensory neurons, and peripheral organs to avoid unwanted side effects and mortality in PD patients. To that effect, we have created a powerful toolkit of enhancer-based AAVs with commercially available PHP.eB capsid, which enables precise delivery of genes of interest to diverse cell types within the CNS with inherently low off-target expression. Our enhancer-AAVs showed strong and specific drive hAADC expression in striatal medium spiny neurons (pan-MSNs), indirect or direct MSNs, striatal cholinergic neurons, and midbrain dopamine neurons following systemic delivery in mice. The lead pan-MSN vector was further evaluated in non-human primates (NHP) following intraparenchymal and intracerebroventricular delivery, demonstrating cross-species expression and translational capability. We tested the efficacy of our lead pan-MSN vector in a 6-OHDA toxin model and two genetic PD models in mice, Mitopark and MCI, using multiple behavioral paradigms like accelerating rotarod, open field, contralateral paw touches, and gait analysis. Our work showed that expressing hAADC in all MSNs by systemic (IV) delivery ameliorated specific motor-related deficits in these models. A single administration of a lower dose of L-Dopa further improved their motor behaviors, which could better the quality of life by delaying the onset and possibly diminishing the detrimental side effects of L-Dopa observed in the patients. Furthermore, our lead pan-MSN vector showed more robust behavioral rescue when compared to ubiquitous CMV-promoter AAV when administered locally to the dorsal striatum of mice, suggesting the superiority of a cell-type specific intervention. In summary, our work provides strong proof-of-concept data in support of enhancer-AAVs as potential circuit-selective therapies for treating PD. Cell-type specific expression of hAADC via a non-invasive route of administration has the potential to improve motor functions in PD patients alone or alongside a lower dose of L-DOPA, bypassing invasive brain surgery to achieve a similar therapeutic effect.

1491. Biodistribution of AAV6.2-mCherry in C57BL/6J Mouse Dosed via Nose-Only Inhalation Route

Mayuri Prasad[1], Justine Damiano[2], Phillip Gouldthorpe[2], Ambre Brink[1], Lori Bedient[2], Emily Resseguie[2], Sheri Vesperman[1], Sarah Wills[1], Simon Moore[3], Brian E. Mcintosh[1]

[1]Labcorp, Madison, WI,[2]Labcorp, Somerset, NJ,[3]Labcorp UK Limited, Huntingdon, United Kingdom

In the past 7 years the United States Food and Drug Administration (USFDA) has approved 5 Adeno associated virus (AAV) based gene therapy products treating a range of disorders and deadly monogenic diseases. In order to meet demands of the evolving AAV gene therapy product landscape, successful AAV vector delivery technique is necessary to evaluate appropriate cell targeting and sometimes even lab personnel safety. Monogenic pulmonary diseases such as cystic fibrosis and α-1-antitrypsin (AAT) deficiency, require targeted delivery of AAV gene therapy aerosolized droplets to respiratory tract airway epithelium cells via an inhaled route. In this study, we demonstrate and establish a rodent, nose-only AAV inhalation model for assessing the efficiency of administration, biodistribution, toxicity and the persistence of an AAV6.2 expressing mCherry. The study design was reviewed and approved by the Institutional Animal Care and Use Committee at Labcorp, Madison, WI. Male C57BL/6J mice were administered AAV6.2-mCherry aerosols at concentrations of 3.61×10^9 viral genome copies/L for 6 or 60 minutes to achieve 1 log fold different doses. The target delivered dose of animals administered AAV6.2-mCherry aerosols for 6 minutes was 2.3×10^{10} GC/kg and for animals administered AAV6.2-mCherry aerosols for 60 minutes was 2.3×10^{11} GC/kg. Biodistribution, toxicity and persistence of the AAV6.2 was evaluated after 2-and 4-weeks. The AAV aerosol was generated using an Aeroneb Solo nebulizer into a nose-only exposure system. qPCR was used to evaluate the aerosol concentration and particle size of aerosol samples collected from the exposure system. The dosing procedure was performed within a biosafety cabinet in an ABSL2 designated area in the facility. In addition, various mitigation strategies were employed to ensure that personnel and laboratory exposure was minimized. The persistence of the viral genome and tissue-specific transduction efficiency was evaluated by qPCR, Immunohistochemistry for the mCherry protein and Qualitative Whole Body Fluorescence Assay in respiratory and other major organ system tissues. No AAV6.2-mCherry-related adverse clinical observations or mortality were noted during the study, and expression of mCherry was limited to respiratory system tissues. Mass median aerodynamic diameter (MMAD) of the AAV6.2-mCherry was towards the upper limits of respirable droplet size, yet contained viral aerosol that could reach the pulmonary parenchyma. A dose dependent increase in transduction efficiency was seen in selected respiratory tissues via qPCR analysis. Minimal or minimal to slight expression of mCherry protein was seen in the trachea and tracheal bifurcation, respectively, in animals administered $\geq 2.3 \times 10^{10}$ GC/kg AAV6.2-mCherry and was limited to the mucosal epithelial cells. In the lung, minimal to slight expression of mCherry protein was

seen in mucosal epithelial cells of the bronchi in animals administered ≥2.3 x 10^{10} GC/kg AAV6.2-mCherry. Minimal to moderate expression of mCherry protein was observed in the respiratory epithelium of the nasal turbinates in animals administered ≥2.3 x 10^{10} GC/kg AAV6.2-mCherry. Our data demonstrates the feasibility of using AAV nose-only murine inhalation model in AAV based toxicology and biodistribution studies aimed at monogenic pulmonary diseases. We were able to safely and efficiently administer AAV6.2-mCherry droplets simultaneously in multiple animals and minimize viral contamination in the facility by adopting contamination mitigation strategies. The development of this AAV inhalation murine model is a promising path forward in the safety assessment of inhalation gene therapy studies focused on pulmonary diseases such as Cystic fibrosis and α-1-antitrypsin (AAT) deficiency.

1492. Investigating the Mechanisms of AAV-Mediated Dorsal Root Ganglia (DRG) Toxicity by Single Nucleus RNA Sequencing in C57BL6 Mice

Sam Hana[1], Dan Ferretti[2], Benjamin Doyle[2], Zachary Hawley[2], Patrick Cullen[2], Thomas Carlile[2], Christelle Lasbleiz[3], Maria Zavodszky[2], Nadine Mastre Frances[3], Fergal Casey[2], Shih-Ching Lo[2]

[1]Biogen Inc | PSL-EPHE, Montpellier, France,[2]Biogen Inc, Cambridge, MA,[3]PSL-EPHE, Montpellier, France

Somatosensory neurons play a critical role in the sensation and the responses to external stimuli. Sensory neurons have shown to be susceptible to toxicities induced by high doses of adeno-associated virus (AAV) and AAV gene products. This pathology is generally characterized by neuronal and axonal degeneration in NHPs, piglets, rats and others. In this report, mice were shown to exhibit molecular and transcriptomic alterations consistent with findings in prior studies. Wild-type C57BL6 mice were intrathecally dosed with AAV9-duplex-amiR vector (PackGene Biotech) at various doses, animals were then sacrificed for lumbar DRGs used in single-nucleus RNA sequencing. At 3 weeks post-injection, serum neurofilament light (NfL) levels surge in response to the AAV9 vector. A notable reduction of neuronal (>50%) and Schwann nuclei (~8%) were detected in mice with high serum NfL levels. A new cluster labelled repair/activated satellite glial emerges along with an increase in T cells and macrophage cells. Key developmental and repair associated (axonal guidance) genes were upregulated in repair/activated satellite glia. Innate and adaptive immune genes were upregulated in macrophages and T cells. This study provides valuable cell type specific mechanistic insights in response to AAV-induced DRG toxicity in mice. These findings may aid in designing of immunosuppressant-based mitigation approach to alleviate AAV-related DRG toxicity for improved use of gene therapies in treating CNS diseases.

Friday Posters: AAV Vectors - Product Development Manufacturing and Approval Considerations

1493. Intact Mass Analysis of Adeno-Associated Virus (AAV) Capsid Proteins Using a LC-QTOF Mass Spectrometer

Xiaomeng Xia, Evelyn Wang, Yoshiyuki Okamura, Tairo Ogura

Shimadzu Scientific Instruments, Columbia, MD

Over the last three decades, the field of gene therapy has witnessed remarkable progress, evolving from laboratory experiments to the approval of products by the Food and Drug Administration (FDA). Adeno-associated viruses (AAVs) have emerged as widely utilized vectors in gene therapy due to their high transduction rates, wide tissue specificity, low immunogenicity, and minimal genotoxicity. AAVs comprise two primary components: a viral vector protein capsid and encapsulated DNA transgene. The AAV capsid consists of three highly homologous viral proteins (VPs) known as VP1, VP2, and VP3. The comprehensive characterization of these VPs, encompassing their sequence, stoichiometry, and post-translational modifications (PTMs), is crucial due to their pivotal role in viral infectivity and vector potency. LC-MS is known to be a powerful analytical technique by offering a robust method to directly measure the protein molecular weight, thus providing both specificity and sensitivity for rapid confirmation of AAV capsid serotypes. However, several challenges remain to be addressed for the analysis of AAVs compared with conventional recombinant proteins. AAV samples exhibit greater structural complexity and are typically present at very low concentrations. Consequently, the LC-MS platform chosen for characterizing AAVs must possess exceptional sensitivity for detecting these rare viral proteins and ensure precise measurement of their intact mass. In this study, we present the characterization of AAV capsid proteins using liquid chromatography and mass spectrometry (LC-MS) based assays, specifically intact mass and PTMs. AAV8 was chosen as a specific case study. The titer of the AAV8 sample received was 4.691E12 vp/mL. The AAV8 sample underwent treatment with 10% (v/v) acetic acid for 15 minutes, followed by centrifugation at 12,000 rpm for 5 minutes. The dissociated AAV8 proteins were analyzed using LC/MS-QTOF, employing a Shim-pack Scepter C4 column on a Shimadzu LCMS-9030. The C4 column was pre-conditioned with 0.1% difluoroacetic acid to increase the separation of the viral proteins. Mobile phases were 0.1% formic acid in water and acetonitrile without any ion-pairing reagent, which minimized the mass spectrometer fouling. The chromatographical separation of three viral proteins of AAV8 capsid was achieved in a gradient of 30 minutes. The intact mass workflow in Protein Metrics (PMI) was employed for the deconvolution of intact protein spectra. The masses for peaks at 5.59, 6.02, and 6.84 min were calculated to be 81,747.5, 66,598.2, and 59,804.5 Da upon MS charge deconvolution using PMI. The peak eluting at 8.15 min was found to have a mass of 50,593.0 Da, matching the mass of a VP3 fragment resulting from hydrolysis. The observed masses were agreeable with the theoretical masses of VP1, VP2, VP3 and VP3 clip, suggesting that the developed method can measure intact VP masses. The accurate mass measurement also provides a means to deduce the

potential PTMs on the VPs including acetylation and phosphorylation. For example, VP3 and VP3 clip show a mass difference of 42 Da between the measured mass and the corresponding theoretical mass, suggesting the addition of N-terminal acetylation as the potential molecular form, whereas the peaks showing 80 Da mass shift on VP2 were attributed to the phosphorylated proteoforms. VP1 was observed with both acetylation and phosphorylation PTMs from the mass shift. In conclusion, a LC-MS based method was developed to enhance the thorough characterization of AAV capsid proteins. This contributes to improved analyses of AAV capsid proteins, enhancing understanding and providing guidance for the development and manufacturing of new AAV therapeutics.

1494. Breakthrough Technology for AAV Mass Production -One-Step Producer Cell Lines Establishment with Originally Designed Novel Plasmid-

Yusuke Mori, Taichi Muraguchi, Katsuko Sato
Fujifilm Corporation, Kaisei-machi, Kanagawa, Japan

[Purpose] Recombinant adeno-associated virus (rAAV) vectors are popular emerging modalities for gene therapy. Current manufacturing processes using plasmid-polymer complex transfection are expected to be insufficient to meet the demand for the estimated patient numbers, due to difficulties in controlling the plasmid-polymer complex during manufacturing . The plasmid-polymer complex size changes with time and impurities, creating difficulties in handling at production scale. The high cost of the plasmid itself is another limiting factor. To solve these problems, we have developed "AAV producer cell lines" in which the genes necessary for AAV production were incorporated into the chromosomes of the production cells, and established a method for high production of AAV vectors using these cell lines. [Methods] A unique design was constructed in which the genes required for AAV production, REP/CAP/Helper/GOI, were carried in a single plasmid and a drug-inducible switch was incorporated to avoid cellular damage caused by AAV gene expression. Plasmids were integrated into the HEK293 cell chromosomes, and cell lines with all genes incorporated were selected within 2 months. [Results] The established AAV producer cell lines showed proliferation comparable to the parental HEK293 cells without inducers. Subsequently, AAV production was confirmed by the addition of inducers. The culture was expanded in the bioreactor and reached a cell density of 30 Mcells/ml, and then >$1x10^{12}$ vg/ml AAV vectors were produced by adding the inducer. Furthermore, the cell culture medium was withdrawn from the perfusion reactor every 24 hours for 7 consecutive days, and AAV production was induced with the withdrawn cell culture medium, allowing the continuation of high production. In the near future, this technology will be able to meet various needs such as mass production and scale-up/down of vector manufacturing.

1495. Small Molecule Screen Identifies Targets That Increase AAV9 Production in Suspension HEK293 Cells

Francesca Ispaso[1], Kaylin Fisher[1], Francis Grafton[1], Markus Hörer[2], Chris A. Reid[1], Mo Mandegar[1]
[1]Ascend Gene and Cell Therapies, Alameda, CA,[2]Ascend Gene and Cell Therapies, Munich, Germany

The use of recombinant AAV as a vector for gene delivery is widespread, with over 900 pre-clinical and clinical programs underway. However, inefficient manufacturing methods result in high costs, limiting the availability of gene therapies. In this study we describe a high-throughput small molecule screening strategy to identify compounds that increase the capacity of cells to produce AAV9. Previously we had reported identification of a novel small molecule (SM-016) from a screen of 3,000 bioactive molecules that we validated in shake flasks and Ambr15 bioreactors. For our current study we wanted to further expand on the diversity of biological targets screened. In this study, we first developed a miniaturized suspension adapted high throughput screening strategy: ATLAS (Arrayed Targeted Library for AAV Screening). We performed optimization studies to show translatable, reproducible, and comparable AAV9 yields from 96 well to 125mL shake flask format. Next, we performed a screen using a curated compound library of over 700 small molecules. Targets identified include epigenetic modulators, DNA damage response, GPCR and transmembrane transporters, cell cycle modulators, anti-infection, and metabolic targets. Evaluation of top hits are currently underway.

1496. Advancing Serological AAV Assays with Human Chimeric Antibody Standards

Dana Holzinger[1], Silja Syrbe[1], Lisa Mutz[1], Christina Querfurth[1], Katharina Hauser[1], Klaus-Ingmar Pfrepper[1], Morten Seirup[2], Trish Hoang[2], Marjeta Urh[2], Caroline Odenwald[1], Maik Lander[1]
[1]PROGEN, Heidelberg, Germany,[2]Promega Corporation, Fitchburg, WI

Recombinant adeno-associated virus (AAV) vectors are leading tools for viral gene therapy. However, many humans in the general population have developed antibodies against AAV as a result of naturally acquired infections, which might affect efficiency and safety of the gene transfer using AAV vectors. Therefore, testing for pre-existing AAV antibodies in patient sera is an indispensable step for the selection of patients for AAV gene therapy clinical trials. The use of suitable positive controls for the development of reliable and reproducible serological AAV assays is crucial. Therefore, we developed recombinant human chimeric AAV antibodies based on our exclusive portfolio of neutralizing anti-AAV mouse monoclonal antibodies (see antibody clones in Tab. 1). The antibodies retain the identical variable region compared to the mouse monoclonal AAV antibodies while containing a human Fc region. This allows the detection with an anti-human secondary antibody and ensures comparability with human serum antibodies. Here, we show characterization data of our new human chimeric antibodies, including binding affinity, cross-reactivity and their application in serological assays.

1497. Unraveling AAV Bioprocessing: Advanced Analytics for In-Depth Insight and Process Optimization

Qiuge Zhang, Morgan Ludwicki, Jacob Calhoun, Masa Nakamura, Mauhamad Baarine
3M HealthCare, Saint Paul, MN

In Adeno-Associated Virus (AAV) manufacturing, the lack of comprehensive analysis on AAV quality and host cell DNA removal at each unit operation through the entire bioprocess is impeding our ability to identify the key steps for further optimization. This study tried to bridge the knowledge gaps by developing advanced analytics capabilities to characterize both AAV quality and impurities from upstream to downstream. In a case study, we varied nuclease concentrations during cells lysis, clarified the lysates using the charge-based 3M™ Harvest RC Chromatographic Clarifer, and processed the AAV-containing fluids through AAVX affinity chromatography. We employed qPCR for residual host cell DNA/plasmid DNA quantification and droplet digital PCR (ddPCR) to profile residual host cell DNA size distribution after each unit operation. Additionally, ELISA (Enzyme-Linked Immunosorbent Assay), ddPCR, Stunner, and SEC-MALS (Size-Exclusion Chromatography with Multi-Angle Light Scattering) were utilized to assess AAV quantity and quality at different steps in the purification process. This comprehensive analytical study throughout the entire bioprocess has helped us develop an understanding of the DNA impurity removal dynamics. The investigation also enabled us to pinpoint the key clarification step to simultaneously simplify the AAV purification process bioprocess and improve the purity of the resultant AAV.

1498. A Versatile Suspension-Based Platform for the Manufacturing of AAVs

Ahmed Youssef, Melanie Langhauser, Andreas Schulze, Alexandra Schoberth, Florian Sonntag, Markus Hoerer, Karl Heller
Ascend, Planegg-Martinsried, Germany

Recombinant adeno-associated virus (**rAAV**) is among the most widely used viral vectors for gene therapy. However, **vector manufacturing** remains a challenge as the demand for high quality AAV vectors is far greater than the available capacity, hence manufacturers tend to scale up the process which impacts the costs as well as the quality of the AAV produced. Additionally, manufacturing processes vary from one AAV serotype to another and show dependency on vector length and molecular configuration, increasing the time for process development, scale-up and having AAV ready for clinical supply. We have invested in developing a **robust modular suspension platform** process that minimizes batch variability and builds quality into the product by design. Using high-throughput scale-down models this process decreases complexity, increases the flexibility for scale-up, and thereby decreases the cost of goods (COGs). Our platform is an **end-to-end process solution**, composed of multiple unit operations that are differentiated from the industry. This process platform was optimized for vector yield and potency at best possible quality, to align with the stringent, continuously evolving regulatory constraints, while allowing for flexibility and adaptability to specific customer program needs. We present here **yield and product-related impurity data** for the most frequently clinically applied AAV serotypes at different bioreactors scales using our proprietary split two plasmid platform. We are continuously expanding our data to show universal applicability of our modular platform over a wide range of AAV serotypes. The modularity of our platform and our continuous investment in understanding process dependencies that require specific solutions, offers the necessary flexibility to quickly adapt the manufacturing process to specific product needs. This streamlines overall process development and scale-up and reduces overall development costs. We continue to **innovate AAV gene therapy** with a major focus on CMC to support the field in making AAV gene therapy accessible to patients suffering from more common diseases with higher risk benefit profiles and accordingly high regulatory bars. Our commitment is to develop the safest possible products for our clients and their patients.

1499. Characterization of Recombinant Adeno-Associated Virus 2 rAAV2 Capsid Content Variation for Enhanced Gene Therapy Efficacy

Michael J. Born
Process Analytical Development-Viral Vectors, MilliporeSigma - Carlsbad, Carlsbad, CA

rAAV have revolutionized the field of gene therapy, exhibiting immense potential in treating a diverse range of diseases. Understanding and characterizing the AAV capsid content variation is crucial for optimizing their efficacy. Here, we will present AAV2 capsid characterization data from upstream and downstream vector processing. Our study aims to comprehensively characterize the critical quality attributes of AAV2, including empty/full ratios, partially filled capsids, and various biophysical properties. By leveraging advanced analytical techniques, we elucidate the impact of these factors on the process performance of AAV2 in gene therapy applications. The investigation of AAV2 capsid content variation is vital for unraveling the complexities associated with vector production and optimizing therapeutic outcomes. The findings presented shed light on important considerations for the design and development of AAV-based gene therapies.

1500. Advancing AAV Bioprocessing: Cost-Effective Clarification with a Charge-Based Chromatographic Clarifier

Morgan Ludwicki, Qiuge Zhang, Jacob Calhoun, Mauhamad Baarine, Matthew Peters, Joris Van de Velde
3M Healthcare, St. Paul, MN

AAV (Adeno-Associated Virus) bioprocessing poses a unique challenge in that the cells often must be lysed in order to extract and harvest the AAV particles from the host cell culture. The lysis of the cells concurrently releases host cell DNA which must then be removed during the purification process. Typically, expensive nucleases are deployed to degrade the host cell DNA prior to clarification. Our solution addresses this challenge by employing the charge-based 3M™ Harvest RC Chromatographic Clarifier to remove host cell DNA and substantially reduce the amount of nuclease utilized in the purification process. Through experiments with varied nuclease concentrations during lysis, we demonstrate that Harvest RC can effectively remove

host cell DNA while achieving high AAV recovery yield and substantial turbidity reduction. A case study further demonstrated the seamless processing of clarified fluid on AAVX affinity chromatography, achieving equivalent AAV quality and purity. The Harvest RC-based clarification process has been effective with multiple serotypes, is scalable across device sizes, and is compatible with upstream and downstream unit operations. This versatility positions Harvest RC as an adoptable solution for AAV bioprocessing, streamlining the workflow by enabling high AAV quality and reduced costs.

1501. AAV Vectors Produced by the AAVone Single-Plasmid AAV Production System Show Low Levels of rcAAV

Rongze Yang[1], Zhen Shi[1], Yu Liu[1], Yuyan Wang[1], Yuling Dai[1], Leming Wang[1], Cuiping Chen[1], Haniya Zaidi[1], Jiarui Liang[1], Ngoc Tam Tran[2,3], Daozhan Yu[1], Phillip WL Tai[2,3], Qizhao Wang[1]

[1]AAVnerGene Inc., Rockville, MD,[2]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[3]Department of Microbiology and Physiological Systems, UMass Chan Medical School, Worcester, MA

We previously reported the development of an all-in-one, single-plasmid AAV production system, namely AAVone, in which the Ad helper genes (*E2A*, *E4orf6*, and *VA RNA*), AAV helper genes (*rep* and *cap*), and the AAV vector genome are consolidated into a single compact plasmid (pAAVone). This design has a 13-kb 'backbone' (*i.e.*, obligate plasmid sequences not packaged into vectors), which is significantly larger than AAV's packaging capacity. In this system, an AAV vector can be efficiently generated by simply transfecting the corresponding pAAVone plasmid into host cells. The system shows a two- to four-fold increase in AAV productivity, compared to traditional triple-plasmid transfection production system for the same transgene. One major concern for the AAVone system is the potential for generating replication-competent (rc) AAV, since *rep*, *cap*, and the inverted terminal repeat (ITR) sequences are present in the same plasmid. To test the rate of rcAAV in AAVone system, we employed three different methods: (1) Using qPCR primers targeting both ITR and *rep*, comparable levels of ITR-*rep* hybrids, which represent a potential for rcAAV contamination, were observed at relatively low percentages, in both the AAVone and triple plasmid systems. (2) For a comprehensive analysis of recombination events, we employed single molecule, real-time (SMRT) sequencing to examine AAV-like genomes. The analysis revealed that the probability of ITR-rep-cap triple-chimeras was 0.046% (90 out of 196,753) in the AAVone system and 0.021% (27 out of 131,989) in the triple-plasmid system, and none of these sequences exhibited an intact wtAAV-like, typical rcAAV structure (ITR-rep-cap-ITR). (3) Moreover, a cell-based assay(Conducted by WiXi Apptec) indicated that rcAAV level from the AAVone-produced vector negative at 10^9 vector genome level. These results indicate that the AAVone system can effectively produce AAV vectors with low risk of rcAAV. AAVone represents a revolutionary AAV production system to make AAV gene therapy more accessible and affordable.

1502. Scalable, High-Titer Production of Clinical Grade Adeno Associated Virus in the Gibco™ CTS™ AAV-MAX Helper-Free AAV Production System

Chao Yan Liu[1], Kenneth W. Thompson[1], Paula Decaria[2], Kyle Williston[1], Collin Rasmussen[1], Mariah Weinkauf[1], Natalie Miller[1], Emily Jackson-Holmes[3], Jonathan Zmuda[1]

[1]Thermo Fisher Scientific, Frederick, MD,[2]Thermo Fisher Scientific, Logan, UT,[3]Thermo Fisher Scientific, Carlsbad, CA

Production of high-titer AAV at clinical scales remains a significant challenge for the gene therapy industry. Developers need to understand how to optimize, scale, and qualify their manufacturing process for AAV production under the tightest of timelines. Due to high demand in the gene therapy space, effective solutions to address these challenges must be developed and implemented. Until recently, AAV production took place primarily in adherent cultures using 293T cells in the presence of fetal bovine serum; however, such adherent systems suffer from a number of significant drawbacks including difficulty in scaling up, the presence of the SV40 large T antigen in the producer cell line as well as cost, consistency and regulatory considerations stemming from the use of animal sera. To address these shortcomings, we developed the Gibco™ CTS™ AAV-MAX Helper-Free AAV Production System, a chemically defined, suspension based AAV production system that allows for scalable, high titer production of AAV viral vectors in a non-293T cell lineage. The AAV-MAX system comprises all of the components required for scalable AAV production in mammalian cells including: (1) a clonally-documented, high-titer 293F-derived producer cell line (VPC2.0), (2) a chemically defined growth and expression medium, (3) a production enhancer, (4) a cationic lipid-based transfection reagent and booster, (5) a protein-free complexation buffer, and (6) a Polysorbate 20-based lysis buffer. The AAV-MAX system delivers AAV titers at ≥5x10^{10} viral genomes per mL (vg/mL) across multiple AAV serotypes with excellent scalability from multi-well plates to stirred tank bioreactors making the AAV-MAX system an ideal production platform for generating clinical grade AAV. Here, we provide characteristics around the key components of the system to assist in the development of robust AAV production processes from bench to clinical/commercial scales.

1503. Evaluation of Media Additive for Enhancing rAAV Productivity in Triple Transfection Platforms

Harini Dhamodaran Sampath, Misha Chittoda, Swetha Kannan Iyer, Lisa Stukenborg, Shawn Bourque, Aditya Utturkar, Samantha Desmarais, Neil Shah, Pete Clarner, Junghae Suh, Davide Gianni

Gene Therapy Accelerator Unit, Biogen, Cambridge, MA

Over the last decade, there has been significant and progressive growth in the number of AAV (Adeno Associated Virus) gene therapy programs moving into clinical trials, supported by the recent approval of multiple rAAV-based gene therapies. This translated into an increased demand for clinical and commercial grade rAAV vectors, thus exposing weaknesses and limitations of the current rAAV

manufacturing paradigms. Hence, extensive interest has been focused on the refinement of existing processes to improve the capability to generate high-quality material in a scalable fashion while abating manufacturing costs. The use of media additives has been historically adopted in biologics production processes as a key approach to address this problem. Here, we demonstrate that supplementation of compound X in the production medium at the pre-transfection phase can increase rAAV productivity in adherent triple-transfected human embryonic kidney (HEK293T) cells up to six-fold. The media additive was assessed at different concentrations showing a dose-response effect. Genome titer improvement was confirmed to be scalable across two different scales (T150 flask and CellSTACK®-10 chamber) as well as transgene-independent. Critical quality attributes such as potency and viral genome integrity are currently being assessed. Furthermore, the optimal time for addition, and identification of the molecular target(s) associated with the observed effects, will be investigated. These findings confirm the value of chemical additives to overcome some of the challenges associated with rAAV manufacturing and highlight the impact of an improved understanding of the cellular pathways regulating rAAV production on the development of focused screening of new compounds.

1504. Novel Dual-Plasmid System: Next-Generation AAV Production Strategy with High Productivity and High Quality

Weixiao Huang[1], Danqing Xiao[1], Longxiang Sheng[1], Xueer Yao[1], Ye Bu[1], Paul Li[2], Liying Yang[1], Xin Swanson[1]

[1]PackGene Biotech INC, Houston, TX,[2]PackGene Biotech, Houston, TX

The traditional triple-plasmid transfection system has been widely employed in industrial AAV manufacture due to its stable scalability and flexibility. Approximately two decades ago, a dual-plasmid system, consolidating RepCap and adenovirus helper genes into a single plasmid, was developed to reduce the cost of GMP-level plasmid manufacture and simplify the process. However, challenges such as relatively low productivity, quality issues, and the risk of replication-competent AAV (rcAAV) persist in the dual-plasmid system. In this report, we present a novel dual-plasmid system featuring a uniquely designed TP vector with optimized sequences and arrangement of vector elements. Our findings indicate that this novel system demonstrates higher AAV productivity and quality compared to the traditional triple-plasmid system, with minimal risk of rcAAV contamination. For process development, we screened seven different transfection reagents and identified a low-cost option suitable for high-titer production in the dual-plasmid system. Transfection process parameters have also been optimized to enhance productivity and reduce process-related impurities. To assess scalability, we tested the system with various therapeutic Gene of Interest (GOI) plasmids on both Ambr 250 bioreactor and 3L stirred bioreactor, demonstrating either equal or higher yields and lower process-related impurities for the dual-plasmid system. In conclusion, we have developed a next-generation dual-plasmid AAV production system that establishes a new manufacturing process platform with high productivity, quality, and cost-effectiveness.

1505. A Genome-Wide High-Throughput Gain-of-Function Screen Identifies Novel Targets for Improved AAV9 Production

Chad Wang[1], Muskan Sheth[1], Francesca Ispaso[1], Isha Ukani[1], Markus Horer[2], Mo Mandegar[1], Chris A. Reid[1]

[1]Ascend Gene and Cell Therapies, Alameda, CA,[2]Ascend Gene and Cell Therapies, Planegg, Germany

Recombinant AAV, a widely used vector for in vivo gene delivery, is being utilized in ongoing pre-clinical and clinical programs. Current manufacturing inefficiencies lead to high costs, poor yields and compromised quality in gene therapy products. The high costs restrict broader application, while quality issues affect the vector's potency, immunogenicity and overall safety, necessitating higher dosages and increasing the risk of severe adverse events following dosing. Our study utilized the ATLAS (Arrayed Targeted Library for AAV Screening) miniaturized screening platform to systematically over-express approximately 18,000 ORFs, aiming to enhance AAV9 production. Our screen identified transcription factors, epigenetic regulators, DNA replication factors, RNA regulators, protein ubiquitination, and metabolic targets as primary enhancers of AAV9 production. Confirmatory studies indicated a dose-dependent increase in AAV9 production, up to 3-fold from baseline. Moreover, we confirmed that these factors do not negatively impact the potency of AAV. Next, we confirmed these findings in other AAV serotypes including AAV2, 5, and 8. Further work is in progress to identify lead hits which next will be validated in our current manufacturing platform at Ambr15 scale towards yield, potency and key quality parameters focusing on product-related impurities.

1506. High-Throughput Purification Suite Enabling Quality Determination in AAV Bioreactor Development

Matthew G. Petroff[1], Lavoisier Ramos-Espiritu[2], Mi Jin[3], Jonathan Palmer[1], Conor Leahy[1]

[1]Technology Development, Spark Therapeutics, Philadelphia, PA,[2]Technology Development, Spark Therapeutics, Monroe Township, NJ,[3]Spark Therapeutics, Philadelphia, PA

The upstream (USP) production of AAVs generates multiple product variants, such as fragments, empty capsids, or capsids with incorrect transgene. Purification is typically required prior to assessing these variants in a cell culture, bottlenecking optimization of quality in bioreactor processes. We describe a high-throughput (HT) workflow to enable quality assessments of bioreactor cultures. The workflow combines automated miniature chromatography to support affinity purification of small-scale cultures, and a HT testing strategy to facilitate rapid turnaround of key product attributes, including empty and partial concentrations and viral protein ratio. In the first case study, this workflow enabled the understanding of product quality from the triple-transfection industry standard. The HT affinity product was subsequently purified through HT polishing chromatography, revealing key bioreactor parameters that led to product variants not removed by the platform downstream process. In a second case study, the workflow supports understanding quality during development of

cell culture process intensification. Overall these tools enable improved understanding of upstream processes for improved drug substance quality and manufacturing robustness.

1507. Preparation and Administration of Low Dose AAV Drug Products via Systemic, CNS and Ophthalmic Delivery Routes: Complexities and Solutions

Smrithi Padmakumar, Leslie Lam, Andrew Jones, Mi Jin
Drug Product Development, Spark Therapeutics, Philadelphia, PA

Ensuring patient safety and efficacy during preparation and administration of low dose AAV drug products can be significantly challenging due to concerns such as adsorption losses, impact on Critical Quality Attributes, particle leaching, microbial contamination etc. The complexity of available specialized administration devices (used particularly for CNS and ocular delivery), filters, infusion components and closed system transfer devices (CSTD) with multiple contact parts and large surface areas may exacerbate the problem. Probable risks include loss in titer and potency imparted by AAV adsorption to product contact surfaces, as well as sub-visible particle (SVP) formation compromising the vector quality. In addition, complex surgical procedures may require extended hold or operation time bringing risks to both product stability and patient safety. This also emphasizes the requirement to develop stable formulations particularly compatible with the intended route of administration and simpler approaches to make the administration process error free and less complex. Herein, we present a few examples from case studies for IV, CNS and ocular administration of low dose AAV drug products and the associated risk mitigation strategies.

1508. Development of Off-the-Shelf pRepCap and Customizable pGOI Plasmids for AAV Production

Ruigong Wang[1], Siddhartha Paul[1], Olga Nikiforova[1], N'Dea Wheeler[1], Johann Umali[1], Kavita Sapru[2], Bhargavi Kondragunta[1]
[1]Internal R&D and Product Development, Catalent Pharma Solutions, Baltimore, MD,[2]IPT - Process Development, Catalent Pharma Solutions, Baltimore, MD

Recombinant adeno-associated viral (AAV) vectors have emerged as one of the powerful tools in the field of human gene therapy, based on their excellent safety profile and ability to achieve long-term efficacy both in pre-clinical and clinical models. AAV-based gene transfer vector manufacturing usually involves transient co-transfection of human embryonic kidney (HEK) 293 cells with three vector plasmids. The quality and titer of AAV product has been correlated with improved vector design. Standardized plasmids could greatly speed-up AAV production platform development along with reducing the variability of these critical raw materials. At Catalent, we have now developed off-the-shelf (OTS) RepCap vectors, along with a novel customizable ITR (Inverted terminal repeat)-plasmid backbone to add to our repertoire of vectors. We recently developed multiple pRepCap plasmids for serotype such as AAV1, AAV3, AAV8, and AAVrh10, which are uniquely offered by Catalent as OTS plasmids. We designed these plasmids by assembly of IP-free elements to achieve maximum productivity, stability, and safety. The pRepCap plasmids offered at Catalent resulted in high vector genome titer, above 1E11 vg/mL by digital droplet PCR, along with low host cell DNA (hcDNA), ≤ 200ng normalized hcDNA per 1E13 vector genome, and percent full capsid between 50- 80 % by AUC (analytical ultra-centrifugation) following one-step affinity purification. These vectors have been integrated with Catalent's UpTempo^{SM}AAV Platform Process. We recently also developed a customizable pGOI plasmid, including customizable features for clients, such as enhancer, promoter, and regulatory elements, along with multiple cloning sites.We have evaluated our pGOI plasmids with GFP (Green Fluorescent Protein), and pGalacorin® gene sequences in conjunction with our proprietary clonal HEK-293 cell line. Each of these plasmids has been transformed into E. coli strains, and high producing clones with highest plasmid titer and quality were selected for generating Research Cell Banks (RCBs). Currently R&D grade plasmid and GMP plasmid are ready to be offered to clients to support clinical manufacturing of AAV gene therapy products.

1509. Process Development to Achieve a Novel, Scalable and Highly Cost-Effective Method of AAV Manufacturing Using Whole Plants as Bioreactors

Kevin Wong, Pranav Dinesh Mathur, Qingqing Xie, Terri Grider, Finley Burns, Katarina Dumar, Matthew Schafer, Jake Connors, Daniel Gibbs
Cirsium Biosciences, San Diego, CA

Introduction: Advancements in the development of plant expression vectors and glycoengineering have positioned plants as a superior option for biologic production. Manufacturing costs, scalability, and production capacity heavily influence product market availability, affordability, and profitability. Gene therapy manufacturing faces challenges in these aspects. Plant-based systems offer advantages in reducing the production cost of recombinant biologics and simplifying scale-up by bypassing the necessity for significant capital investments in sophisticated cell culture facilities and expensive culture media for biomass generation. Therefore, we have developed a novel AAV-manufacturing platform using transient gene expression in whole plants to produce high quality AAV vectors that are significantly cheaper and faster to manufacture. Methods: Plant expression plasmids containing each of the required components (Capsid, Rep, GOI and helper genes) for producing AAV were transformed into Agrobacterium bacteria. Cultures of these bacteria were used to infiltrate Nicotiana Benthamiana (N. Bentha) plants grown in an environmentally controlled grow room via hydroponics. We used vacuum infiltration to infiltrate the N. Bentha plants with the Agrobacterium containing the necessary plasmids, wherein the plant leaves are submerged into infiltration media and then subjected to a negative atmospheric pressure. Post infiltration, plants were grown for another ~1 week after which the leaves were homogenized to obtain the crude lysate. Post clarification, we concentrated the cleared lysate using Tangential Flow Filtration, purified by FPLC affinity chromatography and enriched for full capsids using Iodixanol gradient purification. We conducted several quality assays on the AAVs produced by this method. Results: Agrobaterium containing our recombinant plasmids were able to successfully infiltrate the N. Bentha plants and assemble

the AAV vectors in the leaf cells. We demonstrated yields of greater than 1e14 viral genomes from 1 kilogram of plant biomass, equating to roughly 10-15 plants. We employed identical downstream purification methods typically utilized for purifying AAVs from mammalian cell cultures and achieved comparable recovery percentages. Quality testing showed that purified AAVs had 90% full particles, contained significantly below the FDA recommended endotoxin, and were free of any bacteria, fungi or mycoplasma. Plant produced AAV was infectious to the cells in vitro and ex vivo and in vivo. Conclusion: We were able to successfully use transient expression methods in whole plants to produce high-quality and potent AAVs carrying the GFP gene. Using this AAV manufacturing method reduces the upstream cost of AAV production by over 10-fold. This method does not require excessive amounts of high-quality plasmids or scaling up of cell cultures and therefore drastically reduces the scale up time. The conventional mammalian-based system encounters reliability challenges during the scale-up process. Conversely, in the plant-based manufacturing method, individual plants function as modular and predictable bioreactors, rendering this approach highly scalable with exceptional reliability and speed, with potentially unlimited capacity. In summary, this innovative method of AAV manufacturing holds significant promise. This innovative approach holds promise for revolutionizing AAV manufacturing and enhancing global access to gene therapies.

1510. Vial Containment Systems for Gene Therapies

Margaret Craig, Page McAndrew

Scientific Communications, West Pharmaceutical Services, Inc., Exton, PA

Background Viral vector based gene therapies typically are stored and distributed at ultra-low temperature. There are several requirements of the vial containment system (i.e., vial, elastomer stopper, seal): - maintain container closure integrity (CCI) performance - present no adverse interaction with gene therapy - provide adequate recovery and functionality of vector Understanding performance against these requirements is essential for a manufacturer to decide if a vial containment system is suitable. The purpose of the present study was a multi-year characterization of the performance of vial containment systems comprising cyclic olefin polymer (COP) vials, bromobutyl elastomer stoppers with ethene tetrafluoroethene (ETFE) laminate film facing drug product] and aluminum seals. **Results** CCI performance (laser-based headspace analysis with both oxygen and carbon dioxide) evaluation was made of vial containment systems stored at -80°C for up to two years. Example data are shown in the Figure. No ingress of oxygen was observed over 1 year and only a small amount (5%) was observed over 2 years (likely through permeation of COP vial). There was no system breach. Potential interaction with drug product was evaluated in two ways. The first was by exposure of model proteins to COP vials, glass vials, and various stoppers under agitated conditions and measuring the levels of particles formed and protein loss - both indicators of unwanted interaction that may be extrapolated to virus capsids. Example data are shown in Table 1 - stoppers with ETFE gave enhanced performance as indicated by a lower level of particle formation and better protein recovery. Virus recovery and functionality were evaluated after storage at -80°C and thaw for selected adeno-associated viruses, adenoviruses, and lentiviruses. Example data for the adenovirus Ad5.F35-CMV-eGFP are shown in Table 2. The system comprising COP vials performed equivalent, within error limits, to the standard polypropylene screwcap vial system. **Conclusion** All factors considered (CCI performance, reducing risk of potential interaction, virus viability), vial containment systems comprising COP vials, bromobutyl elastomer stoppers with ETFE laminates, and aluminum seals, offer very good performance for the storage of virus-based gene therapies versus systems comprising glass or polypropylene. Table 1. Particle Formation and Protein Loss upon Exposure of Select Protein to Elastomer Stoppers with and without ETFE Laminate Film

Stopper	Particles per ml (1-10 µm) after 6 hrs agitation	Recovery at 24 hrs (%)
with ETFE	44	98
without ETFE	290	95

Table 2. Vitality of Select Adenovirus after Storage at -80°C in COP and Polypropylene Containment Systems

Ad5.F35-CMV-eGFP **14 days at -80°C**	**Recovery** (viral particles per ml)	**Functionality** (fluorescence absorption units)
COP System	2.3×10^{11}	4.3×10^{5}
Polypropylene System	2.6×10^{11}	4.3×10^{5}

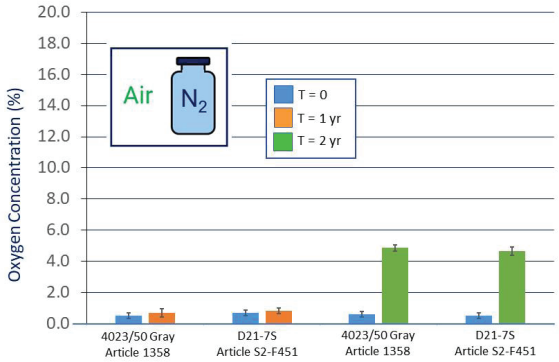

Figure. CCI Performance after Storage at -80°C for One and Two Years

1511. A High Throughput AAV Production Method Development to Support Preclinical Studies

Nannan Jia, Shiliang Hu, Yoni Bason, Nicholas J. DiGioia, Yinxing Chen, June Deng, Janvi Shah, Noel Walsh, William Lee, Lauren Drouin, Matthias Hebben, Jing Liao

Alexion Genomic Medicine, AstraZeneca Rare Disease, Lexington, MA

The cost of adeno-associated virus (AAVs) manufacturing remains a significant challenge in genomic medicine. Preclinical studies, including in vitro and animal studies, demand less total vector genome (vg) but higher throughput for testing multiple AAV vector candidates concurrently. Traditional production methods, encompassing both upstream and downstream purification, limit high throughput production. To address this, we developed mAAVRx, a novel 2-plasmid design that achieves high-yield, high-quality, and potent AAV vectors in scalable suspension HEK293 cells. This optimized upstream process enables high throughput production when combined with an efficient downstream purification. Traditional purification methods, such as

chromatography with CsCl ultracentrifuge, are time-consuming and pose constraints. To address this, we developed a high throughput purification method to enhance efficiency. Various purification methods were tested, and vector titer and recovery rates were measured. To validate potency, luciferase was used as a reporter gene, and vectors purified by different methods were transduced into Huh7 cells. The results indicated that vectors purified by traditional methods exhibited a wide signal range linearly related to dose, which signal range could represent by one of new developed high throughput purification method, while other methods showed a narrow range, reaching a signal plateau easily. To further validate in vivo, vectors with different full capsid percentages were used by spiking empty capsid into a full capsid vector prep, and the experimental results demonstrated similar readouts for 100%, 50%, and 20% full capsid vectors. In contrast, 5% full capsid showed about a 2-fold decrease of in-vivo potency. This suggests that plateau effects with empty capsids are more dramatic in vitro than in vivo. In summary, the high throughput purification method, combined with mAAVRx, streamlines vector production for preclinical studies. Vectors purified by the high throughput methods meet the needs of small-scale in-vivo studies, providing reliable data. However, challenges remain in removing empty capsids and addressing impurities for in vitro studies, necessitating further refinement.

1512. Development of an Assay to Perform High-Throughput Drug Screen in HEK293 Cells to Improve AAV Vector Production

Santosh Panthi, Alan Baer, Nirjal Bhattarai

Office of Therapeutic Products, US Food and Drug Administration, Silver Spring, MD

Adeno-associated vector (AAV)-based gene therapy holds great promise for treating a range of human diseases. Despite the significant potential of AAV vectors in gene therapy, challenges persist in producing high-quality vectors on a large scale. Therefore, innovative strategies are needed to improve the AAV vector manufacturing process. Currently, AAV vectors are commonly produced using HEK293 cells, but during production, the activation of various cellular responses has been observed. The impact of these cellular responses on vector production and quality remains unknown. To explore this, we sought to perform a high-throughput drug screen in HEK293 cells, utilizing commercially available drug libraries that target antiviral, inflammatory, cell signaling, and checkpoint pathways to identify restriction factors that affect AAV quality and yield. To perform such a drug screen, first, we needed a high-throughput screening assay. Here, we report the development of a high-throughput drug screen assay that can be employed to identify small molecule compounds to improve AAV vector production in HEK293 cells. This 96-well plate assay uses an AAV-luciferase vector in adherent HEK293 cells, and the assay is reproducible, robust, and exhibits a high signal-to-noise ratio. Current studies are underway to identify compounds that improve AAV production using this high-throughput assay. Once chemical compounds are identified and their cellular targets in HEK293 are validated, we aim to develop a novel HEK293 producer cell line with knockouts of inhibitory cellular factors using CRISPR/Cas9. This novel HEK293 producer cell line may help to improve AAV vector quality and yield during manufacture.

1513. Development of an Analytical Method for AAV Capsid Proteins for Use in Stability Studies

Aitor Navarro Nieto

Viralgen Vector Core, San Sebastian, Spain

Gene therapy based on adeno-associated virus (AAV) vectors is now a reality, with several products already approved by the FDA and EMA (HEMGENIX®, LUXTURNA®, ROCTAVIAN® ZOLGENSMA®,) and some more to come in the following years. In parallel to this evolution, the requirement for fast and reliable characterization of the Critical Quality Attributes (CQAs) to ensure AAV product quality is also increasing. Among those CQAs, the viral capsid proteins (VP) charge distribution is important for the tropism and potency of the different serotypes. The capsid protein's charge heterogeneity can account for possible post-translational modifications (PTM) that can happen during different steps of AAV vector manufacturing or storage; some of these modifications can hinder the development of gene therapy products. To monitor these modifications, we have developed a method based on imaged capillary isoelectric focusing (icIEF). Since different AAV products can require different formulation buffers which are not always compatible with icIEF analysis, we have developed a procedure that can be theoretically used with any product and then adjusted to obtain the best results in terms of reproducibility. It was previously shown that deamidation of amino acids on the surface of the AAV capsids correlates with charge heterogeneity modifications of the capsid proteins and can have an impact on vector potency. Using icIEF, we show here that the deamidation of AAV9 capsid proteins over time is correlated with the reduction of vector potency. We also checked if this reduced potency was correlated with capsid disassembly. We believe such a method could be beneficial for the development of improved formulation buffers.

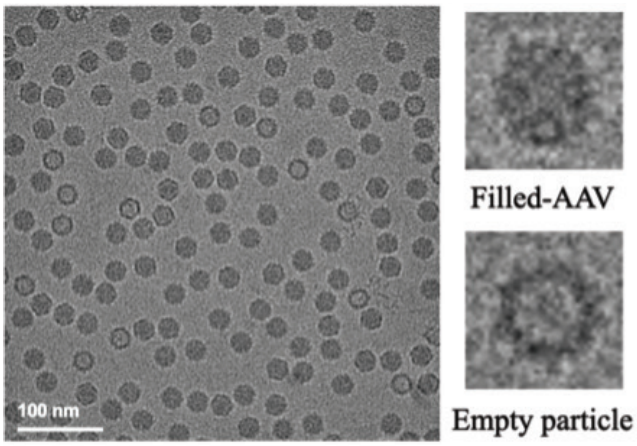
1514. Addressing Downstream Purification Challenges: Solving AAV2 Aggregation Issue and Developing Innovative Approaches for Empty Capsid Removal

Ting Yang[1], Jeffrey Kan[1], Chinmay Patkar[2], Gina Zhang[2], Yiling Fang[2], Robert Lu[3]

[1]Process Development, Frontera Therapeutics, Bedford, MA,[2]Analytical Development, Frontera Therapeutics, Bedford, MA,[3]Technical Operation, Frontera Therapeutics, Bedford, MA

Two distinct case studies are highlighted in this presentation. The first delves into the challenges posed by the propensity of AAV2 capsid to aggregate, particularly under low ionic strength buffer conditions. These aggregation issues have significantly complicated downstream purification process development. The narrative unfolds with the successful resolution of aggregation. Additionally, insights are shared on addressing aggregation occurring during the final UFDF formulation step.The second case study explores an innovative method targeting empty capsid removal, Frontera's purification platform showcases its effectiveness in reducing empty capsids to less than 1% in the final drug substance. This breakthrough underscores the platform's capability in enhancing the purity of the drug substance and mitigating potential immunogenicity concerns.

1515. Forced Degradation Study on the AAV Empty Capsid



Alesha Arshad[1], Jack Eifert[1], Alexander Yarawsky[1], Dana Holzinger[2], Lisa Mutz[2], Lake Paul[1], Angela Mohs[1]
[1]BioAnalysis LLC, Philadelphia, PA,[2]PROGEN, Heidelberg, Germany

Recombinant adeno-associated viruses (AAVs) have become widely used in gene therapies. The AAV viral vector consists of a protein capsid packaging the single-stranded DNA encoding for the gene of interest. To date, over 13 different naturally occurring serotypes have been discovered which have tropism for different tissues. All serotypes consist of a total of 60 molecules of a mixture of three viral proteins VP1, VP2 and VP3 in the estimated ratio of 1:1:10. Stress studies play an important role in identifying potential degradation pathways which might affect the AAV transduction efficiency. Little is currently known about the degradation pathway of different AAV serotypes. In this study we focus on two serotypes, AAV8 and AAV9, that are commonly used in the development of gene therapy products. A forced degradation study is performed which compares the effect of oxidative stress, low pH, high pH, and freeze-thaw stress on the empty AAV protein capsid. Size exclusion chromatography, dynamic light scattering, sedimentation velocity analytical ultracentrifugation and mass spectroscopy are used to identify the degradation mechanism for the two serotypes.

1516. Development of Image Analysis Methods to Characterize the Wider Adeno-Associated Viral Products Using 100-keV Cryo-Electron Microscopy

Haruka Nishiumi[1], Kiichi Hirohata[1], Mitsuko Fukuhara[1,2], Aoba Matsushita[1], Yasuo Tsunaka[1], Mark Allen Vergara Rocafort[1], Takahiro Maruno[1], Tetsuo Torisu[1], Susumu Uchiyama[1,2]
[1]Department of Biotechnology, Osaka University, Suita, Osaka, Japan,[2]U-Medico Inc., Suita, Osaka, Japan

Adeno-associated viral (AAV) vectors have been the leading platform for gene delivery, especially for *in vivo* gene therapy. AAV-related drugs are safer and more effective than other virus-mediated drugs owing to the non-pathogenicity and specific tropism of AAVs. Meanwhile, one of the significant challenges regarding the AAV vector is the excessive production of empty particles (EPs). EP is a gene-lacking AAV capsid and is generated at the same time as fully genome-containing AAV particles (FPs) during manufacturing. EPs can inevitably be contained in AAV products, potentially leading to reduced transduction efficiency and increased immunogenicity. Therefore, removing EPs and determining the FP to EP ratio (F/E ratio) of AAV products are recommended. To date, several methods to evaluate the F/E ratio and eliminate the EPs in AAV products have been proposed such as analytical ultra-centrifugation (AUC). These methods achieved the high resolution to separate the FPs and EPs; however, most approaches have still challenges in evaluating the exiguous EPs contained in highly purified AAV products. Hence, in this study, we developed image analysis methods to extend the range of F/E ratios using cryo-electron microscopy (cryo-EM). Cryo-EM can visualize the FPs and EPs while showing different morphology that reflects the encapsulated genome owing to their different electron densities inside the capsid; therefore, FPs and EPs can be discriminated through image analysis. Using our developed image analysis methods, we successfully calculated the F/E ratios of various AAV products while showing excellent correlation with theoretical F/E ratios determined using band sedimentation AUC. Subsequently, we assessed the performance of our image analysis methods in evaluating the F/E ratio of highly purified AAV products (purity > 95%). As a result, our methods provided the F/E ratios of highly purified AAV products containing less than 10% of EPs. Furthermore, we demonstrated that our methods revealed the differences in the F/E ratios arising from the different numbers of density gradient ultracentrifugation implementations. These results indicate that our image analysis methods can support the robust characterization of AAV products containing a wide population of EPs with high accuracy, leading to potential improvement of the safety of AAV medication in clinical trials.

1517. Identification of an AAV Affinity Chromatography Elution Buffer That Maximizes Product Recovery and Minimizes Product Degradation

Sierra VanSuch, Ryan DeGroot, Ashley Sacramo, Benjamin Wright
Process Development, Solid Biosciences, Boston, MA

Recombinant adeno-associated virus (rAAV) continues to be a promising vector for delivery of gene therapies due to its proven success in clinical trials and high potential for treatment of diseases with unmet medical needs. To meet the clinical and commercial demands while ensuring an effective product, manufacturing sufficient rAAV quantities while maintaining superior product quality is of paramount importance. Chromatography-based purification methods using AAV Affinity resin are commonly used during manufacture of rAAV due to their ability to effectively remove process and product-related impurities. However, to efficiently elute rAAV vector from these resins at acceptable recoveries, harsh buffer conditions, such as low pH, are typically employed that often result in a rapid negative impact to product quality, such as increased product aggregation or decreased product activity. Here, we discuss development work that was performed on an rAAV Affinity chromatography step that identified modifications to the elution buffer pH, elution buffer components,

and eluate collection method/neutralization that resulted in a two-fold improvement in product recovery, reduced impact to product, and improved manufacturability.

1518. A High Quality *Minicircle* Production Scale-Up Success Story: AEX-HPLC In-Process Controls to Guide Upstream Process Modification

Ram Shankar, Nina Schäffer, Christa Krüsemann, Marco Schmeer, Martin Schleef

PlasmidFactory GmbH, Bielefeld, Germany

Minicircles enhance the quality of AAV vectors in the context of the packaged genomes thanks to the elimination of false encapsidation of plasmid backbone sequences. *Minicircle* DNA production starts with the propagation of a parental plasmid (PP) molecule within a bacterial host strain. At the end of the cultivation phase, an *in vivo* recombination is triggered that allows the *minicircle* (MC) region containing the Gene of Interest (GOI) to be separated as an independent supercoiled construct. The resulting mix of DNA molecules is called a recombination product (RP) which is taken through further proprietary purification stages to obtain the pure MC free of side products such as miniplasmid (MP) which contains the plasmid backbone. Capillary Gel Electrophoresis (CGE) is a routine analytical tool to characterise the final purified MC product. Although CGE can be used to analyse RP, its applicability as an in-process control is limited to cases where the MC and MP have different sizes. When MC and MP are of similar sizes, one had to rely on agarose gel electrophoresis for the differentiation between the two molecules, wherein again a meaningful quantification based on band intensity is not possible. We employed Anion Exchange High Performance Liquid Chromatography as a second method to analyse one-step purified RP samples from our upstream department. AEX-HPLC could beautifully complement the data from CGE and was able to resolve the MP and MC of sizes 4.6 kb and 4.5 kb. Measuring the MC content in fermentation samples gave us unprecedented insight into RP composition and allowed us to adjust the upstream process with the aim of maximising DNA yield per batch. Interestingly, we found that parameters such as induction timepoint and specific growth rate at induction notwithstanding, the proportion of MC in the RP was quite stable whereas the levels of PP and MP balanced each other out. Since only the total amount of these two contaminating molecules mattered in the downstream purification and not the individual amounts, variations in these two molecules could be followed without any consequence. The CGE data for proportion of PP correlated over the entirety of the production project with that from the HPLC data. The final purified MC DNA amount matched with the prediction from in-process controls (27% of RP). We achieved an overall scale up of MC production in *High Quality* grade of over 30X. To allow for possible losses in amount during purification, a large amount of starting material as RP was produced as a safety net. Nevertheless, the final MC product overshot the required amount by 3X. Scaling up MC production is required to cover the increasing demands of starting material for large scale AAV vector production while ensuring vector safety and quality according to regulatory guidelines. On the other hand, large scale production of *minicircles* in *High Quality* grade is also attractive for non-viral vector applications which are making a big comeback.

1519. Matrix Approach for Potency Assay Development of Cell and Gene Therapy Products - A Case Study for Adeno-Associated Virus (AAV) Vectors

Karen Doucette, Sascha Karassek, Marina Alber, Ulrike Herbrand

Biologics Testing, Charles River Laboratories, Erkrath, Germany

Objective: Develop a phase-appropriate potency assay matrix for an AAV gene therapy product. Introduction: Potency assays for cell and gene therapy (CGT) products are more complex than other molecules since these products have several mechanisms of action (MoA), higher variability in the manufacturing process, and limited material for testing. The MoA of an AAV gene therapy product includes a multi-step process of infection, transcription, translation, and function. This complexity presents a challenge to developers to identify a single in vitro assay that reliably and accurately measures potency which is also correlated to in vivo activity. Authorities therefore recommend a matrixed approach for potency assay development for CGT products. This case study illustrates a phase-appropriate potency assay matrix approach reflecting the complex MoA of an AAV gene therapy product. Description: Three separate analytical methods were developed to reflect the MoA of an AAV product: RNA expression of exogenous transgene by RT-qPCR, protein expression by flow cytometry, and activity by functional reporter gene assay. Data is presented from two AAV serotypes and targets. Each method involved transduction of AAV reference material in HEK293T cells to demonstrate dose response over a range of MOI and stability indicating properties when exposed to varying stressed conditions. For functional activity, a test and reference material were evaluated in parallel in a cell-based reporter gene assay for determination of relative potency. Luminescence, as measure of dose dependent activation of that reporter system, was quantified with a plate reader, and the data was plotted and analyzed with a four-parameter logistic fit using PLA 3.0. Conclusions: All developed cell-based assays were specific for the intended AAV product and demonstrated stability indicating properties. These methods can serve as building blocks to develop a potency assay matrix for AAV products with varying capsid serotypes and therapeutic transgenes. It is important to plan sufficient time for thorough assay development and understanding of the capabilities and limitations of each method. Optimal conditions might vary from lot to lot, even with a well-controlled production process; therefore, system suitability criteria need to be set thoughtfully after thorough product characterization. Meetings and contact with regulatory authorities is important to support long term strategic planning for the potency assay matrix approach.

1520. Streamlined Process for Large Scale cGMP Plasmids Manufacturing at Low-Cost Utilizing Continuous Flow Alkaline Lysis, Depth Filters for Clarification, and Two-Step Chromatography

Yujun Wang[1], Xianxiao Chen[1], Guoqiang Li[1], Yanping Yan[2], Hua Zhang[1], Ming Zhong[1], Xiulian Sun[1]

[1]uBriGene Biosciences International Co., Suzhou, China,[2]uBriGene Biosciences International Co., Jinan, China

High-quality plasmids are critical starting materials for packaging viral vectors for gene therapy (e.g. Lentiviruses and rAAVs) using the multiple transient transfection method. Linearized plasmids also serve as templates for *in-vitro* transcription of RNA vaccines and drugs. CGMP-compliant production of large quantities of plasmids at a low cost has emerged as a major demand within the CGT industry. As a one-stop CDMO service provider in the GCT industry, here we present a streamlined process for plasmids manufacturing. It features optimized induction strategies to boost plasmid amplification in *E. coli* culture to as high as 0.5 grams per liter. Bacterial cells are harvested by concentration and exchanged into a resuspension buffer with tangential flow filtration (TFF). Alkaline lysis is carried out via an enclosed contentious flow system, comprising single-use tubing and a mix with no requirement for complex and pricey equipment. Divalent salts are added to the neutralization stage of cell lysis to promote precipitation and removal of host cell RNAs. Clarification of lysis is achieved by depth filtration, which compared to centrifugation is fully enclosed and more scaling-friendly. Anion exchange chromatography (AEX) and hydrophobic interaction chromatography (HIC) are used respectively to capture plasmid from clarified lysis and to enrich supercoiled plasmid species. Notably, AEX with membraneous matrix is utilized, so a higher flow rate can be supported compared to traditional columns packed with resins. Because of this high flow rate of loading, pre-chromatographic TFF concentration can be omitted to save material cost and operation time. The downstream recovery rate has been proven to be stable between 40% to 50% and typical contamination levels are competitive in the industry. In summary, we have streamlined the process for cGMP manufacturing of plasmids at a scale as large as tens of grams at low cost for applications in viral and non-viral vector production.

1521. A Reliable and Robust Methodology for AAV Genome Quantification Using Droplet Digital PCR

Jennifer Srnak, Yicheng Zhao, Andrew Charles Hedman, Shou Liu, Hung Do, Lin Liu

M6P Therapeutics, St. Louis, MO

Adeno-associated virus (AAV) serves as a prevalent gene therapy vector, yet inconsistencies exist in determining its viral concentration within the field. Labs employ an array of techniques—like qPCR, silver stains, and ELISA—to assess correctly packaged viral particles. The need to identify and develop a dependable and standardized method to measure complete viral genome packaging is at the forefront for advancing the field. Drawing from available literature, we conducted a comprehensive survey of existing standard operating procedures for viral genome packaging using the droplet digital PCR (ddPCR), uncovering discrepancies in previously established methodologies. Notably, gene of interest measurements often deviated from adjacent sequence measurements such as promoters or inverted terminal repeats (ITRs). This problem might stem from two potential sources: either the viral genome was truncated, or the protocol required further optimization. Through modification of multiple protocol parameters—such as DNase I digestion, capsid lysis methods, dilution schemes, and restriction enzyme digestion—we carefully refined our approach to improve reliability and consistency. During this progress, a crucial aspect was rectified: the ratio between the ITRs and other genomic components (the gene of interest and regulatory sequence elements) began aligning at the anticipated 2:1 ratio. This alignment correlated with a fully packaged AAV genome, underscoring the unique single-stranded genome structure of AAV with ITRs at both ends that is crucial for stability and packaging efficiency. In addition, our adjustments yielded more highly reproducible results and aligned more closely with measurements from capsid-specific assays such as silver stains. Here, we describe this reliable and robust methodology for AAV genome quantification using the ddPCR system and AAVs produced from a variety of vendors.

1522. Development of an Inducible AAV Rep and Cap Gene-Integrated Production Cell Line for Efficient AAV Manufacturing

Tianqi Jiang[1], Xiaojing Sheng[2], Yixiong Chen[2], Qing Lin[2]

[1]Dept. of Discovery, Lingyi Biotech Co., Ltd., Shanghai, China,[2]Lingyi Biotech Co., Ltd., Shanghai, China

The production of adeno-associated virus (AAV) predominantly utilizes transient triple-plasmid transfection in HEK293-based cells, a method underpinning five of the seven EMA/FDA-approved AAV gene therapy products due to its high product quality assurance. However, the substantial costs of transfection reagents and plasmid production, combined with the limited stability of the transfection complex and challenges in achieving efficient mixing in bioreactors, restrict the scalability of this method, particularly beyond 500-liter production volumes. These limitations highlight the urgent need for an advanced AAV production cell line that integrates all necessary components for efficient AAV production. Addressing this need, our study introduces a novel AAV production cell line, termed 293RSS1.0, through the integration of inducible expression cassettes for AAV Rep and Cap proteins, driven by proprietary inducible promoters and regulatory elements. This strategic integration facilitates the conditional expression of key viral proteins crucial for AAV packaging. The resulting cell line, 293RSS1.0, exhibits exceptional stability across over 20 passages, minimal leakage of Rep and Cap proteins, and a substantial increase in expression upon inducer addition. Significantly, the 293RSS1.0 cell line demonstrates versatility in AAV production, compatible with transient transfection using a Helper plasmid and an AAV gene of interest (GOI) plasmid alongside inducer supplementation. This adaptability positions the 293RSS1.0 cell line as a promising foundation for the development of a comprehensive, cost-effective, and scalable AAV production platform.

1523. An Integrated Process Characterization Approach to Enable Accelerated Commercialization Timeline of an Adeno-Associated Virus Based Treatment for Sanfilippo Syndrome

Jack Ren

Pharmaceutical Development, Ultragenyx Inc, Woburn, MA

Mucopolysaccharidosis type III (MPS III), also known as Sanfilippo syndrome, is a rare disorder that primarily affects the brain and spinal cord (central nervous system). To treat this syndrome, Ultragenyx

developed a recombinant adeno-associated virus (rAAV) based gene therapy product, named UX111, which is currently in its late-stage development. Process characterization (PC) and process performance qualification (PPQ) are essential life-cycle events for late-stage therapeutic product development and required BLA-enabling activities. Usually, the PC activities require a lengthy duration (year or even years) to acquire extensive experimental data to define the optimal process operation space. Here, we present an integrated risk-based PC approach to enable an accelerated pathway for biologics license application (BLA). Specifically, UX111 historical manufacturing data, UX111-specific PC data, and rAAV platform PC data are leveraged to generate the process and analytical control strategy (PACS) and to define PPQ ranges. The integrated PC approach not only provided a solid foundation to design a robust and reliable process, but also may enable the timely delivery of drug product to Sanfilippo syndrome patients in need.

1524. Early Planning and Regulatory Interactions to Facilitate the Development of an AAV Gene Therapy for PaVe-GT

Richa Madan Lomash[1], Jean Dehdashti[2], Oleg Shchelochkov[3], Randy J. Chandler[3], Lina Li[3], Irini Manoli[3], Pramod Terse[1], Xin Xu[1], Rodica Stan[1], Dimah N. Saade[4], Philip J. Brooks[2], Donald C. Lo[1], Carsten G. Bonnemann[4], Charles P. Venditti[3], Anne Pariser[2], Elizabeth Ottinger[1]

[1]Therapeutic Development Branch, NCATS/ NIH, Rockville, MD,[2]DRDRI, NCATS/ NIH, Bethesda, MD,[3]NHGRI/ NIH, Bethesda, MD,[4]NINDS/NIH, Bethesda, MD

Gene therapy development presents multiple challenges, and early planning is vital in the implementation and success of such programs. The Platform Vector Gene Therapy (PaVe-GT) program is an NIH initiative developing adeno-associated virus (AAV) gene therapies for four rare diseases of low prevalence: two organic acidemias and two congenital myasthenic syndromes. Utilizing the platform-based approach, the program aims to incorporate efficiencies throughout the pre-clinical and clinical development process and publicly disseminate scientific and regulatory learnings and experience. As we advance the development of these gene therapies, we share the value of establishing a Target Product Profile (TPP) early in the drug development lifecycle to better inform the development steps and guide the desired clinical outcomes for any investigational product. Paving the way for PaVe-GT's first gene therapy lead candidate, AAV9-hPCCA, we also sought early feedback from FDA in an INitial Targeted Engagement for Regulatory Advice on CBER ProducTs (INTERACT) meeting. The primary objective of this meeting was to receive preliminary FDA feedback on our AAV9-hPCCA proof-of-concept animal studies in supporting prospect of direct benefit (PDB) for the proposed patient population, and the manufacturing and desired critical quality attributes (CQAs) for the gene therapy product. Additionally, in planning for the target population, route of administration, and projected clinical dose, we sought FDA feedback on our proposed clinical trial design. The productive discussions and outcomes from the INTERACT meeting have been applied in the further development of AAV9-hPCCA. Of broader relevance to the field, the FDA tentatively agreed that we could leverage capsid related biodistribution data as we develop the next PaVe-GT AAV gene therapy products using the same capsid. Additionally, FDA requested that we take into consideration the route of administration and transgene expression in tissues positive for vector presence in the case of these subsequent products. This can eliminate the need for some of the duplicative animal experiments and create efficiencies in the process. Overall, early implementation of a regulatory strategy, by establishing a TPP, helps to align study objectives across multidisciplinary teams, with the goal of reducing drug development delays. Here, we detail the elements of a TPP and how its utilization can inform a preclinical development program. We also share the regulatory strategy of AAV9-hPCCA with a focus on INTERACT package preparation, and lessons learned from the meeting with the FDA. This communication aims to provide stakeholders resources that can be applied to rare disease drug development in establishing a viable regulatory path, to clinical trial initiation.

1525. Investigating Impact of Two Detergents on Affinity Chromatography in the Purification of Recombinant Adeno-Associated Virus

Hui Zhang, Lijun Wang

CoJourney Bio Ltd., Lower Gwynedd, PA

Efficient release of adeno-associated virus (AAV) from host cells is a pivotal stage in the purification process. Triton X-100, a commonly used nonionic surfactant and detergent for cell lysis, has traditionally shown satisfactory overall recovery in the purification of viral vectors. However, in response to regulatory changes, Triton X-100 has been banned by the European Union in 2021, and in 2024, the CDE has recommended alternative lysis reagents fit for purpose. This study presents a comparative analysis between Triton X-100 and Tween-20 as lysis agents, assessing their effectiveness in cell lysis, dynamic binding capacity (DBC), and yield during affinity chromatography. The results indicate that both agents exhibit similar efficiency in cell lysis, as determined by viral genome (vg) titer. Furthermore, the product quality after affinity chromatography remains comparable. Notably, Triton X-100 displays a non-specific binding interaction with the POROS CaptureSelect AAVX affinity resin, unlike Tween-20. This unique interaction hinders the resin's binding sites, resulting in a reduction of dynamic binding capacity and overall yield compared to Tween-20.

1526. Prequalification of Analytical Test Methods for Determining the Potency of an Adeno-Associated Virus-Based Gene Therapy Product

Amanda Bries, Lakmini Wasala, Adam Slechta, Vickie Dowling, Wayne Yount

Analytical Development, Kriya Therapeutics, Durham, NC

For recombinant AAV based gene therapy products, several analytical tools are required to fully characterize the potency of these complex therapeutics. Factors such as infectivity, empty/full capsid ratio, transgene expression efficiency and protein function should be considered when developing and establishing potency methods. Here we demonstrate a framework for evaluating potency-related method performance early in product development. A clinical candidate AAV vector was concentrated and then used to generate six different

vector genome (vg) concentrations spanning from above to below the specification range. Each test article was subjected to method performance parameters: range, linearity, accuracy, precision, and specificity. HEK293 cells were transduced by the vector at 3 different multiplicity of infection (MOI) targets. Efficiency of capsid uptake into the cell was analyzed by flow cytometry following product specific staining, whereas transgene expression was determined by quantifying protein expression. Each transduction plate contained a reference standard comparator and results were reported as the average relative potency across 3 MOI doses. The impact of varying ratios of empty capsids on AAV potency was also assessed. Linearity was detected across the range of vg concentrations (16-172% of nominal) when compared against the reference standard at 3 MOI doses. Accuracy was achieved for protein expression at both high and low vector doses (83% and 115%, respectively) when compared against the nominal target. Additionally, a high correlation ($R^2 = 0.9962$) between MOI dose and protein expression was observed in the transduced cells. Methods for both capsid infectivity and protein expression demonstrated specificity for the protein of interest, as well as precision at three different levels including repeatability, reproducibility, and intermediate precision. Notably, when evaluating the impact of empty capsids on potency, results indicated that a greater empty to full ratio attenuated protein expression when dosed at a constant vg/cell target. These data demonstrate that analytical potency methods can meet prequalification standards during early phase development. This work supports future method qualifications and long-term strategies for potency characterization.

1527. Lessons Learned in a Pre-IND Meeting for an AAV-Based Gene Therapy for a Rare Disease

Rodica Stan[1], Richa Madan Lomash[2], Oleg Shchelochkov[3], Irini Manoli[4], Jennifer L. Sloan[5], Randy J. Chandler[3], Venkata RM Mangalampalli[6], Pramod Terse[1], Jean Dehdashti[7], Xin Xu[1], Carsten G. Bonnemann[8], Charles P. Venditti[4], Philip J. Brooks[7], Elizabeth A. Ottinger[1]

[1]NIH/NCATS, Rockville, MD,[2]NCATS, Rockville, MD,[3]National Institutes of Health, Bethesda, MD,[4]NIH, Bethesda, MD,[5]National Human Genome Research Institute, Bethesda, MD,[6]NIH - National Center for Advancing Translational Science (NCATS), Rockville, MD,[7]NIH/NCATS, Bethesda, MD,[8]NINDS/NIH, Bethesda, MD

The Platform Vector Gene Therapy (PaVe-GT) program is an initiative started by a multi-disciplinary group of collaborators to develop adeno-associated virus (AAV) gene therapies for four rare diseases. Specifically, PaVe-GT seeks to increase the efficiency of clinical trial startup by using the same gene delivery system and manufacturing methods for multiple rare disease gene therapies. The regulatory pathway used for the development of the first PaVe-GT platform product can be applied to the next products, and moreover, the process efficiencies and regulatory lessons learned with one product will most likely reduce the time to Investigational New Drug (IND) submission for the remaining PaVe-GT products in development. Public dissemination of the regulatory lessons acquired overall with the platform may also benefit other sponsors in the development of AAV gene therapies for rare diseases. The first PaVe-GT investigational gene therapy product, AAV9-hPCCA, is being developed to treat propionic acidemia resulting from a deficiency of propionyl-CoA carboxylase, alpha subunit (PCCA). As part of a Type B pre-IND meeting with the Food and Drug Administration (FDA), the Agency reviewed our regulatory package and provided valuable feed-back for the proof-of-concept studies in a propionic acidemia mouse model, manufacturing process and analytical testing of AAV9-hPCCA, as well as pivotal efficacy study, GLP toxicology study, and clinical protocol synopsis. The FDA concurred with critical aspects of our manufacturing, pre-clinical and clinical development program and provided detailed recommendations for potency assay development, compatibility protocol design, and clinical trial cohort selection. This input will help us complete the IND-enabling studies and prepare the IND submission. In conclusion, early planning and regulatory interactions with the FDA can help design a better drug development plan and reduce failure mode. The knowledge gained by advancing PaVe-GT program's first product through pre-IND stage will be applied to the other investigational products under development and is being disseminated to the public to aid sponsors of other AAV gene therapy efforts for rare diseases. This research was supported in part by the Intramural research program of the NCATS, NIH.

1528. Forced Degradation of KRIYA-893 Vectors to Demonstrate Product Stability with Stability-Indicating Assays

Catherine Dial, Robert Damitz, Victoria Dowling, Wayne Yount

Kriya Therapeutics, Morrisville, NC

Full understanding of AAV vector degradation pathways and degradation products is limited, which poses a challenge for the development of investigational products. Because recombinant AAV products are comprised of protein and DNA, there are many possible degradation pathways that must be considered during vector development, manufacture, and storage. KRIYA-893 is an investigational gene therapy comprising two AAV1 vectors that contain expression cassettes for insulin and glucokinase for the treatment of type I diabetes. These AAV1 vectors have shown excellent stability at -80°C and after freeze-thaw cycling in the clinical formulation. Forced degradation studies were performed on KRIYA-893 vectors to understand what stresses cause instability and what analytical methods can be used to assess product stability. By comparing degradation profiles, differences in stability of the two component vectors were examined. To understand degradation pathways, the component vectors were subjected to physical and chemical stresses which represented extreme conditions that may be encountered during product manufacture, storage, and handling including: exposure to acidic (pH 2, 4), alkaline (pH 8, 10), thermal (40°C), photooxidative (~2000 lux), and chemical oxidative (1 - 30000 ppm H_2O_2) conditions for durations ranging from 4 hours to 14 days. Product attributes evaluated included appearance, vector genome titer (ddPCR), capsid titer (Gyros), capsid purity (CE-SDS), aggregation (SEC), capsid charge distribution (AEX), genome integrity (CE), and relative potency by protein expression (cell-based assay). These degradation conditions generally resulted in changes to one or more product attributes that were readily detected by the analytical methods used. Highly acidic

conditions for extended durations caused viral genome degradation detectable by CE and ddPCR and accompanying decreases in vector potency. Thermal stress caused a positive shift in capsid charge distribution and decreased potency. Highly alkaline conditions caused a negative shift in capsid charge distribution, but no impact to vector potency was observed. High concentrations of hydrogen peroxide resulted in an almost complete loss of potency at very short durations with no other detectable product attribute changes. Longer duration exposure to oxidants caused decreases in capsid and genome titer and chemical modifications to capsids. The same degradation pathways were observed for both vectors, however the magnitudes of soluble aggregates formed, genome and capsid titer decreases, and vector genome degradation differed between insulin and glucokinase vectors. Conditions encountered during AAV manufacturing and handling have the potential to cause product degradation. The changes identified in this study can inform limits for manufacturing and supply chain control strategies. While most of the degradation pathways identified were common for AAV1 component vectors, some results suggest there may be differences in stability of two vectors of a single serotype that arise from inherent differences, supporting that the vector genome can contribute some modes of instability. A broad analytical panel is needed to detect these product quality changes to ensure gene therapy products have optimal and consistent quality attributes important for product safety and efficacy.

1529. An Improved Affinity Chromatography Process for Adeno-Associated Virus, Serotype 6 (AAV6)

Laura E. Pickrell, Kelley Kearns, Thomas C. Scanlon
Repligen, Lebanon, NH

Improved methods for purifying recombinant adeno-associated virus (rAAV) vectors can greatly facilitate manufacturing scale-up, while reducing costs. The present work focuses on improving recovery of AAV6 capsids from the affinity capture step and demonstration of resin reuse using sodium hydroxide. Capsid recovery at pH 3 can be improved using AVIPure® AAV6 resin, compared to other affinity resins. High-throughput screening and optimization of elution conditions can also enable similarly high capsid recoveries at a softer pH elution condition to alleviate potential concerns regarding viral stability. The alkaline stability and process robustness using AVIPure AAV6 are demonstrated, along with the effects of elution pH, conductivity, salt type, and additives on overall yield and purity.

1530. Utilization of Tenaya's AAV Productivity Boosting Small Molecule (SMB) for Intelligent Design of HEK293 Cell Line to Improve AAV Productivity

Jackson Leong, Beatriz Lim, Farshad Farshidfar, Brooke Rathie, XiaoShan Ke, Joe Woods, Sushanthi Ramesh, Bill Prince, Frank Jing, Kee-Hong Kim
Tenaya Therapeutics, South San Francisco, CA

Adeno-associated virus (AAV) gene therapy is quickly becoming a safe and effective therapeutic modality for the delivery of potentially curative treatments for genetic diseases. One of the major challenges associated with AAV GT is to cost effectively produce AAV Drug Product (DP) with adequate levels of critical quality criteria (safety, identity, strength, purity, potency, and quality). Triple transient transfection using HEK293 process is widely used in both clinical and commercial scale manufacturing. The main limitation of HEK293 is scalability and viral productivity. Tenaya has developed a proprietary Small Molecule Booster (SMB) that can significantly improve AAV productivity in HEK293 transient transfection process using different HEK293 cell lines, processes, and cell culture medium for a wide range of AAV serotypes. Using RNA-Seq, Tenaya has identified multiple genes that are influenced by the addition of SMB. Using genome editing, Tenaya has generated multiple proprietary HEK293 cell lines with improved AAV productivity, demonstrating the unique advantage of HEK293 cell line engineering guided by small molecule booster vs. conventional genome-wide screening strategies.

1531. Development of a Scalable High Yield HEK293 Expression Platform for AAV Manufacturing

Charles Feathers[1], XiaoShan Ke[1], Brooke Rathie[1], Jackson Leong[2], Joseph Woods[1], Frank Jing[2], Bill Prince[1], Kee-Hong Kim[1]
[1]Tenaya, South San Franscisco, CA,[2]Tenaya Therapeutics, South San Francisco, CA

Adeno-associated virus (AAV) gene therapy is quickly becoming a safe and effective therapeutic modality for the delivery of potentially curative treatments for genetic diseases. One of the major challenges associated with AAV GT is to cost effectively produce AAV Drug Product (DP) with adequate levels of critical quality criteria (safety, identity, strength, purity, potency, and quality). Triple transient transfection using HEK293 process is widely used in both clinical and commercial scale manufacturing. The main limitation of HEK293 is scalability and viral productivity. A number of novel expression technologies have been developed in recent years to improve AAV productivity in HEK293 suspension system, but have yet to prove scalability beyond bench-scale. At Tenaya, we have developed a proprietary transfection-based HEK293 expression platform technologies resulting in a scalable process and significantly increase yields, with 7 to 10 times the upstream cell culture titer of conventional plasmid systems and 2 to 3 times yield of novel plasmid systems. Characterization of the AAV products made by Tenaya's proprietary HEK293 platform have been demonstrated to be comparable to traditional plasmid subunit stoichiometry, % full capsids and in vitro expression.

1532. Engineering and Banking of Differentiated iPSC Cells from Wildtype and Isogenic Homozygous Null iPSC Cells to Support Potency Assay Development

Xiaoshan Ke, Jane Yang, Isaac Peria-Gil, Alex Aycinena, Tisho Tefera, Jun Liu, Charles Feathers, Frank Jing, Bill Prince, Kee-hong Kim
Tenaya Therapeutics, South San Francisco, CA

Potency assessment development for AAV Gene Therapy is crucial to support adeno-associated virus (AAV) vector release and is required

for future marketing authorization. Potency assay development is especially challenging for AAV GT used in cardiovascular indications as the products are structural proteins instead of enzymes. One of the key requirements for development of functional potency assay is having a readily available biologically relevant cell line. To meet this need, Tenaya has developed a robust and scalable differentiation process for Induced Pluripotent Stem Cell Derived Cardiomyocytes (iPSC-CMs) suitable for continued potency assay development from early phase potency assay qualification to late phase validation to support routine product characterization and release purposes. This process has demonstrated efficiency of differentiation and maintenance of both wildtype and homozygous null cell lines which exhibit disease phenotypes. Additionally, the iPSCM-CM cell line generated using Tenaya's process is comparable to commercial sources in terms of quality, purity, and performance.

1533. Development of Highly Productive, Rhabdovirus-Free SF9 Insect Cell Line for Large-Scale AAV Production for Cardiovascular Gene Therapies

Jackson Leong, Charles Feathers, Tae Won Chung, Xiaoshan Ke, Sushanthi Ramesh, Frank Jing, William Prince, Kee-Hong Kim

Tenaya Therapeutics, South San Francisco, CA

Adeno-associated virus (AAV) has become a safe and effective modality for in-vivo delivery of gene therapy (GT) into patients suffering genetic diseases. Recent approvals of AAV-based gene therapies, with dozens more in the late-stage development, highlight the increasing demand for efficient and cost-effective large-scale AAV manufacturing with high productivity and consistent quality across scales. Sf9/recombinant baculovirus expression vector system (BEVS) remains as one of well-established production platforms for AAV manufacturing with several advantages over HEK293 platform using the triple transient transfection. While the HEK293 platform can rapidly supply AAV vectors for research and early-stage clinical trials, Sf9/BEVS boasts high packaging efficiency (vector genome yield) and reliable scalability that is suitable for large-scale AAV manufacturing to deliver therapies to larger patient population. Since the identification of a novel invertebrate Rhabdovirus (SfRV) in ATCC Sf9 cell line by the FDA in 2014, demonstrating adequate clearance of rhabdovirus from Sf9/BEVS has been challenging and costly, especially for early stage AAV GT products. In this work, we report the successful development of the new generation of Sf9 cell line that is SfRV-free at Tenaya Therapeutics, which can critically improve the safety and purity of AAV produced in Sf9/BEVS system. Furthermore, Tenaya's SfRV-free cell line also demonstrates excellent scalability, producing AAV at significantly higher productivity compared to SfRV containing Sf9 cells across shake flask, benchtop bioreactor (3 L), and pilot-scale bioreactor (200 L) with comparable product quality and potency. Additionally, the SfRV-free cell line outperforms other commercially available SfRV-free Sf9 cell lines in both serum-free and chemically defined cell culture medium.

1534. Development and Scale Up of a Robust End-to-End Manufacturing Process for High Quality AAV Production

Azam Hassaninasab

Process Development, Elevate Bio, Waltham, MA

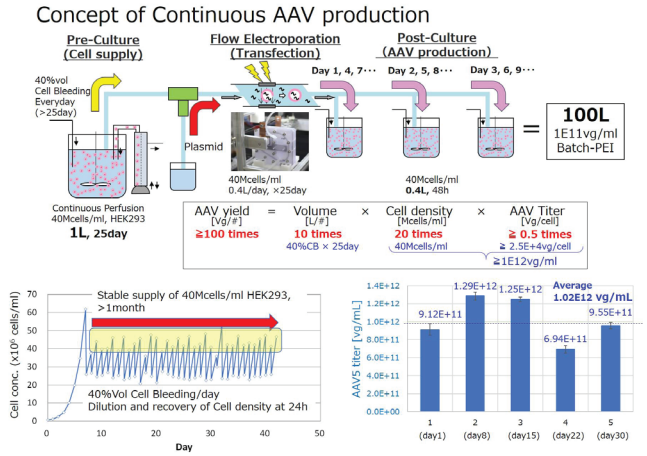
Adeno-associated virus (AAV)-based gene therapies have demonstrated substantial therapeutic benefit for the treatment of a variety of disorders and have been commercially approved. With promising clinical data and continued success in pre-clinical and clinic studies, AAV-based gene therapies have emerged as a new class of molecular medicines. Yet, there is limited AAV GMP manufacturing capacity and robust processes readily available for the development of novel AAV therapeutics. Here we describe an end-to-end AAV manufacturing process that was optimized for AAV5 vectors attaining high genome titers and a significantly improved downstream processing yield. During upstream process development, several DOE studies were performed to fine tune critical process inputs. As a result of the work, there is a significant improvement in productivity as well as 60% increase in full capsid from upstream crude harvest. The downstream process was also fully developed based on a two-column chromatography strategy. Several DOE screens were conducted to improve the affinity capture and the IEX purification steps. The recovery of AAV5 affinity capture increased from 45% to >80%. Importantly, the step recovery of IEX was greatly improved with full capsid enrichment >70%, which was confirmed by analytical ultracentrifugation (AUC) data. In addition, a significant reduction in the impurity levels was achieved using this purification scheme, including more than 7 logs reduction in host cell protein (HCP) levels bringing those levels below the detectable limit in final AAV product. Moreover, data also demonstrated multiple logs of DNA impurities reduction in downstream process. The process was successfully scaled up from 2 L to 50L in order to generate representative material for Non-Human Primate (NHP) studies.

1535. Purification of Adeno-Associated Virus Serotype 9 from HEK293 Cell Lysate via the Flow-Through Affinity Adsorbents

Wenning Chu, Stefano Menegatti

Department of Chemical and Biomolecular Engineering, North Carolina State University, Raleigh, NC

Adeno-associated viruses (AAVs) are the vector of choice for delivering gene therapies that can cure inherited and acquired diseases. Clinical research on various AAV serotypes significantly increased in recent years alongside regulatory approvals of AAV-based therapies. The current AAV purification platform relies on protein ligands—typically camelid antibodies—that provide high binding capacity and selectivity but suffer from high cost and harsh elution conditions (pH < 3) that can harm the transduction activity of recovered AAVs. Addressing this challenge, we introduced the flow-through affinity chromatography that target the HCPs in Human Embryonic Kidney (HEK) 293 cell lysate and enable AAVs flow through directly with low retaining. This study describes the mixture of an adsorbent A & adsorbent B, and the mixture of an adsorbent A & adsorbent C, at a volume ratio of 0:1, 1:4, 1:3, 1:2, 1:1, respectively. With the continuing injection of 20 CVs of AAV9 HEK293 Lysate at 1-min residence time, both the mixture of an adsorbent A & adsorbent B, and the mixture of an adsorbent



A & adsorbent C show the ability to remove medium components (conductivity dropped from~15 mS/cm to ~10 mS/cm) and HEK HCPs (UV_{280nm} dropped from~900 mAU to ~100 mAU) with the increase of volume ratio of adsorbent A&B or A&C from 0:1 to 1:1. Meanwhile, the logarithmic removal values of HEK HCPs were increased first until reaching to a volume ratio of adsorbent A &B or A&C at 1:3 with a cumulative LRV up to 1.6, and corresponding cumulative AAV9 yield above 78%, then kept drop after that. Because of its flow-through mode, the downstream purification process can be utilized to a broad range of the other AAV serotypes with minimal intervene of transduction efficiency.

1536. Scalable Flow through Electroporation for High Yield Continuous AAV Production

Takashi Yakushiji, Yoichi Nagai, Michiko Edo, Atsushi Inada, Masafumi Nishino, Nozomu Tonoike, Yuka Kobayashi, Yusuke Mori

FUJIFILM Corporation, Ashigarakami-gun, Japan

In recent years, several recombinant-AAV (rAAV) - based gene therapies have gained regulatory approval, and the number of rAAV therapies in development pipelines continues to increase. It is expected that as rAAV based therapies begin to be applied to more common conditions and are systemically administered, the need for large scale supply of rAAV will increase. Increasing productivity of conventional PEI Triple Transfection based rAAV production by increasing the cell concentration and/ or using larger volume bioreactors are problematic due to the difficulty controlling the complicated reaction between the PEI-Plasmid complex and cells. To accelerate rAAV clinical research and meet the potentially enormous future demand, high-yielding breakthrough rAAV production technologies are needed. We have developed a PEI-Free Continuous rAAV production system that combines high density HEK293 perfusion cell culture with a Scalable Flow Electroporation device with very high Electrode durability. HEK293 cells were cultivated in a 1L bioreactor at a concentration of 40Mcells/ml using an ATF based perfusion system. Cells were continuously withdrawn as a cell bleed at a rate of 40% of the bioreactor volume each day for one month. The withdrawn cells were continuously electroporated using a novel flow electroporation device connected aseptically to the bioreactor. The electroporation device was used without replacement for one month, and a cumulative total of over 10,000 pulses were applied to the cell suspension via the electrodes. On 5 days (day1, 8, 15, 22, and 30), the cell suspension was continuously mixed with rAAV plasmids (pGFP, pRC5, and pHelper) before electroporation and the transfected cells fed into a recovery bioreactor. An average of 1E12vg/ml rAAV titer was achieved 48h post electroporation on each occasion. These results demonstrate supply of high-concentration HEK293 cells continuously for one month, good electrode durability in the Flow electroporation device across 10,000 pulses which is sufficient to continuously operate for 1 month, and consistent transfection and AAV production across this period. It is expected that if plasmids were continuously supplied for the 30 day duration a total of 1E16vg of rAAV would be produced for a 1L bioreactor. This yield corresponds to a 100-fold increase in output compared to using a bioreactor of the same volume in batch mode with PEI transfection. We have demonstrated proof of concept of an innovative continuous rAAV production platform and are continuing to further improve efficiency and scale up to support larger bioreactor volumes. This scalable platform may enable mass production from modestly sized bioreactors and contribute to the acceleration of clinical development and commercialization of rAAV.

1537. Advanced Approach to the Purification and Characterization of AAV Vectors Based on Equilibrium Density Gradient Ultracentrifugation

Kiichi Hirohata, Yuki Yamaguchi, Takahiro Maruno, Takayuki Onishi, Tetsuo Torisu, Susumu Uchiyama

Department of Biotechnology, Graduate School of Engineering, Osaka University, Suita, Japan

For the development of gene therapy products using AAV vectors, one of the challenges is the removal of product-related impurities including empty particles. The presence of empty particles may be a cause of reducing therapeutic efficacy and increasing the risk of immunogenicity. Hence, a number of methodologies have been reported for both the purification of AAV vector in the downstream process and the evaluation of the ratio of full to empty particles, regarded as a critical quality attribute (CQA). In addition, the viral protein (VP) stoichiometry of the capsid has been recognized as a CQA and quality control (QC) because several studies suggested a correlation between the VP stoichiometry and transduction efficiency. To meet this increased demand of the quality of AAV vectors, there is a need to develop a further approach that can assess the particle heterogeneity contained in AAV vectors in detail. Equilibrium density gradient ultracentrifugation (DGE-UC) is a conventional but effective approach to the purification and characterization of AAV vectors. Under a cesium chloride (CsCl) density gradient, particles are separated based on the differences in buoyant density at equilibrium. Due to its high density resolution and sensitivity, DGE-UC is now a powerful method that can evaluate even full particles with different VP stoichiometry. We demonstrate the utility of DGE-UC in achieving the separation and fractionation of full particles with different VP stoichiometry. Quantitative analysis can also be performed using analytical ultracentrifugation (AUC) instrument equipped with optical detection system. We are in the process of evaluating various AAV vectors to validate the practical applications of AUC utilized optimization of DGE-UC.

1538. Quantitative Analysis Reveals the Impact of the Empty to Full Capsid Ratio on AAV Vector Transduction *In Vivo*

Shiyong Wu[1], Kentaro Yamada[1], Lohra M. Miller[2], Xin Li[1], Miguel Gonzalez[1], Sreevani Arisa[1], Jiahe Tian[3], Martin F. Jarrold[4], Roland W. Herzog[1], Weidong Xiao[1], Benjamin E. Draper[2], Junping Zhang[1]

[1]Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN,[2]Megadalton Solutions Inc., Bloomington, IN,[3]Department of Molecular Biology and Genetics, Cornell University, Ithaca, NY,[4]Chemistry Department, Indiana University, Bloomington, IN

Monitoring the empty/partial to full capsid ratio is crucial throughout AAV-based gene therapy development for product safety and efficacy. Particle effects on transduction may be linked to their abundance, but existing technology poses challenges for the exact ratio analysis of each AAV vector preparation. Charge detection mass spectrometry (CD-MS) emerges as a robust tool, enabling accurate quantification of these ratios at different scales. Here we employed CD-MS to quantitatively analyze various empty-to-full capsid ratios and their impact on AAV vector transduction in vivo. The two pAAV-ApoE-hAAT-hFIX (Padua) and AAV8-ApoE-hAAT-CohFVIII vectors were produced in suspension HEK293 cells by the triple transfection system. The vectors were purified by iodixanol gradient ultracentrifugation. To get various ratios of empty vs full capsid particles, the vectors from the first-round purification were subjected to a second-round gradient ultracentrifugation, and then different fractions were separately harvested. All the vector preparations were characterized by CD-MS and then injected into hemophilia A (HA) or hemophilia B (HB) mice for transgene expression and immunoassays. For AAV-ApoE-hAAT-hFIX (Padua) vectors, the empty to full capsid ratio for 1st round purification was around 90:10. The ratios of three fractions (Fraction 1-3) from 2nd round purification were 99:1, 80:20, 10:90 from the top to bottom three layers, respectively. Injecting equal amounts of AAV capsid particles from both purification rounds showed a significant difference in hFIX expression at mRNA level, consistent with their full particle abundance. Nonetheless, no significant changes in anti-AAV8 IgG levels were observed. Further experiments used AAV-ApoE-hAAT-hFIX particles with equivalent gene copies from both rounds, in which the bottom fraction 3 yielded highest hFIX expression but showed no changes in anti-AAV8 IgG levels among various groups. The same procedure was applied to AAV8-ApoE-hAAT-CohFVIII vectors. The three vector fractions from the second-round purification along with the first-round AAV vector, was respectively administered to HA mice with equal gene copies. Their ratios of empty to full capsids were around 100, 47:53, 6:94, and 92:8, respectively. Notably, Fraction 3 from the bottom layer, which contained the lowest ratio of empty particles, exhibited the highest transgene expression, while Fraction 1, with the highest ratio of empty particles, showed the most pronounced immunogenicity by enhanced α-TNF, α-IL1, and ISG-15 expression. Additionally, Fraction 1 also exhibited the highest anti-AAV8 IgG response compared to the other groups. Fraction 2 and Fraction 1 had lower anti-AAV8 IgG than that of the first-round vector preparation. These findings suggest that a high concentration of empty AAV particles may adversely affect transgene expression and potentiate the host's immune response. Lowering empty particles in AAV vectors are essentially for gene therapy efficiency. Especially, for research grade AAV vectors, monitoring a lot-to-lot variation in the ratio of empty to full capsids is required to ensure experiment consistency.

1539. AE1-BHK Novel Cell Line for rAAV Production of Multiple Serotypes for Gene Therapy Applications

Amber Chevalier Plambeck, Grace Loegering, Andrzej K. Noyszewski, Santhalingam Elamurugan, Alex Deiulio, Erica Kelly Venberg, Jeremy Houser, John Ballantyne, Michael Chambers, James Brown, Jagadish Loganathan

Agathos Biologics, Fargo, ND

Adeno-associated virus (AAV) vector-based gene therapies have attracted increasing interest for the treatment of monogenic disorders and as a valuable research tool to study gene function. Currently, the HEK293 Ad5E1 packaging cell line is the most popular platform for producing AAV of different serotypes due in part to the simple triple transfection production process. In addition to increasing the yield and scalability of HEK293, developers are looking to new cell lines for improving rAAV production and to address ethical concerns with cell lines derived from aborted fetal tissue. We have previously shown the mammalian platform AE1-BHK (formerly BHK-[wt E1]) stably expresses the E1 proteins with high cell growth and was able to produce rAAV2 using the same triple transfection process as used with HEK293. In the current work, we present data for other serotypes scaled up in cell stacks and purified and we show infectivity data for the rAAV produced in AE1-BHK. These data show AE1-BHK is a flexible platform to produce rAAV of different serotypes by triple transfection.

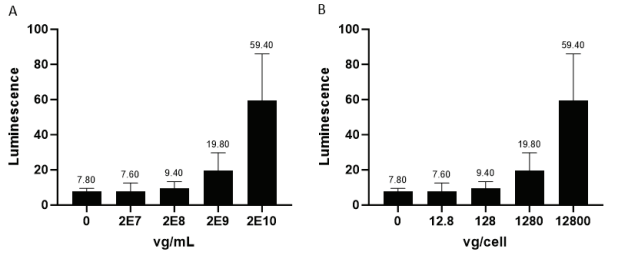


FIGURE 1. Luciferase activity from HepG2 cell line infected with rAAV8-luciferase. (A) HepG2 cells were infected with rAAV8- luciferase at different vg/mL (B) same data as (A) expressed as vg/cell. The data shown here are the mean ± SD from 5 technical replicates of one experiment.

1540. Establishment of Serum Free Suspension Adapted AE1-BHK-S Novel Cell Line for the Manufacturing of rAAV

Santhalingam Elamurugan, Amber Chevalier Plambeck, Grace Loegering, Andrzej K. Noyszewski, Alex Deiulio, Erica Kelly Venberg, John Ballantyne, Michael Chambers, James Brown, Jagadish Loganathan

Agathos Biologics, Fargo, ND

Adeno-associated virus (AAV) vectors are a promising biological product for gene therapy due to their non-pathogenic nature, ability to infect both dividing and non-dividing cells, and robust transgene expression. Adherent HEK293 is a well-established cell line for producing rAAV and has been successfully adapted to grow

in suspension in animal component-free chemically defined media and is commonly used for rAAV production at large scale. Here, we show a novel AE1-BHK cell line that stably expresses the Ad5 E1 proteins which can produce rAAV of different serotypes by the triple transfection method. To scale-up the production we adapted the adherent AE1-BHK cell line to a suspension AE1-BHK-S cell line using serum-free chemically defined media. We will present data on efforts to select clones based on robust growth and high cell density and evaluation of the clones for suspension virus production.

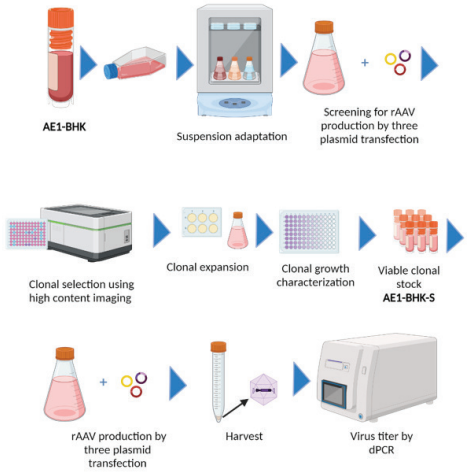

FIGURE 1 Workflow for AE1-BHK serum free suspension adaptation and clonal selection to create AE1-BHK-S for rAAV production.

1541. Optimization of AAV Production Yields through Dual Transfection

Sarath C. Mandava, Adam S. Cockrell, Lauren Peters, Margaret Moran, Neil Templeton, Ben Wright, Jen C. Gifford

Solid Biosciences, Charlestown, MA

Adeno-associated virus (AAV) vectors have emerged as versatile tools for gene therapy applications, necessitating the continual improvement of production methodologies to enhance yields and minimize undesired effects related to safety. This study investigates a dual transfection approach for AAV production, comparing its efficiency to the conventional triple transfection process currently in use. Our results demonstrate a consistent 2-3-fold increase in AAV production yields when employing the dual transfection approach across various capsid and gene of interest (GOI) combinations tested, highlighting this production method as a potential alternative to supply large amount of virus for in vivo gene therapies with high needs at reduced costs. Moreover, the dual transfection approach exhibits similar product quality attributes when compared to similar triple transfection generated AAV. Through a comprehensive series of in vitro assays, we analyzed various parameters including but not limited to vector purity, titers, transduction efficiency, and capsid integrity. Our findings not only underscore the enhanced productivity achieved with dual transfection but also emphasize its potential to streamline AAV production processes and reduce cost of goods, while mitigating concerns related to mispackaging, product quality and replication competent (rc)_AAV. This optimized approach holds promise for advancing the scalability and cost-effectiveness of AAV vector manufacturing, thereby contributing to the ongoing development and accessibility of gene therapy applications.

1542. Integrated Development of a Scalable, High Productivity, and High Yield Manufacturing Process to Enable Supply of an Investigational rAAV Gene Therapy to Treat Duchenne's Muscular Dystrophy

Dennis P. Chen, Wei Xue, Logan K. Nichols, Jian Lin, Mike Dullen, Carli D'Antonio, Amy Medeiros, Greg Mantenuto, Chao Huang, Jan Thomas Panteli, Patrick Hossler, Matt Marrichi, James Warren

Pharmaceutical Development, Ultragenyx Pharmaceutical Inc., Woburn, MA

Systemic delivery of recombinant adeno-associated virus (rAAV) gene therapies to treat neuromuscular genetic disorders such as Duchenne muscular dystrophy (DMD), require high doses (e.g., ≥ 1E+14 GC/kg of body weight). However, low batch productivity leads to high manufacturing costs and challenges to clinical supply. There is an urgent need to improve existing rAAV manufacturing platforms to achieve robust, high-yielding, scalable and cost-effective processes to meet high dosing requirements and reduce the overall cost of treatment. We employed a cost-effective and scalable rAAV production process using our Pinnacle producer cell-line/adenovirus helper platform that reduces the high cost of goods sold (COGS) associated with transfection-based processes. Through optimization of our intensified upstream process, we've increased the productivity of our rAAV expression platform and designed a robust downstream process capable of handling the challenging feed stream of a high-cell density production, while consistently achieving the desired product quality. Herein, we highlight the key results from our harvest clarification development, emphasizing the interdependence between upstream and downstream processing. We demonstrated improvement over our legacy platform batch process by increasing upstream volumetric productivity and process yield 5-fold to achieve approximately 1E+12 GC/mL; and developed a robust approach to the removal and inactivation of the adenovirus helper virus. Furthermore, our COGS analysis shows that our process intensified platform can reduce the number of cGMP batches required to initiate clinical studies compared to our legacy process at significantly reduced cost while meeting high dosing requirements for the treatment of DMD.

1543. High-Throughput Workflows to Accelerate Development of Chromatographic Purification of rAAV Viral Vectors

Ryan H. DeGroot, Sierra VanSuch, Ashley Sacramo, Ben Wright

Solid Biosciences, Charlestown, MA

Establishing a robust and scalable chromatographic full capsid enrichment step for adeno-associated virus (AAV) gene therapies presents an evolving challenge as novel combinations of capsids and genes of interest are continually developed. Traditional chromatographic development systems often require large quantities of feed-stream material, costly consumables, and a significant personnel commitment

to plan, setup, and execute these experiments. Thus, high-throughput screening workflows at small-scale that provide directionally relevant performance data can be instrumental to the rapid, efficient, and successful development of a chromatographic process step. Here, we discuss development and application of a high-throughput workflow to screen and optimize an anion exchange (AEX) chromatography step for enriching full AAV capsids using an automated liquid handling system and micro-scale columns that delivers comparable process performance in terms of chromatographic profiles, step yield, and product quality as traditional bench-scale columns.

1544. Case Study on Insect Cell-Produced AAV6 Gene Therapy Vector in a Rhabdovirus-Free Sf9 Cell Line

Thera Mulvania[1], Brooks C. Hayes[1], Scott Walker[1], Buel D. Rodgers[2], Joseph Rininger[3]

[1]Expression Systems, LLC, Davis, CA,[2]AAVogen Inc., Rockville, MD,[3]Latham Biopharm Group, Elkridge, MD

Developing AAV gene therapeutics for systemic delivery presents unique manufacturing challenges that are potentially addressed using inherently safe and scalable insect cell production systems. This presentation provides a case study of production and activity of AVGN7, an AAV6-based gene therapeutic for treating rare neuromuscular diseases, using this system. The upstream manufacturing process employs a newly introduced expression system comprised of a rhabdovirus negative clonal Sf9 RV-Free cell line derived from a single cell printing method, as well as a co-developed chemically defined insect cell medium. Upstream process development employs intracellular capsid detection in concert with GFP expression from the ITR-containing vector. This novel approach allows for screening of expression conditions that lead to successful co-expression of the required components for AAV production. Preliminary studies demonstrate the ability to produce high levels of AAV expression using a high cell density, high MOI (multiplicity of infection) methodology. Downstream processes for purification will be discussed along with assessments of bioactivity and post-translational processing of capsid proteins.

1545. Assessment of Host Cell DNA in AAV Gene Therapy Product Using PacBio Sequencing

Hsin-I Jen[1], Wei Zhang[2], Xiaohui Lu[3]

[1]Analytical Development, Ultragenyx, Woburn, MA,[2]Ultragenyx Pharmaceutical, Acton, MA,[3]Ultragenyx Gene Therapy, Woburn, MA

The presence of residual host cell DNA in gene therapy products is a critical concern for patient safety, given the associated uncertainties and potential risk of oncogenicity. To understand the characteristics of encapsidated host cell DNA, PacBio sequencing (Sequel II) was employed to determine the size and the transcription potential of the residual host cell DNA fragments.This study first assesses the accuracy of PacBio sequencing in detecting fragments of different sizes. Different proportions of inverted terminal repeats (ITR)-containing fragments of different sizes were deliberately spiked into the viral DNA before undergoing PacBio library preparation and sequencing. ITR sequences in viral genomes were known to be crucial for second-strand synthesis and transcription. It is also notoriously hard to sequence by traditional Illumina sequencer. Subsequent analysis quantified the percentage recovery of spiked-in fragments, demonstrating the detectability and accuracy of PacBio sequencing across various fragment sizes.Next, various viral products were sequenced using PacBio and the results revealed that the majority of host cell DNA does not contain ITR. Additionally, among all the analyzed host cell DNA, no complete coding sequences were observed. The absence of a complete coding sequence and ITRs in the identified host cell DNA indicates a low likelihood of safety risk associated with unintended host cell protein expression.

1546. A Commercially Producible Non-Lethal Virus Insect Cell Line

Shixian Zhang, Yan Wu, Yujing Liu, Yangyang Sheng, Xin'an Lu

Beijing Cygenta BioTechnology Co., Ltd, Beijing, China

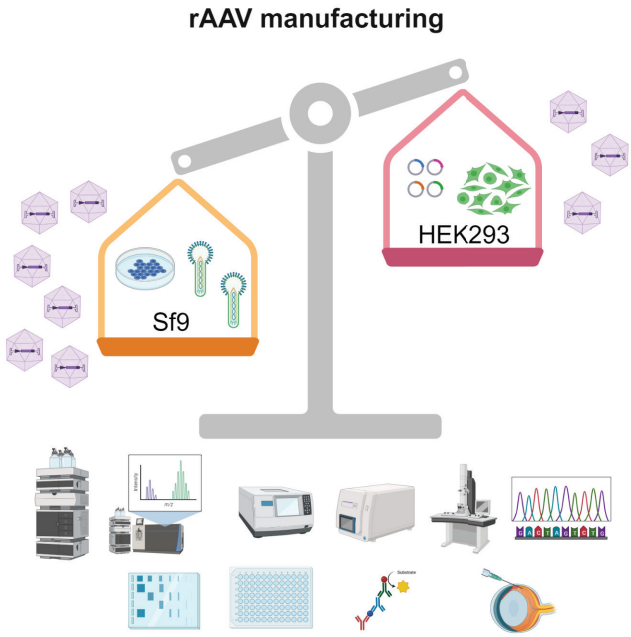
The baculovirus expression system stands out as a robust tool for producing recombinant proteins, vaccines, and AAV vectors. In 2014, the FDA reported contamination of commercially produced baculovirus cell lines sf21 and sf9 cells with rhabdovirus, emphasizing the need for rhabdovirus-free insect cells to ensure the safety of biological products. In this study, we successfully established a rhabdovirus-free Sf9 (RVF-Sf9) insect cell line using a monoclonal screening method with antiviral reagents. The RVF-Sf9 cell line, cultured for 44 passages, exhibited no rhabdovirus detection, maintaining stable doubling time and cell viability across passages. Baculovirus titers at different passages showed no significant differences. Genomic copies of Adeno-Associated Virus Vectors (AAV2-VEGF) produced in RVF-Sf9 and SF9 (with rhabdovirus) cells were comparable. Further production of AAV2-VEGF in 200-liter batches demonstrated a higher crude harvest yield of 5X10^14 vg/L using RVF-Sf9 cells compared to 3X10^14 vg/L with SF9, with no discernible differences in purity or product characteristics. Our results showcase the successful creation of a stable rhabdovirus-free cell line, providing a safer platform for commercial baculovirus system production.

1547. Development of Orthogonal Cell-Based Potency Assay to Demonstrate the Biological Effect of AAV Vector-Based Gene Therapy Products

Sree Kattala, Kalpana Rajanala, Subechhya Neupane, Dinesh Kumar Singh, Pushpendra Singh, Arun Upadhyay

Research and Development, Ocugen Inc, Malvern, PA

Background: Gene therapies show great potential in treating inherited diseases and have been increasingly proven successful across a broad spectrum of conditions, ranging from systemic diseases to ocular disorders. However, the manufacturing of gene therapy is a complex and resource-intensive process that requires rigorous quality control measures across various production batches. In order to ensure the consistency of each batch of gene therapy and determine the effectiveness of the product over time under diverse storage conditions, an in vitro cell-based potency assay is essential. This assay is critical



in establishing comparability across different manufacturing batches, both in clinical trials and for eventual commercial use. **Methodology:** In this study, we developed a matrix-based approach for *in vitro* cell potency assay that allows to measure the transduction, expression, and biological effect of a therapeutic transgene. For our ocular gene therapy product, multiple retinal cell lines were screened to determine the transduction efficiency; for this, AAV-GFP was used with a GFP-based imaging approach. Thereafter, AAV containing the transgene was used to assess the transduction efficiency and RNA level expression using the qPCR method. Subsequently, the biological effect of the transgene was evaluated using a luminescence-based approach. These assays were qualified for different parameters such as reproducibility, specificity, selectivity, and dose-dependence linearity according to the gene therapy potency assay regulatory guidance. These potency assays are vital in assessing the product quality and were used as release and stability indicating methods and meet the regulatory expectations for gene therapy products. **Results:** Ocugen developed a cell-based system that can reproducibly quantify the functional efficacy of different AAV-based gene therapy products. These cell-based potency assays are orthogonal and show a strong cross-correlation to one another with a dose-dependent effect of gene therapy products. We demonstrate that this potency assay showed acceptable assay performance and was deemed comparable across manufacturing batches. Further, this approach would help in evaluating the variability and stability of this gene therapy product during the product life cycle. These assays are easy to implement and can be adapted to other AAV gene therapy products and used to reliably assess the molecular function of other products.

1548. Comprehensive Head-to-Head Comparisons Demonstrated Key Advantages of The Sf9 System Over HEK293 in rAAV Manufacturing

Shengjiang Shawn Liu[1], Jinzhong Li[1], Sameera Peraramelli[1], Ningguang Li[1], Alan Chen[1], Minghua Dai[1], Fang Liu[2], Yanbao Yu[3], Ying Li[1], Eduardo Santillan[1], Kevin Lin[1], Derrick Huynh[1], Shuyi Li[1], Li Ou[1]

[1]Avirmax, Inc., Hayward, CA,[2]Stanford University, Stanford, CA,[3]University of Delaware, Newark, DE

Recombinant adeno-associated (rAAV) vectors could be manufactured by plasmid transfection into human HEK293 cells or baculovirus infection of *Spodoptera frugiperda* (Sf9) insect cells. However, systematic comparisons between these two systems using large-scale, high-quality AAV vectors are lacking. rAAV from Sf9 cells (Sf9-rAAV) at 2-50 L and HEK293 cells (HEK-rAAV) at 2-200 L scales were manufactured and systematically characterized. SDS-PAGE identified non-GOI impurities and differences in the VP1:2:3 ratio, while agarose gel electrophoresis observed multiple bands that indicate truncated genomes. Sf9-rAAV had up to 40-fold higher yields than HEK-rAAV across various scales, measured by ddPCR. Electron microscopy observed a lower full/empty capsid ratio in HEK-rAAV (70.8%) than Sf9-rAAV (93.2%), while dynamic light scattering (DLS) and HPLC analysis showed that HEK-rAAV had more aggregation. NGS with PacBio and Illumina showed that HEK-rAAV had ~10-fold more host cell DNA and more chimeric events with host cell DNA. LC-MS/MS identified different post-translational modifications (PTM) profiles, with more phosphorylation, acetylation, methylation, ubiquitination, and glycosylation, but less deamination in Sf9-rAAV. Furthermore, Sf9-rAAV had a higher $TCID_{50}$/vg than HEK-rAAV, indicating better infectivity. Additionally, Sf9-rAAV achieved higher *in vitro* transgene expression of Aflibercept, measured by ELISA. Finally, after intravitreal dosing into a mouse laser choroidal neovascularization model, Sf9-rAAV and HEK-rAAV achieved similar efficacy in reducing lesions. Overall, this study detected notable differences in the physiochemical characteristics of HEK-rAAV and Sf9-rAAV. However, the *in vitro* and *in vivo* biological functions of the rAAV from these systems were highly comparable. Sf9-rAAV may be preferred over HEK293-rAAV for advantages in yields, full/empty ratio, scalability, and cost.

1549. A Robust Upstream Process for AAV8 Production Scaled up from 15 Liters to 1000 Liters

Shixiong Dong

OBiO Technology (Shanghai) Corp., Ltd., Shanghai, China

Adeno-Associated Virus (AAV) has emerged as a pivotal tool in gene therapy, distinguished by its low immunogenicity, minimal toxicity, and non-pathogenic characteristics. While various methods exist for AAV production, the transient transfection of suspension HEK293 cells with three plasmids remains the predominant approach for large-scale production. Challenges arise in large-scale AAV production during HEK293 transfection exceeding a 1000-liter working volume, including (a) large-scale HEK293 suspension cell culture, (b) rapid mixing of DNA-PEIpro complexation in a large volume, and (c) rapid transfer of large volume transfection complexes into the bioreactor. Leveraging insights from prior small-scale bioreactor experiences, we optimized and developed the production process in a 2000-liter single-use bioreactor, culminating in a successful run. We present key data as follows: • Upstream harvest virus titer: 1.97E+11 vg/ml (ddPCR) • Host cell DNA residue: 3.4 ng/1E+12 vg • Host cell protein residue: 2 ng/ml • Full virus percentage: 84.2% (AUC) • Downstream total

harvest ratio: 34% Significantly, virus yield and impurity levels closely match the 200-liter data, demonstrating successful scale-up from a 15-liter reactor to a 2000-liter reactor. This achievement represents a groundbreaking advancement in overcoming the challenges associated with large-volume HEK293 transient transfection processes.

1550. The AAV Analytical Toolbox - A Comparison of Multiple Methods, Instruments and Data

Agnieszka Lass-Napiorkowska, Henry George
MilliporeSigma, St. Louis, MO

AAV (Adeno-Associated Virus) analytics is a key element in the development of robust AAV production, purification and polishing platform. Only reliable, accurate and reproducible analytical techniques enable optimization of AAV upstream and downstream processes. This poster focuses on comprehensive comparison of analytical methods used for AAV2, AAV5 and AAV6 titer assessment (Elisa, ddPCR), % full comparison (ddPCR/Elisa vs SamuxMP mass photometer vs CDMS vs AUC), content of AAV packaging (Illumina NGS, ssDNA extraction vs CGE), aggregation (DLS, AUC), purity (SDS-PAGE, CGE) and biological activity (HeLa-based infectivity assay).

Friday Posters: AAV Vectors - Immune Modulation

1551. Engineering Human CNS Receptor-Targeted Capsids for Improved Antibody Evasion

Simon Pacouret, William Donahoe, John W. Harvey, Pamela P. Brauer, Qingxia Zheng, Chin-Yen Lin, Binhui Zhao, Gabrielle Clouse, Qin Huang, Jencilin Johnson, Casey Keyes, Catherine P. Pirtle, Jarrett Rios, Albert T. Chen, Fatma Elzahraa Eid, Andrew J. Barry, Yujia A. Chan, Ken Y. Chan, Benjamin E. Deverman
Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA

Adeno-associated virus (AAV) capsids have been successfully engineered via surface loop modifications to target different organs such as the central nervous system (CNS), muscle, retina, and liver following systemic delivery. However, the population of patients that can benefit from AAV-based gene therapies is limited by pre-existing neutralizing antibodies (NAbs) to AAV capsids. NAbs not only activate the complement system but can hinder AAV transduction and thus the gene therapy's efficacy. Therefore there is a need for capsids with reduced sensitivity to antibodies that are compatible with surface loop modifications that confer enhanced in vivo tropisms. In this work, we aimed to reduce the NAb sensitivity of novel capsids developed by our group that cross the blood-brain barrier (BBB) via interactions with human CNS receptors such as human Transferrin Receptor (TfR1). Through sequential steps, we generated a library of TfR1-targeting capsids diversified at five distributed surface locations. We then subjected the library to high-throughput neutralization assays, in the presence of increasing concentrations of human intravenous immunoglobulin (IVIG), with transduction of human brain endothelial cells as a readout. Based on library screening data, we identified several capsid variants that (1) exhibited decreased neutralization by human IVIG, (2) retained their ability to transduce human cells via interactions with TfR1, and (3) possessed production fitness scores that were comparable to AAV9. We are now evaluating these capsids individually for their manufacturability, TfR1-dependent transduction, BBB crossing in vitro and in vivo, and maintained transduction efficiency in the presence of human sera. Ultimately, this work should yield novel antibody-evading capsids that can be used in combination with other capsid modifications that confer enhanced in vivo functionalities.

1552. CpG Content of Adeno-Associated Viral Vectors Can Be Manipulated to Control Neuroanatomical and Synaptic Impacts

Connor E. Dunn[1], Brigett V. Carvajal[2], Jie Ma[1,2], Caroline Jung[2], Ai Vy Nguyen[2], Christos Suriano[1,2,3], Lisa M. Boulanger[1,2]
[1]Department of Molecular Biology, Princeton University, Princeton, NJ,[2]Princeton Neuroscience Institute, Princeton University, Princeton, NJ,[3]Department of Biology and Sokol Institute for Pharmaceutical Life Sciences, Montclair State University, Montclair, NJ

Recombinant adeno-associated viruses (rAAVs) are used extensively as gene delivery vectors for basic research and are the basis of multiple FDA-approved gene therapies. Despite AAV's overall strong safety profile, the host immune response can constrain transgene expression and cause tissue-specific forms of toxicity. To realize the potential of AAV-mediated gene delivery, it is important to manage harmful and efficacy-limiting immune responses. In the rodent nervous system, AAV can unexpectedly disrupt neuronal morphology and synaptic communication, changes that are prevented by blocking the innate immunoreceptor Toll-like receptor 9 (TLR9). The AAV genome contains unmethylated cytosine-phosphate-guanine (CpG) motifs that are ligands for TLR9, and lower CpG content has been correlated with reduced immune responses and enhanced transgene expression in preclinical and clinical studies. We hypothesized that depleting CpG motifs from the AAV genome would protect neurons from TLR9-mediated structural and functional dysregulation. To directly test the impact of CpG depletion on responses to AAV in the brain, we reduced the number of CpG dinucleotides in the AAV1-*pCAG-FLEX-EGFP* genome by ~60%. To do this, we removed all CpG dinucleotides from the intronic regions and from the transgene, where we made codon-optimized synonymous mutations. These substitutions did not affect expression of the encoded transgene (EGFP), which was detected at comparable levels in the brains of mice that received intraparenchymal injections of either intact or CpG-depleted AAV. However, CpG depletion of the AAV genome fully prevented the loss of dendritic complexity seen with intact AAV1-*pCAG-FLEX-EGFP*. CpG depletion also prevented impacts on synaptic transmission that occur with intact AAV1-*pCAG-FLEX-EGFP*. Taken together, these findings suggest that CpG depletion can protect neurons from harmful TLR9-mediated impacts of AAV. To facilitate the design and adoption of CpG-minimized AAVs, we created a web-facing application that allows users to (1) quantify the CpG content of ssDNA sequences using multiple metrics, including RF3, a measure created by J. Fraser

Wright that differently weights known TLR9 -activating and -inhibiting motifs and aims to estimate TLR9 activation potential; (2) interactively explore the CpG content of a library of over 130 commonly-used AAV components, including ITRs, promoters, and transgenes; and (3) deplete CpG dinucleotides from noncoding regions and use codon-optimized synonymous mutations to deplete CpGs from coding regions. To our knowledge, this study provides the first evidence that CpG depletion can combat immune-mediated impacts of AAV on neural circuits. It also provides a community tool to streamline the use of CpG minimization or depletion as a non-invasive, cost-effective strategy to improve the safety and efficacy of AAV-mediated gene delivery.

1553. Benchmarking Natural and Synthetic AAV Capsids for Neutralizing Antibody Evasion

William Donahoe, Simon Pacouret, Pamela P. Brauer, John W. Harvey, Catherine P. Pirtle, Ken Y. Chan, Yujia A. Chan, Benjamin E. Deverman

Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA

Adeno-associated viruses (AAVs) exhibit significant promise as delivery vehicles for gene therapy but their broad applicability is hindered by pre-existing immunity in patients. Efforts have been made to circumvent neutralizing antibodies (NAbs) by employing various capsid engineering strategies such as capsid shuffling, mutagenesis of monoclonal antibody (MAb) footprints, and modifying naturally occurring serotypes with relatively low NAb binding. However, data is lacking on how well different capsids can evade NAbs relative to each other. To bridge this knowledge gap and set a baseline for our internal efforts to develop capsids with improved antibody evasion, we assessed the relative neutralization effectiveness of two pooled human IgG batches against natural serotypes (AAV1, AAV4, AAV8, and AAV9), loop VIII modified capsids (AAV-BI28 and Dyno bCap1), MAb footprint mutagenesis capsids (CAM130 and AAVhum.8), and capsid shuffling/hybrid variants (AAV-DJ and AAVrh32.33). Specifically, we determined the concentration of each pooled human IgG sample required to trigger a 50% reduction in AAV transduction efficiency (IC50) for each capsid. We used this control dataset to evaluate our progress in engineering an antibody evasion phenotype in AAV-BI-hTFR1, a blood-brain barrier (BBB)-penetrating capsid that targets the human Transferrin Receptor (TfR1). Among the naturally occurring serotypes, AAV1 and AAV4 had the lowest and highest IC50, respectively. Across all capsids tested, AAVrh32.33 had the highest IC50. Altering loop VIII alone had no impact on AAV9 resistance to pooled human IgG in the specific cases of AAV-BI28, Dyno bCap1, and AAV-BI-hTFR1. CAM130, AAVhum.8, and AAV-DJ were all more resistant to pooled human IgG than their parental capsids, with 1.2-1.6, 1.9, and 1.8-2 fold higher IC50s, respectively. Lastly, modification of multiple sites on the AAV-BI-hTFR1 capsid yielded novel variants with IC50s up to 3.58-fold greater than that of the parental capsid, AAV9. This comparative analysis will help guide future engineering endeavors focused on developing novel AAV capsids with enhanced resistance to neutralizing antibodies.

1554. Rapamycin is an Important Component of an Immunosuppression Regimen to Inhibit Capsid-Specific Humoral Immune Responses in High-Dose AAV Gene Therapy in Cynomolgus Macaques

Deniz Erturk-Hasdemir[1], Weasel Scott[1], Leah N. Cardwell[1], Justin Serio[1], Sanket Bhagat[1], Lina Song[1], Lorraine Sullivan[1], Stephanie M. Morin[1], Brian E. McIntosh[2], K. Reed Clark[1], Lorelei Stoica[1], Barbara A. Sullivan[1]

[1]Ultragenyx Pharmaceutical Inc., Novato, CA,[2]Labcorp Drug Development, Madison, WI

Host immune responses against recombinant adeno associated viruses (rAAVs) pose a significant challenge for safe and effective gene therapy. Some patients receiving high systemic doses of rAAVs in different clinical trials have experienced serious adverse events such as thrombotic microangiopathy (TMA) with hemolytic anemia, thrombocytopenia, and atypical hemolytic uremic syndrome (aHUS) leading to kidney damage due to complement activation. A proposed mechanism for complement activation is the binding of IgM and IgG anti-capsid antibodies to rAAV vectors in circulation to form rAAV-antibody immune complexes that trigger the classical complement pathway. We hypothesize that prophylactic immunosuppression (IS) to inhibit de novo anti-capsid IgM and IgG responses within the first two weeks of dosing may be useful in mitigating complement-mediated adverse events in high-dose rAVV gene therapy. We evaluated IS with prednisolone, rapamycin, and rituximab-pvvr for its ability to decrease the development of anti-capsid IgM and IgG in two non-human primate (NHP) studies. Our previous work showed that prednisolone/rapamycin decreased IgG but not IgM and that a triple IS regimen is necessary to inhibit both IgG and IgM. Here, in a follow-up study we tested whether prednisolone/rituximab-pvvr would be sufficient to inhibit anti-capsid humoral immune responses. An investigational AAVhu37 gene therapy vector expressing human microdystrophin (μDys) for the treatment of Duchenne muscular dystrophy was administered at 2e14 VG/kg in male cynomolgus macaques. Seronegative animals for both anti-AAVhu37 neutralizing antibodies (NAb) and for AAVhu37 anti-capsid IgGs were included. Animals received either AAVhu37 vector or vector along with one of the following IS regimens: prednisolone/rituximab-pvvr or prednisolone/rapamycin/rituximab-pvvr. Plasma, serum, and whole blood were assessed at different time points to evaluate immune endpoints such as anti-capsid IgM and anti-capsid IgG levels, platelet numbers, and complement protein levels. Whole blood was monitored throughout the study for B cell numbers and rapamycin levels. Rapamycin levels were above the target level of 12 ng/mL for the duration of the study. Peripheral B cells were depleted (75-100%) by rituximab-pvvr. The AAVhu37-μDys gene therapy was well tolerated with no adverse effects noted during this study. A transient elevation in liver enzymes (ALT, AST) was observed in all dose groups within the first week following vector dosing. The combination of prednisolone/rapamycin/rituximab-pvvr demonstrated a significant decrease in the anti-capsid IgM and IgG levels compared to the no IS group, consistent with our previous work. Prednisolone/rituximab-pvvr did not have a significant effect on mean IgM or IgG levels compared to the no IS

group. The extent of peripheral B-cell depletion correlated with the anti-capsid antibody levels. Four days after vector administration, the prednisolone/rapamycin/rituximab-pvvr group exhibited significantly (~1000-fold) higher vector genome DNA levels in the serum compared to the no IS group. A transient increase in complement proteins and a transient decrease in platelet numbers were observed in only a subset of animals from all dosed groups within the first week. The combination immunosuppression regimen of prednisolone/rapamycin/rituximab-pvvr was well tolerated, reduced anti-capsid IgM and IgG, and increased VG levels in the serum following high-dose rAAV gene therapy with AAVhu37. These results suggest that rapamycin is an important component of the IS regimen to reduce anti-capsid humoral immune responses.

1555. Elucidating the Impact of AAV Immune Complexes on Macrophage Uptake and Chemokine Induction

Robert J. Jimenez, Blake Williams, Michael R. Emami, Melissa J. Spencer

Department of Neurology, David Geffen School of Medicine at UCLA, Los Angeles, CA

High systemic doses of AAV have been associated with excessive complement activation, which can lead to thrombotic microangiopathy and organ damage. Previous human studies have indicated that AAV-dosing activates classical complement, which is dependent on the presence of AAV-antibody complexes (Salabarria et al, 2023). In murine models that emulate antibody-dependent complement activation it has been shown that certain myeloid-derived chemokines (CXCL10, MCP-1, and MIP-1β) are also dependent on the presence of antibody-AAV immune complexes (Emami et al, 2023). To better understand how classical complement influences induction of myeloid-derived chemokines, we used C1qa knockout mice (Jackson Labs *B6(Cg) C1qatm1d*(EUCOMM)Wtsi/TennJ) as C1q is the first complement protein to recognize antibody opsonized immune complexes. C1q homozygous knockout mice and C57Bl6/J wildtype mice were given an initial dose of empty AAV9 vector to prime adaptive immunity and given a second dose of AAV9_CMV_mCherry (1.16 E14 vg/kg) four weeks later. Plasma was collected before dosing, and then five hours and two weeks after each dose. Chemokines were assessed and observed to be elevated in an antibody dependent manner in both genotypes. Despite equal antibody levels in both genotypes, C1q knockout mice showed inflated chemokine responses. To further elucidate if the elevated chemokine response was antibody or complement mediated, we used an *in-vitro* system to test in parallel the chemokine activation signatures between complement or antibody-AAV immune complexes. After exposure to antibody-AAV immune complexes, THP-1 induced macrophages showed an antibody-dependence on both AAV uptake and transgene expression, leading to the concomitant induction of myeloid derived chemokines. This chemokine induction was partially blunted by blocking FcR1 and eliminated by blocking both FcR1 and FcR3 simultaneously. C3b opsonization of AAV particles did not increase AAV uptake nor chemokine induction of THP-1 macrophages. However when C3b was converted to iC3b, induction of chemokines was observed. These data suggest that AAV entry to macrophages likely occurs through an Fc receptor-dependent mechanism, and once internalized, activates macrophages. The study also suggests that there may be redundancy between Fc receptors on macrophages. Finally, our data also show that C3b and iC3b do not promote AAV entry, but that C3b processing to iC3b can induce chemokines in the absence of AAV internalization. These data provide insight into how antibody- and complement opsonization of AAV influence macrophage uptake and chemokine production.

1556. A Strategy to Select Minimally Immunogenic Candidate AAV Vectors to Treat GNE Myopathy

Bradley A. Hamilton[1], Rachana Patil[1], Benjamin Ruland[2], John Day[3], J. Fraser Wright[1]

[1]Pediatrics, Stanford School of Medicine, Stanford, CA,[2]Computer Science, Stanford University, Stanford, CA,[3]Neurology, Stanford School of Medicine, Stanford, CA

Innate immune responses to AAV vectors have emerged as a significant safety concern, especially after high dose systemic administration. Toll-like receptor 9 (TLR9)innate immune receptor activation has been indicted as a potentiator of serious adverse events. CpG dinucleotides in AAV genomes are TLR9 ligands, but their removal can produce unanticipated effects. GNE myopathy is characterized by progressive skeletal muscle weakness caused by mutations in the enzyme responsible for producing sialic acid. Strategies to realize the benefit of AAV based gene therapy for GNE myopathy and other neuromuscular diseases must include efforts to reduce the inherent innate and adaptive immunogenicity of AAV vectors through better design and manufacture, reduction of dose coupled with increased expression efficiency, and predicting and modulating immune responses pre- and post-vector administration. Here, we provide a vector development strategy centered on selection of minimally immunogenic open reading frames (ORFs) achieved through CpG reduction and measured by our novel assay, which opsonizes vectors with engineered antibodies prior to peripheral blood mononuclear cell (PBMC) exposure, revealing detectable interferon alpha 1 (IFNa1) secretion from PBMCs to measure TLR9activation by proxy. Using our previously reported algorithm accounting for CpG frequency, methylation status, and the TLR9 stimulatory or inhibitory potential of CpGs intetranucleotide contexts, we generated six candidate CpG reduced ORFs encoding GNE kinase with low normalized risk factors. We then cloned these sequences into expression plasmids with identical distal genetic elements. Next, we transfected HEK293T cells and probed for GNE kinase expression by western blot. The wildtype ORF (GNE1-001) expressed well and set a threshold to be met by CpG reduced ORFs to justify further characterization. Candidates GNE1-005,GNE1-006, GNE1-007, GNE1-008, and GNE1-009 all expressed less efficiently thanGNE1-001 and were excluded from development. Control sequence GNE1-002 was CpG elevated through traditional codon optimization and obtained significantly higher expression than GNE1-001, as predicted. Interestingly, GNE1-004 contained zero CpGs, and achieved expression slightly greater than wildtype GNE1-001. This relative expression pattern was recapitulated in other relevant cell lines andGNE1-001, GNE1-002, and GNE1-004 ORFs were used to produce AAV vectors. The normalized risk factor scores for the three vectors were 7.62 for the wildtype GNE1-001ORF with 17 CpGs, 16.5 for the codon optimized GNE1-002 ORF with 40 CpGs, and3.7 for the GNE1-004 ORF with zero CpGs. We then exposed PBMCs isolated

from random healthy donors to antibody-opsonized vectors. We did not detect meaningful differences at MOI 1e4, but when we increased MOI to 1e5 up to 30-fold increases in GNE1-002 vector stimulated IFNαsecretion were observed compared to the GNE1-001 sequence. Surprisingly, the zero CpG containing GNE1-004 ORF vector was more than two-fold more immunostimulatory than the wildtype sequence. In a subsequent PBMC assay of the same vectors, we employed small molecule inhibitors verifying that IFNαsecretion was TLR9 dependent. This study highlights the unprecedented value of our novel biological assay to reveal immunological phenomena that cannot be predicted in silico and raises the intriguing possibility that CpGs in TLR9 inhibitory tetranucleotide contexts should be included in AAV ORFs to counter the immune stimulatory CpGs in AAVITRs.

1557. Innate Immune Avoidance by Extracellular Vesicle Associated AAV (EV-AAV)

Bradley A. Hamilton[1], Demetri de la Cruz[2], Rachana Patil[1], Ming Cheng[2], J. Fraser Wright[1], Casey A. Maguire[2]

[1]Pediatrics, Stanford School of Medicine, Stanford, CA,[2]Neurology, Harvard Medical School, Charlestown, MA

Immune responses to AAV vectors are a significant safetyconcern. Toll-like receptor 9 (TLR9) innate immune receptor has been implicatedas a potentiator of serious adverse events. Methods modeling human innateresponses to AAV have been lacking. However, we recently described an assay exposinghuman peripheral blood mononuclear cells (PBMCs) to AAV opsonized withengineered antibodies which stimulate the release of interferon-α (IFNα), a proxy signal for TLR9activation.Here we investigated extracellular vesicle associated AAV(EV-AAV) vectors, which are a subpopulation of vectors generated duringproduction in 293 cells that resists neutralizing antibodies. Additionally, EVsdisplay phosphatidyl serine on their surface, a lipid moiety that dampensinnate immune stimulation. We therefore hypothesized EV association would reducevector immune stimulation in our assay. We purified EV-AAV2 by size exclusionchromatography, and AAV2 by density gradient ultracentrifugation. Both vectortypes packaged an identical AAV2-CAG>GFP expression cassette. We isolated PBMCs from random healthy donors and exposed themto opsonized EV-AAV2 and controls. We did not detect IFNα secretion from untreated PBMCsor after AAV2 empty capsid exposure. Similarly IFNα stimulation by AAV2-GFP was undetectable,likely due to insufficient internalization by plasmacytoid dendritic cells(pDCs). However, opsonized GFP vectors induced IFNα secretion consistent with increasedpDC uptake. Opsonized AAV empty capsids did not elicit IFNα secretion, consistent with a lackof genomic TLR9 ligands. Importantly, EV association significantly reduced IFNα secretion from PBMCs isolatedfrom donor 63 (p=0.0369) and donor 64 (p=0.0020), compared to standard AAV2-GFP,while insignificant differences were observed with donor 62. Our data suggest that host-specific factors modulate theimmune response to EV-AAV. We therefore performed a neutralizing assay with reserveddonor plasma, revealing the rank order of IFNα response magnitudes correlated with donor neutralizingtiters (Donor 63 > Donor 62 > Donor 64). These data hint that an upstreamevent might both sensitize pDCs to AAV as well as increase neutralizing titers.Additional verification of endogenous antibody removal during PBMC isolationwill help answer this question. We hypothesized effector cell activation would also be reducedby EV association. After IFNα assaywe FACS gated PBMCs on CD19-CD3+CD8+ cytotoxic T lymphocytes (CTLs) and probed forCD25 and CD69 activation markers. Likely due to a short 24 hour post-exposureculture, the differences in CD25 expression between conditions were inconsequential(>2%). CD69 was expressed near baseline in each AAV-empty capsid conditionand in all conditions without opsonization. However, in opsonized AAV2-GFP conditions,CTLs expressing CD69 increased by 25%, 15% and 10% for donors 62, 63, and 64,respectively. Moreover, EV-association conferred 14%, 25%, and 48% reductions inCD69+ CTLs when compared to matched controls. EV-AAV holds potential for mitigating critical immuneresponse challenges now faced in AAV gene therapy. This study highlights thepotential of a novel PBMC assay to interrogate innate immune responses, andshows the innate immune avoiding potential of extracellular vesical associatedAAV in orthogonal assays. Future studies will describe the mechanism ofvesicle-mediated immune avoidance, be it through antibody evasion, phosphatidylserine-mediated inhibition, or both.

1558. Improvement of Transduction Efficiency of Adeno-Associated Vector (AAV) by Extracellular Vesicles (EVs)

Yasunari Matsuzaka

Division of Molecular and Medical Genetics, Center for Gene and Cell Therapy, The Institure of Medical Science, Tokyo, Japan

Introduction: AAV vectors are derived from non-pathogenic viruses and capable of transferring genes into non-dividing cells. In addition, gene expression is maintained in target cells for long periods of time. However, the gene transfer efficiency is reduced by the neutralizing antibodies against the viral capsid of the AAV vector. To overcome this problem, we are trying to improve the gene transfer efficiency of the AAV by constructing "vexosomes" which are nanoparticles in which AAVs are encapsulated in EVs. Materials and Methods: By using AAV and EVs extracted from the media of cultured cells, we tried to incorporate AAV particles into EVs by membrane fusion methods (post-loading methods). To compare the gene transfer efficiency between AAVs and vexosomes, these vectors were inoculated into cultured cells and the gene transfer efficiency was evaluated by luciferase activity. Results: Vexosomes outperform AAV in gene delivery efficiency to RD cells *in vitro*. In addition, the gene delivery rate of vexosomes increases with a higher number of EVs particles for a given amount of AAV genome copies. In the fusion experiments of EVs with AAVs using detergent, higher concentrations of the detergent were not correlated with higher encapsulation efficacy. These findings suggest that relatively mild encapsulation condition is an important factor for the integrity of proteins on EVs that play an important role in their binding to cells. Conclusions: The efficiency of gene transfer using vexosomes was higher than that of AAV *in vitro* experiments. The preparation of vexosomes by incorporating AAV particles into EVs using post-loading methods is an effective way to improve gene transfer efficacy. Gene transfer using vexosomes can improve therapeutic effects for various diseases.

1559. Immunosilencing of a Promiscuous T Cell Epitope in AAV9 Gene Therapy Vector by Rational Design Chimerism

Sojin Bing[1], Morten Seirup[2], Trish Hoang[2], Susana Najera[1], Collin Britten[3], Stephanee Warrington[4], Shian-Ling Chu[1], Ronit Mazor[1]

[1]FDA, Silver Spring, MD,[2]Promega Corporation, Fitchburg, WI,[3]Waters, Santa Barbara, CA,[4]CBER, Food and Drug Administration, Silver Spring, MD

Despite the high safety profile demonstrated in clinical trials, adeno-associated virus (AAV)-mediated gene therapy still faces considerable obstacles due to its immunogenicity. Here, we silenced the most immunodominant T cell epitope in AAV9 through rational design chimerism. The new chimeric vectors maintained their functions and potency, including yield, cellular specificity, in vitro and in vivo transduction efficacy, and biodistribution in mice, while not eliciting any cellular immune responses.

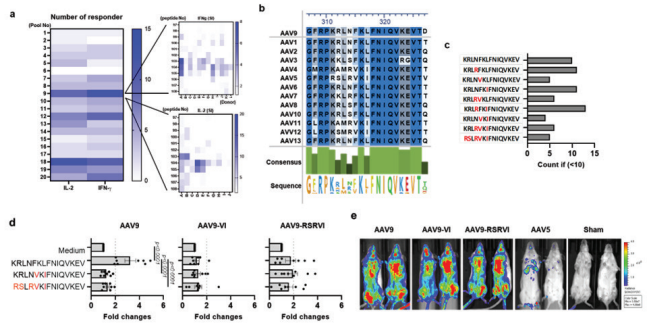


Fig 1. a. Responses of PBMCs obtained from 52 donors to peptide pools from AAV9 VP1 protein were measured by IL-2 and IFN-γ ELISpot assays. PBMCs from healthy donors were stimulated with empty AAV9 capsid for 14 days, followed by restimulation with peptide pools spanning the amino acid sequence of AAV9 VP1. After 24 hours, IL-2 and IFN-γ producing cells were detected by ELISpot assays. **b.** VP1 peptides 103-105 in AAV1-13 serotypes were aligned using DNAstar software showing a high degree of conservation with the exception of amino acids R312, L313, N314, F315, and L317. **c.** Binding affinity of peptides to 27 HLA class II alleles were predicted using the IEDB T cell epitope prediction tool. The number of alleles were counted if their percentile ranks predicted by the IEDB methods were below 10%. **d.** PBMCs were stimulated with the indicated AAV vectors for 14 days. Cells were re-stimulated with individual peptides, and the IFN-γ producing cells were measured by ELISpot assays. **e.** NanoLuc-expressing chimeric AAV9 variants (1E11 vg/mouse) were injected in BALB/c mice intravenously. Representative image of NanoLuc expression in the mice 8 days after vector administration.

1560. The Presence of CpG Dinucleotides in an AAV Transgene Induces a Plasmacytoid Dendritic Cell-Like Population Expressing the Fc Receptor Very Early After Vector Administration in Mice

Justin Glenn, Henos S. Negash, William Marcus Henry, Randolph Qian, Ye Liu, Joseph T. Bruder, Subha Karumuthil-Melethil, Olivier F. Danos

REGENXBIO Inc., Rockville, MD

AAV-mediated gene therapy is a promising platform for treating severe diseases; however, host-derived, antagonistic immune responses to the vector components still limit its use. Unmethylated CpGs in AAV vector DNA activate the innate immune response through TLR9 stimulation and enhance adaptive immune responses against both the AAV capsid and transgene product. We previously observed that CpG depletion increased the expression of a human IgG transgene product (TP) by 2-3-fold as early as 24 hours post-vector administration in mice. This was not accompanied by changes in AAV genome biodistribution or transgene mRNA levels, but instead with CpG-dependent differences in the abundance of a pDC-like population. This $PDCA^{lo/-}CD11b^{+}$ myeloid population was increased in the presence of CpG dinucleotides within the AAV genome. Here, we sought to determine a potential mechanism by which the induced myeloid cells reduce TP levels. *Ex vivo* studies revealed that these cells could directly bind and sequester the TP via Fc-FcγR engagement. This interaction was prevented by switching TP from IgG to an Fc-less, Fab form. Further characterization confirmed the inflammatory activation status of these cells by IRF7 positivity and revealed heterogeneity in their immune stimulatory potential. Thus, we extend the mechanisms of TLR9-mediated antagonism in AAV gene therapy to include the actions of a previously unreported pDC-like cell population.

1561. Identification of a Novel Strategy to Modify AAV Vector Capsid to Reduce Immunogenicity

Winston Colon-Moran, Alan Baer, Santosh Panthi, Nirjal Bhattarai

OTP/TVBB, FDA/CBER, Silver Spring, MD

AAV vectors are commonly used for vector-based gene therapies; however, host immune responses against AAV and/or transgene present a safety risk to subjects and can reduce therapeutic efficacy. To address this, we hypothesized that incorporating immunomodulatory factor(s) derived from naturally occurring human viruses into the AAV capsid may reduce AAV immunogenicity. To this end, we studied two immunomodulatory proteins expressed by the hepatitis B virus, e antigen (HBeAg) and s antigen (HBsAg), and its effect on human T cell activation (TCA). We found that HBeAg, but not HBsAg, inhibited T cell receptor-mediated TCA. Activation of human T cells with PMA and Ionomycin, which bypasses TCR and activates distal T cell signaling was not affected by HBeAg, suggesting that HBeAg specifically inhibits proximal TCR signaling. Deletion mutagenesis studies identified a short 11 amino acid peptide (11mer) derived from HBeAg that is sufficient to inhibit TCA. Mechanistically, we found that 11mer peptide inhibited activation of Interferon regulatory factor 3 (IRF3), potentially contributing to HBeAg-mediated inhibition of TCA. The 11-mer peptide was inserted into variable region (VR) III of the common VP3 region, which is exposed on the surface of the capsid. Importantly, *in silico* analysis showed that the insertion of the 11mer peptide did not affect the AAV capsid structure. Current studies are underway to assess quality, potency, and immunogenicity of the modified AAV vector and delineate mechanisms for the inhibition of T cell activation.

1562. Empty Capsid Immunization Prevents AAV8-Mediated Gene Transfer in a Dose-Dependent Manner in Cynomolgus Monkeys

Geoffrey DeCouto, Megumi Adachi, Nakyo Heo, Cristina Rodriguez Mateo, Su Liu, Bala Medicherla, Damir Simic, Carlos Fonck

Astellas Gene Therapies, South San Francisco, CA

Introduction. Immune responses against adeno-associated viruses (AAVs), which are used for gene therapy, have been reported to limit tissue transduction and diminish efficacy. In particular, antibody production, including IgGs against viral capsid proteins, is thought to block access to cells and contribute to faster clearance of viral vectors.

Despite the importance of understanding immune responses and how they interfere with AAV-based therapeutics, the field continues to struggle with establishing experimental models in which to induce and measure antibody levels that prevent successful AAV-based gene transfer. In this study we examined the impact of varying concentrations of empty AAV8 capsids on antibody production, transduction and transgene expression following AAV8 gene therapy in cynomolgus monkeys. *Methods*. Cynomolgus macaques, ~2.5 years old, were screened for pre-existing neutralizing antibodies (Nabs) against AAV8 capsids. Animals with Nab titers ≤1:5 were designated as immunologically naïve (IN), and animals with Nab titers >1:160 were designated as immunologically active (IA). Monkeys were distributed into the following groups: 1) IN that received vehicle control, 2) IN treated with an AAV8 gene therapy construct coding for a protein under the control of a muscle-specific promoter (AAV8-MSP, 1e14 vg/kg), and 3) IA treated with AAV8-MSP (1e14 vg/kg). Groups 4-7 were IN treated with increasing concentrations of empty capsids (equivalent to 1e7 - 1e13 vg/kg) followed by AAV8-MSP (1e14 vg/kg) 8 weeks later. Monkey sera were collected at various timepoints and analyzed for Nab and total antibodies (Tab). Twelve weeks after AAV8-MSP administration, monkeys were euthanized, and heart and skeletal muscles were analyzed for vector copy number (VCN), protein expression, and transgene protein enzymatic activity. *Results*. Vehicle control animals displayed no significant changes in Nab or Tab over time. Importantly, 8-20 weeks after receiving empty capsids, monkeys revealed a dose-dependent increase in Nab and Tab with temporal fluctuations consisting of a biphasic increase followed by a plateau. Heart tissue showed an empty capsid dose-dependent decrease in AAV8-MSP VCN and transgene protein enzymatic activity. Interestingly, groups 3 and 7 had similar and relatively low VCN and enzymatic activity over baseline, implying effective transduction blockade. In addition, heart enzymatic activity had an inverse correlation to antibody levels measured 8 weeks after empty capsid dosing (R^2: Nab = 0.57, Tab = 0.66). Compared to heart, lower values for VCN and enzymatic activity were observed in skeletal muscles including quadriceps, biceps, and triceps in all treatment groups. *Conclusions*. We evaluated the impact of AAV8 capsid immunization on transgene transduction and expression of an AAV8 therapeutic in cynomolgus macaques. The antibody response was dose-dependent and titratable; a high dose of empty capsids (1e13 vg/kg) prevented transduction and transgene protein enzymatic activity in target tissues, while a low dose (1e7 vg/kg) of empty capsids conferred no inhibitory activity. Our data also show that Tab titers appear to have slightly better correlation with VCN values and enzymatic activity compared to Nabs. Additionally, the relatively weak correlation between antibody levels and transduction and expression suggests that other factors not accounted for in this study may contribute to decreased transduction and expression of AAV8-based gene therapy. Nonetheless, this study identified AAV8 capsid doses and their corresponding Ab level increases that prevented effective AAV8 gene transfer.

Friday Posters: Lysosomal Storage Disorders

1564. Lentiviral Vector Optimization for the Preclinical Development of Hematopoietic Stem Progenitor Cells (HSPCs)-Gene Therapy(GT) for Mucopolysaccharidosis Type IVB (MPSIVB)

Mucopolysaccharidosis type IVB (MPSIVB) is an ultra-rare inherited lysosomal storage disorder caused by b-galactosidase (b-GAL) deficiency, a lysosomal enzyme encoded by the *GLB1* gene. No approved therapy is available to treat MPSIVB patients who manifest severe skeletal alterations and neurological involvement. Based on recent data demonstrating the superior safety and efficacy of hematopoietic stem progenitor cell-gene therapy (HSPC-GT) to treat similar lysosomal storage disorders (LSDs), we aim to develop a HSPC-GT strategy for MPSIVB within the framework of an innovative platform approach for LSDs with skeletal involvement. We designed and tested different lentiviral vectors (LVs) to achieve b-GAL overexpression and release in human mobilized-peripheral blood (mPB) HSPCs. We found that the LVs bearing the human GLB1 cDNA (normal and codon-optimized) allowed the intracellular overexpression of the therapeutic enzyme, which, on the contrary, was present at low levels in the extracellular space of the transduced cell progeny (myeloid cells and osteoclasts), limiting the metabolic correction of patients' cells in in vitro cross-correction assays. We hypothesized that the low amount of b-GAL enzyme in the extracellular space was associated with a temperature-dependent stability of the human enzyme, which is low at 37°C. On the contrary, human mPB HSPCs transduced with the LVs encoding for the murine b-GAL released supranormal levels of the therapeutic enzyme in the absence of cell toxicity, which restored the enzymatic activity in patients' cells. Moreover, human HSPCs overexpressing the murine b-GAL efficiently engrafted and reconstituted the hematopoietic system, similar to untransduced and LV-human GLB1 transduced HSPCs upon transplantation into

NSGW41 mice. Importantly, we detected a significantly higher level of b-GAL activity in the bone marrow of mice transplanted with HSPCs transduced with the LV-murine GLB1. We further proved that the murine b-GAL was internalized and targeted into the lysosomal compartment of patients' cells as the human enzyme and excluded immunogenicity of the murine enzyme in short- and long-term in vitro assays. In conclusion, our data support the use of the murine *Glb1* transgene for HSPC-GT development at a pre-clinical level in *Glb1*-/- mice and for future clinical translation.

1565. Pre-Clinical Development of an Ex-Vivo Lentiviral-Based Hematopoietic Stem/Progenitor Cells (HSPC)-Gene Therapy (GT) for Mucopolysaccharidosis Type IVA (MPSIVA) as Part of an Innovative GT Platform Approach for LSDs with Skeletal Involvement

Stefania Crippa[1], Margherita Berti[2], Ludovica Santi[2], Giada De Ponti[2], Raisa Hernandez[1], Pamela Quaranta[2], Matilde Cossutta[1], Erika Zonari[1], Selene Ceriotti[1], Ilaria Visigalli[3], Luca Basso-Ricci[1], Paola Albertini[4], Francesca Sanvito[4], Antonella Paoli[5], Nicola Volpi[6], Amelia Morrone[7], Marina Radrizzani[1], Rossella Parini[8], Serena Scala[2], Alessandro Aiuti[2,9,10], Maria Ester Bernardo[2,9,10]

Mucopolysaccharidosis type IVA (MPSIVA) is a lysosomal storage disease (LSD) caused by the deficiency of the lysosomal enzyme N-acetylgalactosamine-6-sulfatase (GALNS), characterized by severe skeletal dysplasia, which the currently available therapies fail to cure. Our study aims at developing hematopoietic stem progenitor cells (HSPC)-gene therapy (GT) for MPSIVA as part of an innovative GT platform approach for LSDs, based on recent data proving the safety and efficacy of HSPC-GT for the treatment of other LSDs. To this aim, we generated a 3rd-generation lentiviral vector encoding for the GALNS enzyme (LV-GALNS), using the same LV construct of the MPSI-IH clinical trial (ClinicalTrials.gov, NCT03488394) to transduce human mobilized peripheral blood (mPB) CD34$^+$ cells. Transduced cells showed proper clonogenic and proliferative capability *in vitro* and significantly overexpressed and released the GALNS enzyme. Using the conditioned medium from LV-GALNS transduced myeloid culture, we restored GALNS expression and activity in patient-derived fibroblasts, mesenchymal stromal cells (MSCs), and MSC-derived osteoblasts. Importantly, LV-GALNS human mPB CD34$^+$ cell derived-osteoclasts secreted GALNS, possibly functioning as a resident source of enzyme for skeletal cross-correction. When transplanted in sub-lethally irradiated NSG mice, LV-GALNS mPB CD34$^+$ cells efficiently engrafted and repopulated the hematopoietic system. Importantly, we detected a significantly higher level of GALNS enzyme in the bone marrow of mice treated with HSPC-GT. To test the superior efficacy of GT compared to standard treatment, we have recently generated a GALNS knock-out animal model by CRISPR-Cas9 technology, which shows signs of skeletal disease, including shorter bones, reduced mineral density, and osteoblast number, in addition to a swollen, disorganized, and inflamed growth plate compared to age- and sex-matched wild-type controls. Finally, we tested the clinical-grade LV-GALNS in human HSPCs to identify the best-performing transduction protocol for future manufacturing processes. Altogether, our preclinical results show efficient transduction of human HSPCs without signs of toxicity, the release of supranormal levels of the therapeutic enzymes from the hematopoietic progeny of transduced cells, capable of metabolically cross-correcting patients' cells. The planned Proof-of-concept study in MPSIVA mice will further implement our data to support the clinical development of HSPC-GT for MPSIVA treatment.

1566. An Analysis of Biomarkers for the Early Diagnosis and Evaluation of Gene Therapy for Niemann-Pick Disease Type C

Chika Watanabe[1], Eriko Jimbo[1], Yoshie Kurokawa[1], Miyuki Watanabe[1], Karin Kojima[1], Kazuhiro Muramatsu[1], Keitaro Miyoshi[2], Masamitsu Maekawa[2,3], Chen Wu[4], Miki Igarashi[4], Yoshikatsu Eto[4], Katsuhito Asai[5], Tsuyoshi Teshima[5], Shin-ichi Muramatsu[6], Hitoshi Osaka[1], Takanori Yamagata[1,7]

[1]Department of Pediatrics, Jichi Medical University, Shimotsuke, Japan,[2]Faculty of Pharmaceutical Sciences, Tohoku University, Sendai, Japan,[3]Department of Pharmaceutical Sciences, Tohoku University Hospital, Sendai, Japan,[4]Advanced Clinical Research Centre, Institute of Neurological Disorders, Kawasaki, Japan,[5]Gene Therapy Research Institution Co., Ltd., Kawasaki, Japan,[6]Division of Neurological Gene Therapy, Jichi Medical University, Shimotsuke, Japan,[7]Tochigi Rehabilitation Center, Utsunomiya, Japan

Niemann-Pick disease type C1 (NPC1) is a congenital disorder caused by variants of the *NPC1* gene, which is involved in cholesterol transport in lysosomes. The clinical manifestations of NPC1 include liver failure, neurological and psychiatric symptoms, and pulmonary failure that occurs from neonatal to adult age. An onset in infancy results in rapid progression and a poor prognosis. With no essential treatment options available, we developed gene therapy for NPC1. An early diagnosis and treatment are crucial for improving the therapeutic efficacy. Therefore, it is necessary to establish specific biomarkers for the early diagnosis and treatment. **Methods:** We generated an adeno-associated virus (AAV) vector that expressed human *NPC1* under the cytomegalovirus (CMV) promoter (AAV-CMV-*hNPC1*) and injected it into the left lateral ventricle and cisterna magna on day 3 or 5 of life, with a total of 1.35×10^{11} vector genomes per mouse. We then explored novel biomarkers using a non-targeted metabolomic analysis of plasma from *NPC1*$^{-/-}$ and *NPC*$^{+/+}$ mice. In addition, biomarkers such as 7-ketocholesterol (7-KC), cholesterol, lyso-sphingomyelin (lysoSM),

and *N*-palmitoyl-O-phosphocholine-serin (PPCS) were analyzed in the mouse plasma and liver before and five weeks after vector injection into the ventricles and cisterna magna. **Results:** Our gene therapy prolonged the survival of treated homo-knockout (*NPC1*$^{-/-}$) mice by an average of 105 days, improved Rota-rod performance, and preserved cerebellar Purkinje cells. Of the 393 compounds identified, 17 were candidates for novel biomarkers, including guanidoacetic acid and N1-methylguanosine. In the plasma of NPC1 patients, no significant differences in compounds were found between the patients and controls. However, some compounds were found to be elevated in adult patients but not in children. PPCS levels in plasma and 7-KC, cholesterol, and lysoSM levels in the liver were elevated in *NPC1*$^{-/-}$mice, but no decrease was noted in AAV vector-treated *NPC1*$^{-/-}$mice. **Discussion:** The levels of biomarkers varied by age, so further research is needed to determine the appropriate biomarkers for newborn screening. The vectors injected into the central nervous system reached the liver. We continued to analyze the biomarkers at increasing dosages. Our gene therapy for NPC1 mice was effective for managing neurological symptoms, which are the leading cause of death. Therefore, we are currently preparing for a clinical trial.

1567. EXG110: Promising Gene Therapy for Fabry Disease - Achieving Complete Substrate Correction in Mice and Exceptionally Robust GLA Expression in NHPs

Shaoyong Li, Hong Wang, Pengfei Yu, Chunjuan Song, Mingwen Liu, Qingzeng Wang, Wei Hu, Xin Xin, Zhenhua Wu, Guo-jie Ye

Exegenesis Bio Inc., Lower Gwynedd, PA

Fabry disease (FD) is a rare metabolic disorder caused by deficiency of lysosomal enzyme α-galactosidase A (α-Gal A) activity due to deleterious mutations in the *GLA* gene. Accumulation of substrates within lysosomes results in cellular dysfunction and multiple organ damage. The current enzyme replacement therapy requires bi-weekly infusion, however, only minimal clinical effects in myocardial tissue were achieved. To provide a single administration with long-lasting effects, we developed a gene therapy product EXG110 for FD. EXG110 comprises a novel and highly efficient liver-muscle targeting Adeno-associated virus (AAV) capsid and an optimized human *GLA* transgene expression cassette. A single intravenous injection of EXG110 to 4-month-old male Fabry mice (*Gla* KO*)* assigned to 3 dose groups resulted in dose-dependent α-Gal A activity in the plasma throughout the duration of 8-week study. The efficacy of EXG110 treatment was evaluated by measuring the levels of substrate lyso-Gb3 with LC-MS/MS, and immunostaining of the substate Gb3 in the key tissues. The low dose (2e11 vg/kg) of EXG110 treatment corrected the lyso-Gb3 to near a normal level in the plasma, liver and heart, and significantly reduced the lyso-Gb3 level in the kidney as well. The Fabry mice treated with medium dose (2e12 vg/kg) exhibited complete substrates correction in the liver and heart, and with nearly normal lyso-Gb3 levels in the plasma and kidney. Furthermore, the renal cortex of Fabry mice treated with medium dose showed complete Gb3 clearance. As expected, the high dose (2e13 vg/kg) of EXG110 treatment resulted in complete correction of substrate levels in plasma and all key tissues including liver, heart and kidneys. An on-going 8-week dose-response study in Fabry mice was carried out to explore the minimum effective dose of EXG110. Dose-dependent α-Gal A activity and expression in the plasma were observed. To assess if EXG110 could mediate robust and stable α-Gal A expression and activity in non-human primates (NHPs), adult male Cynomolgus macaques were intravenously administrated with 3 doses of EXG110 in a staggered manner and monitored for at least 13 weeks. One monkey, dosed with 2e13 vg/kg, exhibited up to 1,750-fold increase of α-Gal A activity in the plasma compared to baseline level. The enzyme activities in the liver, heart, skeletal muscle of this animal were 54-fold, 80-fold, and 134-fold, respectively, over that of control animal. The monkeys dosed with 2e12 vg/kg and 6e12 vg/kg of EXG110 exhibited 221-fold and 629-fold higher plasma α-Gal A activity above baseline, respectively. Stable α-Gal A activity in the plasma has been observed for at least 18 weeks after the administration of EXG110. In summary, EXG110 demonstrated notable efficacy in Fabry mice and superior α-Gal A activity in NHPs. These preclinical findings support the ongoing clinical development of EXG110 for Fabry disease.

1568. Novel Ubiquitous Promoters Evade Transgene-Specific Immune Responses and Drive Widespread Therapeutic Transgene Expression in a Mouse Model of Pompe Disease

Baodong Sun

Pediatrics, Duke University School of Medicine, Cary, NC

Background: Systemic correction of muscle and the brain is desired for the treatment of Pompe disease, an inherited lysosomal storage disorder caused by acid alpha-glucosidase (GAA) deficiency. AAV-mediated gene therapy with current ubiquitous promoters often causes strong transgene-related immune responses that eliminate human GAA (hGAA) expression quickly in Pompe disease (GAA-KO) mice. We have recently identified a 356-bp human G6PC minimal promoter that displays unexpected high activity in mouse heart and skeletal muscle (the full length G6PC promoter is only active in liver and kidney). To further boost transgene expression in skeletal muscle, we have synthesized a hybrid promoter (CRM4-G6PC) by combining a 434-bp high potency human skeletal muscle-specific transcriptional cis-regulatory module (hSk-CRM4) with the 356-bp G6PC minimal promoter. Here we tested these two promoters in AAV-mediated gene therapy in GAA-KO mice. **Methods:** We constructed AAV9 vectors expressing hGAA driven by the G6PC promoter (AAV9-G6PC-hGAA) and the CRM4-G6PC hybrid promoter (AAV9-CRM4-G6PC-hGAA) and intravenously injected them at the same dose ($1x10^{13}$ vg/kg) into 14-week-old GAA-KO mice. Tissues were collected after 3 weeks to assess hGAA expression and glycogen reduction. For a longer-term (12-week) experiment, 19-week-old GAA-KO mice were intravenously injected with the AAV9-CRM4-G6PC-hGAA vector at a dose of $1x10^{13}$ vg/kg. **Results:** In the 3-week experiment, both AAV treatments led to significantly increased GAA activities in all tested tissues including the liver, heart, quadriceps, gastrocnemius, diaphragm, spleen, kidney, and the brain (**Figure 1**). The AAV9-CRM4-G6PC-hGAA treated mice had significantly higher GAA activities in the heart and limb muscles than the AAV9-G6PC-hGAA treated mice (**Figure 1**). Both AAV9-G6PC-hGAA and AAV9-CRM4-G6PC-hGAA vectors nearly cleared glycogen accumulation in liver, and both significantly reduced glycogen contents

in heart (-46% and -81%, respectively), quadriceps (-41% and -52%), gastrocnemius (-34% and -38%), and diaphragm (-53% and -55%). There was no difference in glycogen content in the brain between AAV-treated and untreated mice. Secreted hGAA protein was detected in the blood from mice treated with either vector, and there was no anti-GAA antibody detected in any of these mice. In the 12-week study, GAA activities were significantly increased in liver, heart and skeletal muscles of AAV-treated mice. Glycogen contents were significantly reduced by the AAV treatment in heart (- 94%), quadriceps (-19%), gastrocnemius (-40%), and diaphragm (-64%), accompanied by the improvement of muscle functions by treadmill and rota-rod tests. **Conclusion:** The G6PC minimal promoter is a unique ubiquitous promoter that drives high-level hGAA expression in liver, muscle, and many other tissues without causing anti-hGAA antibody response in GAA-KO mice. The addition of the muscle enhancer CRM4 greatly increases the promoter activity in the cardiac and skeletal muscles. These novel promoters can be broadly used for gene therapy for inherited disorders that affected multiple tissues including muscle.

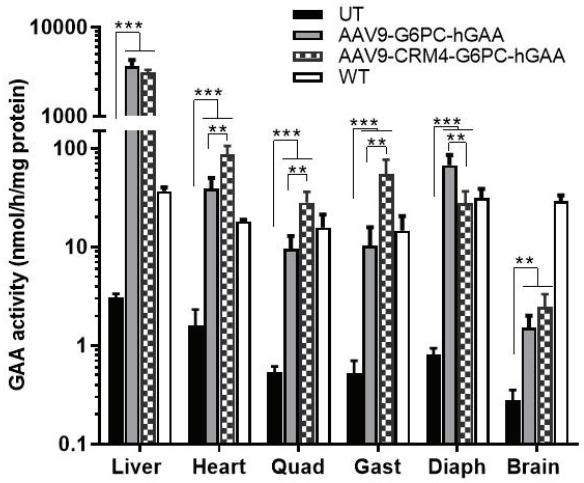

Figure 1. GAA activity in tissues of GAA-KO mice 3 weeks following AAV administration. n=6 for the untreated (UT) and AAV-treated mice; Data shown as mean ± SD. ** p<0.01, ***p<0.001. Wild-type mice (WT, n=5) were included as normal reference.

1569. Preclinical Studies of AAV Vectors with Tissue-Specific, Tandem, and Ubiquitous Promoters for Mucopolysaccharidosis Type IVA Mice

Shunji Tomatsu, Shaukat Khan, FNU Nidhi, Eliana Benincore

Nemours Children's Health, Wilmington, DE

Mucopolysaccharidosis type IVA (MPS IVA) is a lysosomal storage disorder caused by a deficiency of *N*-acetyl-galactosamine-6-sulfate sulfatase (GALNS), leading to the accumulation of storage materials (keratan sulfate and chondroitin-6-sulfate) and developed severe skeletal dysplasia. Enzyme replacement therapy and hematopoietic stem cell transplantation are in practice but have limited impact on skeletal lesions. Gene therapy using adeno-associated virus (AAV) is rapidly growing to treat metabolic diseases. We previously showed that liver-targeted AAV gene transfer of human GALNS expressed supraphysiological levels of the enzyme in blood and multiple tissues and partially improved storage materials and vacuolization of chondrocytes in bone lesions. In this study, we investigated 9 vectors; liver-specific AAV8 vectors with TGB or LSPX promoter, AAV8 and AAV9 vectors in liver-muscle tandem (LMTP), liver-bone tandem (LBTP), and ubiquitous (CAG) promoters in MPS IVA mice to compare therapeutic efficacy on the biochemical markers and bone pathology. All AAV constructs except AAV8-V2-TBG provided supraphysiological levels of GALNS enzyme activity in plasma of MPS IVA mice from 6 weeks to 16 weeks (at autopsy). AAV9-LMTP gave the highest enzyme activity on average. GALNS enzyme activities were also detected in various tissues, including bone. AAV8-CAG and AAV9-LMTP provided the highest enzyme activities in most tissues. All vectors normalized KS levels in plasma, liver, and bone. All vectors showed over 20 vector copy numbers (VCN) in liver, and AAV9-LMTP provided the highest VCN in bone and muscle. Anti-GALNS antibodies were raised in any vector at 16 weeks old. Pathological analyses demonstrated the reduction or complete absence of vacuolated cells in heart muscle and valves in any vector, while bone pathology was improved most with the AAV8-CAG and AAV-LMTP vectors. Overall, all vectors investigated indicated a substantial improvement in biochemical parameters and pathology. This summary of data moves to setting up the clinical trial for MPS IVA

1570. Optimization of Systemic AAV9 Gene Therapy in Niemann-Pick Type C1 Mice

Avani Mylvara[1,2], Cristin Davidson[1,2], Tansy Gu[2,3], Alana L. Gibson[2,4], Laura Baxter[2], Art Incao[2], Charles P. Venditti[2], William Pavan[2], Forbes D. Porter[1]

[1]National Institute of Child Health and Development, Bethesda, MD,[2]National Human Genome Research Institute, Bethesda, MD,[3]University of North Carolina, Chapel Hill, Chapel Hill, NC,[4]University of California San Diego, La Jolla, CA

Niemann-Pick disease, type C1 (NPC1) is an uncommon, fatal neurodegenerative disease resulting from pathological variations of the *NPC1* protein that encodes a lysosomal cholesterol transport protein. Despite extensive research over the past decades exploring potential therapies, individuals with NPC1 in the United States lack any approved regulatory therapy, and only a single approved therapy is available in other countries. Studies involving both systemic and direct central nervous system delivery of AAV9-*hNPC1* have demonstrated significant alleviation of the disease in murine NPC1 models. To assess the impact of dosage on efficacy of gene therapy in NPC1 mice, we administered three different doses of AAV9-*hNPC1* at the weaning age. The medium dose was further examined to assess a therapeutic window of efficacy and was administered at pre-, early, and post-symptomatic time points. Our findings indicate that higher doses administered systemically to *Npc1*^{m1N} mice and at earlier time points result in increased lifespans and delayed disease progression. Analysis of viral copy number and distribution of AAV9-*hNPC1* revealed that earlier administration of the gene therapy product led to greater transduction in the central nervous system. These results offer crucial insights for clinical trial design, suggesting that intervening earlier in a pre-symptomatic disease state with a sufficiently high dose likely will yield better outcomes for NPC1 individuals.

1571. Liver-Directed Gene Targeting as a Potential Therapy for Fabry Disease

Himanshi Saxena[1], Jessica Biasizzo[2], Rossana Domenis[2], Lorena Zentilin[3], Andrea Dardis[4], Andrés F. Muro[1]

[1]International Centre for Genetic Engineering and Biotechnology (ICGEB), Trieste, Italy,[2]Institute of Clinical Pathology, Department of Laboratory Medicine, University Hospital of Udine, Udine, Italy,[3]ICGEB, Trieste, Italy,[4]Regional Coordinator Centre for Rare Diseases, University Hospital of Udine, Italy, Trieste, Italy

Fabry disease (FD) is an X-linked inherited, lysosomal storage disorder caused by Alpha Galactosidase-A (GLA) gene mutations. This gene encodes for the GLA enzyme, responsible for glycosphingolipids (like globotriaosylceramide, Gb3) catabolism. Gb3 accumulation in lysosomes results in systemic clinical manifestations and reduced lifespan. Enzyme replacement therapy (ERT) and chaperone therapy are the available treatments for FD however, noncurative and with limitations. We developed a potential therapeutic approach based on the permanent genetic modification of hepatocytes to express the GLA enzyme by targeting the albumin locus *in vivo*. To model late-onset and early-onset FD, we treated juvenile (P30) and neonatal (P5) Fabry mice (Gla KO) with an AAV8 donor vector containing mAlb homology arms and a WT or codon-optimised (CO) version of the human GLA cDNA that improves translation about 4-6-fold over the WT sequence. To increase safety of the procedure avoiding concerns related to the use of programmable nucleases, we applied a nuclease-free approach coupled with the treatment with fludarabine, which enhances gene targeting rate. Juvenile Fabry animals were treated only with the donor vector (3.0E13 vg/kg) and fludarabine. resulting in increased plasma GLA activity compared to donor-only treated mice which was stable till the termination of the experiment at 5 months of age, accompanied by 80-95% of lyso-Gb3 clearance. As a comparison, the donor vector treatment was coupled with the CRISPR/SaCas9 AAV-mediated delivery (donor, 3.0E13 vg/kg; SaCas9, 6.0E12 vg/kg) to increase targeting efficiency resulting in elevated GLA enzyme activity, accompanied by a 70-80% reduction in Lyso-Gb3 accumulation in liver, kidneys and heart, compared to untreated mutant mice. The treatment of neonatal P5 Fabry mice with donor and SaCas9 AAVs was significantly more efficient than in juvenile animals due to the increased targeting rate in proliferating hepatocytes, reaching up to 8-9% with the highest dose (3.0E14 vg/kg). In fact, we completely cleared lyso-Gb3 in plasma and target organs with the highest dose, while 10x lower dose (3.0E13 vg/kg) resulted in 95-98% reduction in plasma and target organs, higher than that obtained in juvenile Fabry mice. A dose escalation study with liver-specific AAV-mediated episomal gene therapy was done as a proof-of-principle in juvenile Fabry KO mice. Animals treated at 3.0E12vg/kg and higher doses were able to reduce substrate accumulation by 98-100% in plasma and target tissues with the CO-GLA cDNA. Treatment with the lowest dose of the CO-GLA AAV vector (3.0E11vg/kg) resulted in the clearance of 85-95% lyso-Gb3 in the bloodstream and tissues proving the efficacy of the treatment for late-onset FD. ERT-treated animals were considered for comparative evaluation of the treatment, which were less efficient than the lowest AAV dose to clear lyso-Gb3 from plasma and tissues.We showed that treatment of early-onset FD is very effective with a genome targeting strategy, while non-integrating AAV-mediated liver gene therapy is very efficacious for late onset FD, even at low AAV doses. This data is inclined towards a promising one-shot therapy approach to ameliorate the phenotype irrespective of the mutation, targeting both the early and late-onset FD conditions. To test the translational applicability of this integrative strategy, AAV-LK03 vectors containing human ALB homology arms have been successfully tested in the HuH-7 human liver cell line and in primary cultures of human hepatocytes, and are being validated in humanized mice to generate consistent preclinical support.

1572. Development of a Hematopoietic Stem Cell Gene Therapy for Infantile GM1 Gangliosidosis

Linda Bucciarelli, Camilla Fabris, Elena Scarabello, Massimo Accardo, Valentina Poletti, Alessandra Biffi

Department of Pediatric Hematology and Oncology Center, Woman's and Child Health, Università Degli Studi Di Padova, Padova, Italy

GM1-gangliosidosis (GM1, OMIM #230500) is a rare, recessive Lysosomal Storage Disease caused by mutations in the *GLB1* gene encoding the β-galactosidase (β-gal) enzyme. The enzymatic deficiency induces several mechanisms of cell and organ damage resulting in severe and progressive neurodegeneration, and premature death of the patients. Effective LSD treatment requires a prompt and robust enzyme delivery both to the Central Nervous System (CNS) and the periphery. Carriers with ≥20% of residual activity are asymptomatic (Sopelsa et al. 2000), defining a minimal therapeutic goal. Hematopoietic Stem/progenitor Cell (HSC) Gene therapy (GT), based on the transplantation of autologous HSCs genetically-modified *in vitro* by lentiviral gene transfer, showed safety and transformative clinical efficacy in pioneer academic clinical trials for two rare LSDs: Metachromatic Leukodystrophy (MLD, Biffi et al. 2013, Sessa et al. 2016, Fumagalli et al. 2022) and MPS IH (Gentner et al. 2021). As HSC GT may represent a valuable therapeutic option also for GM1, we designed and developed an HSC GT strategy for GM1 gangliosidosis based on the use of a lentiviral vector (LV) encoding either a codon-optimized sequence of the human *GLB1* gene (hu*GLB1*co) or the murine (mu) *Glb1* cDNA. In GM1 patient-derived primary fibroblasts, transduction with both LVs determined a dose-dependent and supra-physiological enzyme expression, with the murine enzyme resulting ~6-fold more active than the human one. Both LVs produced a correctly processed β-gal, secreted and uptaken by target cells. hu*GLB1*-LV determined phenotypical cell correction, evaluated as rescue of lysosomal storage and swelling, with an average vector copy number (VCN) of ≥ 3. A proof-of-concept of efficacy study was conducted in the murine model of the disease, *i.e.* *Glb1*$^{-/-}$ mice, employing both LVs. The study included Busulfan-myeloablated 8-weeks old GM1 mice receiving *Glb1*$^{-/-}$ HSCs transduced with the therapeutic LVs (GT) or WT cells (HSC transplantation), and many control groups: GM1 mice receiving HSCs transduced with a control (GFP) LV, WT mice receiving mock-transduced cells and untreated WT and GM1 mice. At the end of the study (10 months post-transplant) enzymatic activity in the bone marrow (BM) of the *Glb1*$^{-/-}$ mice was rescued, reaching up to the WT range in mice receiving HSCs transduced with the mu*GLB1*-LV (with a mean VCN of 2 in the BM), and 41% of the WT level with the hu*GLB1*co-LV (with a mean VCN of 5 in the BM). In the brain, β-gal activity was also rescued up to ~28% and 20% of the WT level with the mu- and hu-LV, respectively; values that resulted therapeutic in clinical studies for other neuro-LSDs (Gentner et al. 2021, Fumagalli

et al. 2022). Biochemical correction was coupled to a significant amelioration of the neuromuscular phenotype evaluated by the rotarod, hanging and balance beam tests, in addition to an increased survival of GT-treated mice. In summary, we provided early proof of efficacy of HSC GT approach in relevant preclinical disease models to be potentially instrumental to a future clinical translation and identified in the murine cDNA a potentially novel therapeutic opportunity to be explored further.

1573. Real Time Tracking of AAV Gene Therapy via MR Imaging

Thomas J. Meade

Chemistry, Northwestern University, Evanston, IL

Challenge: The gene therapy field lacks disease-specific and robust biomarkers by which it can track therapeutic effects. **Solution:** We have developed a platform of MR imaging contrast agents that are conditionally activated by the product(s) of gene therapy in vivo **(Figure 1)**. The number of academic and biotech-led programs has significantly risen in the last few years, with over 2400 ongoing clinical trials by the end of 2023. It is an exciting and hopeful new era for the gene therapy field. However, ensuring effective clinical trials with shortened paths to approval will require robust biomarkers to track therapeutic effects. To date, there is a lack of non-invasive ways to determine biodistribution or activity levels of these therapies in the body and CNS in patients. This is a significant hindrance, leaving physicians guessing which organs or structures are effectively treated, and due to the lag time associated with clinical disease progression, this limitation ultimately impacts the evolution of treatment modalities. The need for non-invasive, disease-specific biomarkers that reflect treatment efficacy is paramount and not limited to gene therapy. Still, it applies to anything that augments the targeted enzyme activity (including enzyme replacement therapy (ERT), transcriptional read-through agents, and chaperone therapies. Here, we describe the development of a new MRI-based technology to track enzymatic activity enhancement in any organ, peripheral nervous system (PNS), or central nervous system (CNS) over time, and thus, it has the potential to play a critical role in the development and refinement of treatments for *many monogenetic enzymatic deficiencies*. Since these agents are specific to the disease, not the therapeutic modality, advancing this technology applies to the entire lysosomal disease field.

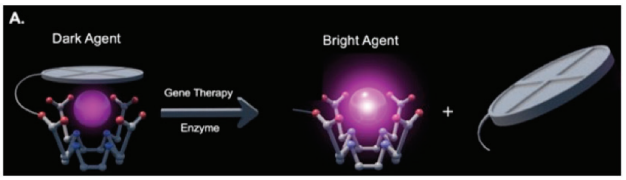

Figure 1A. Schematic of enzyme an *activated* MR contrast agents that monitor *in vivo* gene expression. These agents make possible quantitative, real-time tracking of gene therapy by MR imaging.

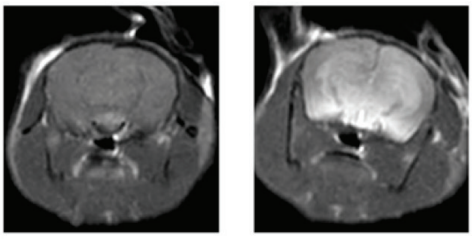

Figure 1B. Pre- and Post MR images of a knockout mouse that was treated by AAV gene therapy. **Left**: Pre-Contrast: **Right**: After intrathecal injection of contrast, no enhancement is observed in wild type animals, however after thalamic injection of gene therapy for β-gal, strong enhancement of the brain is observed, with the greatest in areas with increased CSF (lateral ventricles and ventral aspect of the brain). The significant increase in contrast indicates that the agent was "turned on" by the enzyme delivered by gene therapy.

1574. Peripheral and Behavioral Impacts of AAV Gene Therapy in a Mouse Model of Niemann-Pick Disease, Type C1

Benjamin E. Epstein, Gabrielle M. Soden, Arturo A. Incao, William J. Pavan

National Human Genome Research Institute, National Institutes of Health, Bethesda, MD

Niemann-Pick disease, type C (NPC) is a rare, fatal lysosomal storage disease affecting approximately 1:100,000 births in the United States. NPC is monogenic with autosomal recessive inheritance, and it is caused by mutations in either the *NPC1* or *NPC2* genes, which together function to export unesterified cholesterol from lysosomes. Primary clinical signs of NPC are neurodegenerative, including cerebellar ataxia and cognitive impairment, though visceral symptoms are prevalent as well, with 40% of NPC patients presenting with hepatosplenomegaly in their first year of life. No FDA-approved therapies currently exist

for NPC, though multiple clinical trials are in progress. Previous studies in mouse models of NPC have shown that adeno-associated virus (AAV)-based gene therapy can extend lifespans, slow symptom progression, and reduce neuronal death in the central nervous system (CNS). However, while neurological impacts have been well characterized, the impact of gene therapy on peripheral organs has not been thoroughly examined, particularly in mouse models administered highly efficacious gene therapy treatments. To establish the peripheral impacts of NPC in gene therapy-treated mice, we administered gene therapy in one of four different combinations of AAV serotype, age of delivery, and delivery method to cohorts of NPC1 mutant mice and compared disease outcomes, visceral pathology, and behavioral phenotypes. We found that while all treatments improved outcomes in mice, specific impacts on the periphery varied by treatment method. In particular, NPC1 mice with extended lifespans due to CNS-restricted AAV delivery displayed late-stage visceral pathology distinct from and more severe than normally observed at end stage in mice administered no treatment or less efficacious treatments. Further, while all methods improved behavioral phenotypes, different treatment methods had greater impacts on different individual behaviors assessed. These findings demonstrate the potential for previously unobserved disease manifestations to emerge late in the context of highly efficacious gene therapy treatment of NPC1, and they may suggest the possibility for further improved long-term efficacy by focusing on peripheral treatment in conjunction with the CNS.

1575. AAV-Mediated PPT1 Replacement and Cross Correction for Treating CLN1 Batten Disease

Suhail Alam, Apeksha Khatiwada, Daniel M. Cohen, Drew R. Peterson, John White, Melissa Derby, Bo Wang, Mohamad Nayal, Mallory Becker, Manju Benakanakere, Heena Beck, Charlie Li, Renee Gentzel, Jodi L. McBride, Maria Grazia Biferi, Elizabeth Ramsburg

Spark Therapeutics, Philadelphia, PA

CLN1 Batten disease is a progressive neurodegenerative disease caused by a biallelic loss of function mutation in a lysosomal enzyme called Protein Palmitoyl Transferase 1 encoded by the *PPT1* gene. Cells lacking PPT1 are unable to clear lysosomal contents which directly compromises cellular health resulting in a range of clinical symptoms including profound neurological dysfunction. Notably, CLN1 disease impacts the entire central nervous system. Regions exhibiting the most severe neuronal loss include the cerebral cortex, basal ganglia nuclei, thalamus, cerebellum, spinal cord, and retina. Children who develop the most aggressive infantile-onset form of CLN1 disease typically succumb to the disease in early childhood while those developing the disease later in life may survive to early adulthood. We are developing an adeno-associated virus (AAV)-mediated gene therapy approach with the goal to have ubiquitously expressed PPT1 throughout the brain and spinal cord of affected individuals. PPT1 is a secreted enzyme, which makes this a suitable candidate for maximizing efficacy through cross-correction. We will present data on the preclinical development of this approach, including the use of *in silico* tools to engineer PPT1 protein designs with enhanced secretion properties, the selection of lead candidates in cellular models, and the biodistribution results from preclinical animal studies. Studies in mice and sheep demonstrated that intra-cerebroventricular administration of vectorized PPT1 transgene in a proprietary AAV facilitates efficient vector distribution and transgene expression in crucial CNS regions affected by CLN1 disease. A long-term efficacy study conducted in the *Ppt1* deficient mouse model also revealed positive outcomes. Preliminary findings indicate that our treatment successfully preserves motor functions, prolongs survival, and is well tolerated. Taken together, these studies encourage continued preclinical exploration of this gene therapy-focused strategy for the treatment of CLN1 Batten disease.

Friday Posters: Heart, Lung, and Kidney Diseases

1576. KRT7 Lineage Expansion Following Bleomycin Injury in an IPF Ferret Model

Shuang Wu[1], Ian Driver[2], Meihui Luo[1], Hikaru Miyazaki[2], Jing Wang[1], Dimitry Popov[2], Smitha Shambu[2], Aleksandra Tata[3], Martin B. Jensen[2], Miao Yu[1], Ziying Yan[1], Douglas J. Bartels[1], Xingshen Sun[1], Purushothama Rao Tata[3], Xiaoming Liu[1], Vishwaraj Sontake[2], John F. Engelhardt[1]

[1]University of Iowa, Iowa City, IA,[2]Gordian Biotechnology, South San Francisco, CA,[3]Duke University School of Medicine, Durham, NC

IdiopathicPulmonary fibrosis (IPF) is a progressiveand irreversible disease with an unknown etiology, characterized by lungscarring and remodeling involving excessive deposition of extracellular matrix(ECM). It is currently an incurablelung disease with limited therapeutic options. Gene and cell therapies are a promisingapproach for treating a range of fibrotic diseases, including IPF. However, theprogress in developing these innovative therapies has been considerably impededdue to the absence of suitable IPF animal models, which hinders fullyunderstanding disease pathogenesis, a crucial foundation for approachinggenetic therapies. Recognized for their similarities in airway anatomy, lungcell biology, and physiology with humans, domestic ferrets stand out asexcellent models for respiratory disease research. Consequently, we undertookthe characterization of a bleomycin (BLM)-induced IPF ferret model, assessingalterations in histopathology, pulmonary function, biomarkers, and cell typecomposition of the IPF lung. The IPF ferret lung exhibited human analogoushistopathological features, such as honeycomb structures, proximalization ofthe distal airspaces, ECM deposition, a biomarker profile, and decreasedpulmonary compliance. Singlenuclei RNA sequencing (snRNA-Seq) analysis demonstrated that thetranscriptional profile and cell type composition of BLM-induced ferret lungwas closer to human IPF lung, compared to the BLM-induced murine lung. Differentiallyexpressed genes (DEGs) and cell type analysis further revealed that cytokeratin7 (KRT7) was strikingly upregulated in a fraction of transitional alveolartype-2 (AT-2) and type-1 (AT-1) cells and aberrant basaloid cells of the IPFferret lung, which was further validated by immunofluorescence staining. To betterunderstand the origins of KRT7 cells during disease progression, *KRT7*- CreERT2:*ROSA26*-mTmG doubletransgenic ferrets

were induced with tamoxifen to genetically label KRT7 cells EGFP+. BLM-injured *KRT7*-CreERT2:*ROSA26*-mTmG ferretsdemonstrated a dynamic change of KRT7-positive lineage cells in lung during theprogression of fibrosis. KRT7-positive cells within the alveolar regions of thelung expanded significantly during early phases of injury and then laterdeclined as terminal fibrotic stages were achieved, mirroring changes in KRT7expression evaluated by snRNA-seq. Prior to injury KRT7 expression cells in thelung appeared to express both AT-1 (AGER) and AT-2 (SFTPB) cell markers, but unidentifiedcell types were also observed. We are currently identifying and validating celltype transitions of KRT7 lineage cells following BLM injury by scRNA-seq and FISH.KRT7-positive lineages in the alveolar regions of the lung may represent a stemcell compartment that facilitates repair could be a therapeutic target for gene and cell therapy for IPF.

1577. Hermansky-Pudlak Syndrome: Gene Therapy Assessment for HPS-1-Associated Pulmonary Fibrosis in a Novel Hps1 Knockout Mouse Model

Gustavo Nieto-Alamilla[1], Molly Behan[1], Shachar Abudi-Sinreich[1], Marina Zieger[2], Payam Khoshkenar[3], Mahin Shaimonti Hossain[4], Resat Cinar[5], Bernadette Gochuico[1], Christian Mueller[6], William A. Gahl[7], May Christine Malicdan[8]

[1]Human Biochemical Genetics Section, Medical Genetics Branch, National Human Genome Research Institute, Bethesda, MD,[2]UMass Chan Medical School, Worcester, MA,[3]UMass Medical School, Worcester, MA,[4]Undergraduate Scholarship Program, OD, NIH, National Human Genome Research Institute, Rockville, MD,[5]National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, MD,[6]Sanofi Genzyme, Framingham, MA,[7]National Human Genome Research Institute, Bethesda, MD,[8]National Institutes of Health, Bethesda, MD

Hermansky-Pudlak syndrome type 1 (HPS-1) is a complex autosomal recessive disorder characterized by albinism and bleeding predisposition. It is part of a heterogeneous genetic syndrome with eleven types (HPS-1 to HPS-11), each associated with specific mutations in genes involved in lysosome-related organelles complex biogenesis. Current treatments, like lung transplantation, have limitations, necessitating alternative approaches. Previous work using a spontaneous murine mutant (Hps1ep/ep) elucidated disease mechanisms but lacked insights into spontaneous PF development. Gene therapy offers promise for HPS-PF treatment. This study introduces a novel Hps1 model and explores HPS1 gene augmentation. To understand HPS-1 and identify PF markers, we generated a CRISPR-Cas9-engineered knockout mouse model ($Hps1^{\Delta/\Delta}$), characterizing it at the cellular and molecular levels. AAV-based gene therapy (AAV5 and AAV8) aimed to identify predictive surrogate endpoints for HPS-PF outcomes. AAVs containing enhanced green fluorescent protein or mouse Hps1 gene were systemically delivered, with saline injections as controls. $Hps1^{\Delta/\Delta}$ mice exhibited clinical manifestations seen in HPS-1 patients, including reduced gene and protein expression, platelet abnormalities, and PF. Tropism analysis showed Hps1 expression in the lungs post-AAV treatment. AEC2 size was reduced in AAV-treated mice. AAV8-Hps1-treated mice exhibited significant pulmonary function improvements, indicating therapeutic potential. These findings highlight gene therapy advancements for HPS-1 PF, offering transformative treatment possibilities. Ongoing research is crucial to refine gene therapy, ensuring long-term safety and efficacy for HPS1-PF patients.

1578. Preclinical Optimisation of Lentiviral Delivery to Piglet Lungs for Gene Therapy of Surfactant Deficiencies

Craig McDougall[1], Cathy McLaughlin[1], Elisabeth Thornton[1], Christina Vrettou[1], Kamran Miah[2], Emily Castells[2], Rebecca Dean[2], Mariana A. Viegas[2], Stephen C. Hyde[2], Deborah R. Gill[2], Gerry McLachlan[1]

[1]The Roslin Institute, University of Edinburgh, Edinburgh, United Kingdom,[2]University of Oxford, Oxford, United Kingdom

Introduction. Surfactant protein deficiencies account for 10% of childhood interstitial lung disease and the prognosis depends on the specific protein that is deficient. Infants with severe surfactant protein B (SP-B) deficiency or double null mutations in ABCA3, a protein that transports surfactant lipids to lamellar bodies, present shortly after birth with respiratory distress and failure. Despite ventilation and treatment with synthetic surfactant, they rarely live beyond the first few months of life. An effective gene therapy for surfactant deficiencies has the potential to be transformative. **Methods**. A proprietary Simian Immunodeficiency Virus (SIV) based lentiviral vector, pseudotyped with Sendai Virus F/HN proteins and expressing EGFP, was delivered to the lungs of ventilated neonatal piglets. This was performed by multisite bronchoscopic instillation via an endotracheal tube to model clinical delivery of vector to the lungs of ventilated infants. At post-mortem, precision cut lung slices (PCLS) were prepared to assess the impact of vector dose and volume on the distribution and type of transduced cells. We used quantitative immunohistochemistry (IHC) with antibodies against EGFP as well as alveolar type I (ATI) and type II (ATII) pneumocytes. Transgene mRNA was quantified by qRT-PCR and localised by hybridisation chain reaction (HCR) assays to detect transgene mRNA, Surfactant Protein-C mRNA (ATII cells) or AGER-1 mRNA (ATI cells). **Results**. We hypothesised that delivery of a given vector dose in a larger volume can reduce the heterogeneity of transduction/transgene expression. Multisite instillation with small volumes of concentrated vector at two doses was compared with lavage-like delivery of a similarly high dose of vector in a larger volume. Multisite instillation of 5x 2e8 TU or 5x 1e9TU in small volumes (300ul per site) resulted in dose-dependent expression of EGFP but showed significant heterogeneity with approximately 50% of captured images showing no detectable EGFP, and efficiency ranging from 0 to 98% of alveolar epithelial cells in individual images. Delivery of the 5x 1e9TU dose in larger volumes (8ml per site) reduced the number of images without detectable EGFP (31% images and a range from 0 to 17% EGFP-positive cells per image). The overall average efficiency in the latter study was 4% EGFP+ alveolar epithelial cells. Increasing the dose further (5x 3e9TU) in the same volume (8ml per site) reduced the number of images with no GFP to 15% and increased the average expression to 8% of cells (Range 0-27%). The reduced heterogeneity from delivery in larger volume is supported by more consistent transgene mRNA levels in tissue samples across the lung. Expression of both mRNA and protein has been demonstrated in ATII cells. **Conclusion.** We have shown that multisite bronchoscopic instillation

of a lentiviral vector via a catheter can be optimised to provide more evenly distributed transgene expression throughout the lung and is compatible with treatment of a ventilated infant with surfactant deficiency. Importantly we have demonstrated transduction of target ATII cells for processing surfactants via lamellar bodies for secretion in the lung. In addition, the progenitor nature of ATII cells supports the notion of long-term efficacy from a single dose. Further studies in piglets will help to optimise dose and delivery protocols and will aid calculations of the required dose projected to reach the therapeutic level of expression in the target cells, in clinical trials.

1579. Lymphoid Enhancer Binding Factor 1 Inhibits Airway Glandular Basal Cell Differentiation into Epithelial Secretory Cells

Jing Wang, Shuang Wu, Meihui Luo, Miao Yu, John F. Engelhard, Xiaoming Liu

Department of Anatomy and Cell Biology, University of Iowa, Iowa City, IA

Asthma is a chronic pulmonary disease characterized by eosinophil-mediated airway inflammation, airway hyperresponsiveness (AHR), and airway remodeling. It involves hyperplasia of goblet cells and remodel of submucosal glands (SMGs), and excessive secretion of mucus. Among these features, aberrant differentiation of goblet cells and hyperplasia of SMGs are the disease hallmarks. The changes in cell-type composition and the imbalance in airway epithelial-cell function, the remodeling and dysfunction of SMGs are involved in asthma pathogenesis and airway remodeling. Therefore, components of molecular signaling pathways that regulate the regeneration of airway epithelia and the development of SMGs may be effective targets in gene and cell therapies for airway disease associated with asthma. A key signaling component during SMG development is the well-known transcription factor lymphoid enhancer binding factor 1 (Lef-1), which is also activated during epithelial repair and airway remodeling following airway injury. However, the mechanisms by which Lef-1 regulates the differentiation of secretory cells and the remodeling of SMGs in the context of asthma-associated inflammation have not been investigated. We have utilized lineage tracing mouse lines that carries either a *Lef-1* gene knockout (KO) or a knock-in (KI) to create ovalbumin (OVA)-induced asthma model. The mice were sensitized by applying OVA (1.0mg/kG in 8.0mg/mL of Alhydrogel) once weekly for three weeks, and then the response was boosted by intratracheal instillation of OVA (1.0mg/kG in saline) three times at one-week intervals. We then assessed changes in the cell type composition of airway epithelia and SMGs in a mouse model of asthma, as well as an air-liquid interface (ALI) culture model and an organoid culture model generated from SMG glandular cells isolated from these animals. Analysis of the lineage-tracing mouse linerevealed aberrant inflammation and the presence of Muc5ac- and Muc5b-positive secretory epithelial cells in the trachea and intrapulmonary airways. Analyses of the ALI and organoid cultures demonstrated that *Lef-1* overexpression strikingly inhibited the differentiation of secretory cells but induced that of ionocytes (assessed by staining for Barttin CLCNK Type Accessory Subunit Beta). In contrast, the IL-13, a central cytokine that drives airway epithelial dysfunction in the context of asthma, significantly induced the differentiation of secretory cells but inhibited that of ionocytes in the in vitro models. However, simultaneous overexpression of *Lef-1* and exposure of IL-13 had no impact on either the proliferation of airway basal cells or the differentiation of ciliated cells. Similarly, conditional KO of *Lef-1* had no effect on the differentiation of these cell types. These results clearly implicate *Lef-1* in regulating the differentiation of SMG cells into airway secretory cells vs ionocytes. We are currently evaluating the cell-type composition of tracheal and intrapulmonary airway epithelia, as well as SMGs, in the conditional *Lef-1* gene modified lineage tracing mice in the context of OVA-induced asthma. Given the role of *Lef-1* in regulating the differentiation of epithelial secretory cells and ionocytes, it represents a candidate target for genetic and cell therapy for asthma-associated airway disease.

1580. Mucin Targeted Gene Therapy for Asthma

Sahana Kumar[1], Maria Rife[1], Margaret Scull[1], Gregg Anthony Duncan[2]

[1]Biological Sciences, University of Maryland, College Park, College Park, MD,[2]University of Maryland, College Park, MD

Asthma is a globally burdensome respiratory disease, affecting millions worldwide. It is characterized by chronic airway inflammation, airway remodeling, and impaired mucociliary clearance (MCC). Mucus comprises gel-forming mucin proteins mucin 5B (MUC5B) and mucin 5AC (MUC5AC). Healthy airway mucus is predominantly composed of MUC5B, with reduced MUC5AC. However, in individuals with asthma, biochemical analysis of their mucus revealed a shift from MUC5B to MUC5AC as the predominantly secreted mucin. These changes to mucus composition have been shown to impair MCC and obstruct airways due to increased mucus plugs in asthma patients. Given the overproduction of MUC5AC in the asthmatic airway, we hypothesized delivery of MUC5AC siRNA to the airway epithelium, could improve MCC, reduce airway hyperreactivity, and improve asthma symptoms *in vitro* and *in vivo*. For *in vitro* studies to validate MUC5AC as a relevant therapeutic target in asthma, immortalized basal human airway epithelial (HAE) cells were differentiated into secretory and ciliated cells by culturing at air-liquid interface (ALI). To establish an asthma-like phenotype, ALI cultures were stimulated with cytokine interleukin-13 (IL-13). We utilized adeno-associated virus serotype 6 (AAV6), which shows tissue tropism for lungs, as the viral vector in these experiments. To determine if AA6 could penetrate the mucus barrier in asthmatic airways, multiple particle tracking (MPT) analysis was used to compare AAV6 diffusion in mucus from unstimulated and IL-13-stimulated ALI cultures. To characterize AAV6 transduction in HAE cells, AAV6 expressing enhanced green fluorescent protein was used to assess transduction efficacy. The efficacy of AAV6 carrying MUC5AC-siRNA (AAV6-MUC5AC-siRNA) to silence MUC5AC was evaluated using immunofluorescence and quantitative real-time polymerase chain reaction (qRT-PCR).MPT analysis of AAV6 in HAE mucus with and without IL-13 stimulation revealed that the mean squared displacement of AAV6 was similar in unstimulated and IL-13 stimulated mucus, indicating AAV6 can diffuse through asthma-like mucus barrier enriched with MUC5AC (Fig 1A). MPT analysis further revealed changes in mucus microstructure in IL-13-stimulated mucus, indicated by increased pore sizes (Fig 1B). AAV6 transduced unstimulated and IL-13 stimulated HAE cells at multiplicities of infection 10^4 and 10^5 (Fig 1C). Initial studies of AAV6-MUC5AC-siRNA showed promise, with expected trends of elevated

MUC5AC messenger RNA expression in IL-13-stimulated mucus and reduced expression in the AAV6-MUC5AC-siRNA treatment group (Fig 1D). Future and ongoing work includes evaluating MCC in MUC5AC-siRNA-treated HAE cultures and proof-of-concept *in vivo* studies using a mouse model of allergic asthma. If successful, this gene delivery approach could open avenues for mucin-targeted therapies aimed at asthma and other related chronic lung diseases.

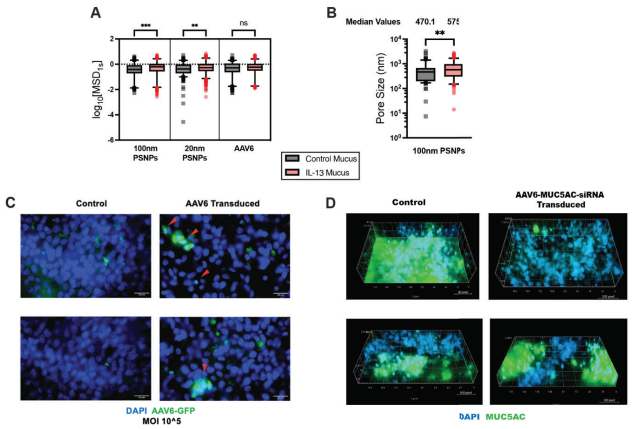

Figure 1. AAV6 penetrate mucus barrier and delivers siRNA.
(A) Box-and-whisker plots of log-based 10 of MSD at t=1s of 100nm PSNPs, 20nm PSNPs and AAV6 in untreated control (black) and IL-13 stimulated (red) HAE mucus are shown. Horizontal bars represent median values. Data sets statistically analyzed with One-Way ANOVA Kruskal-Wallis test: *** $p < 0.001$. **(B)** Calculated pore size in control (black) and IL-13 stimulated (red) HAE mucus based on 100nm PSNP diffusion in mucus. Data sets statistically analyzed with two-tailed Mann-Whitney test: ** $p<0.01$. (**C**) AAV6-eGFP transduction in differentiated IL-13 stimulated HAE cells 3 days post-infection at MOI 10^5 (scale bar=20μm). The red arrows indicate clusters of transduced cells. **(D)** Representative Z-stack images of HAE ALI cultures treated with and without AAV6-MUC5AC-siRNA. MUC5AC (green) is highly expressed in untreated controls while expression is reduced in treated groups.

1581. Transduction Efficiency of Adeno-Associated Virus and Lentiviral Vectors in Murine Lungs and Precision-Cut Lung Slices Derived from Various Species

Brenna A. Y. Stevens[1], Madison E. Hughes[1], Nicole Zielinska[1], Howard L. Erin[1], Jeff L. Caswell[1], Karimi Khalil[1], Bernard Thebaud[2], Yanlong Pei[1], Sarah K. Wootton[1]

[1]Pathobiology, University of Guelph, Guelph, ON, Canada,[2]Ottawa Hospital Research Institute, Ottawa, ON, Canada

Intro: Cystic Fibrosis and other monogenic lung diseases have long been a pertinent target for viral vectored gene therapies. The most clinically relevant viral vectors are adeno- associated viruses (AAV) and lentiviruses (LV). In this work, the potential of both vectors for lung gene delivery is evaluated in a murine model. Furthermore, it is widely observed that *in vitro* transduction by AAV-based vectors does not reliably correspond to *in vivo* transduction. Precision-cut lung slices (PCLS) offer a promising *ex vivo* model with many advantages over traditional cell culture. They retain similar diversity of cell types, structural architecture, and microenvironment, as lung tissue. It is hypothesized that PCLS can be used as a tool to more accurately predict *in vivo* viral-vectored transduction efficiency. **Methods:** Here, $4x10^8$ transducing units (TU) of three different pseudotyped LVs and $1x10^{11}$ vector genomes (vg) of AAV6.2FF or AAV9 carrying the reporter gene human placental alkaline phosphatase (AP) were administered intranasally to BALB/c mice (n=4) to evaluate each vector's efficiency as a gene therapy vector. Mice injected with PBS were used as negative controls. After 21 days, the lungs were harvested and either visually stained for AP expression or homogenized and run on AP enzymatic activity assays to quantify levels of AP expression. Histological slides were prepared, and AP stained to determine what cell types were being transduced by each vector. Additionally, PCLS were generated from BALB/c mice, pigs, cows, sheep, and rabbits. The slices were then transduced with either lentiviral and AAV vectors, or exclusively the AAV vectors. The PCLS were harvested 5 days post-transduction for staining and AP activity analysis. **Results:** The *in vivo* administration of AAV6.2FF-AP and AAV9-AP in mice resulted in robust and widespread expression of AP in the lungs, with a trend of AAV6.2FF outperforming AAV9. Similarly, in murine PCLS AAV6.2FF transduction produced high AP expression, while AAV9 transduction resulted in lower expression. In mice, the *in vivo* administration of VSV-G and ZebovΔmucin-pseudotyped LV induced little to no AP expression, while GP64-pseudotyped LV led to moderate AP expression. In murine PCLS, AP levels were low after all lentiviral pseudotype transduction. However, in porcine PCLS both AAV6.2FF and LV transduction resulted in high AP expression. AAV6.2FF transduction was effective in PCLS of all tested species. Transgene expression by GP64 pseudotyped LV was higher than expected; however, AAV6.2FF outperformed all LV vectors tested in both *ex vivo* PCLS and *in vivo* murine lungs. **Conclusions:** Due to the high correlation between PCLS and *in vivo* transduction results, it is evident that PCLS are a useful model to rapidly screen gene therapy candidates and bridge the gap between *in vitro* and *in vivo* data. AAV6.2FF also displayed a wide species tropism in PCLS. This is the first evidence of bovine and porcine lung transduction by AAV6.2FF. Given the availability of clinically relevant porcine models for cystic fibrosis, this supports the use of AAV6 and AAV6.2FF in the development of a gene therapy treatment for cystic fibrosis.

1582. Enhancing Airway Transduction Using AAV Equipped with Advanced Barcoding Methods for CF Gene Therapy

Ashley L. Cooney[1], Yonghong Chen[2], Brian Lewandowski[2], Priyanka K. Newase[1], Beverly L. Davidson[2], Paul B. McCray[1]

[1]University of Iowa, Iowa City, IA,[2]Children's Hospital of Philadelphia, Philadelphia, PA

Approximately ~10% of people with CF do not benefit from current CFTR modulators, including those with nonsense or splicing mutations and those intolerant of the medications. This motivates our investigations into genetic therapies including gene addition and gene editing. A key limitation to applying these and other emerging technologies to CF is effective therapeutic delivery. Adeno-associated virus (AAV) is a broadly useful vector for delivery to many cell types and is safe unless delivered at very high doses. Because of its persistence as an episome, expression lasts for months or years in slowly dividing cells. While past CF clinical trials using AAV2 were unsuccessful, many of the contributing limitations have been identified including poor transduction efficiency and inappropriate expression cassette design. Here, we address the inefficiency of current AAVs by taking advantage of an AAV library screen. Using advanced AAV barcoding methods and screening in multiple large mammalian species, we identified capsid variants that can transduce target cell types at doses 1 to 2 logs lower than currently available capsids. Additionally, libraries of

capsids from multiple serotypes were screened in primary air-liquid interface cultures of human airway epithelia (HAE) isolated from CF and non-CF individuals. One consistently enriched variant, BLD034, shows significantly enhanced transduction properties compared with the benchmark AAV2.5T capsid in HAE, even in the absence of the proteosome inhibitor doxorubicin (Dox). To test the transduction ability of BLD034 in a relevant airway model, HAE were transduced from the apical surface with AAV2.5T and AAV-BLD034 overnight in the presence or absence of Dox. By 21 days post-transduction, GFP expression in HAE transduced with BLD034 was robust relative to AAV2.5T in the absence of Dox. In the presence of Dox, these results were further amplified. Ongoing experiments are testing minimal effective dose and complementing CFTR in CF HAE. AAV capsids designed with advanced barcoding techniques provide opportunities for improved potency and may omit the need for concomitant proteasome modulation in airway gene therapy applications.

1583. COVID-19 and Its Associated Variants

Ghazala Rubi Rubi

Central Research Lab & Molecular Genetics Pathology, Lahore General Teaching Hospital, Lahore, Pakistan

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is an enveloped RNA beta-coronavirus virus that is corona viridae-related. It originated in Wuhan, China in December 2019 and is known to cause COVID-19 illness. SARS-CoV-2 posed a major threat to the world in concern of health along with trade and medical facilities. COVID-19 patients experience comorbid conditions like severe fever, typhoid, myocarditis, and a fatal black fungus attack. World Health Organization declared COVID-19 as an emergency on 30th January 2020 and a pandemic on 11th March. As of right now, COVID-19 has been verified to have infected over 100 million people across 210 nations, and 2 million of those infections have resulted in death. RT-qPCR (Reverse transcriptase qualitative PCR) test is performed if any symptoms exist, and isolation is necessary for three to five days after the confirmation. In Pakistan, it was reported firstly on 26th February 2020 by the Pakistan government when two persons were found infected with the disease. SARS-CoV-2 changes its genome constantly and results in the emergence of different variants in different waves. Pakistan has faced 6 sequential waves since 2020 to date, each associated with different variants and overlapping variants. The first wave was associated with B.1, B.1.471, B.1.36, second with B.1.36.31, B.1.247, B.1.1.1, B.1.160, B.1.471, B.1.562, B.1.1.7, B.1.1.250, B.1.261, B.1.351, P.1, third with B.1.1.7, B.1.351, P.1, B.1.617.2, B.1.36, B.1.468, B.1.1.413, A.27, fourth with P.1, B.1.617.2, fifth with Omicron (B.1.1.529) and sixth with new sub variants of Omicron (BA.4 & BA.5). In terms of severity and infectivity, Omicron and its sub variants differ from Delta and other SARS-CoV-2 variants. In this review, we have discussed SARS-CoV-2 spike mutations, its variants along with their origin & association to wave(s), and its scenario in Pakistan.

1584. Demonstration of the Feasibility of AAV Vector-Mediated Gene Therapy for Alport Syndrome Using a Newly Established Floxed Mouse Model

Ranjan Das[1], Taisuke Furusho[1], Anusha Sairavi[1], Hideyuki Hakui[1], Shuhua Luo[1], Lena Li[1], Jeffrey H. Miner[2], Hiroyuki Nakai[1,3]

[1]Molecular and Medical Genetics, Oregon Health and Science University, Portland, OR,[2]Division of Nephrology, Washington University School of Medicine, St. Louis, MO,[3]Molecular Microbiology and Immunology, Oregon Health and Science University, Portland, OR

Alport syndrome (AS) is characterized by abnormalities in glomerular basement membranes (GBMs), leading to chronic kidney disease (CKD) in patients. This results from mutations in the *COL4A3*, *COL4A4*, or *COL4A5* genes, each of which encodes a different alpha chain of type IV collagen. Approximately 80% of individuals with Alport syndrome have the X-linked type (XLAS) due to a mutation in the *COL4A5* gene. Here, we establish a novel Col4a5-LoxSTOPLox-KnockIn (LSL-KI) XLAS mouse model using CRISPR-Cas9 and demonstrate therapeutic effects in XLAS mice following AAV-Cre vector administration at ages both before and after CKD is manifested. In this study, a LSL cassette containing an SV40pA-derived STOP signal was introduced into intron 1 present downstream of the 431-bp-long (contributing to the first 27amino acids) exon 1 of the mouse *Col4a5* gene located on the plus strand of chromosome X. Two founder mice were obtained from CRISPR-Cas9-treated embryos, and a colony was established. Male hemizygous mice developed significant proteinuria and elevated serum creatinine (sCr) and blood urea nitrogen (BUN), and died or reached an experimental endpoint for humane euthanasia around the age of 30 weeks due to renal failure. This newly developed mouse model manifested CKD in a manner similar to that of the well-established Col4a5 G5X XLAS mouse model. In a proof of concept (POC) study, bilateral renal pelvis injection was performed on young 5 to 6-week-old LSL-Col4a5 hemizygous male mice with either vehicle only or 3 x 10^{11} viral genomes (vg) of AAVKP1-CAG-Cre (n=2 in each group). Thirteen-weeks post injection, recovery of Col4a5 was clearly observed in GBM and tubular basement membrane (TBM) in one of the AAV vector-injected mice, where no expression of Col4a5 was detected in the vehicle treated group. Improvement of blood biomarkers was also evident in KP1 treated group (24-week-old) compared to vehicle group (26-week-old) (KP1 vs. vehicle -> BUN: 52.0 vs. 132.5 mg/dL, Cr: 0.2 vs. 0.8 mg/dL and Hb: 12.6 vs. 6.7 g/dL). In the second POC study, three Col4a5-LSL hemizygous male mice were intravenously injected with 6.8 x 10^{11} vg of AAV9-CAG-Cre vector at the age of 17 weeks, when these mice already manifested CKD. Ten-weeks post injection, one of the AAV vector-injected mice was assessed for Col4a4 and Col4a5 expression in kidney by immunofluorescence microscopy. In contrast to control hemizygous mice, vector-treated mice showed restoration of both Col4a4 and Col4a5 within the GBM. Surprisingly, the remaining two vector-treated mice did not exhibit loss of body weight until 36 weeks of age and survived for more than 39 weeks, surpassing the age by which all untreated XLAS mice would succumb or reach the endpoint. In macroscopic observations, AAV vector-treated XLAS mice demonstrated visual improvements in kidney structure. The kidneys of untreated mice were shrunken, and irregular and granular on the surface. On the other hand, the kidney surfaces of AAV vector-treated

counterparts were relatively smooth. Moreover, the kidney size and shape were normal in these treated mice, closely resembling those of wild-type mice. These observations demonstrate that KP1 and AAV9 vectors effectively transduced podocytes, leading to the restoration of heterotrimeric type IV collagen expression and its incorporation into the GBM. Thus, we demonstrate for the first time the efficacy of AAV vector-mediated gene therapy for Alport syndrome, and importantly the therapy is effective even after the establishment of CKD.

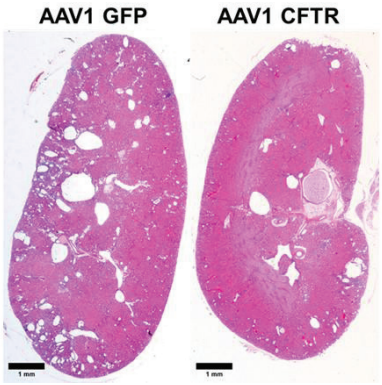
1585. Direct Delivery of a Novel AAV Gene Therapy to the Kidney Enables Podocyte Targeting for the Treatment of Glomerular Diseases

Sam Illingworth[1], Kritima Gurung[1], Valeryia Kuzmuk[1], Hannah Wood[1], Demetris Taliotis[1,2], Gavin Walsh[1,2], Moin Saleem[1,2], Alice Brown[1]

[1]Purespring Therapeutics, London, United Kingdom,[2]Universtity of Bristol, Bristol, United Kingdom

Adeno associated vector (AAV) gene therapy has the potential to treat a wide range of kidney diseases via targeted delivery of genes to podocytes, a kidney cell type instrumental in renal function. Despite the potential to impact many kidney conditions, podocyte targeted AAV gene therapy has proven challenging. This is due to technical and physiological hurdles limiting the ability of AAV to be effectively and specifically delivered to podocytes. We have developed a novel AAV gene therapy and local administration procedure able to deliver transgenes effectively, specifically and safely to podocytes. The podocyte is the central player in the primary function of the kidney, filtration of the blood, and dysregulation of podocyte proteins is implicated in numerous monogenic and non-monogenic kidney disorders. We have exemplified our approach through pre-clinical development of PS-001, a novel locally delivered AAV gene therapy that delivers the podocin gene, *NPHS2*, to the podocyte. Mutations in the *NPHS2* gene are the most common cause of monogenic paediatric nephrotic syndrome, a severe kidney disease which results in renal failure and requirement for kidney transplantation in childhood. PS-001 consists of a capsid that is highly effective at transducing human podocytes and promoter that drives gene expression of podocin specifically in the podocyte. Functional gene expression of podocin was demonstrated in *in vitro* studies in podocytes from *NPHS2* nephropathy patients. PS-001 efficacy, safety and potential for clinical translation has been robustly demonstrated in rodent disease models and in large animal studies in Gottingen Minipigs. Murine *in vivo* proof of concept studies were conducted in a knock-in model of a mutated *nphs2* gene variant most commonly associated with disease in humans ($nphs2^{R140Q/-}$). Using a murine analogue of PS-001, podocin expression was measured in kidney glomeruli and significant efficacy demonstrated via rescue of kidney function. This was shown by resolution of severe proteinuria (mean ACR ug/mg 6049 ± 2803 vs 192 ± 51 in PS-001 treated animals, n=11), improved serum albumin (g/L 27.50 ± 3.33 g/L vs 30.75 ± 2.46 in PS-001 treated animals, p=0.021) and improvement in kidney histopathology (mean sclerosed glomeruli 81% ± 19 vs 18.75% ± 12 in PS-001 treated animals, P<0.0001). The methods to translate the approach to the clinical setting using local administration were established in pigs. Administration of PS-001 resulted in transgene mRNA expression across 89% ± 11% of kidney glomeruli as assessed by RNAScope (n=3 pigs), and transgene derived podocin could be specifically detected in podocytes as assessed by immunofluorescence analysis. Using qPCR, RT-PCR and ELISA it was shown that following local administration, podocin gene expression was restricted exclusively to the kidney glomerulus, where podocytes are located, with gene expression undetectable in off-target organs including the liver. Additional toxicological assessments of kidney and other organs, urine and blood analyses, and post-study histopathological assessments revealed no treatment-related safety concerns. Collectively, we present data showing development of an AAV gene therapy and method of administration for the delivery of transgenes specifically to kidney podocytes. We have shown transgenes can be efficiently targeted to podocytes to replace defective genes or to use the podocyte as a protein factory to modulate glomerular biology. This technology therefore provides an important novel modality for potentially treating a broad range of kidney disease.

1586. AAV1 CFTR Gene Therapy Successfully Reduces Cysts in a Mouse Model of Autosomal Dominant Polycystic Kidney Disease



Cristian Ciobanu, Liudmila Cebotaru

Medicine and Physiology, Johns Hopkins University, Baltimore, MD

Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the formation of multiple large fluid-filled cysts that displace normal renal tissue and lead to end-stage renal disease by the sixth decade of life. Current potential therapies for ADPKD involve treatment of the symptoms associated with kidney disease and/or organ transplantation. Tolvaptan, a new drug in clinical use, is limited by side - effects. Cyst growth involves fluid secretion into the cyst lumen through the action of CFTR, located at the luminal membrane. We showed that CFTR correctors such as VX-809 alter the location of CFTR in cystic epithelia from the apical to the basolateral membrane, thereby reducing cyst formation. Here, we propose the novel hypothesis that a gene therapy based on CFTR can prove effective in reducing kidney damage in ADPKD. One of the most commonly discussed challenge is the size exclusion by the glomerulus that retards movement of virus particles into the glomerular filtrate. We would argue that the kidney is a highly vascular organ with networks of peritubular capillaries supplying blood to the cortical regions and the vasa recta supplying blood to the medulla. To provide data showing that kidney transduction via systemic delivery is feasible, approximately 1-month-old, $Pkd1^{R3277C/R3277C}$ ($Pkd1^{RC/RC}$) mice were injected intraperitonially with 2×10^{12} particles/kg of AAV1 containing either GFP or Δ27-264-CFTR (referred to as GFP or CFTR-vector). Δ27-264-CFTR is a truncated version of CFTR that increases expression of endogenous CFTR via transcomplementation. Animals were necropsied 2 months after treatment. Remarkably the cyst area and size were less in the CFTR- compared to GFP-vector treated animals. We were able to detect vector genomes at $>4x10^5$ vector genomes/ug DNA and mRNA expression at $4\text{-}8x10^4$ copies/ug DNA after vector instillation. To determine the location of the vector induced transduction we performed confocal microscopy. Tissues were co-stained with either NHE3 or ENaC to highlight proximal or collecting duct expression, respectively. Expression of GFP and CFTR above background levels consistent with protein expression were

generated by both vectors. We detected more GFP in the vector-treated cystic cells compared to surrounding tissue suggesting that AAV1 is more specific for cysts than the cells surrounding the cysts. We detected more CFTR IF at the basolateral membrane in AAV1-CFTR treated kidneys suggesting that CFTR was restored to its normal location. These experiments demonstrate convincingly that kidneys of RC/RC animals can be transduced by AAV1 and that phenotypic correction of defective function can be achieved.

AAV1 CFTR reduces area and number of the cysts.

Friday Posters: Neurologic Diseases

1587. Characterization of Brain Transduction Capability of a Peptide-Displaying AAV Vector in Mice, Rats and Non-Human Primates

Maria Bunuales[1], Miguel Chillon[2], Assumpcio Bosch[3], Manuela Gonzalez-Aparicio[1], Angeles Garduno[1], Maria Espelosin[1], Marta Garcia-Gomara[1], Ana Garcia-Osta[1], Mar Cuadrado-Tejedor[1], Jose L. Lanciego[4], Ruben Hernandez-Alcoceba[1]

Pathology, Anatomy and Physiology Department, School of Medicine, University of Navarra. CIMA, Pamplona, Spain

Different screening methods are being developed to generate adeno-associated viral vectors (AAV) with the ability to cross the blood-brain barrier (BBB) upon intravenous administration. Recently, the AAV9P31 stood out as the most efficient version among a library of peptide-displaying capsids selected in C57BL/6 mice using RNA-driven biopanning. In this work we have characterized in detail its biodistribution in different mouse strains (C57BL/6J and Balb/c), as well as Sprague Dawley rats and non-human primates (Macaca fascicularis). Using GFP and NanoLuc reporter genes, we confirmed homogeneous infection and transgene expression across the cerebrum, cerebellum and brainstem of mice injected intravenously with AAV9P31. A more restricted pattern was observed upon intracerebroventricular or intraparenchymal injection. Peripheral organs transduced upon intravenous administration included lung, liver, peritoneum, heart and skeletal muscle. Transgene expression in the brain was observed as early as 72 hours after intravenous administration in 2 weeks-old C57BL/6J mice, and it was stable during more the 3 months follow-up. However, the ability of AAV9P31 to cross the BBB was not observed in rats and macaques. Brain penetration was also limited upon intracerebroventricular (icv) administration in macaques, whereas direct injection into the susbtantia nigra led to local neuronal transduction. We conclude that the AAV9P31 capsid is an excellent tool for transduction of mouse brain.

1588. Innovative Device for Concomitant Neural Recordings and Drug Delivery into the Brain - Feasibility Bench and *In Vivo* Studies

Guadalupe Zepeda[1], Su-youne Chang[2], Jiwon Kim[2], Inyong Kim[2], Maria F. Porto Cruz[1], Alfonso Chavez[1], Mary McNeil[1], Maria Vomero[1], Camilo Diaz-Botia[1], Dave Rosa[1], Gregory A. Worrell[2], Aura Kullmann[1]

[1]NeuroOne Medical Technologies Corporation, Eden Prairie, MN,[2]Mayo Clinic, Rochester, MN

Convection enhanced delivery (CED) of therapeutic compounds (e.g. drug, gene or stem cells) into the brain has been increasingly used in clinical trials for a variety of neurological conditions, including Parkinson's disease, epilepsy and others. The existing CED devices consist of cannulas able to deliver infusate, but unable to record neural activity. This severely limits the ability to evaluate compound effects both in acute settings (e.g. impact of delivery on physiological cell activity) and long-term settings (e.g. evaluation of therapy efficacy for therapies intended to alter neural activity). We propose a new device that combines delivery with on-site recordings. This device consists of a stereoelectroencephalography (sEEG) electrode equipped with a unique accessory catheter that can be connected to a syringe infusion pump. The sEEG electrodes are FDA-cleared for stereotactic implantation in desired brain regions and indicated for temporary (<30 days) monitoring, recording and stimulation of neural activity. Currently these electrodes are routinely used in clinical practice in the evaluation of patients with drug resistant epilepsy. The feasibility of this prototype system was demonstrated in bench and in vivo testing in a rat model. Bench testing was conducted to evaluate infusion rates, reflux and infusion/diffusion volume relationship. Experiments performed in 0.6 % agarose gel using 1% Methylene Blue dye showed CED can be achieved. In vivo testing was conducted in a rat model to demonstrate feasibility of neural recordings pre- and post- drug delivery. The sEEG electrode was implanted into the hippocampus. Baseline neural activity was recorded for ~30 min, after which penicillin (5000 units/µl; 5 µl) was infused at rate of 0.5 µl/min. This elicited seizure-like episodes consisting of large amplitude bursts of coordinated activity interspaced by quiet periods. Histological examination of the brain tissue using hematoxylin and eosin showed an ellipsoidal shape diffusion volume. These experiments provide proof of concept that the prototype is able to perform the desired functions, monitor neural activity and deliver therapeutic compounds. The availability of drug delivery capability in an sEEG can potentially have significant impact on the screening, safety

and efficacy of the treatments. In acute settings, real time monitoring of the effect of therapy on cellular activity can be used as a screening and/or safety indication (e.g. does the compound and/or delivery impact neuronal activity, does it have negative impact on the cells). In long term settings, it can be used to directly assess the onset, mechanism of action and efficacy of therapeutic compounds, especially for therapies intended to alter neural activity (e.g. for epilepsy).

1589. Optimal AAV Serotype / Promoter Combinations to Target Specific Cell Types in the Marmoset Brain

Hirokazu Hirai[1,2], Ayumu Konno[1,2], Yasunori Matsuzaki[1,2]

[1]Department of Neurophysiology and Neural Repair, Gunma University, Maebashi, Japan,[2]Viral Vector Core, Gunma University, Maebashi, Japan

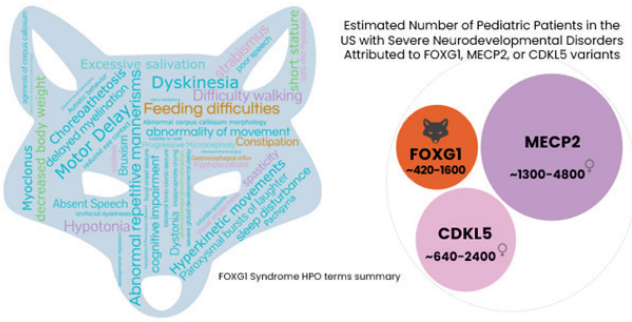
To express transgene with high specificity and efficiency in specific cell types, it is crucial to combine a serotype that is highly infectious for the target cell type with a target cell type-specific promoter. However, the tropism of different serotypes to marmoset brain cells has not been systematically investigated. In this study, we investigated the tropism of nine different serotypes for various neuronal and glial cells in the marmoset cerebral cortex.Nine serotypes of AAV (AAV1, 2, 5, 6, 7, 8, 9, rh10, and DJ) that express green fluorescent protein (GFP) under the control of the ubiquitous chicken β-actin hybrid (CBh) promoter were injected into the cerebral cortex of marmosets. Four weeks after the AAV injection, ratios of GFP-expressing cell types to total GFP-labeled cells were immunohistochemically examined.While the proportions of neurons and glia to total cells in the marmoset cerebral cortex were approximately 55% and 45%, respectively, majority of the GFP-expressing cells (82-97%) in the AAV-treated cortex were neurons, indicating that all AAV serotypes tested, especially AAV2 (97.0 ± 0.6%) and AAV-rh10 (96.9 ± 0.8%), have a marked tropism for neurons. All AAV serotypes tested caused GFP expression in both excitatory and inhibitory neurons, with AAV-rh10 showing a preference for excitatory neurons and AAV2 showing a preference for inhibitory neurons.All nine serotype AAVs transduced glial cells with significantly lower efficiency, and most of transduced glia were oligodendrocytes. Among nine serotypes examined, AAV5 most efficiently transduced oligodendrocytes, which accounted for approximately 18% of all GFP-labeled cells.In addition to the CBh promoter, AAVs with other ubiquitous cytomegalovirus (CMV) or CAG promoter also failed to transduce astrocytes: however, all nine AAV serotypes, especially AAV7, with the astrocyte-specific human GfaABC1D promoter efficiently and selectively transduced astrocytes, suggesting that every AAV serotypes tested can infect astrocytes, but the incorporated ubiquitous promoters are not functional in astrocytes. Moreover, we assessed AAVs carrying cell type-specific promoters, in terms of specificity and efficiency of target cell transduction, when packaged using serotypes with infectious to target cells and those with low infectivity to target cells. Our results indicate that serotypes that achieve efficient target cell transduction in the marmoset cerebral cortex are AAV-rh10 for excitatory neurons, AAV2 for inhibitory neurons, AAV5 for oligodendrocytes, and AAV7 for astrocytes.

1590. AAV-Mediated Gene Augmentation Therapy for NEK1-ALS

Katharina E. Meijboom[1], Desiree M. Baron[1], Debra Cameron[1], Erinn Ives[1], Aparna Sreeram[1], Ana Rita Batista[2], Janice A. Dominov[1], Cathleen Lutz[3], Robert H. Brown[1], John E. Landers[1]

[1]UMASS Chan Medical School, Worcester, MA,[2]UMass Chan Medical School, Worcester, MA,[3]The Jackson Laboratory, Bar Harbor, ME

Amyotrophic lateral sclerosis (ALS) is a terminal neurodegenerative disease that affects upper and lower motor neurons, leading to progressive muscle weakening and respiratory failure. Loss-of-function mutations in NIMA-related kinase 1 (NEK1) constitute a major genetic cause of ALS in both familial and sporadic ALS cases, accounting for 2 to 3% of all cases. To develop and test a NEK1 gene augmentation therapy, we created a mouse model with a nonsense mutation in the mouse NEK1 gene. This mutation resulted in a complete absence of NEK1 protein in homozygous mice. Preliminary data show that homozygous mice are noticeably smaller and have a significantly reduced bodyweight measured from three weeks onwards compared to heterozygous and WT littermates. Mice are currently 16 weeks old; any effect on lifespan has yet to be determined. We will further establish other NEK1 phenotypes, such as motor disturbances, DNA damage, cilia formation and nuclear envelope integrity. In NEK1 patient-derived fibroblasts and induced motor neurons, we observed DNA damage and diminished nuclear envelope integrity. To rescue any behavioral and molecular phenotypes *in vitro* and *in vivo*, we are designing AAV-mediated NEK1 augmentation strategies. Thus far, heterozygous neonatal NEK1 mice received intracerebroventricular injections of AAV-PHP.eb-hNEK1 driven by the MSCV promoter. This resulted in 11.6 and 1.8 vg/diploid genomes and significant expression of hNEK1 transcripts in the brain and spinal cord, respectively. We are exploring diverse NEK1 augmentation strategies, including different NEK1 transcript variants, AAV serotypes, promoters, and regulatory elements. Our objective is to establish effective therapeutic interventions for NEK1-related ALS, evaluating outcomes in both homozygous NEK1 mice and patient-derived cells.



1591. Estimating Patient Prevalence for Complex Neurodevelopmental Disorders: The Emerging Face of FOXG1 Syndrome

Karen E. Malone[1], Katarina Mueller[2], Mary Grace Shine[2], Jae Lee[2], Soo-Kyung Lee[2,3]

[1]GeneScape, Leiden, Netherlands,[2]Department of Biological Sciences, The State University of New York at Buffalo, Buffalo, NY,[3]FOXG1 Research Foundation, San Francisco, CA

Background and objectives: Understanding the scale of unmet need for specific severe neurodevelopmental disorders (NDD) remains very challenging, in part due to the many overlapping clinical features associated with global and developmental delays, and the variability of epilepsy phenotypes. FOXG1 Syndrome is a prime example of this challenge and requires definitive genetic diagnosis to be identified. We provide the first prevalence estimates of FOXG1 Syndrome based on genetic surveys of severe NDD patients. **Methods:** We conducted a systematic literature review and meta-analysis of studies performing genetic testing panels on cohorts of severe NDD within the last ten

years. We compiled 13 studies (after omitting one outlier enriched for FOXG1 patients), totaling nearly 36,000 severe NDD patients. **Results:** The proportion of severe NDD attributed to FOXG1 was 0.20% [95% CI: 0.16 - 0.25%]. For comparison, MECP2 and CDKL5 patients accounted for 0.55% [95% CI: 0.48 - 0.64%] and 0.34% [95% CI: 0.28 - 0.40%], respectively. This corresponds to an estimated prevalence of 0.6 - 2.2 FOXG1 patients per 100,000 children or ~420 - 1600 patients in the United States. The estimated prevalence of CDLK5 patients was 1.8 - 6.6 cases per 100,000 female children, and the estimated prevalence of MECP2 patients was 3.5 - 13.2 cases per 100,000 female children. **Conclusions:** FOXG1 Syndrome was previously considered an ultra-rare indication potentially occurring in ~1 per million children. Our study based on genetic testing demonstrates the FOXG1 patient population is expected to be approximately one third the size of the MECP2 patient population which is primarily associated with Rett Disease. Uncoupled from Rett Disease clinical criteria, both FOXG1 Syndrome and CDKL5 Deficiency represent distinct and sizable patient populations. This shows the value of genetic testing in diagnosing these complex diseases and paints a more up-to-date picture of the scale of unmet need, that will support further drug development strategies.

1592. Synthetic Morphogenesis to Improve Early Brain Organoid Models

Catherine A. Hamann, Cheryl Quartey, Ethan S. Lippmann, Jonathan M. Brunger

Vanderbilt University, Nashville, TN

Introduction: During development, signaling centers organize cellular differentiation via coordinated morphogen production. As ectodermal cells undergo neurulation, morphogen networks shape the neural tube and early structures of the central nervous system. Notochord-derived sonic hedgehog (SHH) specifies formation of the floor plate, which serves as a source of SHH to pattern cells of the neural tube and define the dorsal-ventral axis. A number of diseases and disorders, such as nonsyndromic holoprosencephaly, are caused by SHH and other early developmental genetic mutations. However, few brain organoid protocols focus on incorporating signaling centers, instead relying on small molecules and proteins applied with little to no spatial organization. Protocols have been developed to generate drug-inducible organoids consisting of a floor plate-like signaling center using human pluripotent stem cells (hPSCs), which have resulted in markers of successful dorsal-ventral patterning. **Methods**: Leveraging artificial gene circuits, we take a synthetic morphogenesis approach to uncover the design rules required to program hPSCs to autonomously form a floor plate region that serves as an organizing center to further elaborate neural tube formation in an organoid. Thus, we engineered hPSCs that produce SHH under the control of the customized signaling receptor synNotch. Like native Notch (**Figure 1Ai**), synNotch (**Figure 1Aii**) responds productively to artificial juxtacrine cues, such as transmembrane ligands on neighboring cells, leading to highly localized transgene expression. We engineered synNotch hPSCs to produce SHH, and our previous results show via qRT-PCR that successful juxtacrine binding of synNotch hPSCs potently upregulates SHH in response to the synNotch transmembrane ligand, GFP. **Results**: SynNotch induction results in domains of high FOXA2 expression (floor plate marker) while also showing low PAX6 (dorsal tissue marker), as assessed by immunofluorescence (**Figure 1B**). Following successful tissue formation in 2D, we generated 3D organoids whereby a small region of the organoid consists of SHH-producing cells, which can be activated by surrounding GFP-presenting cells, making up the remainder and majority of cells within the organoid (**Figure 1C**). SynNotch induction and subsequent SHH expression results in regions of high FOXA2 expression polarized at one end of the organoid (**Figure 1D**), presumably in and around the artificial cell signaling center. **Conclusions**: Future work will expand on this synthetic morphogenesis approach to build a floor plate organizing center and analyze additional markers of dorsal-ventral patterning. This work has the capacity to study early developmental events and can be used as a tool to study preclinical gene and cell therapies, including those related to SHH and early embryonic development.

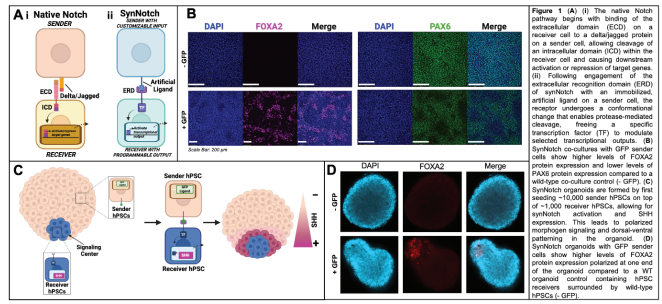


Figure 1 (A) (i) The native Notch pathway begins with binding of the extracellular domain (ECD) on a receiver cell to a delta/jagged protein on a sender cell, allowing cleavage of an intracellular domain (ICD) within the receiver cell and causing downstream activation or repression of target genes. (ii) Following engagement of the extracellular recognition domain (ERD) of synNotch with an immobilized, artificial ligand on a sender cell, the receptor undergoes a conformational change that enables protease-mediated cleavage, freeing a specific transcription factor (TF) to modulate selected transcriptional outputs. (B) SynNotch co-cultures with GFP sender cells show higher levels of FOXA2 protein expression and lower levels of PAX6 protein expression compared to a wild-type co-culture control (- GFP). (C) SynNotch organoids are formed by first seeding ~10,000 sender hPSCs on top of ~1,000 receiver hPSCs, allowing for synNotch activation and SHH expression. This leads to polarized morphogen signaling and dorsal-ventral patterning in the organoid. (D) SynNotch organoids with GFP sender cells show higher levels of FOXA2 protein expression polarized at one end of the organoid compared to a WT organoid control containing hPSC receivers surrounded by wild-type hPSCs (- GFP).

1593. Identification of Artificial microRNAs Targeting C9orf72 Sense and Antisense Transcripts for ALS Treatment

Gabriela C. Toro[1], Sha Zhu[1], Hongxing Wang[1], Weiqun Zhang[1], Na Liu[1], Joan Shen[1,2], Lingzhi Zhao[1,2]

[1]NeuShen Therapeutics, Lexington, MA,[2]Co-corresponding authors, Lexington, MA

Hexanucleotide repeat expansion (HRE) in the C9orf72 gene is the most common genetic cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Pathogenic mechanisms involve a toxic gain of function of RNA and/or dipeptide repeats from both C9orf72 sense transcript and anti-sense transcript as well as C9orf72 loss of function. A recent clinical trial utilizing an oligonucleotide antisense (ASO, BIIB078) targeting the G4C2 sense repeat RNA assessed the hypothesis of gain of toxic function. The results showed a substantial reduction in sense RNA foci and dipeptides; however, no clinical benefits were observed, suggesting that reducing sense C9orf72 alone may not suffice to alleviate C9orf72 HRE toxicity. Furthermore, a recent study demonstrated that expression of C4G2 antisense repeats,

rather than G4C2 sense repeats, impairs TDP-43 function in induced pluripotent stem (iPS) neurons. This underscores the potential role of antisense C4G2 RNA repeats in the pathomechanisms of C9orf72 HRE toxicity, suggesting that lowering antisense C4G2 repeats or both antisense and sense repeats may be necessary. However, the expression of C9orf72 antisense is notably low in cell lines including immortalized neuronal cell lines and iPSC-derived neurons, which poses a significant challenge in the discovery of effective antisense silencers. To address this, we embarked on constructing a series of assays with the goal of identifying microRNAs (miRNAs) targeting both antisense and sense C9orf72 transcripts. For rapid screening, we adapted a Renilla/Firefly dual luciferase reporter cell-based assay and developed a method capable of quantifying sense and HRE-containing antisense C9orf72 expression simultaneously in a single run. Using this assay, we identified several potent sense and antisense miRNAs, demonstrated by a robust reduction (> 85%) in C9orf72 reporter signal when co-transfected with a reporter plasmid carrying sense and antisense strands. Moreover, when constituting one sense and one antisense miRNA into a dual miRNA format, we observed an enhanced decrease in the reporter signal compared to either the sense miRNA or the antisense miRNA alone, indicating a potential synergic action by sense and antisense miRNAs. Next, we designed customized sense- and antisense-specific droplet digital PCR (ddPCR) assays, enabling the quantification of very low copies of antisense and sense C9orf72 expressed in C9orf72 ALS patient-derived lymphoblastoid cell line (LCL) cells. Using the ddPCR assay, we have validated a few active sense and antisense miRNAs, previously screened from the reporter assay. Our preliminary characterization indicates a potential advantage in concurrently expressing miRNAs targeting both sense and antisense strands to lower C9orf72 expression. Dual silencers demonstrating efficacy in both assays are selected for future development of Adeno-Associated Virus (AAV) gene therapy to treat C9orf72 HRE-caused ALS.

1594. Development of a Disease Modifying Adeno-Associated Virus-Based Combination Gene Replacement Therapy for Multiple System Atrophy

Yezheng Tao, Wei Cheng, Pengjuan Ma, Shin-Shay Tian, Xiaoping Zhao

Shanghai Vitalgen BioPharma Co., Shanghai, China

Multiple system atrophy (MSA) is a neurodegenerative disorder clinically characterized by autonomic failure, parkinsonism, and ataxia, resulting from the selective deterioration and loss of neurons in the striatonigral pathway, olivopontocerebellar pathway, and autonomic systems. MSA is a rapid progression and life-threatening disease with an urgent need for disease-modifying therapies that can halt the disease progression and improve the patients' life span. The precise etiology of MSA is unclear. Based on the disease pathogenesis, the major pathogenic mechanisms include the formation of toxic oligodendroglial cytoplasmic inclusions (GCIs) containing filamentous α-synuclein (oligodendrogliopathy) and mitochondrial dysfunction-induced oxidative stress and neuronal damages. These two mechanisms are thought to collaborate to accelerate the loss of functional neurons. To address its complex disease mechanisms, we developed an AAV9-based MSA combination gene replacement therapy VGN-R12a, designed to reduce GCIs and slow down neurodegeneration simultaneously by targeting the different aspects of MSA pathology as described above. To test the *in vivo* efficacy of VGN-R12a, we established an in-house mouse model to mimic the oligodendrogliopathy and mitochondrial dysfunction of MSA. We first generated a transgenic mouse in which mutated human α-synuclein (α-synuclein A53T) was specifically expressed in oligodendrocytes using the proteolipid promoter (PLP-Syn-A53T). These mice exhibited significant increases of the α-synuclein oligomers in their midbrain, striatum, cerebellum, and brainstem, accompanied by motor deficits in open field task. 3-nitropropionic acid (3-NP), a mitochondrial toxin, was used to induce mitochondrial dysfunction in these mutant mice to accelerate the decline of motor function and enhance neurodegeneration, closely mimicking the MSA pathology. VGN-R12a was tested in the MSA mouse model described above through intracerebroventricular injection. We found that VGN-R12a could dose-dependently alleviate the MSA phenotypes, as well as reduce the levels of phosphorylated α-synuclein, a biomarker for synucleinopathies. In conclusion, our data suggest that VGN-R12a has the potential to be an effective disease-modifying therapy for MSA.

1595. vMiX, an Innovative AAV-Based RNA Interference Platform: First Applications to Treat ALS

Romain Joubert[1], Zoe Walker[1], Deborah Ojutalayo[1], Alice Gennari[1], Louise Reilly[1], Yalem Bekele[1], Joana Furtado[1], Catia Andreassi[1], Olivier Brock[2], Amrita Abhilash[1], Paniz Hosseini[1], Samamtha Correia[1], Philip Coan[1], Carlos Miranda[1], John Isaac[1], Christopher E. Shaw[1,2]

[1]AviadoBio, London, United Kingdom,[2]King's College London, London, United Kingdom

Amyotrophic Lateral Sclerosis (ALS) is a devastating neurodegenerative disorder due to the degeneration of motor neurons in the brain and spinal cord. It causes a progressive loss of voluntary muscle control, resulting in paralysis and fatal respiratory failure. Mutations in many genes have been implicated in disease pathogenesis but the mis-accumulation of TDP-43 drives disease pathogenesis in ~95% of patients. Expanded polyglutamine repeats in the Ataxin-2 gene (*ATXN2)* >30 are a risk factor for ALS and Frontotemporal Dementia (Glass 2022). Knockout and knockdown of ATXN2 in mice significantly slows disease progression in TDP-43 overexpressing mouse models (Becker 2017), thus, *ATXN2* silencing has emerged as a therapeutic strategy to treat ALS. To enable RNA interference, we generated a novel adeno-associated viral vector expressing a transcript encoding micro-RNA (miRNA) that can rapidly be modified to generate guide sequences that target any transcript in any species. miRNA processing involves various enzymes that sequentially cleave primary miRNA (pri-miRNA) transcripts to generate guides within the RNA-induced silencing complex capable of binding to specific mRNA sequences leading to their degradation of suppression of translation. Our vector has a hybrid miRNA scaffold designed to to optimise miRNA processing by Drosha and Dicer and enhance guide strand selection. Moreover, the pri-miRNA expression employs pre-mRNA 3' end cleavage in its processing, demonstrating for the first time that an RNA of interest can be expressed outside the canonical promoter - transcript - termination signal design. The performance

of our vMiX vector was compared to commercially available miR155 miRNA constructs with identical guides and assessed using luciferase reporters. The miR155 vector exhibited variable levels of knockdown (30-75%) depending on the targeted mRNA region (5'UTR, coding sequence, 3'UTR), while our vMiX vector, expressing the same miRNAs consistently achieved an 80% knockdown. To test the specificity of our new vector, the knockdown was evaluated against a wild-type and a codon-optimized mRNA coding for the same protein (3 mutations outside the seed sequence). Using protein analysis, vMiX showed an 81% knockdown of the wild-type target but had no activity against the codon-optimized one, demonstrating that, unlike endogenous miRNA, vMiX requires a full sequence match to induce silencing, thereby increasing specificity and reducing the risk of off-target effects. vMiX was developed as an RNAi platform. Using *in silico* design we generated multiple miRNA candidates targeting genes implicated in ALS pathogenesis including superoxide dismutase 1, *C9orf72*, and *ATXN2* and assessed their potency for knockdown and processing by quantifying guides and guide:passenger ratio across multiple species (human, primate, mouse, and pig). Two separate *in vivo* studies were carried out using miRNA targeting human *ATXN2* in a mouse model expressing the human transgene with 72 CAG repeats. Intrathalamic injections of an AAV9-miR-ATXN2 in adult mice revealed a dose-dependent response in *ATXN2* mRNA knockdown. vMiX demonstrated highly specific and robust *in vitro* and *in vivo* knockdown, and efficient targeting in multiple cell types. While the vMiX vector designed to target *ATXN2* holds promise for treating sporadic ALS its potential extends to silencing other targets of interest for addressing various disorders in brain and other organs. *(Glass et al., Brain 2022. Becker et al., Nature 2017.)*

1596. Systemic Gene Replacement Therapy Corrects Neurological Phenotype in a Mouse Model of NGLY1 Deficiency

Ailing Du[1], Xuntao Zhou[2], Lingzhi Ren[1], Nan Liu[1], Chen Zhou[1], Jialing Yang Liang[1], Guangping Gao[1,2], Dan Wang[1,3]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Department of Microbiology and Physiological Systems, UMass Chan Medical School, Worcester, MA,[3]RNA Therapeutics Institute, UMass Chan Medical School, Worcester, MA

NGLY1 deficiency (OMIM #615,273) is an ultrarare autosomal recessive deglycosylation disorder caused by biallelic mutations in the *NGLY1* gene encoding cytoplasmic peptide: N-glycanase (NGLY1). NGLY1 is ubiquitously expressed and normally functions as a de-N-glycosylating enzyme that, together with the 26S proteasome, degrades misfolded N-glycosylated proteins in the cytoplasm. Patients suffer from multisystemic involvement including developmental delay, intellectual disability, scoliosis, hypotonia, motor deficit, and liver dysfunction; the neurological manifestations represent the major disease burden. Currently, there is no treatment for this disease. Unlike in humans, NGLY1 deficiency in C57BL/6J mice is embryonically lethal, posing a significant challenge to studying the disease mechanisms and testing AAV-based gene therapy *in vivo*. In this study, we obtained a *Ngly1* inducible knock-out (iKO) C57BL/6J mouse model. This iKO mouse is homozygous for a loxP-flanked *Ngly1* exon and carries a tamoxifen-inducible, ubiquitously expressed *cre* transgene that enables tamoxifen-dependent *Ngly1* knockout after birth. We showed that tamoxifen treatment induced 80-90% knockdown of *Ngly1* expression in multiple tissues including the liver, heart, skeletal muscle, spinal cord, and brain, resulting in symptoms recapitulating human disease, including elevation of the biomarker GlcNac-Asn (GNA), motor deficits, kyphosis, Purkinje cell loss, and gait abnormalities. We designed a codon-optimized human *NGLY1* transgene cassette driven by a chicken beta-actin promoter and packaged it into two capsids, AAV9 and AAV.PHPeB. Systemic administration of the AAV.PHPeB vector to iKO mice after disease onset led to higher transgene expression in the central nervous system (CNS) than AAV9, and better correction of multiple disease features at 8 weeks post-treatment. Furthermore, another cohort of AAV.PHPeB-treated animals were monitored over a year and showed near-complete normalization of the neurological aspects of the disease, demonstrating the durability of gene therapy. Our data suggest that brain-directed *NGLY1* gene replacement via systemic delivery is a promising therapeutic strategy for NGLY1 deficiency. Although the superior CNS tropism of AAV.PHPeB vector used in this study does not translate to primate, emerging AAV capsids with enhanced human CNS tropism will enable future translational studies. G.G. and D.W. are co-corresponding authors

1597. SOD1 Gene Repression Mediated by Zinc Finger Repressors (ZFRs) as a Therapeutic Approach for SOD1-Mediated ALS

Andrew Young, Kenneth Kim, Jill Cifrese, Asa Hatami, Jisoo Lee, Patrick Dunn, David Paschon, Marian Glynn, Cecelia Paculba, Toufan Parman, Emily Tait, Stephen Lam, Sarah Hinkley, Alicia Goodwin, Alex M. Ward, Kathleen Meyer, Bryan Zeitler, Amy M. Pooler

Sangamo Therapeutics, Inc., Richmond, CA

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease that leads to degeneration of motor neurons in the spinal cord and brain. This loss of motor neurons results in loss of muscle control, paralysis, and eventual death. Superoxide dismutase 1 (*SOD1*) is a gene that codes for an enzyme that protects cells from free radical damage. Mutations in *SOD1* account for 10%-20% of inherited forms of ALS. These mutations are thought to manifest ALS symptoms through a mechanism whereby toxic aggregates of misfolded SOD1 protein accumulate in motor neurons leading to neuron dysfunction and loss. Targeting SOD1 for repression using antisense oligonucleotides such as Tofersen, which recently received conditional approval, improved clinical biomarkers of SOD1 ALS in human patients, suggesting SOD1 repression as an attractive therapeutic target. Zinc finger proteins (ZFs) are DNA-binding proteins that can be engineered to specifically bind any genomic sequence. When fused to a transcriptional regulatory domain such as KRAB, these zinc finger repressors (ZFRs) can reduce the expression level of a targeted gene. In a proof-of-concept study, we engineered ZFRs with human SOD1 repression activity for use as potential therapeutics for SOD1 mutation-associated ALS. We designed a library containing 100s of ZFRs targeting human sequences near the *SOD1* transcriptional start site. The library was initially screened in human and rodent neuronal cell lines. Lead ZFRs were then packaged into AAV and screened in human iPSC-derived GABAergic and mouse primary cortical neurons *in vitro*. We identified ZFRs that repressed human *SOD1* mRNA in neurons by more than 50% over a wide dose

range with minimal to no detectable off-target activity as measured by global transcriptomics analysis. These results show a proof-of-concept that ZFRs may provide a potential novel therapeutic approach for preventing or slowing the progression of ALS.

1598. Disruption of Aberrant Splicing of STMN2 by Gene Editing with a Type V CRISPR-Cas Enzyme as a Potential Treatment for ALS

Priscilla D. Negraes[1], Peter D. Buckett[1], Jace Jones-Tabah[1], Anthony J. Garrity[1], Mishti Bose[1], Sevda Lule[1], Andrew Park[1], Nolan Sheppard[1], Linh B. Truong[1], Qiyuan Yang[1], Ivan A. Kristanto[1], Maximiliano F. Presa[2], Jennifer Ryan[2], Erin Merkel[1], Christina Noe[1], Jenny V. Tobin[1], Lijun Liu[1], Florie Borel[1], Cathleen Lutz[2], John E. Murphy[1], Chee Yeun Chung[1]

TDP-43 is a nuclear RNA-binding protein that regulates RNA processing. In many neurodegenerative diseases such as amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTD), TDP-43 is mis-localized and accumulated in the cytoplasm, a pathological hallmark of these conditions. The lack of nuclear TDP-43 in disease contexts results in aberrant splicing and processing of numerous genes. One of the most highly down-regulated is STMN2, which encodes for a microtubule-binding protein that controls axonal outgrowth and is highly expressed in motor neurons. Prior studies suggest that nuclear depletion of TDP-43 results in the aberrant splicing of STMN2 and loss of full-length functional STMN2, which may contribute to the pathology in ALS. To explore a potential treatment for ALS, we used gene editing with a Type V CRISPR-Cas enzyme to disrupt aberrant splicing of STMN2 by creating larger deletions of ~10 base pairs. We first screened in HEK cells multiple type V CRISPR nucleases and guides spanning the 310 base pair aberrantly spliced novel exon of STMN2 (exon 2A) that includes cis-acting elements such as a splice acceptor site, a TDP-43 binding region and a polyadenylation site. Nuclease/guide pairs with efficient indel formations from the HEK screening were tested in SH-SY5Y cells under TDP-43 knockdown to identify the pairs that were capable of reducing aberrant splicing and promoting an increase of full-length STMN2 mRNA. Several nuclease/guide pairs disrupting the splice acceptor site resulted in the effective reversal of aberrant splicing and increase of full-length STMN2 mRNA, but not the other cis-acting elements, thus defining the splice acceptor as the relevant target. These findings were replicated in human induced pluripotent stem cell (iPSC)-derived motor neurons. Moreover, the disruption of aberrant splicing using the nuclease/guide pairs in human motor neurons reversed the axonal loss caused by TDP-43 knockdown. Finally, the most potent nuclease/guide pairs, ABR-001 variant and gX, and ABR-004 variant and gY, were packaged into a rh10 serotype AAV vector and injected into neonatal mice transgenic for the human STMN2 exon 2A locus. In these mice, efficient editing as well as the reversal of STMN2 aberrant splicing were observed. In summary, we have identified multiple type V nuclease/guide pairs that reverse the aberrant splicing of STMN2 and the disease-relevant phenotypic consequences due to TDP-43 nuclear depletion in a cell line, in motor neurons and in a mouse model. Together, these findings have the potential to pave a path towards a CRISPR gene editing therapeutic for ALS.

1599. Leveraging *In Silico* and *In Vitro* Modeling for Optimization of Intrathecal AAV9 Delivery to the Brain: Validation in Nonhuman Primates and Translation to Human Rett Syndrome Patient Anatomy

Bryn Martin[1], Lucas Sass[1], Mohammadreza Khani[1], Ostin Arters[2], Stuart Sater[1], Howard Dobson[3], Scott Haller[4], Richard Watts[5], Kathrin Meyer[6], Deep Singh[7]

[1]Alcyone Therapeutics, Lowell, MA,[2]Alcyone Therapeutics, Inc., Moscow, ID,[3]InVicro, Needham, MA,[4]Charles River Laboratory, Wilmington, MA,[5]Yale University, New Haven, CT,[6]Nationwide Childrens Hospital, Columbus, OH,[7]Alcyone Therapeutics, Waltham, MA

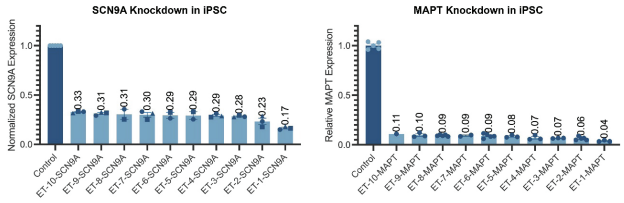
Background Targeted, consistent, and safe delivery of genetic therapies to the brain is critical for effective treatment of CNS disorders. To date, researchers are attempting to optimize CSF delivery by choice of injection location. There are currently no validated tools for prediction of CSF solute transport in nonhuman primates (NHP) or transformation to humans. It is often overlooked that NHP CNS anatomy lacks similitude to humans. Thus, NHP delivery optimization may not equate to humans. Alcyone Therapeutics' Falcon™ platform includes novel computational modeling and a lumbar-access intrathecal intra-CSF delivery system that can target drugs to the brain, spinal cord or brain and spinal cord together, while being safe and clinically scalable. We used Falcon™ to optimize AAV9 delivery to the CNS and then validate NHP model predictions using AAV9.CB.GFP administered by either Falcon™ or lumbar puncture (LP). We also developed the first Rett Syndrome disease-specific model to optimize AAV delivery taking into consideration disease-related alterations of CSF flow that may impair drug transport. **Methods** CSF geometry and flow data was collected from NHPs via MRI. These measurements defined the 3D computational fluid dynamics (CFD) simulation and 3D printed models representing details of NHP brain and spinal cord anatomy including CSF flow and cisterns. We used this system to compare and optimize delivery parameters for widespread brain and spinal cord targeting and compared various protocols to LP injections. To validate the model predictions, seronegative NHPs (3-6 yrs) were co-infused with gadolinium and AAV9.CB.GFP via LP (n=5) or the optimized Falcon™ delivery (n=5). Biodistribution was analyzed 3w later by immunohistochemistry, ddPCR (DNA/RNA) and western blots. Drug flow was compared via gadolinium concentration. Following NHP model validation, we developed the first model systems of Rett syndrome patient anatomy using the same methods and optimized AAV delivery to the human disease anatomy to improve dosing in future clinical trials. **Results** We validated the model systems with in vivo NHP biodistribution confirming model predictions. Falcon™ was significantly superior, reaching the cranial space 1-5 min post-injection, while LP required 30-60 min. At 30 mins post injection, gadolinium concentration was significantly greater throughout the cortical gray matter and basal ganglia with Falcon™ vs. LP. In vivo PD showed Falcon™ vg per diploid genome was significantly higher throughout brain regions compared to LP. The Rett disease-specific

model showed significant alterations in terms of neuroanatomy and CSF flow that would impact AAV delivery to the brain. **Conclusion** Alcyone Therapeutics' Falcon™ platform includes a novel state-of-the-art modeling system including precise and anatomically detailed models of NHPs, healthy humans and humans with Rett Syndrome, as well as a lumbar-access intrathecal intra-CSF delivery system. The modeling predictions were validated using AAV9.CB.GFP in NHPs showing faster and broader distribution of AAV9 in the brain with Falcon™ which led to significant improvement in biodistribution. The improved targeting of the CNS was also reflected by significantly reduced liver off target effects. We optimized the approach for Rett Syndrome for upcoming clinical studies. Importantly, our delivery system and models can also be used to optimize repeat dosing of small molecules, ASOs and RNA gene therapy as it is designed for permanent implantation.

1600. PMP22 Gene Repression Mediated by Zinc Finger Repressors (ZFRs) as a Therapeutic Approach for CMT1A

Esmeralda Ponce, Odessa Yabut, Daniel Chung, Ken Kim, Victoria Chou, David Ojala, Annemarie Ledeboer, Andrew Young, Amy Pooler

Sangamo Therapeutics, Inc., Richmond, CA



Charcot-Marie-Tooth disease 1A (CMT1A) is an inherited, progressive peripheral neuropathy. Symptoms of CMT1A include weakness and atrophy of muscles within the legs and arms impairing movement and balance. Symptoms typically appear in early adolescence and continue to progress throughout the patient's life and there are currently no disease modifying treatments available. The cause of CMT1A is duplication of the PMP22 gene which codes for a peripheral myelin transmembrane glycoprotein. Overexpression of the PMP22 gene leads to an inability of Schwann cells (peripheral myelin producing cells) to properly myelinate large axons, leading to disruption of myelination, dysfunction in peripheral nerve conduction and eventual axonal loss. Zinc finger proteins (ZFs) are DNA-binding proteins that can be engineered to specifically bind any genomic sequence. When fused to a transcriptional regulatory domain such as KRAB, these zinc finger repressors (ZFRs) can reduce the expression level of a targeted gene. In a proof-of-concept study, we engineered ZFRs targeting PMP22 repression with sequences conserved between mouse, NHP and human for use as potential therapeutics for CMT1A. We designed a library containing 100s of ZFRs near the PMP22 transcriptional start site. The library was initially screened in both neuronal and Schwann cell lines from humans and rodents. Taking advantage of the tunability of our zinc finger platform we selected ZFRs capable of partial PMP22 repression to avoid any potential negative consequences associated with a complete loss of PMP22 expression. Lead ZFRs were then packaged into AAV vector and screened in CMT1A patient-derived fibroblasts in vitro. Select ZFRs demonstrated greater than 50% repression of total PMP22 transcript in patient derived fibroblasts. The data presented here support continued development of PMP22-targeting ZFRs as a potential therapeutic approach for the treatment of CMT1A.

1601. Identification of Potent and Selective AAV-miRNA Candidates to Knockdown Non-Monogenic Neurological Targets *SCN9A* (Pain) and *MAPT* (Tauopathies)

Chao Tai, Veda Tatavarty, Szu-Ying Chen, Sawyer Randles, Mirella Rivera-Velazquez, Steven Tan, Puja Dhanota, Serena Liu, Alex Diaz de Arce, Pingping Jia, Sammy Liang, Keiko Takahashi, Mark Elegue, Sirika Wood, Suresh Poda, Stephanie Tagliatela

Encoded Therapeutics, South San Francisco, CA

Rationale: Adeno-associated virus (AAV)-mediated microRNA (miRNA) expression provides potential long-term knockdown of target genes following a one-time administration. This is an attractive strategy for central nervous system (CNS) applications when compared with chronic repeat dosing required for short interfering RNA (siRNA) or antisense oligonucleotides (ASOs). Utilizing Encoded's vector engineering platform, we identified several potent and target-specific miRNA candidates to effectively knockdown two clinically relevant non-monogenic neuronal targets: *SCN9A* and *MAPT*. *SCN9A* encodes the voltage-gated sodium channel alpha subunit 1.7 ($Na_V1.7$), which is associated with pain sensation. Clinically, *SCN9A* variants lead to hypoalgesia or hyperalgesia phenotypes (secondary to loss- or gain- of-function mutations, respectively). *MAPT* encodes tau, which regulates microtubule dynamics in neurons. Pathologic *MAPT* variants are associated with tauopathies, and in Alzheimer's disease, increases in tau pathology are closely associated with disease progression. **Methods:** Using computational methods, we identified over 7,000 potential miRNAs within *MAPT* and *SCN9A* pre-mRNA. We selected the top 50 miRNA candidates based on cross-species sequence homology (for future *in vivo* testing), minimal to no predicted off-target effects per *in silico* predictions, and favorable miRNA stability and processing features. Here we present *in vitro* knockdown potency in HEK-293T cells and two lines of human iPSC-derived neurons for the top miRNAs selected. **Results: *SCN9A* knockdown:** The top 10 of 50 tested miRNA candidates achieved a 66-83% knockdown of the endogenous *SCN9A* gene in cell lines tested. While exhibiting substantial knockdown of the target gene, these candidates exhibited minimal off-target effects on related sodium channels (*SCN1A*, *SCN2A*, *SCN3A*, *SCN8A*, *SCN10A*) across all cell types tested. This profile of selectivity is desirable since small molecule inhibitors face challenges with selective $Na_V1.7$ inhibition. ***MAPT* knockdown:** Similarly, the top 10 of 50 tested miRNA candidates achieved 89-96% knockdown of endogenous *MAPT* in cell lines tested. Off-target analysis of the top miRNA candidates is currently underway. **Conclusion:** Taken together, our miRNA platform enables the discovery of potent and specific candidates that knockdown disease-relevant genes in the CNS with the potential to significantly impact the treatment landscape for various neurological and genetic disorders. **Figure 1.** miRNA candidate screening yields robust endogenous *SCN9A* and *MAPT* knockdown in human iPSC-derived neurons. Cells were treated with AAV-based-miRNA candidates. *SCN9A* expression assessed reveals up to 83% knockdown (left) and *MAPT* up to 96% knockdown (right). Data points are biological replicate means, with error bars indicating SEM.

1602. Intravenous Administration of BBB-Penetrant AAV Gene Therapy Provides Broad and Robust CNS TAU Lowering in a Tauopathy Mouse Model

Hechen Bao, Shiron J. Lee, Cansu Colpan, Elisabeth R. Knoll, Ching-Lien Fang, Barbara S. Bueno, Gretchen Rivera, Maneesha A. Paranjpe, Brian C. Ezell, Kyle Grant, Rajeev Sivasankaran, Dinah W. Y. Sah, Todd A. Carter, Wencheng Liu

Voyager Therapeutics, Lexington, MA

Progression and spread of tau pathology in the human brain correlates well with cognitive decline in Alzheimer's disease (AD). A potential therapeutic approach for AD is to reduce tau (MAPT, microtubule associated protein tau) protein levels in the central nervous system (CNS). Anti-sense oligonucleotides (ASOs) have been shown to reduce tau expression and tau pathology in preclinical and clinical studies. However, this approach requires repeated administration of the ASO via intra-ventricular or intrathecal administration. Here, we demonstrate that a single, intravenous (IV) administration of a blood-brain barrier (BBB)-penetrant, self-complementary adeno-associated virus (scAAV) gene therapy reduces tau expression in the CNS of a tauopathy mouse model expressing human tau. In silico and in vitro screening for MAPT mRNA reduction led to the identification of candidate siRNA sequences that robustly lowered MAPT mRNA. This was followed by insertion of candidate siRNA sequences into proprietary, primary artificial microRNA (pri-amiRNA) backbones for AAV delivery. The efficacy of one pri-amiRNA candidate, TAU-2023, delivered by a BBB penetrant AAV capsid, was then thoroughly evaluated in vivo in hTau mice, which express all six isoforms of human MAPT. The results demonstrated a dose-dependent increase in vector genomes and concomitant MAPT mRNA knockdown, in multiple brain regions of AAV-treated hTau mice, four weeks post-injection. MAPT mRNA reductions ranged from 70% to 90% relative to the vehicle-treated hTau mice. Total tau protein levels were also significantly reduced, with average reduction ranging from 50% to 70%, in multiple brain regions. Treatment with TAU-2023 was well-tolerated with no notable test article related changes in body weight or cage-side observations up to two months post dose. Additionally, small RNA sequencing demonstrated favorable efficiency and precision of pri-amiRNA processing. Current research aims to evaluate the effectiveness of TAU-2023 in reducing pathological tau in a tauopathy mouse model. Results to date indicate that the combination of a potent and well-tolerated, MAPT targeting pri-amiRNA and a BBB-penetrant capsid could represent a promising one-time, IV treatment option for AD and other tauopathies.

1603. Preclinical Assessment of JAG201, a Clinical Stage Gene Therapy for Severe Neurodevelopmental Disorders Caused by Mutations or Deletions in *SHANK3* Including Phelan-McDermid Syndrome (PMS) and Autism Spectrum Disorder (ASD)

Michael Hughes, Janet Do, Daniel McCoy

Jaguar Gene Therapy, Lake Forest, IL

Background: The SH3- and ankyrin repeat (SHANK) protein family are major scaffolds of the post-synaptic density of excitatory synapses, where SHANK3 contributes to synaptic integrity by connecting ion channels and glutamatergic receptors to the cytoskeleton and proteins that facilitate intraneuronal signaling pathways. In cases of *SHANK3* haploinsufficiency, caused by loss of function mutation or chromosomal deletion encompassing *SHANK3*, patients present with a debilitating neurodevelopmental disorder characterized by severe intellectual disability, impaired or absent speech and language, severely disrupted sleep, reduced motor function, behavioral challenges, and autism and/or autistic features. Genetic sequencing studies indicate that *SHANK3* mutations or deletions may be present in ~1% of patients with ASD, equating to about 30,000 patients in the US. JAG201 is as an investigational AAV9-based gene therapy intended to deliver a functional version of *SHANK3* to treat PMS and *SHANK3* haploinsufficiency caused by loss of function mutation or deletion. Here, we present efficacy data following intracerebroventricular (ICV) administration of JAG201 in a mouse model of *Shank3* deficiency. *Methods:* On postnatal day 14 (±2 days), *Shank3*$^{\Delta 4\text{-}22}$ mice received either a single unilateral ICV administration of vehicle or JAG201 at a dose range of 2.40E09 to 2.75E11 vg/animal. Animals were followed for up to 10 months post-treatment, with assessments of established neurobehavioral phenotypes carried out to characterize therapeutic efficacy of JAG201. Postmortem analyses included assessment of JAG201 protein expression and functional binding partners in synaptic membrane preparations, biodistribution of JAG201 vector DNA and RNA via droplet digital PCR analysis, and RNA fluorescence *in situ* hybridization. *Results:* In mice, JAG201 led to improvements in several assessed neurobehavioral deficits at dose levels of ≥6.00E10 vg/animal. Specifically, (i) EEG evaluation of a restorative sleep marker deficit demonstrated significant improvement in *Shank3*$^{\Delta 4\text{-}22}$ mice treated with JAG201 at the 6.00E10 and 1.20E11 vg/animal dose levels; (ii) Open field test, evaluating motor and explorative behavioral deficits, demonstrated a significant increase in distance travelled of *Shank3*$^{\Delta 4\text{-}22}$ mice treated with JAG201 at doses of ≥6.00E10 vg/animal; and (iii) Rotarod test, evaluating motor-coordination deficits, demonstrated a significant increase in the latency to fall of *Shank3*$^{\Delta 4\text{-}22}$ mice treated with JAG201 at the 6.00E10 and 2.75E11 vg/animal dose levels. Synaptic membrane preparation analysis demonstrated a dose-dependent increase in JAG201 protein expression levels in the brains of treated *Shank3*$^{\Delta 4\text{-}22}$ animals. Finally, neurobehavioral improvements correlated with a significant increase in Homer1 levels in the synaptic membrane of JAG201-treated *Shank3*$^{\Delta 4\text{-}22}$ animals, demonstrating an improvement in a synaptic physiological deficit via recruitment of a SHANK3 functional binding partner. JAG201 DNA and RNA biodistribution assessed at 3- and 10-months post-treatment showed widespread rostrocaudal transduction and persistent transgene expression

throughout the CNS in a dose-dependent manner in *Shank3*$^{\Delta 4\text{-}22}$ mice treated with JAG201. *Conclusion:* These data demonstrate therapeutic benefit of ICV administered JAG201 on established neurobehavioral and synaptic physiological phenotypes in an animal model of *Shank3* deficiency. Unilateral ICV administration of JAG201 also results in widespread biodistribution and persistent transgene expression throughout the CNS. A first-in-human clinical study with JAG201, an AAV9-based gene therapy targeting *SHANK3* mutation- or deletion-related disorders, is slated to begin this year.

1604. The Mouse Aspa Promoter Contains Tissue-Specific Enhancers and Silencers

Thomas Leland[1], Mengtian Cui[1], Tapan Sharma[1], Suk Namkung[1], Sophia Liu[1], Jackson McGowan[1], Fang Zhang[1], Yue Zhang[1], Touraj Farzani[1], Guangping Gao[1,2], Phillip Wl Tai[1,2]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Microbiology and Physiological Systems, UMass Chan Medical School, Worcester, MA

Canavan disease (CD) is a lethal inherited leukodystrophy resulting from loss-of-function mutations in the *aspartoacylase (ASPA)* gene. In preclinical mouse studies performed in our lab, a CD gene therapy using a ubiquitously expressed human *ASPA* transgene (*CMV-CBA*-h*ASPA*) packaged into an adeno-associated virus (AAV) vector rescued the disease phenotype of a CD mouse model. At full dose, ubiquitous ASPA expression also resulted in enhanced rotarod performance. This phenotype was recapitulated by astrocyte-restricted overexpression of ASPA, suggesting that in addition to rescuing the disease phenotype, ASPA expression in astrocytes enhances motor performance. Gene therapies primarily rely on capsid tropism and the regulatory elements present in the transgene cassette to drive the transduction of target cells. Ideally, the set of transduced cells is comprised entirely of those that are in need of the therapy, but off-target expression is commonplace. Moreover, there may be reasons why a constitutive promotor is a better choice for a given vector, but it is important to explore endogenous promoters as they show potential for limiting levels of off-target expression. Challenges remain with such promotors as their sequence boundaries are often poorly defined, limiting our ability to mimic the complex regulatory circuits governing native gene expression.We are currently investigating the mouse *Aspa* promoter to understand the function of its putative enhancers, initially defined by epigenetic marks found 5' of the gene. We hypothesized that the endogenous promoter would transduce fewer off-target tissues and cell-types than *CMV-CBA*, and would retain the expression dynamics of the endogenous *Aspa* gene. We cloned a set of *Egfp* vector plasmids bearing m*Aspa* promoter variants with each defined region deleted individually or in combination, and packaged them into AAV9 for systemic injection into neonatal C57Bl/6 mice. m*Aspa* promoter activity exceeded that of the *CMV-CBA* control in brown fat, was equivalent in liver, and lower in heart and brain. In whole-brain, deletion of a putative central nervous system (CNS) enhancer did not decrease activity. In liver, heart, and brown adipose tissue, the deletion increased promoter activity, suggesting that the CNS enhancer acts as a repressor in these tissues. Deletions of a putative peripheral tissue (PT) enhancer led to diminished promoter activity, but only in the presence of the CNS enhancer. This finding suggests that the CNS enhancer acts to modulate the activity of the PT enhancer in a tissue dependent manner.These data demonstrate that the native *Aspa* promoter exhibits a complex regulatory program which remains functional when incorporated into an AAV vector and delivered outside of its normal chromosomal context. The putative PT enhancer appears to be broadly active, and the putative CNS enhancer appears to repress activity in off-target tissues. We are continuing to investigate the cell- and tissue-dependent activities of the m*Aspa* promoter elements to gain further insight into the mechanisms of *Aspa* transcription. G.G. and P.T. are corresponding authors

1605. Shank3 Gene Activation Mediated by Zinc Finger Activators (ZFAs) as a Therapeutic Approach for Phelan-McDermid Syndrome

Daniel Chung[1], Siavash Fazel Darbandi[1], Seemin Ahmed[2], Esmeralda Ponce[1], Jason Eshleman[1], Patrick Dunn[1], Toufan Parman[1], Sookhee Park[2], Andrew Fitzgerald[2], Gibbs Nasir[2], Bob Radeke[1], Jisoo Lee[1], Giulia Cisbani[3], Tim Kröcher[3], Chiara Melis[3], Sarah Zander[3], Mirjam Zachow[3], Claudia Schober[3], Michael Helwig[3], Sarah Hinkley[1], Alicia Goodwin[1], Alaric Falcon[1], Eloise Hudry[2], Katie Worringer[2], Gregory Davis[1], Bryan Zeitler[1], Andrew Young[1], Amy Pooler[1]

[1]Sangamo Therapeutics, Inc., Richmond, CA,[2]Novartis, Cambridge, MA,[3]Evotec SE, Hamburg, Germany

Phelan-McDermid syndrome (PMS) is a rare genetic condition characterized by clinical features with varying severity, including intellectual disability, absent or delayed speech, and autism spectrum disorders (ASD). PMS is caused by a deletion or structural change in chromosome 22 or a pathogenic variant of the *SHANK3* gene. *SHANK3* encodes a synaptic protein localized at excitatory synapses to organize scaffolding proteins crucial for proper synapse formation or dendritic spine maturation. Mutations or loss of a *SHANK3* allele due to copy number variations can lead to SHANK3 haploinsufficiency causing synaptic and circuitry deficits associated with PMS. We are utilizing our proprietary Zinc Finger Activator (ZFA) platform to selectively upregulate gene expression by tethering Zinc Finger Proteins to a trans-activation domain. In a proof-of-concept study, we demonstrated Shank3 upregulation at mRNA and protein levels *in vitro* with zero to minimal off-targets in primary cortical neurons derived from wildtype (WT) and *Shank3*$^{(+/\Delta C21)}$ mutant mice. Further, we confirmed AAV-ZFA dose-dependent upregulation of *Shank3 in vivo* in relevant brain regions of WT mice by bulk tissue and single-cell mRNA and protein expression analyses. Thus, our results support the development of ZFAs to specifically restore SHANK3 to physiological levels, providing a potential precision therapy for PMS. These data support further development and investigation of ZFAs as a therapeutic option for neurodevelopmental disorders caused by genetic haploinsufficiency.

1606. Titratable Control of Neuronal Activity Using Precision Genetic Neuromodulation

Calvin Chad Smith, Alba Guijarro Belmar, Sylvain Gigout, Hanna Luniak, Miranda Mathews, Panayiota Demosthenous, Riccardo Privolizzi, Zinicola Zinicola, Brandon Roberts, Andrew Murray, Robert Brownstone
Sania Therapeutics, London, United Kingdom

Many neurological diseases can be attributed to abnormal electrical activity of specific neural circuits. If we could normalize the electrical activity of selective populations of neurons, we could develop a new generation of treatments for a wide range of neurological disorders. Genetic therapies provide a potentially powerful route to this kind of treatment if they could be targeted to the malfunctioning neural circuits and if they provided a mechanism for titrating neural activity in a way that could be controlled by the patient and physician. This type of precision therapy requires two key components: (a) a targeting vector system so that neuronal activity can be corrected selectively in dysfunctional circuits without altering the properties of neighbouring cells and brain regions; and (b) a tunable physiological system to increase or decrease neuronal activity through an easily administered (e.g. oral) medication. Sania Therapeutics is developing a precision therapy for neural circuits by leveraging a combination of intersectional technology platforms that allow for the targeted delivery of chemogenetic proteins through engineered AAV vectors. This approach will allow us to selectively modulate neural circuit activity in disease states while minimizing adverse effects associated with current therapies. Chemogenetics refers to the alteration of electrical activity of a neuron via the use of a genetically delivered protein that responds to a systemically delivered ligand. From a therapeutic perspective, the ideal chemogenetics system would have several properties: i) minimal effects on baseline neuronal activity in the absence of an activator; ii) potent and titratable effects on neuronal activity in response to an activator; (iii) activated by a drug that can be readily administered orally and has minimal effects on non-expressing cells; and iv) validated efficacy in humans. Here we present data showing the efficacy of our lead chemogenetic ion channel candidate (SRx-C490) for modulating excitability in two distinct sub-types of human iPSC derived neurons, motor neurons (MN) and sensory neurons (SN). We show that SRx-C490 can be delivered to MNs and SNs using AAVs and activated by low doses of an FDA approved oral medicine to produce titratable reductions in activity. We first assessed population level spontaneous activity using high density microelectrode arrays, showing that SRx-C490 had no effect on baseline (no activator) spontaneous activity of MNs. However, administration of the activator induced dose-dependent reductions in network activity for SRx-C490 transduced MNs. We next used patch clamp electrophysiology to assess the effect of SRx-C490 on high resolution MN firing characteristics and excitability at baseline, and at a range of activator doses. We show that AAV-mediated expression of SRx-C490 has minimal effect on baseline MN firing characteristics, but the activator induced reductions in excitability at doses that were sub-threshold for control neurons. Specifically, nanomolar activator doses reduced motor neuron excitability by 80% in SRx-C490 transduced motor neurons, while GFP transduced motor neurons were unaffected. We also evaluated the efficacy of SRx-C490 in hIPSC SNs with patch clamp electrophysiology. Similarly to MNs, SRx-C490 had minimal effect on baseline activity in SNs but the activator reduced excitability by up to ~75% at low doses. In summary, we show that AAV-delivered SRx-C490 is effective at reducing excitability in two distinct neuronal subtypes when activated by an FDA approved medicine. This novel chemogenetics system, in combination with Sania's cell-type specific AAV capsids, demonstrates the potential of our platforms to generate precision therapies for multiple neurological disorders.

1607. Intracerebroventricular AAV9 Delivery of Creatine Transporter Restores Peripheral Creatine in a Mouse Model of SLC6A8 Disorder

Troy B. Webster[1], Robyn T. Binsfeld[1], Ilona Tkachyova[2], Melissa Mitchell[1], Steven J. Gray[3], Andreas Schulze[2], Jagdeep S. Walia[1]
[1]Queen's University, Kingston, ON, Canada,[2]The Hospital for Sick Children, Toronto, ON, Canada,[3]University of Texas Southwestern, Dallas, TX

SLC6A8, or creatine transporter, is an active transporter responsible for cellular creatine uptake. SLC6A8 deficiency is an X-linked genetic disorder induced by loss of function mutations in *SLC6A8,* resulting in a severe depletion or absence of creatine in the central nervous system. The most notable role of creatine is as a phosphate buffer for ATP, increasing the energy storage capacity of high energy cells such as neurons. Disease manifestation includes a wide range of symptoms, including developmental delay, intellectual disability, motor function impairment, seizures, and hyperactivity. The primary cause of the disease is thought to be primarily due to the absence of creatine in neurons. However, creatine plays an important role in many peripheral organs, and supplementation is ineffective at restoring cellular creatine in the absence of a transporter. Previously, we shared the proof-of-principle that AAV9 delivery of a codon-optimized *SLC6A8*, via intracerebroventriular (ICV) route, can fully restore brain creatine and improve behavioral phenotypes. However, SLC6A8 disorders have also been shown to have effects on the peripheral organs, such as abnormalities in the heart, muscle, and immune system, as well as in the brain. Here, we administered self-complementary AAV9 encoding codon-optimized SLC6A8 at postnatal D0 at three different dosages via ICV injections. Five weeks post-injection, we measured creatine, creatinine, arginine, and guanidinoacetate in the heart, muscle, brain, liver, and spinal cord via mass spectrometry. Treatment resulted in significant restoration of creatine and creatinine to both the heart and muscle tissues compared to vehicle controls. Liver creatine was not significantly elevated, and guanidinoacetate and arginine were constant across all treatments. This data shows that gene therapy may be able to improve some of the peripheral phenotypes of SLC6A8 disorders in addition to the previously shown effects on the brain.

1608. Intravenous Gene Therapy Provides a Long-Term Correction of White Matter Vacuolation and Motor Deficits in a Mouse Model of Megalencephalic Leukoencephalopathy with Subcortical Cysts

Alejandro Brao[1,2], Ángela Sánchez[1,2], Irina Rodríguez[1,2], Esther Prat[3,4], Virginia Nunes[3,4], Miguel Chillón[1,2,5], Raúl Estévez[3,4], Assumpció Bosch[1,2,6]

[1]Departament de Bioquímica i Biologia Molecular & Institut de Neurociències, Universitat Autónoma de Barcelona (UAB), Bellaterra, Spain,[2]Unitat Mixta UAB-VHIR, Vall d'Hebron Institut de Recerca (VHIR), Barcelona, Spain,[3]Departament de Ciències Fisiològiques, Institut d'Investigació Biomèdica de Bellvitge (IDIBELL) - Institut de Neurociències, Universitat de Barcelona, L'Hospitalet de Llobregat, Spain,[4]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Madrid, Spain,[5]Institut Català de Recerca i Estudis Avançats (ICREA), Barcelona, Spain,[6]Centro de Investigación Biomédica en Red de Enfermedades Neurodegenerativas (CIBERNED), ISCIII, Madrid, Spain

Megalencephalic leukoencephalopathy with subcortical cysts (MLC) is an infantile onset leukodystrophy characterized by white matter oedema for which there is no efficient treatment. Most MLC patients (~75%) suffer from a biallelic loss-of-function of *MLC1* and develop progressive white matter swelling and vacuolation, leading to early-onset macrocephaly, cerebellar ataxia, spasticity and muscle stiffness, epileptic seizures, and mild cognitive decline. While the physiological role of MLC1 is not fully elucidated, it is known that it is enriched at the astrocyte-astrocyte cell junctions, where it interacts with a myriad of water and ion channels, G protein-coupled receptors, and other membrane-bound proteins, regulating their localization, activity, and derived signaling pathways. Hence, mutations in MLC1 result in the deregulation of its interacting partners as well as the unbalancing of brain water and ion homeostasis. Our goal is to design and optimize a gene therapy strategy using the *Mlc1*$^{-/-}$ mouse model, but also to identify novel indicators that can be used to eventually validate its therapeutic effect. As a proof of concept, we intravenously injected $1{\cdot}10^{12}$ vg of AAV9P31 carrying the human *MLC1* cDNA under the control of the human astrocyte-specific promoter gfa2 (AAV9P31-gfa2-MLC1) to 10-month-old *Mlc1*$^{-/-}$ mice, 5 months after the onset of white matter vacuolation, a hallmark of the disease. This resulted in a long-term astrocyte-driven expression of MLC1 as later as 1 year after viral vector administration in all brain areas analyzed, as confirmed at the RNA and protein levels. In vivo magnetic resonance imaging (MRI) revealed a complete normalization in signal abnormalities associated with brain water accumulation, including a significant decrease in T_2 and mean diffusivity (apparent diffusion coefficient), two key parameters altered in MLC patients. Histopathological analyses showed a full rescue of cerebellar white matter vacuolation, hence confirming in vivo MRI findings. On the other hand, our gene therapy halted the progression and even abolished the motor deficit we first describe in this model, despite the late age of administration. Briefly, *Mlc1*$^{-/-}$ mice develop a progressive hindlimb impairment as seen in motor tests specifically used for cerebellar ataxia-like behaviors in mice, such as hindlimb clasping or hanging wire tests. Treated mice experimented a steady, but prolonged recovery of this phenotype and behaved like healthy controls 1 year after AAV administration. Taken together, our results not only demonstrate the long-term effectiveness of our treatment, but also provide new, valuable insights into the pathophysiology of MLC.

1609. Development of a Robust Zinc Finger Activation Platform for Treatment of Neurological Disorders

Irene Tan, Gillian Houlihan, Jenny Hodges, Siavash Darbandi, Heather Kozy, Esme Ponce, Dan Chung, Bhakti Kadam, Yolanda Santiago, Andrew Olin, Qi Yu, Bryan Zeitler, Annemarie Ledeboer, David Paschon, Gregory Davis

Sangamo Therapeutics, Inc., Richmond, CA

Many neurological disorders are caused by haploinsufficiency, or a heterozygous genotype leading to loss of function in one allele of a gene. These mutations can lead to neurodevelopmental impairments that can affect learning, self-control, and cognition. One strategy to address such disorders is the targeted upregulation of the wild-type allele using sequence specific transcription factors, such as zinc finger activators (ZFAs), to restore normal protein levels in the brain. However, long-term and high-level expression of certain published transactivation domains (TADs) in neurons can lead to undesired levels of differentially expressed genes (DEGs) and poor tolerability in vivo. To overcome this limitation, we have assessed a large panel of human TADs that, when linked to Sangamo's proprietary engineered ZF proteins, showed favorable profiles in various screening cell lines, including high specificity and selective, dose-dependent activation of therapeutically relevant target genes. These ZFAs were then packaged into AAV, transduced into neurons, and assessed for their activity and specificity in long-term experiments. Robust on-target activation was observed along with varying levels of genome-wide gene dysregulation which was TAD dependent. Importantly, several ZFAs were identified that elicited little to no gene dysregulation , whereas ZFAs utilizing conventional TADs exhibited a high number of DEGs. Finally, a four-week in vivo study was performed in which a highly-specific, genome orthogonal ZF was linked to the top-performing TAD candidates, packaged into a blood-brain penetrant AAV (AAV.PHP.B), and systemically delivered to the brain of wild-type mice via intravenous injection. Mice transduced with AAVs delivering ZFAs with our highly-specific TAD candidates survived to the end of the study with no neuroinflammation or neuronal loss observed in the brain or spinal cord, confirming the in vivo tolerability of these ZFAs and underscoring the importance of careful specificity assessments in vitro. These data demonstrate the power of the ZF activation platform Sangamo has developed and its potential to treat a variety of neurological diseases.

1610. Reinstatement of *Tcf4* in Juvenile Pitt-Hopkins Syndrome Model Mice Suggests the Importance of Early Intervention for TCF4 Reinstatement Strategies

Lucas M. James, Eric B. Gao, Benjamin D. Philpot

UNC Chapel Hill, Chapel Hill, NC

Pitt-Hopkins syndrome (PTHS) is a severe neurodevelopmental disorder caused by haploinsufficiency of the Transcription factor 4

(*TCF4*) gene. PTHS clinically presents with intellectual disability, lack of speech, motor delay, breathing disruption, seizures, sleep disturbance, hypotonia, and GI problems. Currently, there are only FDA-approved treatments for symptom management and recent studies have focused on developing therapeutics to treat PTHS at its genetic cause via gene therapy. PTHS symptoms emerge in early life with hypotonia and missed developmental milestones; however, diagnosis requires genetic testing which often does not occur in young individuals. TCF4 is most highly expressed during development, peaking perinatally, and is important for early brain development. TCF4 is particularly important in the forebrain with key roles in progenitor proliferation, neuronal migration, and laminar organization. Therefore, we expect that reinstatement of *TCF4* early in development would confer the greatest therapeutic benefit. While studies in mouse models and human brain organoids demonstrate the transformative potential of an intervention strategy, the critical period for reinstatement of *TCF4* has not been well defined in preclinical models. Research has focused on early postnatal mice and organoids which best model a late-embryonic reinstatement of TCF4 in humans. PTHS is not screened for prospectively prenatally or in infants, so it is critical to determine whether reinstatement of *TCF4* later in life offers therapeutic benefit. We used the conditional-reinstatement mouse model Tcf4-LSL (TCF4 Lox-Stop-Lox) developed by our lab to model a later-in-life reinstatement of *Tcf4*. This mouse model shares phenotypes with other TCF4 haploinsufficiency models, with the added advantage of a Cre-recombinase removable stop cassette to reinstate *Tcf4*. Wildtype and Tcf4-LSL mice were injected retro-orbitally at postnatal day 14 with AAV.PHP.eB-hSyn1-Cre to reinstate biallelic *Tcf4* expression in neurons throughout the brain or AAV.PHP.eB-hSyn1-mCherry as a negative control. Our lab has previously shown that reinstatement of TCF4 expression in neurons with this vector at postnatal day 1 (P1) improved behavioral phenotypes in the Tcf4-LSL model. Following injection at P14, mice began behavioral testing at 9-10 weeks through several behavioral assays previously identified as TCF4-sensitive including open field, elevated plus maze, novel object-location memory, and nest-building assays. Our preliminary data suggests that early reinstatement of *TCF4* holds the greatest potential to treat behavioral symptoms of PTHS; however, our study also encouragingly suggests that cognitive behaviors such as learning and memory may be amenable to reinstatement of *TCF4* later in life. Ongoing work is focused on determining the extent of synaptic and transcriptional improvement following reinstatement of *Tcf4* in juvenile mice.

1612. AAV Mediated Delivery of IL-10 to Demyelinating Lesions in an Animal Model of Multiple Sclerosis Does Not Suppress Disease but Results in Increased Active Lesion Formation

Geoffrey D. Keeler
University of Florida, Gainesville, FL

Demyelination is the destruction of the myelin sheath, or the protective coating surrounding neurons. Demyelination is considered a hallmark characteristic of Multiple Sclerosis and can lead to axonal damage, axonal death, and progressive disability in late disease stages. To date, there is no FDA approved treatment for demyelination. Current, treatment strategies for MS focus on decreasing neuronal inflammation. These treatments have little effect on demyelination and in fact allow continued formation of new lesions. Remyelination is the regenerative process in which the body repairs the myelin sheath. In MS, remyelination occurs but often fails in the majority of lesions. Thus, the induction of remyelination has been postulated to be an effective treatment option for MS, either alone or in conjunction with current treatments. The demyelinating lesion consist primarily of activated microglia and astrocytes. Demyelinating microglia and astrocytes are responsible for producing an inflammatory microenvironment that is hostile to remyelination. Thus, altering the microenvironment of the lesion represents a strategy to increase remyelination. Previously, we showed peripherally injected AAV efficiently crosses the blood-brain barrier and results in robust transgene throughout the brain and spinal cord in an animal model of MS. Here we show that our AAV platform successfully targets lesions sites (Fig1A-D). Next, we investigated the effects of AAV mediated delivery of IL-10 on disease outcomes. We found that our AAV.IL-10 treatment had no effects on the clinical outcome (Fig1E). Interestingly though, we found there to be more active lesions in IL-10 treated animals as compared to PBS and AAV.eGFP treated animals as visualized via Neutral Red Staining (Fig1F-H). These results show that IL-10 exacerbated active lesion development in the CNS of SJL mice suffering from relapsing-remitting MS like disease.

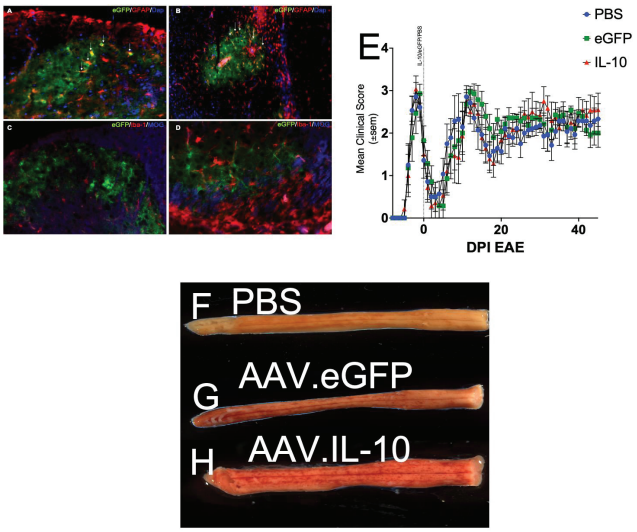


Figure 1: (A-F) Images showing AAV.eGFP targeting demyelinating lesions in brain and spinal cord as indicated by the presence of eGFP in the absence of MOG. (E) Mean Clinical Scores of animals treated with either PBS, AAV.eGFP, or AAV.IL-10, (F-H) spinal cords stained with Neutral Red (red areas represent the presence of active lesions).

1613. *In Vivo* Precise Nuclease-Free Genome Editing of the Murine MeCP2 Gene

Swati Bijlani[1], Ka Ming Pang[1], Sampath Rangasamy[2], Lakshmi Bugga[1], Vinodh Narayanan[2], Saswati Chatterjee[1]
[1]City of Hope, Duarte, CA,[2]TGen, Phoenix, AZ

Rett Syndrome is an X-linked, acquired, neurodevelopmental disorder that leads to loss of cognitive and motor abilities. It is associated with de novo mutations in the MECP2 gene and is almost exclusively seen in females. Males with pathogenic MECP2 mutation rarely

survive. MECP2 is a multifunctional methyl CpG binding protein that mediates transcriptional regulation, chromatin modification and mRNA processing. MeCP2 is expressed in all tissues with highest levels in the brain. It is critical for neuronal development. Over 95% of MECP2 mutations associated with Rett syndrome map to Exons 3 and 4 and alter binding to methylated DNA and interaction with transcription regulators, chromatin modifiers and RNA. It is critical to regulate MeCP2 expression as both under- and over-expression are pathogenic. Recent advances to restore regulated MeCP2 expression have therefore focused on modifying MECP2 gene transfer vectors to include the 3' untranslated region containing miRNA binding sites. Two early-stage clinical trials of gene therapy for Rett syndrome using similar vectors are underway. However, the efficacy and durability of this approach remains unknown. Moreover, due to size limitations, gene therapy vectors do not include all required regulatory elements. In contrast to gene therapy which provides additional episomal copies of the transgene, genome editing corrects the pathogenic MECP2 mutations directly in the genome. We hypothesized that permanent correction of mutations in the genome will retain all native regulatory elements and result in sustained systemic physiologic expression thus avoiding overexpression-related toxicity. Stem cell derived AAVHSCs mediate precise nuclease-free genome editing via homologous recombination (HR) and are not associated with additional mutagenesis unlike nuclease-based editing platforms. AAVHSCs are known to cross blood brain barrier. Thus, systemic administration should treat both peripheral organs as well as the central nervous system. Here, we evaluated the efficacy of HR-mediated editing of the MECP2 gene in vivo. An AAVHSC genome editing vector was designed to correct mutations in Exon 4 of the murine Mecp2 gene and insert a promoterless luciferase open reading frame (ORF) immediately downstream of Exon 4. Successful editing of the Mecp2 gene is expected to insert the promoterless luciferase ORF downstream of Exon 4, with expression driven by the chromosomal Mecp2 promoter. Luciferase expression would then serve as a surrogate for MECP2 expression. The murine Mecp2 editing vector was packaged in AAVHSC15 and injected intravenously in wild type mice at 2.2E+11 vg/mouse. Luciferase expression was followed by serial bioluminescent imaging. Systemic luciferase expression was observed by Day 7 with the highest levels found in the liver, likely due to liver tropism of AAVHSC15. Notably, the expression was stable throughout the duration of study, to 24 weeks post-injection with no associated toxicity. Sequence analysis is underway to further evaluate biodistribution and in vivo editing efficiency. These studies are expected to define the optimal dose range required for widespread restoration of Mecp2 expression in Rett models after systemic delivery. In vivo genome editing studies are also underway to evaluate the correction of an Mecp2 mutation in a mouse model of Rett syndrome. Overall, we demonstrated that in vivo administration of an AAVHSC15 editing vector resulted in durable systemic editing of the Mecp2 gene. Thus, we conclude that the AAVHSC genome editing vectors have the potential to permanently correct MECP2 mutations and restore endogenously regulated protein expression.

1614. Development of a Self-Regulating AAV Gene Therapy for the Safe and Effective Treatment of Rett Syndrome

Monique Otero

UMass Chan Medical School, Worcester, MA

Rett Syndrome (RTT) is a debilitating X-linked neurodevelopmental disorder that affects 1:10,000 girls. RTT is characterized by a period of normal development until 6-18 months, followed by rapid loss of previously acquired skills, resulting in severe neurological and physical disability. RTT patients often lose the ability to walk and talk, but with symptom management can live to middle age or older. A hallmark of the disorder is the loss of functional hand use with stereotypic or repetitive hand movements. RTT is caused by mutations in *MECP2* which encodes methyl-CpG binding protein 2 (MeCP2), an epigenetic regulator that is highly abundant in neurons and critical for normal neurodevelopment, maturation, and function. RTT primarily affects girls, who are heterozygous for the mutation, but in rare cases hemizygous boys are affected and have severe neonatal encephalopathy that is fatal in infancy. RTT is not neurodegenerative and genetic restoration of *MECP2* expression reversed neurological defects and rescued survival in adult RTT mice. In previous studies, AAV delivery of the *MECP2* transgene did not reverse symptoms and resulted in toxic over-expression leading to another neurological disorder: MeCP2-duplication syndrome. Recently the use of truncated or instability prone AAV-MeCP2 transgenes, which attenuate expression, have been successful in extending survival in RTT mice. *MECP2* is a dosage sensitive gene and to keep transgene expression within the therapeutically beneficial window, our lab developed self-regulating, AAV-MeCP2 vectors for the gene therapy of RTT. MeCP2 expression homeostasis requires the upstream positive and negative regulators, Brain-Derived Neurotrophic Factor (BDNF) and microRNA-132 (miR-132), respectively. Our vector delivers the MeCP2 transgene with miR-132 recognition elements to exploit this negative feedback loop. We have generated a series of scAAV9-MeCP2 vectors carrying target sites for miR-132 in combination with various other elements. We are comparing the therapeutic efficacy of these vectors delivered by intracerebroventricular (ICV) injection in neonatal *Mecp2*$^{y/-}$ mice. *Mecp2*$^{y/-}$ males have neurological abnormalities and a survival expectancy of 8-12 weeks. We currently have AAV-treated *Mecp2*$^{y/-}$ mice alive at 30 weeks of age in several treatment groups (Fig. 1). We continue to monitor their body weight and are conducting phenotypic scoring. Additional animals are being enrolled in short-term studies to analyze MeCP2 expression by immunoblotting and immunofluorescence of CNS as well as in peripheral tissues.

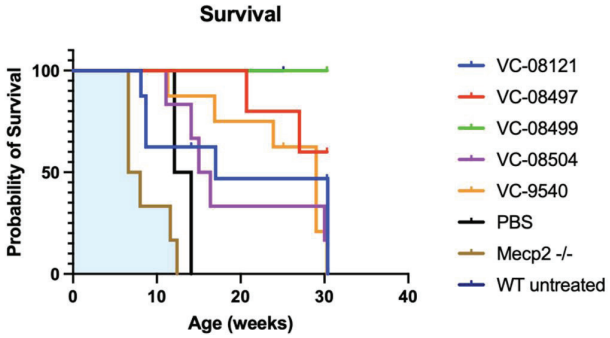

Figure 1: Improved survival of Mecp2y/- male mice after neonatal ICV treatment with scAAV9-Mecp2 vectors

1615. Rescuing STXBP1 Haploinsufficiency in Patient Derived iPSCs Using AAV Mediated Gene Replacement

Sakshi Arora[1,2], Elisa A. Waxman[1,2], Lea V. Dungan[1,2], Deborah L. French[1,2], Benjamin L. Prosser[2,3], Beverly L. Davidson[1,2]

[1]Center for Cellular and Molecular Therapeutics (CCMT), Children's Hospital of Philadelphia, Philadelphia, PA,[2]Center for Epilepsy and Neuro Developmental Disorders (ENDD), The Children's Hospital of Philadelphia, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA,[3]Department of Physiology, Pennsylvania Muscle Institute, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

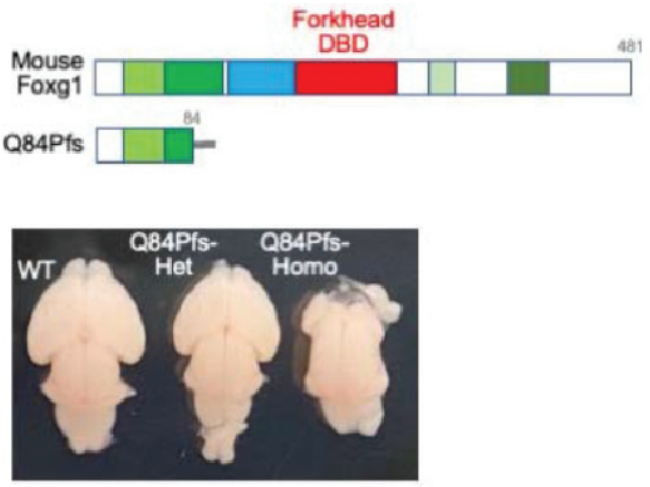
Syntaxin-binding protein 1 (STXBP1, also known as MUNC18-1) plays an essential role in synaptic vesicle fusion and is required for neurotransmitter release, and mutations in *STXBP1* are a leading cause of developmental epileptic encephalopathy. Multiple mutations in *STXBP1* result in premature termination codons, causing transcript nonsense mediated decay and STXBP1 haploinsufficiency. Induced pluripotent stem cells (iPSCs) generated from isolated patient blood samples, and then differentiated into neurons, retain phenotypes of patient neurons, providing a relevant model for screening potential therapies. Given the inherit inefficiencies with standard AAVs in transducing neurons, we first assessed a range of newly discovered AAVs variants emerging from capsid screens in non-human primates (NHP) brains for their abilities to more robustly transduce iPSCs derived neurons. Several variants in this screen showed 2-3 log improved transduction relative to their respective parent serotypes. Next, we cloned and packaged full length STXBP1 cDNA into AAV variant BD004 and BD005, and transduced iPSC-neurons derived from STXBP1 patients. We showed 3-30-fold upregulation of *STXBP1* mRNA and 2-3-fold upregulation of STXBP1 protein in haploinsufficient neurons. Additionally, when applied to patient-derived excitatory cortical neurons AAV-STXBP1 rescued the aberrant electrophysiological phenotypes noted by multi-electrode array (MEA) analysis. Together we present new AAVs for robust transduction of iPSC derived neurons from patient cells, and show their utility for assessing efficacy of AAV-STXBP1 for STXBP1 haploinsufficiency disorders. (S.A. and E.W. contributed equally to this work).

1616. Epigenetic Regulation of Human Prion Expression as a Potential One-Time Treatment for Prion Disease

Shih-Wei Chou[1], Kimberly Marlen[1], David Ojala[1], Patrick Dunn[1], Giulia Cisbani[2], Finn Peters[2], Chiara Melis[2], Jing Hu[1], Qi Yu[1], Matthew R. Tiffany[1], Sarah Mueller[1], Sarah Hinkley[1], Mohad Mehrabian[1], Toufan Parman[1], Marina Falaleeva[1], Alaric Falcon[1], Marian Glynn[1], Kathleen Meyer[1], Amy Pooler[1], Bryan Zeitler[1]

[1]Sangamo Therapeutics, Inc., Richmond, CA,[2]Evotec SE, Hamburg, Germany

Prion disease is a severe, rapidly progressing and invariably fatal neurodegenerative disorder that affects an estimated 1000 new patients per year in the US and Europe. It is caused by the misfolding of the cellular prion protein, PrP, encoded by the *PRNP* gene. There are currently no approved or clinical-stage disease-modifying therapies for the prevention or treatment of prion disease. We have previously shown that a single-administration epigenetic regulation approach using an AAV.PHP.B-delivered zinc finger repressor (ZFR) targeting the mouse *Prnp* gene can achieve >50% reduction of PrP throughout the mouse brain and cerebrospinal fluid (CSF) and result in an unprecedented survival benefit in an aggressive mouse model of Prion disease. Here, we report the development of human *PRNP*-targeted lead ZFRs, delivered intravenously using an engineered blood-brain barrier penetrant capsid. Using cultured human iPSC-derived neurons, we identified highly potent ZFRs that reduced prion mRNA >90% with no detectable off-target activity. Next, we tested top performing ZFRs for target engagement and tolerability in a transgenic mouse model harboring the full-length human *PRNP* locus. The lead candidate ZFRs were well tolerated during the 8-week study, with no significant neuroinflammatory marker elevation or microscopic findings in the brain. Dose-dependent expression of the ZFR and repression of *PRNP* mRNA expression was observed in micro-dissected brain regions. At the bulk level, ZFR treatment reduced PrP protein by 50-80% in various brain regions and the CSF. Multiplexed single-cell analysis demonstrated potent *PRNP* repression in transduced neurons across the brain, including the cortex, thalamus, pons, and midbrain of the treated mice. A lead ZFR is currently under evaluation in nonhuman primates using an engineered AAV capsid with the potential ability to cross the BBB. These results support the accelerated development of a ZFR-based genomic medicine for the treatment of prion disease.



1617. FOXG1 Frame Shift Mutant Mouse Model Revealed Phenotype of FPXG1 Syndrome

Jaein Park[1], Dongjun Shin[2], Shin Jeon[3], Soo-Kyung Lee[1], Jaewon Lee[1]

[1]Biological Science, FOXG1 Research Center / SUNY Buffalo, Getzville, NY,[2]FOXG1 Research Center / SUNY Buffalo, Buffalo, NY,[3]FOXG1 Research Center / University of Pennsylvania, Philadelphia, PA

Single allelic mutations in the gene encoding the forebrain-specific transcription factor FOXG1 lead to FOXG1 syndrome (FS). Patient-specific animal models are needed to understand the etiology of FS, as FS patients show a wide spectrum of symptoms correlated with location and mutation type in the FOXG1 gene. Here we report the first patient specific FS mouse model, Q84Pfs heterozygous (Q84Pfs-

Het) mice, mimicking one of the most predominant single nucleotide variants in FS. Intriguingly, we found that Q84Pfs-Het mice faithfully recapitulate human FS phenotypes at the cellular and brain structural levels. Importantly, Q84Pfs-Het mice exhibited myelination deficits like FS patients. Further, our transcriptome analysis of Q84Pfs-Het cortex revealed a new role for FOXG1 in synapse and oligodendrocyte development. Together, our study revealed the crucial postnatal role of FOXG1 in neuronal maturation and myelination and elucidated the essential pathophysiology mechanisms of FS.

1618. Long-Term Relief of Neuropathic Pain by AAV Expressing Multispecies-Compatible siGCH1

Heesue Chang[1], Minkyung Park[1], Kyoung Jin Lee[2,3], Ji Hyun Kim[2,3], Im Kyung Kang[2,3], Hyochan Park[4], Keerang Park[5], Chan Hee Chon[4], Heuiran Lee[2,3], Ha-Na Woo[3,6], Hyun Ho Jung[1]

[1]Neurosurgery, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Microbiology, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[3]Bio-Medical Institute of Technology, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[4]Inventage Lab, Seongnam, Korea, Republic of,[5]Cedmogen Co, Cheongju, Korea, Republic of,[6]Biochemistry & Molecular Biology, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Introduction: BH4 (tetrahydrobiopterin) is involved in the synthesis of various neurotransmitters affecting homeostatic balance. Although tightly regulated under normal conditions, its intracellular concentration is impaired after nerve injury. GTP cyclohydrolase I (GCH1) has been identified as a critical enzyme responsible for regulation of BH4 levels and is dramatically upregulated in the dorsal root ganglion (DRG) in the course of neuropathic pain. Despite advances in the development of new drugs that address the persistent effects of neuropathic pain, traditional analgesics often lacked specificity and failed to target the underlying causes of neuropathic pain, providing only partial relief. This study aims to develop and evaluate an RNA interference (RNAi)-based AAV designed to specifically downregulate GCH1 mRNA from multiple species and subsequently downregulate BH4 levels, ultimately mitigating neuropathic symptoms in a rat model. **Methods & Results**: We first designed u-siGCH1 and selected most effective multispecies-compatible u-siGCH1 through RT-qPCR and western blot. We then constructed AAV expressing u-siGCH1 (AAV-u-shGCH1) and verified its ability downregulating GCH1. Male Sprague-Dawley rats (200g-220g) were used and grouped into normal (NM), spared nerve injury (SNI), AAV-u-shCON, and AAV-u-shGCH1. Spared nerve injury model was applied and the virus was injected on the post-operative day (POD) 16. Behavior tests were conducted before surgery, post-injection day (PID) 3, 7, 14, 21 and 28. Rats were sacrificed on PID 28 and DRG tissues and blood were collected for immunohistochemical analyses and for examining BH4 concentration, respectively. In vitro assessments showed that the selected u-siGCH1 was remarkably effective in downregulating both GCH1 mRNA and protein levels in human (HeLa), monkey (Vero), and rat (C6) cells. In neuropathic pain model, it was found that AAV-u-shGCH1 group showed a gradual increase in mechanical withdrawal threshold until PID 28, which was statistically significant compared to NM, SNI, and AAV-siCON group. Not only u-siGCH1, but also AAV-shGCH1 effectively downregulated BH4 levels in HeLa cells. **Conclusion**: This study demonstrated that this novel therapeutic approach can provide a long-term strategy to alleviate neuropathic pain through a single treatment, and suggested the potential of gene therapy in the field of neuropathic pain.

1619. Transcriptomics and Proteomics Unravel Molecular Safeguards in Klotho Gene Therapy for ALS

Sergi Verdés[1,2,3], Rubén Guerrero-Yagüe[1,2], Núria Gaja-Capdevila[1,4,5], Judith Sauleda[1,2], Javier Del Rey[1,2], Joan Roig-Soriano[1,2,3], Guillem Chillón[1,2,6,7], Marc Leal-Julià[1,2,3], Laura Rodríguez-Estévez[1,2,3], Miguel Chillón[1,2,3,8], Mireia Herrando-Grabulosa[1,4,5], Xavier Navarro[1,4,5], Assumpció Bosch[1,2,3,5]

[1]Institute of Neuroscience, Universitat Autònoma de Barcelona (UAB), Cerdanyola Del Vallès, Spain,[2]Department of Biochemistry and Molecular Biology, Universitat Autònoma de Barcelona (UAB), Cerdanyola del Vallès, Spain,[3]Mixed Unit UAB-VHIR, Vall d'Hebron Research Institute, Barcelona, Spain,[4]Department of Cell Biology, Physiology and Immunology, Universitat Autònoma de Barcelona (UAB), Cerdanyola del Vallès, Spain,[5]Centro de Investigación Biomédica en Red Enfermedades Neurodegenerativas (CiberNed), Instituto de Salud Carlos III, Madrid, Spain,[6]Center for Cellular and Molecular Therapeutics, Children's Hospital of Philadelphia (CHOP), Philadelphia, PA,[7]Department of Pathology and Laboratory Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA,[8]Institut Català de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

Amyotrophic lateral sclerosis (ALS) gradually weakens and wastes muscles due to the degeneration and loss of motoneurons (MNs). In our previous work, we systemically administered MyoAAV vectors coding for α-Klotho (KL) to SOD1^{G93A} mice. We aimed to enhance KL secretion by skeletal muscles, targeting both MN terminals and muscle endplates. Overexpressing KL in early and symptomatic disease stages preserved neuromuscular function, locomotion, and strength. KL-treated SOD1^{G93A} mice exhibited more surviving spinal and cortical MNs and reduced glial reactivity in the spinal cord. Positive effects correlated with increased neuromuscular junction occupancy, maintained muscle mass, and prolonged survival. Despite

KL being recognized as a pleiotropic protein, its precise protective mechanisms against muscle denervation and MN death in the ALS mouse model remained unclear. To address this, we conducted comprehensive RNA sequencing and proteomic studies in the lumbar spinal cord and gastrocnemius muscles of sKL- and mock-treated animals. Transcriptomic and proteomic profiling of the spinal cord revealed fewer dysregulated genes and proteins in KL-treated $SOD1^{G93A}$ mice compared to mock controls. KL secretion enriched synaptic activity and plasticity, mitigated inflammatory and oxidative responses, and decreased mitochondrial and apoptotic alterations in $SOD1^{G93A}$ mice. In the muscles, KL overexpression had a robust effect, restoring gene expression patterns, particularly increasing the expression of endogenously downregulated proteins in ALS muscles. Predominant corrected pathways were related to muscle contraction and development, as well as the inhibition of fibrosis and atrophy. Klotho upregulated the expression of genes to counteract oxidative stress, calcium buffering proteins, axonal pathfinding factors, and mitochondrial proteins. The inflammatory state induced by ALS was also ameliorated in muscles overexpressing KL. In both tissues, novel roles for KL in promoting ubiquitin-mediated proteolysis and correcting RNA disturbances were discovered. Remarkably, KL induced changes in gene expression patterns only in $SOD1^{G93A}$ animals but not in wild-type-treated mice, emphasizing its specificity in pathological conditions. Overall, functional omics demonstrated the multiple beneficial effects of KL on the altered pathological mechanisms in ALS. Our studies identify new roles for KL and offer insights for future interventions in ALS and other neurodegenerative disorders.

Friday Posters: Ophthalmic and Auditory Diseases

1620. Molecular Mechanism and Gene Enhancement Therapy of Leber Congenital Amaurosis Caused by RPE65 Point Mutations in Patient iPSC Derived RPE Cells

Xiufeng Zhong, Ke Ye, Suai Zhang, Ping Xu, Xiaojing Song, Yuan Wang

State Key Laboratory of Ophthalmology, Zhongshan Ophthalmic Center, Sun Yat-sen University, Guangzhou, China

Purpose: RPE65 plays an important role in the isomerization process of vitamin A in the visual cycle. The loss of function caused by its gene mutation is one of the main causes of Leber congenital amaurosis (LCA). With the development of gene sequencing technology, new mutation sites of RPE65 gene have been continuously discovered, but the pathogenic mechanisms remain largely unknown. We identified a LCA patient carrying heterozygous mutations c. 200T>G and c. 430T>C in the RPE65 gene in clinical practice. This study aims to evaluate the mechanism of retinal degeneration caused by these two novel mutations and explore the effect of gene therapy.Method: An in vitro non-RPE visual cycle pathway was constructed by transfecting plasmids for stable and transient expression of wild-type and mutant RPE65 proteins in HEK293T cells. The expression differences of mutant RPE65 were analyzed by qPCR and Western blot (WB), and the mechanism of down-regulation of mutant RPE65 proteins was investigated. LC-MS was used to evaluate the function of wild-type and mutant RPE65 proteins. In addition, patient-specific hiPSCs were obtained using reprogramming method, and retinal pigment epithelial (iRPE) cells with this heterozygous mutation were obtained by 2D differentiation. The differences between patient-specific iRPE cells and normal iRPE cells/RPE65 knockout (KO) iRPE cells were analyzed by light microscopy, electron microscopy, immunostaining, and WB. RNA-seq was performed to analyze its potential pathogenic mechanism at the transcriptional level. Finally, the therapeutic effect of AAV-mediated gene augmentation using different promoters in patient-specific iRPE cells was evaluated.Results: In the non-RPE system, we detected that the two point mutations reduced protein expression without affecting RPE65 transcription levels by accelerating RPE65 protein degradation under the autophagosome-lysosome pathway. The isomerization activity was abolished because of the mutations. Using a 2D differentiation system, we obtained a large number of normal iRPE, RPE65 KO iRPE and patient-specific iRPE. All three types of iRPE cells exhibited polygonal cell morphology and expressed specific proteins of RPE. However, immunofluorescence and WB analysis showed that this heterozygous mutation significantly reduced RPE65 protein level. RNA-seq analysis showed that mutations of RPE65 did not affect the expression of other genes related to the visual cycle. Additionally, analysis of transcriptomic data suggesting that the reduction of RPE65 protein levels caused by this heterozygous mutation may be related to the function of autophagosome-lysosome pathway. Finally, we designed an AAV vector with a broad-spectrum promoter and an AAV vector that specifically expresses in RPE cells. Both viruses can increase RPE65 protein levels in patient-specific iRPE, but the former is more efficient.Conclusion: The heterozygous mutations c. 200T>G and c. 430T>C in the RPE65 gene affect the stability of the RPE65 protein, leading to abnormalities in the visual cycle pathway and further causing retinal degeneration. This process may be related to the activation of the autophagosome-lysosome pathway. In addition, this study preliminarily evaluated the effect of AAV vectors with different promoters on RPE65 expression, providing a basis for the design of gene therapy vectors.

1621. HUB101 Gene Therapy for Blindness Caused by Pediatric Lebers Congenital Amaurosis (LCA16)

Pawan K. Shahi[1], Meha Kabra[1], Allison Spillane[1], Yu Chang[1], Divya Sinha[2], David M. Gamm[2], Susan Macdonald[3], Jeff Sabados[3], Bikash R. Pattnaik[1]

[1]Pediatrics, University of Wisconsin-Madison, Madison, WI,[2]Waisman Center, University of Wisconsin-Madison, Madison, WI,[3]Hubble Therapeutics, Boston, MA

Inherited retinal disorders (IRD) in children cause progressive loss of vision due to mutations in genes crucial for retinal function. Channelopathies represent a broad category of IRD due to the mutations in genes encoding ion channels that are required for visual information decoding and cellular communication. Understanding the molecular mechanisms of ion channel dysfunction is critical for targeted therapies leading to functional restoration. The retinal pigment epithelium (RPE) is a single layer of cells between the choroid and light-sensitive photoreceptors. These cells express the Kir7.1 ion

channel encoded by the *KCNJ13* gene. Mutations in the *KCNJ13* gene lead to a form of Leber congenital amaurosis (LCA16) and snowflake vitreoretinal degeneration (SVD). In this study, we focused on LCA16 caused by nonsense mutations in the *KCNJ13* gene. We used a preclinical AAV5 to deliver a VMD2 promoter-driven healthy copy of human *KCNJ13* open reading frame (here referenced as HUB-101, from Hubble therapeutics) to RPE cells. HUB-101 transduction of LCA16 patient-derived iPSC-RPE cells resulted in the expression of the Kir7.1 channel and restoration of channel function as measured by single-cell patch-clamp experiments. In our conditional knock-out mouse model lacking the Kir7.1 protein in RPE cells, we delivered HUB-101 by subretinal injection. It not only expressed the protein, but it also enhanced the c-wave amplitude in electroretinography (ERG). The c-wave represents light-evoked RPE cell response attesting to functional restoration in vivo. With the recent approvals of gene transfer therapy for clinical trials for other diseases, HUB-101 is designed for treating LCA16 blindness. Beyond treating visual impairment, HUB-101 gene therapy holds promise for genetic ion channelopathies such as neurological diseases.

1622. AXV-101, a New Codon-Optimised *BBS1* AAV9 Vector Halts Photoreceptor and Outer Nuclear Retinal Layer Organisation Degeneration in a Dose-Dependent Manner

Oriane Guillermin[1], James Grey[1], Gabriela Carreno[1], Nertiyan Elangkovan[1], Nicole Jeffrey[1], Chiara Sidoli[1], Andres Crespo[1], Emma Mustafa[1], Phil Beales[1,2], Elisa Cuevas[1], Victor Hernandez[1,3]

[1]Axovia Therapeutics Ltd, London, United Kingdom,[2]Ggm, GOSICH UCL, London, United Kingdom,[3]Brunel University London, London, United Kingdom

Bardet-Biedl syndrome (BBS) is an autosomal recessive disorder associated with primary cilia dysfunction, presenting with retinal dystrophy and progressive visual loss, amongst other clinical features. *BBS1* is the most common mutated gene found in BBS, with the missense *BBS1* M390R mutation being the most common allele. We have previously demonstrated that different AAV8 vectors, expressing the wild-type BBS1 cDNA under the regulation Rhodopsin Kinase (AAV8-RK-BBS1) and Cytomegalovirus (AAV8-CMV-BBS1) promoters, are safe and able to halt the retinal degeneration in the *Bbs1*$^{M390R/M390R}$ (M390R) mouse. In this study we have improved the efficacy and safety profiles with AXV-101, an AAV9 capsid vector expressing a human codon-optimised BBS1 cDNA sequence (hCOBBS1) under the regulation of the CAG promoter (AAV9-CAG-hCOBB1). To test safety, efficacy, and potency of AXV-101, 1.5µl of three doses of vector were administered subretinally and unilaterally in one bleb at p7-9: low dose ($6.67x10^{11}$vg/ml), medium dose ($3.33x10^{12}$vg/ml) and high dose ($6.67x10^{12}$vg/ml). M390R and Wild-type (WT) groups were dosed, including untreated (contralateral eyes) and subretinal injected retinae with phosphate-buffered saline (PBS) and AXV-101 formulation buffer. Functional and structural readouts were captured at 2.5-, 4- and 6-months of age and included photopic and scotopic electroretinogram (ERG) and retinal Optical Coherence Tomography (OCT). At 6 months the degenerated retina in M390R untreated mice are too thin (ONL) to be accurately measured by automated OCT image segmentation. The ONL thickness of WT retinae treated with either low, medium or high doses maintain a normal structure with a stable ONL thickness at 6 months. At 2.5 months, M390R treated eyes display a dose response in ONL thickness, where PBS and buffer averages are 18 mm and 23 mm respectively, low dose at 25 mm, medium at 28 mm and high dose at 31mm. The dose response continues at 6 months for the medium and high dose while the ONL is missing for the PBS, buffer and low dose treated eyes. At 6 months medium and high doses treated M390R retinae have a 99.3% and 98% chance of retaining the ONL. Overall, there is rescue in ONL thickness from an early timepoint in M390R treated eyes with sustained efficacy up to at least 6 months. These results were corroborated with the histological analysis at 6-month after treatment. Buffer-treated eyes displayed an ONL throughout the entire retina about 2 nuclei thick, However, four out of five M390R eyes treated with medium dose exhibit a rescue patch where the ONL is visibly thicker with a thickness between 9 and 10 nuclei observed, compared with the 11 to 12 nuclei of WT controls. ERG responses show a high variability. When comparing trends of M390R treated with AXV-101 with buffer treated eyes, some retinal function rescue is observable. Notably, rod photoreceptor activity measured by scotopic a and b wave amplitude, is significantly improved in both medium and high dose treatment groups when compared to buffer treated at 4 months. At 6 months, the rescue is maintained for medium and high dose treated eyes for scotopic b wave measurements. We also observed a dose response correlation observed at 6-months when assessing hCOBBS1 transgene expression with low, medium to high dose treatments, correlating with the histological and functional rescue observed. In summary, these results indicate that AXV-101 can halt functional and structural retinal degeneration in the M390R (Bbs1) mutant retinae in a dose dependent manner, with the medium dose ($3.33x10^{12}$vg/ml) the minimum and sufficient dose to sustain photoreceptor survival without any safety concerns.

1623. Development of a Novel Recombinant AAV Gene Therapy rAAV-AIPL1 for Leber's Congenital Amaurosis 4 (LCA4) Disease

Zhuoyu Ni, Fangting Han, Fei Wu, Zicheng Song, Lei Zhang, Shan Fang, Anni Ou, Zeyu Liu, Lei Du, Yitong Hou, Xingxin Chen, Fenghua Wang

Innostellar Biotherapeutics, Shanghai, China

Leber's congenital amaurosis (LCA) is a serious early-onset congenital blinding retinopathy, accounting for more than 5% of hereditary retinal diseases. Affected individuals are diagnosed at birth or in the first few months of life with nystagmus, severely impaired vision or blindness. To date, mutations in about 20 different genes cause LCA. Among which, LCA4 is caused mainly by mutations of acryl hydrocarbon receptor interacting protein like-1 (AIPL1) gene. AIPL1 gene is expressed in photoreceptors and the pineal gland. In the retina, AIPL1 acts as a specialized chaperone of HSP90 and cyclic nucleotide phosphodiesterase PDE6 complex, which is an essential enzyme effector in the phototransduction pathway. Mutations in AIPL1 gene disrupt AIPL1 interaction with HSP90 and prevent assembly of the PDE6 holoenzyme. Reduced PDE6 function leads to intracellular cGMP elevation and prolonged opening of the cyclic nucleotide gated channels and excessive Ca2+ influx, and photoreceptor degeneration and vision deterioration follows. Currently, there is no approved

treatment for LCA4. We developed a novel recombinant adeno-associated virus AAV (rAAV) based gene therapeutics. Capsids from our Capstellar platform can effectively transduce retina cells and deliver human AIPL1 gene driven by a photoreceptor-specific promoter. rAAV-hAIPL1 can be correctly expressed in rodent model and human iPSC-derived retinal organoid (RO) models. The AIPL1 knockout ROs show aberrantly high cGMP level in the photoreceptors due to reduced PDE6 function, while rAAV-hAIPL1 treated RO exhibits relatively normal cGMP concentration, indicating a recovery of PDE6 holoenzyme function. In the aipl1-/- mouse model at the age of 3 weeks, its retina is severely atrophied with photoreceptor cell layer nearly disappeared. When rAAV-hAIPL1 is administered in the subretinal space of aipl1-/- mice, hAIPL1 protein expression is recovered along with significant retention of photoreceptor cell layer and related biomarker expression. In summary, we developed a novel rAAV-hAIPL1 gene therapeutic modality. It can specifically express human AIPL1 protein in photoreceptors. The functional proof-of-concept was also demonstrated in mouse models and human retinal organoid disease models that rAAV-hAIPL1 treatment recover correct hAIPL1 expression and its interaction with its normal chaperon protein HSP90 and recoup PDE6 holoenzyme function, hence, delaying photoreceptor cell degeneration and vision loss. Further studies are underway to support future clinical development.

1624. Nonclinical Evaluation of CTx001, a Gene Therapy for the Treatment of Geographic Atrophy in Age Related Macular Degeneration

Mustafa M. Munye[1], Athanasios Didangelos[1], Sofiya Pisarenka[1], Suhnrita Chaudhuri[1], Rachel Green[1], Peter Emery-Billcliff[1], Nakul Patel[1], Pamela Whalley[1], Parisa Zamiri[1], Simon J. Clark[2], Paul N. Bishop[3], Dennis Keefe[4], Rafiq Hasan[1]

[1]Complement Therapeutics, London, United Kingdom,[2]Eberhard Karls Universitat Tubingen, Tubingen, Germany,[3]The University of Manchester, Manchester, United Kingdom,[4]Complement Therapeutics, Bedford, MA

Introduction: Geographic atrophy (GA) is a leading cause of blindness in the US and Europe and strongly associated with genes that regulate the alternative complement pathway. Poor regulation of the C3 amplification loop results in generation of the potent opsonin C3b leading to inflammation, membrane attack complex (MAC) formation, RPE/photoreceptor cell death and vision loss. Two complement pathway inhibitors have recently been approved by the FDA having slowed disease progression in patients, validating the pathway as a key driver of disease. However, the slowing of disease progression has been modest and to date has not translated to vision preservation. Both treatments also require frequent intravitreal injections impacting adherence. **Results**: CTx001 is an AAV gene therapy encoding a novel soluble and potent complement regulatory protein, mini-CR1, for the treatment of GA. Mini-CR1 is derived from the membrane bound complement receptor 1 (CR1) protein. We show that mini-CR1 supports potent suppression of the C3 amplification loop acting as a co-factor to the Factor I mediated cleavage of C3b with an IC50 of 125nM in human serum. We demonstrate that in contrast to other co-factors being evaluated for the treatment of GA, mini-CR1 supports proteolysis of C3b to iC3b and then to the terminal C3dg fragment thereby reducing levels of the potent C3b and iC3b opsonins. There is growing appreciation of the need for GA treatments to address complement overactivation in both retinal and choroidal compartments, separated by the selective Bruch's membrane. Mini-CR1 successfully crossed enriched Bruch's membrane derived from human donor eyes *ex vivo* and maintained co-factor activity in contrast to larger complement regulators. CTx001 administered by subretinal injection in *in vivo* rodent laser CNV models of disease demonstrated a dose dependent reduction in MAC formation and a reduction in C3b levels in the eyes of treated animals. No adverse findings were reported either systemically or in the eye following subretinal CTx001 delivery. CTx001 was well tolerated in a non-GLP non-human primate (NHP) study at doses up to and inclusive of the maximal feasible dose. A dose response was observed in the levels of mini-CR1 expressed in the vitreous of NHP along with evidence of target engagement with increasing levels of iC3b. All animals progressed to scheduled euthanasia with no gross lesions apparent upon necropsy. There were no test item related clinical observations reported throughout the study. No remarkable findings linked to test item were seen in clinical chemistry, hematology or coagulation parameters. Mild inflammation secondary to the dosing procedure and test item was observed in a dose dependent manner. All ophthalmic findings such as pigment variation, anterior chamber and vitreous cells and retinal hemorrhage were reported as very slight to slight. There were no signs of vasculitis in any dose groups. **Conclusions:** CTx001 is an AAV gene therapy encoding a potent complement regulator that shows promise as a potential treatment for GA. Mini-CR1 effectively suppresses the C3 amplification loop, reducing levels of the opsonins C3b and iC3b. Its ability to traverse Bruch's membrane enables it to address complement overactivation in both retinal and choroidal compartments. *In vivo,* CTx001 produced a significant reduction in MAC formation and C3b levels in rodents and was well tolerated in NHP's. These results support initiation of IND enabling GLP toxicology studies for CTx001.

1625. Preclinical Studies of HG004 Gene Replacement Therapy in Support of Clinical Trial for *RPE65*-Associated Inherited Retinal Dystrophy

Weiwei Wu, Sheng He, Qi Yang, Chenhua Yang, Mengke Zhu, Shaoran Wang, Xuan Yao, Hui Yang, Alvin Luk, Linyu Shi

HuidaGene Therapeutics Co., Ltd., Shanghai, China

Background: Mutations in the *RPE65* gene disrupt the visual cycle, leading to a congenital deficiency in supplying chromophores to rod and cone photoreceptors and resulting in *RPE65*-associated inherited retinal dystrophy (*RPE65*-IRD). Our team has developed an AAV9 gene replacement therapy, HG004, carrying the human *RPE65* gene, and conducted preclinical and IND-enabling studies to support the clinical application of HG004 to treat patients with *RPE65*-IRD. **Methods:** *Rpe65*-deficient mice aged 1 month underwent subretinal injections of either HG004 or a vehicle control. Efficacy was assessed through optical coherence tomography, electroretinography, and histochemical staining. Next, a good laboratory practice (GLP) toxicology study of bilateral injection at three different doses of HG004 was conducted in non-human primates (NHPs), with clinical observation, ophthalmic examinations, vector shedding/biodistribution, and immunogenicity assessments performed at various time points. **Results:** HG004

exhibited a significant amelioration in scotopic b-wave responses across all treatment cohorts compared to the vehicle-injected control group of *Rpe65*$^{-/-}$ mice ($p<0.01$). The rate of restoration surpassed 60% of the wild-type (WT) and was maintained for 34 weeks. The retinal thickness in HG004-treated eyes of 1-month-old *Rpe65*$^{-/-}$ mice resulted in 85% of the WT level while the untreated eyes represented 67% of the WT level at 35 weeks post-injection. In the GLP NHP study, the localization of HG004 predominantly manifested within the retinal tissues, especially in the retina and choroid. No discernible presence in the reproductive system and no manifestations of drug-induced systemic toxicity were observed in NHPs at both the 4- and 13-week post-injection period. Adverse reactions (such as retinal injury at the injection site, vitreous inflammatory cell exudation, and others) were primarily observed within the retinas of all tested NHP groups, suggesting that these non-drug-related events were primarily related to the injection procedure (Figure 1). Immunotoxicity evaluations further demonstrated the absence of drug-induced abnormalities in the whole blood samples of NHPs, and the lack of immune response from AAV or RPE65 antigen-specific T cells in NHPs was also observed. **Conclusions:** Our results across all mouse studies demonstrated dose-responsive restoration of retinal function after the treatment of HG004 with a durable effect in mice for at least 34 weeks after the treatment of HG004. Furthermore, HG004 is safe for use in NHPs. The nonclinical studies supported the evaluation of HG004 in patients with *RPE65*-IRD. The IND has been cleared by the FDA and China CDE, and the Phase I/II clinical trial (NCT05906953) is currently being evaluated in humans.

1626. Preclinical and Phase I Clinical Trial Update of the Safety and Efficacy of SKG0106, a Novel AAV Gene Therapy Product for the Treatment of Neovascular Age-Related Macular Degeneration

Byron Li[1], Yanqun Shu[1], Qiongqiong Ren[1], Peilu Li[1], Huimin Kong[1], Lumei Xiao[1], Bing Wu[1], Sijia Huang[1], Jinxin Deng[1], Zheng Luo[1], Dianyang Chen[1], Youxin Chen[2], Chan Wu[2], Ruoan Han[2], Jay Hou[1]

[1]Skyline Therapeutics, Cambridge, MA,[2]Department of Ophthalmology, Peking Union Medical College Hospital, Beijing, China

SKG0106, which comprises a proprietary capsid and a novel transgene genome encoding an anti-vascular endothelial growth factor (VEGF) protein (Vb24), is a novel recombinant adeno-associated virus (AAV) vector for the treatment of neovascular age-related macular degeneration (nAMD) via intravitreal (IVT) delivery. Upon delivery, the vector transduced retinal cells resulting in effective expression of Vb24, which potently suppressed the action of VEGF in two pharmacologically relevant animal models: a chronic rabbit retinal neovascularization (RNV) model and a monkey choroidal neovascularization (CNV) model. In the rabbit dose range finding (DRF) study, SKG0106 in the dose range of 1E9 to 3E10 vg/eye showed comparable efficacy profiles as Eylea® and lasted until the end of the study (6 weeks) while Eylea® already lost its activity. In the monkey DRF study, SKG0106 showed a dose-dependent effect in reducing CNV grade 4 spot rate, mean spot fluorescein leakage and the thickness of subretinal hyperreflective material (SHRM). The efficacy of SKG0106 at 8E9, 4E10, 2E11 and 1E12 vg/eye was comparable to that of Eylea®, and all dosages were well-tolerated. In a prophylactic long-term study with monkey CNV model, SKG0106 (6E10 vg/eye) exhibited comparable efficacy to that of Eylea® at 6 and 13 weeks following IVT injection. In addition, SKG0106 demonstrated a lasting strong efficacy at the end of 26 weeks. In contrast, Eylea® did not show the inhibitory effect on the lesions. The thickness of SHRM in SKG0106 treated group was significantly thinner than that in both vehicle and Eylea® treated groups. Most importantly, there were no local or systemic adverse events detected in all pharmacological studies and a GLP toxicology study in monkeys. Following the investigational new drug (IND) clearance from both the US FDA and China NMPA, a multicenter, open-label, Phase I trial was conducted in patients with nAMD to evaluate the safety, preliminary efficacy, immunogenicity, and pharmacokinetics characteristics of SKG0106. The study included 3 dose cohorts with 3 patients each at 8E9, 2.4E10 and 7.2E10 vg/eye. Ocular safety, tolerability, best corrected visual acuity (BCVA), retinal central subfield thickness (CST), serum anti-AAV neutralizing antibody titer, and the Vb24 protein level in aqueous humor (AH) were evaluated at baseline, Day-1, Week-2, Week-3, Week-4, and once every 4 weeks after Week-4 up to 48 weeks post dosing. SKG0106 was well-tolerated by all subjects. No dose-limiting toxicities and treatment related serious adverse events were detected up to 30-52 weeks. Asymptomatic trace vitreous cells were observed in a single episode of follow-up 12-16 weeks in patients treated with 7.2E10 vg/eye, which resolved without intervention. More clinical results on BCVA, CST, and Vb24 in AH will be presented at the ASGCT meeting.

1627. Preclinical Evaluation of NG101 for Treatment of Wet Age-Related Macular Degeneration

Juwon Shim, Jeongyun Bak, Youyoung Kim, Hoon Young Kong, Joo Seok Han

Neuracle Genetics Inc., Seoul, Korea, Republic of

Age-related macular degeneration (AMD) is the most common cause of vision loss in individuals over the age of 55, accounting for 6-9% of legal blindness worldwide. Ten to fifteen percent of AMD patients develop choroidal neovascularization (CNV), resulting in wet AMD (wAMD), which accounts for almost 90% of blindness associated with AMD. We developed a novel small promoter, CAT311, derived from the ubiquitous CAG promoter and utilized it in NG101 (AAV8.CAT311AflK), a recombinant adeno-associated virus 8 (rAAV8) encoding Aflibercept, an anti-vascular endothelial growth factor (VEGF) agent, for the treatment of wAMD. To compare transgene expression by the CAG and CAT311 promoters, mice were administered AAV8.CAGGFP or AAV8.CAT311GFP via a single subretinal injection. GFP expression was significantly higher in the retina following the administration of AAV8.CAT311GFP compared to AAV8.CAGGFP throughout 51 weeks. In the laser-induced CNV mouse model, NG101, administered at doses ranging from $1x10^6$ to $1x10^9$ vg/eye, demonstrated a dose-dependent reduction in CNV lesion leakage and size. To evaluate the transgene expression of NG101 in non-human primates (NHPs), cynomolgus monkeys were administered NG101 via a single subretinal injection with doses ranging from $3x10^{10}$ to $1x10^{12}$ vg/eye. The expression of Aflibercept in ocular tissues on day 57 was significantly higher at all doses than the minimum required amount for the treatment of wAMD. Considering the excellent aflibercept expression ability of NG101, we assessed the efficacy of NG101 at doses of $3x10^9$ and $6x10^9$ vg/eye in the NHP CNV model and demonstrated that NG101 effectively inhibited the growth and leakage of new vessels, to the same extent as intravitreal injection of Eylea (2mg). Collectively, these data suggest that NG101, with its efficacy at a low dose, is a promising candidate for wAMD treatment, potentially minimizing toxicities associated with AAV gene therapy.

1628. An Optimized System for AAV Compatible Delivery of Full Length PCDH15 for Treatment of USH1F via RNA End Joining

Claire E. Williams[1], Ryan H. Hsu[2], Kip J. Hermann[1], Lukas C. Bachmann[3], Samuel L. Pfaff[1]

[1]The Salk Institute for Biological Studies, San Diego, CA,[2]The Salk Institute & UC San Diego, La Jolla, CA,[3]Insmed Inc., San Diego, CA

Usher Syndrome 1F (USH1F) is a debilitating disease where patients experience congenital, bilateral, profound sensorineural hearing loss, vestibular areflexia, and adolescent-onset retinitis pigmentosa (RP). USH1F is caused by mutations in one gene, protocadherin-15 (PCDH15) making it an ideal candidate for gene replacement or gene editing strategies for treatment. PCDH15 is a cell-membrane binding protein that is primarily present in stereocilia and the retina and its coding sequence is approximately 5.8 kb, which exceeds the maximum packaging capacity of AAVs. To overcome the size limitations of AAVs for delivery of PCDH15 in a gene replacement strategy, we utilized our novel REJ technology and created five different constructs to optimize the expression of full-length PCDH15 (see abstract: Optimization of RNA End Joining (REJ) to safely and efficiently express large proteins, Bachmann et al.). REJ is a highly efficient mRNA trans-splicing process, which can be used in the delivery of multiple DNA constructs, which post transcription will have the separate RNAs scarlessly recombine in the nucleus, resulting in a full-length mRNA of the desired protein (Figure 1. A). The REJ variants were transfected into HEK293T cells and the expression of the 250kDa PCDH15 dimer was validated by Western blot (Figure 1. B). All screened variants exhibited full-length PCDH15 at varying levels with minimal fragment expression, and an optimal design was found. Proper cell membrane colocalization was confirmed by immunohistochemical visualization (Figure 1. C). Ongoing efforts include functional assays to confirm binding between PCDH15 and its ligand CDH23 (Cadherin-23) and producing AAV for in vivo validation. These findings define an optimized gene replacement system for treating USH1F.

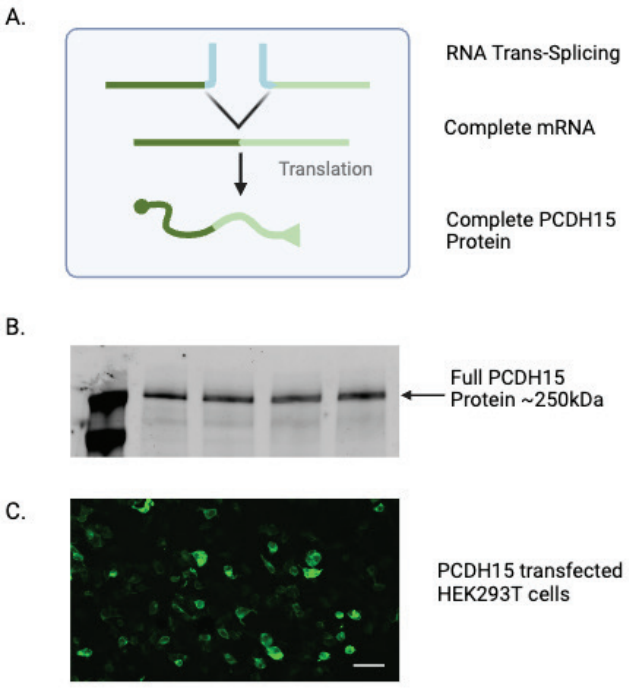

Figure 1. (A) Schematic of REJ-enabled PCDH15 delivery. Binding domains are in blue and the split coding sequence is in green. (B) Western Blot depicting PCDH15 successfully reconstituted in HEK293T cells after transfection with two REJ constructs. (C) Immunohistochemical staining of HEK293T cells after transfection demonstrating cell membrane localization. PCDH15 is visualized in green.

1629. Complehensive Evaluation of Safety and Efficacy of Intravitreal Administration of Three AAV2 Vectors Expressing a Novel Anti-VEGF Molecule in a Nonhuman Primate Model of Choroidal Neovascularization (CNV)

Ethan Li

InnoStellar Biotherapeutic Co., Pudong, China

Inhibition of vascular endothelial growth factor (VEGF) family by intravitreal injections of anti-VEGF molecule(S) for the management of the ocular diseases with pathological neovascularization is a proven treatment. Adeno-associated virus (AAV)-mediated gene therapy has great potential for optimal long-term even life-term treatment of single intravitreal injection (sIVI). In the present study, we investigate efficacy and safety of three intravitreally administered AAV2 vectors expressing a novel anti-VEGF molecule at medium or low doses in a nonhuman primate (NHP) model of choroidal neovascularization (CNV). Persistent expression of anti-VEGF molecule was observed by collecting samples of aqueous humor at different time points from 1 month to 6 months. Laser-induced CNV was inhibited as determined by several ocular tests including imaging techniques of optical coherence tomography (OCT), fundus photos and fluorescein angiography (FA). The level of VEGF in samples of aqueous humor were reduced. Positive expression level of anti-VEGF molecule in different ocular compartments (including retina, choroid, iris/ciliary body, vitreous and aqueous humor) was detected. The biodistrubution of AAV vector DNA in the 16 body tissues as well as in 9 ocular compartments was screened. No immune respones to anti-VEGF molecule were found in ADA assay or IFN-gamma ELISpot assay. Our data suggest that single intravitreal injection of three AAV2 vectors expressing a novel anti-VEGF molecule is safe and may be effective long-term treatment for diseases with ocular neovascularization. The novel anti-VEGF molecule and one vector will be selected for further investigation.

1630. Development of an AAV-Based Gene Therapy for the Ocular Phenotype of Friedreich's Ataxia

Heyu Tang[1], Emily M. Xu[1], Siddhant S. Gupte[1], Kaitlyn R. Calabro[1], Diego S. Fajardo[1], James J. Peterson[1], Hannah L. Friend[1], Sanford L. Boye[2], Shannon E. Boye[3]

[1]Division of Cellular and Molecular Therapy, Department of Pediatrics, University of Florida, Gainesville, FL,[2]Powell Gene Therapy Center, University of Florida, Gainesville, FL,[3]University of Florida, Gainesville, FL

Purpose: Friedreich's Ataxia (FA) is an autosomal recessive neurodegenerative disorder caused by mutations in the *FXN* gene that affects multiple systems. Approximately 30% of FA patients develop ophthalmic symptoms by their second decade of life, which may include nystagmus, saccadic dysmetria, optic nerve atrophy, coupled with the loss of retinal ganglion cells (RGCs) and retinal nerve fiber layer (RNFL) thickness. This study aims to develop and characterize a novel mouse model with *FXN* knocked out specifically in RGCs and to develop an AAV-FXN gene therapy approach that will be evaluated in the model. **Approach:** *Pou4f2*^{Cre} mice (*Pou4f2* promoter driving Cre-recombinase), were bred with *Fxn*$^{+/-}$ mice to generate *Fxn*$^{+/-}$; *Pou4f2*$^{Cre+/-}$ mice. The double heterozygous mice were crossed to *flFxn+/flFxn+* mice to generate *Pou4f2*$^{Cre+/-}$;*flFxn+/Fxn-* (Pou4f2-FXN KO) and *Pou4f2*$^{Cre-/-}$;*flFxn+/Fxn-* (Pou4f2-FXN WT) mice. In-life assessments occurred over 6 months to measure thickness of the RNFL, ganglion cell layer + inner plexiform layer (RGC+IPL), inner nuclear layer (INL), and outer nuclear layer (ONL) via optical coherence tomography (OCT). Full field and pattern ERG (ffERG, pERG) were performed to evaluate retinal function. ffERG measures the response from photoreceptors and bipolar cells, whereas pERG measures specific signals from the RGCs. Pou4f2-FXN WT mice were used as controls. FXN expression will be evaluated by immunohistochemistry (IHC), and immunoblotting. The AAV-P2-V1(Y-F+T-V) capsid, a novel AAV2-based capsid variant developed by directed evolution and rational design, was used to package a construct containing the neuronal specific *Syn1* promoter and FXN-HA (FXN coding sequence plus HA tag) and WPRE element (AAV-FXN). AAV-hSyn1-GFP (AAV-GFP) served as the control. Vectors were intravitreally injected into Pou4f2-FXN KO mice, with one eye receiving AAV-FXN vector and the contralateral eye receiving the AAV-GFP control. Retinal structure and function were/will be assessed by the in-life and post-mortem methods mentioned above. **Results:** Pou4f2-FXN KO mice survived the duration of the study without any health issues and exhibited no ataxia or other symptoms of systematic FXN deficiency. OCT revealed a significant, and progressive decrease in RNFL and GCL+IPL thickness starting at postnatal day 30 (P30). Thinning of the INL was also observed at later time points. pERG data showed a significant difference in P1 waveform amplitudes between the KO and WT as early as P30. By P90, both P1 and N2 waveform amplitudes were significantly reduced in the Pou4f2-FXN KO mice relative to controls. Mice treated with AAV-FXN vector at P30 revealed significant protection of GCL+IPL and INL layers. Significant preservation of pERG was observed by 3 months post-injection. **Conclusions:** We have successfully generated and characterized an RGC-only FXN KO mouse model exhibiting significant and progressive retinal dystrophy. These preliminary data suggest this novel mouse model mimics features of the ocular phenotype observed in FA patients. AAV-medicated FXN expression significantly preserved retinal structure and function in Pou4f2-FXN KO mice. This study has established proof-of-concept for AAV-FXN gene supplementation for the treatment of ocular FA. Future experiments will focus on improvements in vector design and longer-term evaluations of AAV-FXN in the Pou4f2-FXN KO mice.

1631. Delivery to the Suprachoroidal Space of an AAV Vector Encoding a Complement Pathway Inhibitor as a Possible Treatment for Dry Age-Related Macular Degeneration

Mi Shi, April R. Giles, Wei-Hua Lee, Chris Tully, Levi Winter, Ryan Kruse, Jessica Gumerson, Kwi Hye Kim, Ye Liu, Olivier F. Danos, Brendan Lilley

REGENXBIO Inc., Rockville, MD

Dysregulation of the complement pathway plays an important role in the pathophysiology of the dry form of age-related macular degeneration (Dry AMD). Currently approved treatments require frequent injections of complement pathway inhibitors. We examined whether a single ocular delivery of an adeno-associated virus (AAV) vector encoding a complement pathway inhibitor can achieve localized,

durable expression in an effort to identify a potential gene therapy approach for treating Dry AMD. Multiple formats of complement C5 inhibitors were designed for expression from AAV vectors. The affinities toward C5 from human, cynomolgus macaque (NHP) and mouse were examined with a Bio-layer Interferometry assay (BLI), and all inhibitors tested showed sub-nanomolar affinities to their cognate C5 target. Potent inhibitor bioactivity was demonstrated through inhibition of complement activation in hemolysis assays. Additionally, human iPSC-derived RPE cells, when transduced with an AAV vector expressing a C5 inhibitor, displayed a strong inhibition of membrane attack complex (MAC) formation, indicating anti-C5 bioactivity of the secreted transgene product. We further examined ocular expression in mice following subretinal injections of vectors encoding the different inhibitors, and identified a format optimized for ocular biodistribution. We then tested this vector for expression and tolerability in NHP following either subretinal or suprachoroidal injections. The vector was well tolerated as assessed with *in vivo* imaging and ocular tissue histopathology. The bioactivity of *in vivo* expressed C5 inhibitors present in NHP vitreous humor was demonstrated through hemolysis assay. The results here support further preclinical development of a minimally invasive approach to the treatment of Dry AMD that has the potential to reduce the treatment burden and deliver therapeutic molecules directly into the site of pathogenesis.

1632. Beyond AAV, Gene Editing of HSV in Patients with Herpetic Stromal Keratitis

Yujia Cai, Sikai Ling, Shuhui Zhang

Shanghai Center for Systems Biomedicine, Shanghai Jiao Tong University, Shanghai, China

Numerous preclinical studies have shown in vivo CRISPR therapy is an attractive strategy to treat ocular diseases. However, clinical evidences for gene editing in the eyes are still rare. We showed safety and efficacy of applying CRISPR both in preclinical and clinical studies to treat herpes stromal keratitis (HSK). In our study, we used virus-like particle (VLP) to delivery CRISPR/Cas9 in the form of mRNA. In an investigator-initiated clinical study of treating refractory HSK cases with acute corneal perforation, we found neither detectable CRISPR-induced off-target cleavages by GUIDE-seq nor systemic adverse events for 18 months on average in all three patients. The HSV-1 remained undetectable during the study. The same drug has also been under evaluation in a phase I trial. The early results showed that the intrastromal injection of the VLP-delivered CRISPR was well tolerated without seeing major adverse effects. Building on the safety and efficacy from HSK, we also extended VLP-delivered CRISPR for treating glaucoma by targeting mutant gene in the trabecular meshwork (TM), which mediated efficient gene editing in non-human primates. Overall, our studies suggested in vivo CRISPR delivery with VLP holds great potential in treating ocular and infectious diseases.

1633. CRISPR/Cas9-Mediated Gene Editing for Herpes Simplex Virus Reduces Viral Reactivation in a Latent Rabbit Keratitis Model

Nadia Amrani[1], Kevin Luk[1], Pankaj Singh[2], Mason Shipley[2], Meltem Isik[1], Martina Donadoni[3], Anna Bellizzi[3], Ilker K. Sariyer[3], Danna Neumann[2], Jennifer Gordon[1], Guoxiang Ruan[1]

[1]Excision BioTherapeutics, Watertown, MA,[2]University of Wisconsin-Madison, Madison, WI,[3]Temple University, Philadelphia, PA

Herpes simplex keratitis (HSK), caused by HSV-1 infection of the cornea, is a major cause of blindness. In the United States, approximately half million people are afflicted with HSK. HSV-1 is a neurotrophic virus that first enters the axons of sensory neurons, migrates to the trigeminal ganglia (TG) and other ganglia, and establishes lifelong latent infection. Recurrent reactivation of HSV-1 and the infection of the cornea in HSK cause corneal opacity, edema, corneal scarring, and neovascularization, that can lead to irreversible vision impairment and blindness. Currently, there is no vaccine for HSV-1 and treatment with nucleoside analogs, which only inhibit virus replication, cannot cure the infection. Recent studies have shown that genome editing tools can target the HSV-1 and reduce the virus shedding. However, this approach has not been optimized or extensively tested in latent HSV-1 animal models. Therefore, an efficient and safe treatment for HSV-1 keratitis that prevents HSV-1 reactivation from viral latent reservoirs is highly needed.In this study, we utilized CRISPR/SaCas9 to target two critical genes in HSV-1, namely ICP0 and ICP27. The Dual Cut method enables the induction of large deletions in the viral genome, effectively preventing viral escape after DNA repair. Transient transfection of Vero cells with plasmids expressing SaCas9 and paired gRNAs resulted in a significant reduction in HSV-1 viral load and titer. Transduction of Vero cells with all-in-one AAV2 vectors expressing SaCas9 and paired gRNAs nearly eliminated the viral load and titer. To assess the *in vivo* efficacy of CRISPR/Cas9 gene editing, we initially used corneal scarification to deliver all-in-one AAV8 (Y733F) and AAV9 vectors expressing SaCas9 and paired gRNAs to a latent rabbit model of HSV-1 keratitis. This approach led to a remarkable reduction of over 60% in viral shedding from the treated rabbit eyes. Subsequently, we investigated the use of intravenous (IV) administration to deliver the all-in-one AAV9 vector expressing SaCas9 and paired gRNAs in the same rabbit model. Impressively, all but one rabbit treated with SaCas9 vectors exhibited undetectable viral shedding following HSV-1 reactivation. It is important to note that in that one rabbit, we could not detect expression of Cas9, suggesting that there was a technical issue with delivery. Moreover, even at a low AAV dose (6E+12 VG/kg) following IV delivery, we observed substantial levels of AAV vector genomes in the TG where the latent HSV-1 is located. Additionally, we detected a reduction in HSV-1 viral DNA and LAT RNA in the TG of rabbits treated with the AAV9-SaCas9 vector compared to the control group. These results suggest effective targeting of the latent HSV-1 reservoir in the rabbit HSV-1 keratitis model.In summary, our findings demonstrate that the delivery of all-in-one AAV9-SaCas9 vectors can serve as an effective one-time therapeutic strategy for treating HSV-1 keratitis.

1634. Efficacy and Safety of a CasRm-Based Therapy for Choroidal Neovascularization in Non-Human Primates

Hong Zhang[1], Jiawen Luo[1], Cunhua Ji[1], Yan Li[1], Fazhou Zhang[1], Chao Zhu[1], Hui Xu[1], Zhendong Xiao[2], Junjiu Huang[3], Junbin Liang[1]

[1]Reforgene Medicine, Guangzhou, China,[2]Biotherapy Center, The Third Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China,[3]MOE Key Laboratory of Gene Function and Regulation, State Key Laboratory of Biocontrol, School of Life Sciences, Sun Yat-sen University, Guangzhou, China

Introduction Age-related macular degeneration (AMD) is one of the leading blindness diseases in the elderly population, affecting nearly 288 million people worldwide by 2040. Despite several anti-vascular endothelial growth factor (anti-VEGF) injections exhibiting excellent efficacy in the initial two-year treatment for neovascular AMD (nAMD), the visual acuity of the majority of patients after two-year frequent administrations chronically drops down due to subretinal fibrosis or retina atrophy. Additionally, parts of patients with nAMD don't respond to anti-VEGF treatments. Therefore, there is still a larger unmet need for novel, long-term effective treatments for patients with nAMD. Here we present a specialized AAV treatment carrying a novel CasRm system (RM-102) which we have discovered and demonstrated its specific and superior editing efficiency on the target RNA. **Methods** The AAV vectors carrying a CasRm-based target RNA editing system were first generated and purified, then were subretinally administrated into non-human primates (NHP). The choroidal neovascularization (CNV) spots were induced by laser photocoagulation at week 4 post-dose. Then follow-up evaluations for safety and efficacy including fluorescence angiograms (FFA), spectral domain optical coherence tomography (SD-OCT), fundus photography, and post-laser-photocoagulation were conducted. **Results** The incidences of grade IV lesions in animals with two versions of RM-102 treatment at week 2 or 4 post-laser were significantly reduced (RM-102-V1: 4% and 0%, respectively, P<0.05) compared to the control group (45% and 48%, respectively), to the same extent as a 2 mg Eylea intravitreally administered at the time of lesioning (Figure 1A and 1B). The RNA and protein levels of VEGFA related to nAMD were remarkably reduced after 23 weeks post-injection. The findings from OCT and other ocular tests showed that there were no drug-related adverse events, except for reversible mild ocular inflammations in the early phase which are common in gene therapies (Figure 1C). Furthermore, the immunogenicity assay showed that there is no detectable immune response to our CasRm in primates treated with RM-102 (Figure 1D). Moreover, RM-102 was predominantly distributed in ocular tissues and was only detected at low levels in the spleen and liver of a few animals. The viral genomes weren't detected in any other tissues of most animals. **Conclusions** The results from the NHP study suggest that RM-102 administered via a single subretinal injection effectively suppressed the laser-induced CNV and was well tolerated. RM-102 is a novel, long-term treatment for patients with nAMD in response to anti-VEGF as well as patients with diabetic macular edema, and also will bring new trials to the non-responders to anti-VEGF.

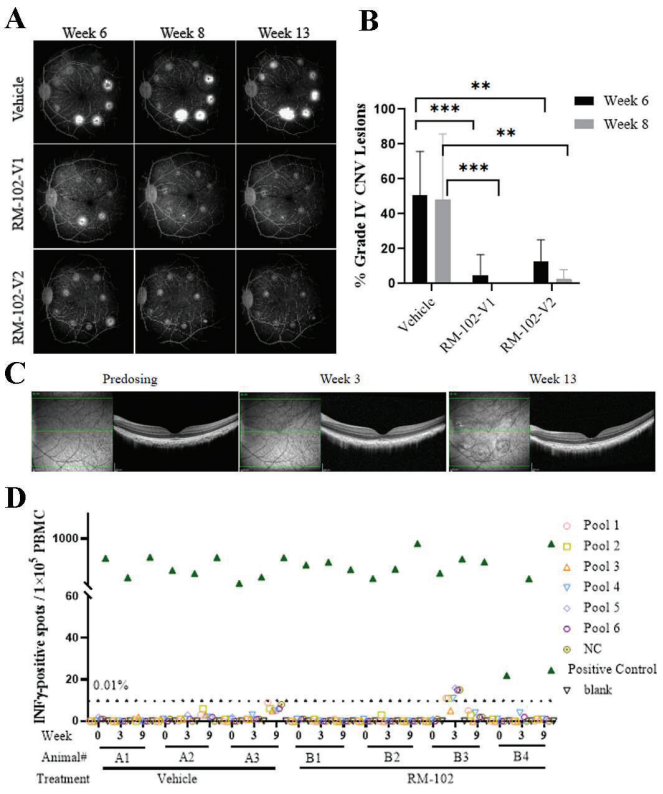

Figure 1. The part of efficacy and safety data of RM-102 in non-human primates

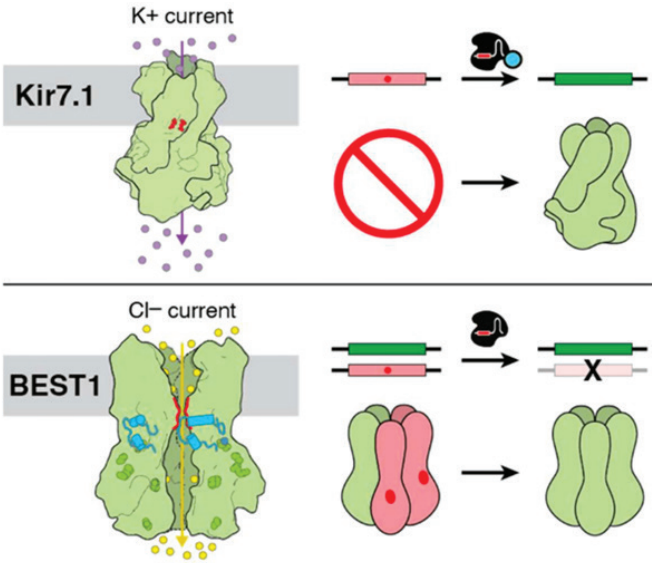

1635. CRISPR Vision Program: Nonviral Genome Editing to Treat Congenital Blindness

Krishanu Saha[1], Mary Haak-Frendscho[2], David M. Gamm[1], Shaoqin Gong[1], William Murphy[1], T. Michael Nork[1], Bikask Ranjan Pattnaik[1], Adam Silverman[2]

[1]University of Wisconsin-Madison, Madison, WI,[2]Spotlight Therapeutics, Hayward, CA

Advances in genetic screening have revolutionized the identification of genetic causes of visual impairment. However, most of these causes are not yet addressable in the clinic. CRISPR genomic medicine is a rapidly evolving area of biomedical research, with its first drug approval in 2023. We present our collaborative CRISPR Vision Program for the nonviral delivery of CRISPR-based genome editors to treat a form of Leber Congenital Amaurosis (LCA) and Best disease as models to facilitate translational research. **Methods:** We established a collaborative academic-industry partnership supported by the US National Institutes of Health. We identified three key projects using genomic editing for a *KCNJ13* mutation causing LCA16 and *BEST1* mutations causing autosomal dominant Best vitelliform macular degeneration (*Figure*). Genomic medicines will be delivered through nonviral nanoparticle or non-packaged delivery formulations. Two cores are evaluating the safety and efficacy of these formulations within models spanning human bioengineered cell culture systems and non-human primates. Finally, a regulatory core aims to share our interactions with the FDA and the larger field to accelerate the development of an investigational new drug application for clinical trials by 2028. **Results:** Synthetic nonviral delivery of adenosine base editor (ABE) corrected *KCNJ13*

disease mutation and restored the encoding inwardly, rectifying potassium (Kir7.1) channel function. Functional restoration was demonstrated in vitro in retinal pigment epithelium (RPE) derived from human induced pluripotent stem cells (hiPSCs). In mouse models, sustained visual function was observed after subretinal injection of the nanoparticles, with normal electroretinogram wave responses and preserved retinal structure. Furthermore, a distinct nonviral formulation of engineered ribonucleoproteins (eRNPs) resulted in robust editing in the RPE after subretinal injection. Finally, evaluation of channel function in Best disease patient-derived hiPSC-RPE cells showed rescue of function upon genome editing, testifying to the efficacy of our strategy. **Conclusions:** We are moving the CRISPR-based medicines into the eye to treat inherited retinal disorders. Our Program could accelerate the development of mutation-specific treatment interventions to match the speed of genetic variant discovery.

1636. Efficient AAV Vector-Mediated Gene Transfer to Mice Inner Hair Cells with High-Concentration of Carbohydrates

Masao Noda[1], Ryota Koshu[1], Mari Shimada[1], Chizu Saito[1], Naomi Takino[2], Mika Ito[2], Makoto Ito[3], Shin-ichi Muramatsu[2]

[1]Otolaryngology, Jichi Medical University, Shimotsuke, Japan,[2]Neurological Gene Therapy, Jichi Medical University, Shimotsuke, Japan,[3]Jichi Medical University, Shimotsuke, Japan

Hearing loss is a common sensory disorder of increasing importance, especially in an aging society where it is also a known risk factor for dementia. Gene therapy targeting the inner ear is a promising approach to treating sensorineural hearing loss. Clinical trials of gene therapy using adeno-associated virus (AAV) vectors are underway in humans and are expected to expand. The efficiency of AAV vector-mediated gene transfer is influenced by serotype, dosage, and animals to be treated. While investigating the effect of hypertonic carbohydrates, an inhibitor of clathrin-mediated endocytosis, on the transduction of engineered AAV vectors, we found that high concentrations of carbohydrates increased transduction efficiency in cultured cells. AAV.GTX is a double tyrosine-mutant form of AAV9 (Y446F and Y731F). AAV.GT5 has triple amino acid substitutions (S472A, S587A, and N706A) in the AAV3B capsid. The transduction efficiency of AAV.GT5 is similar to that of parental AAV3B, but AAV.GT5 has less reactivity to anti-AAV capsid-neutralizing antibodies. In HEK293 and HEI-OC1 cells, a progenitor hair cell line cells, up to 240 mM of sucrose or glucose in the culture medium enhanced the transduction of AAV.GTX and AAV.GT5. We examined whether the addition of high concentrations of sucrose could enhance gene transfer efficiency in the inner ear of adult mice. We made a small incision in the posterior portion of the left auricle under a microscope and drilled a hole into the inner ear bursa of 9-week-old C57BL6/J mice. Cochleostomy was performed to create a small perforation in the basal turn of the cochlea, and the GFP-expressing AAV vector solution (1.3×10^{10} vector genome/ear) was injected with or without 160 or 320mM sucrose. Histological analysis three days after the injection showed that both AAV.GTX and AAV.GT5 showed GFP expression in inner hair cells and spiral ligaments. More than 80% of inner hair cells could be transduced with both AAV vectors. Assessment by auditory brainstem response showed no noticeable hearing loss. This simple and versatile method may be valuable in developing novel gene therapies for adult-onset sensorineural hearing loss.

Friday Posters: Musculo-Skeletal Diseases

1637. Unlocking the Genetic Secrets Behind Familial Recurrent Patellar Dislocation

Liren Wang, Jinzhong Zhao

Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background and aims: Familial recurrent patellar dislocation, a notable orthopedic challenge, is characterized by the recurrent dislocation of the kneecap. This condition is often observed within certain families, suggesting a genetic predisposition. Despite its prevalence, research to date has been limited, with no comprehensive genetic studies encompassing more than one affected family. This study aims to bridge this research gap by identifying genetic factors contributing to familial recurrent patellar dislocation, thereby enhancing our understanding of its pathogenesis and impact on joint health and patient quality of life. Methods: In this pioneering study, we utilized whole-exome sequencing, a powerful tool for uncovering genetic variations. We meticulously analyzed the genetic profiles of six distinct families, each with a documented history of familial recurrent patellar dislocation. Our approach was comprehensive, focusing on identifying common genetic denominators and potential pathogenic mutations across these families. Results: Our extensive analysis revealed a significant finding: a consistent defect in the genes associated with extracellular matrix production was present in all six families. This defect was particularly evident in genes responsible for collagen synthesis, a key component for maintaining connective tissue strength and joint stability. The mutations identified in these collagen-producing genes likely

contribute to the compromised structural integrity of the knee joint, predisposing individuals to recurrent dislocations. Conclusion: This study represents a significant leap in the field of genetic orthopedics, marking it as the largest and most comprehensive investigation into familial recurrent patellar dislocation to date. The findings underscore the crucial role of extracellular matrix-related genes in the development of this condition. These insights open up new possibilities for targeted genetic screening and therapeutic interventions, aiming to mitigate the recurrence of patellar dislocations and improve the quality of life for affected individuals and families.

1638. Examination of Caregiver Perspectives on Genetic Testing and Caregiver Burden of Patients with Native American Myopathy

Magnolia Wang[1], Cynthia M. Powell[2]

[1]Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA,[2]Genetics, University of North Carolina School of Medicine, Chapel Hill, NC

Introduction: Native American Myopathy (NAM, or STAC3 Disorder) is an ultra-rare, autosomal recessive condition originally characterized in the Lumbee Tribe of North Carolina. A founder pathogenic missense variant was identified as the NM_145064.3:c.851G>C mutation of the STAC3 gene, and molecular diagnosis is established by detecting biallelic pathogenic variants. Due to its rarity, NAM and its impact on patients remains poorly characterized. This study examines the perspectives of caregivers on genetic testing, counseling, and caregiver burden, with the aim to provide insight for physicians, scientists, and policy-makers to improve patient care of this ultra-rare disorder. Methods: Patients diagnosed with NAM were identified in the UNC Health System and recruited via email. Either one or both caregivers, or the adult patient themself (aged 26 and over) completed the questionnaire. Responses were evaluated on a 5-point scale, where higher scores were associated with greater outcomes. Scores within one patient cohort were averaged to produce a final score between 0-100. Results: Perspectives on Genetic Testing and Counseling Based on Child Ethnicity: Among the 17 enrolled subjects, 9 (52.9%) were Native American, 5 (29.4%) were Black, and 3 (17.7%) were White and Native American subjects. White and Native American subjects consistently reported greater outcomes compared to their Native American- and Black-identifying counterparts. White and Native American subjects strongly agreed upon the utility of undergoing genetic testing to confirm diagnosis (3, 100%), and that genetic counseling helped manage their diagnosis (3, 100%). This starkly contrasts the large proportion of Black subjects who did not undergo genetic testing (2, 40%), did not find it to be helpful (2, 40.0%), or did not receive genetic counseling (2, 40%). Similarly, a quarter of Native American subjects (2, 22.2%) strongly disagreed with genetic testing or did not find it to be helpful, and more than half (5, 62.5%) either did not receive, strongly disagreed, or remained neutral toward the utility of genetic counseling (Figures 1a and 1b). Perspectives on Caregiver Burden Based on Child Ethnicity: Black and Native American subjects consistently demonstrated greater caregiver burden than their White and Native American counterparts. While White and Native American subjects unanimously reported that they "Never" felt exhausted from child care (3, 100%), around half of Black (2, 40.0%) and Native American subjects (5, 57.1%) described frequent burnout (Figure 1c). All White and Native American subjects concurred that child care did not interfere with work or social activities (3, 100%), but a sizable proportion of Black (1, 20.0%) and Native American (4, 57.1%) did not agree (Figure 1d). Moreover, White and Native American subjects strongly felt that others understood their family situation (3, 100%), yet a majority of Black (4, 80.0%) and Native American subjects (4, 57.1%) lacked this support (Figure 1e).

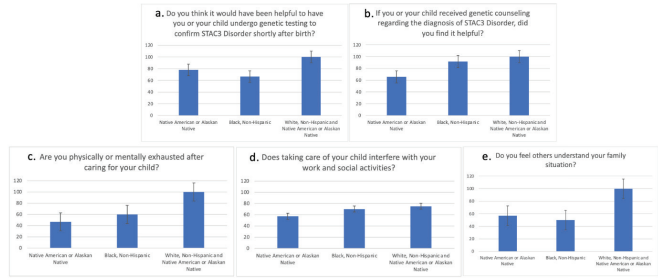

Figure 1.
a: Perspectives on the Utility of Genetic Testing to Confirm STAC3 Disorder Diagnosis
b: Perspectives on the Utility of Genetic Counseling for STAC3 Disorder
c: Perspectives on Physical and Mental Exhaustion Following Child Care
d: Perspectives on Interference of Child Care With Work and Social Activities
e: Perspectives on How Well Others Understood Family Situation

Conclusions: We have characterized the demographics of the 17 enrolled subjects, and identified trends in genetic testing, counseling, and caregiver burden among different ethnic groups. We hope this analysis facilitates research efforts to improve patient care for this ultra-rare genetic disorder.

1639. Development of *In Vitro* Models and Viral Vectors for Targeted Gene Replacement Therapy in Calpainopathy (LGMD2A/R1)

Julienne Dietz[1], Lampros Mavrommatis[2], Wenli Zhang[3], Dirk Grimm[4], Anja Ehrhardt[3], Matthias Vorgerd[5], Eric Ehrke-Schulz[6]

[1]Human Medicine, Center for Biomedical Education and Research (ZBAF), Witten/Herdecke University, Witten, Germany,[2]Ruhr University, Bochum, Germany,[3]Witten/Herdecke University, Witten, Germany,[4]Heidelberg University Hospital, Heidelberg, Germany,[5]Ruhr University, Witten, Germany,[6]human Medicine, Center for Biomedical Education and Research (ZBAF), Witten/Herdecke University, Witten, Germany

Introduction: Calpainopathy, (Limb Girdle Muscular dystrophies 2ALGMD2A/R1) is caused by mutations in the calpain 3 gene (CAPN3), is characterized by progressive, symmetrical weakness of the proximal limb and girdle muscles. Although physical therapy and orthopedic surgery can address symptoms, no disease modifying or curing treatment available. To support the development of targeted gene addition approaches we aimed to develop differentiated human CAPN3 deficient cell culture disease models and explore different muscle specific Adeno associated virus (AAV) derived vectors for CAPN3 gene delivery. **Methods:** We established two genetically different patient derived cell culture disease models with defined CAPN3 mutations. We used immortalized myocytes as well as induced pluripotent stem cells (iPSCs) derived myocytes and applied advanced protocols using electrical pulse stimulation (EPS) to evoke differentiation into Myotubes and sarcomere formation in 2D cell culture. Both models were characterized with regard to differences compared healthy controls. To analyze viral vector mediated CAPN3 gene replacement in the differentiated myotubes, we designed vectors based on muscle

specific capsids of AAV9 and AAVmyo encoding the full length CAPN3 cDNA fused to a GFP gene via a 2A peptide signal under control of the muscle specific MHCK7 promotor. Vector genomes were assembled and vectors were generated and produced to high titers. Subsequently both vectors were utilized to transduce differentiated CAPN3 deficient myotubes and healthy control myotubes. CAPN3 gene transfer and expression was analyzed by RT-qPCR, Western blot and fluorescent microscopy. Systemic *in vivo* delivery of both vectors was performed for biodistribution- and gene expression analysis in mice. **Results:** Both CAPN3 deficient cell culture models were suitable for in vitro differentiation into mature contractile Myotubes and displayed morphological as well as physiological differences compared to healthy controls. AAV mediated gene transfer of the human CAPN3 cDNA resulted in enhanced CAPN3 gene expression *in vitro* and had compensatory effects on mRNA and protein levels in the two different Capn3-disease models. Preliminary *in vivo* experiments showed that systemic delivery resulted in robust CAPN3 gene expression in muscular tissue for both vectors, with AAVmyo showing reduced gene expression in non-target organs. **Discussion:** This study provides novel preclinical *in vitro* disease models that help studying potential treatment options for Calpainopathy and provides insights helping to choose ideal gene transfer vehicle and or transgene expression setup for future translation into *in vivo* studies regarding tissue specificity and expression strength.

1640. Novel, Clinically Relevant Composite Bioassays for Cardiac and Skeletal Muscle Protection as Conferred by Dystrophin-Mimetics

Kyle A. Hubble, Maria P. Corzo, Coral M. Kasden, Alaine I. Castillo, Rufranshell Reyes, Benjamin W. Kozyak, Hansell H. Stedman

University of Pennsylvania, Philadelphia, PA

INTRODUCTION. Despite groundbreaking progress, challenges in interpreting clinical outcomes have complicated the development of effective, durable, and safe gene therapy for Duchenne muscular dystrophy (DMD). DMD results from the lack of functional dystrophin protein, which resides in the costameric lattice linking the extracellular matrix to the intracellular cytoskeleton. Dystrophic muscle is extremely susceptible to eccentric contraction-induced membrane rupture, resulting in myocyte death and muscle wasting. In addition to the skeletal muscle pathobiology, cardiomyopathy is the leading cause of death for DMD patients. The classical primary outcome measure for therapeutic clinical trials for DMD is the North Star Ambulatory Assessment (NSAA), a 17-item functional motor assessment for ambulatory children. Other outcome measures, such as serum markers and muscle biopsies, are highly invasive thus limiting their collection. Here we present clinically relevant composite bioassays to measure cardiac and skeletal muscle protection. One such assay revealed that dystrophin-deficient muscle is ~10,000-fold more susceptible to acute injury than wild type. This assay uniquely revealed the shortcomings of other candidate therapeutics, providing a novel platform for advancing the field. **METHODS.** We established novel assays to measure the extent of acute injury in dystrophic skeletal and cardiac muscle. The susceptibility to contractile-induced skeletal muscle injury was assessed in *mdx* mice. Prompted by our earlier findings of paradoxical changes in serum creatine kinase levels in mdx mice exercised by alternative regimes we have investigated the association of noninvasive urinary N-terminal fragment of titin (NTFT) levels with several provocative muscle contraction regimes. Mice were subjected to downhill treadmill running and urine collection. Following case reports of young DMD patients experiencing myocardial injury due to acute bouts of extreme hypertension and increased afterload, we questioned whether this episodic injury could be modeled in the *mdx* mouse, generally disregarded as a cardiac model for DMD due to its mild phenotype. Increased afterload was chemically induced in *mdx* mice, and circulating cardiac troponin I (cTNI) was measured following a 48-hour drug infusion. **RESULTS.** We developed and validated novel, clinically relevant skeletal muscle and cardiac protection assays to test and resolve investigational therapeutics for DMD. We found that the urinary NTFT to recent downhill distance traveled index was highly consistent in wild type and *mdx* mice as young as 4 weeks old to up to 9 months old. While untreated *mdx* mice exhibited a 10,000-fold increase in NTFT accumulation over WT mice (150.98 vs 0.14 NTFT/distance, $p<0.0001$, respectively), *mdx* mice treated with next generation dystrophin mimetic gene therapies were well protected (1.71 NTFT/distance, p vs untreated *mdx* <0.0001). From our cardiac protection assays, preliminary studies indicate a 25-fold serum cTNI spike in *mdx* mice over WT (9.48 vs 0.38 ng/mL, $p=0.0077$, respectively), while dystrophin mimetic-treated *mdx* mice were approaching WT-like (0.85 ng/mL, p vs untreated *mdx* = 0.1783). **CONCLUSIONS.** Here we present physiologically relevant assays for skeletal and cardiac muscle protection in preclinical DMD animal models. Unlike conventional measures, these assays provide the necessary resolving power to differentiate related treatment groups in blinded studies, with the potential to more confidently predict clinical outcomes of patients in clinical trials. We predict these measures, particularly normalizing urinary NTFT to recent cycles of eccentric contraction, to be an essential component of next generation clinical studies of DMD therapeutics.

1641. Suppression-Replacement Design for Reducing Body Myopathy Using U7 snRNA-Mediated Exon Skipping

Michael Leeson[1], Jachinta Rooney[2], Yaqun Zou[2], Veronique Bolduc[2], Joseph Beljan[3], Kevin M. Flanigan[4,5,6], Carsten G. Bonnemann[2]

[1]NHGRI/NIH, Bethesda, MD,[2]NINDS/NIH, Bethesda, MD,[3]The Ohio State University, Columbus, OH,[4]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH,[5]Departments of Pediatrics, The Ohio State University, Columbus, OH,[6]Department of Neurology, The Ohio State University, Columbus, OH

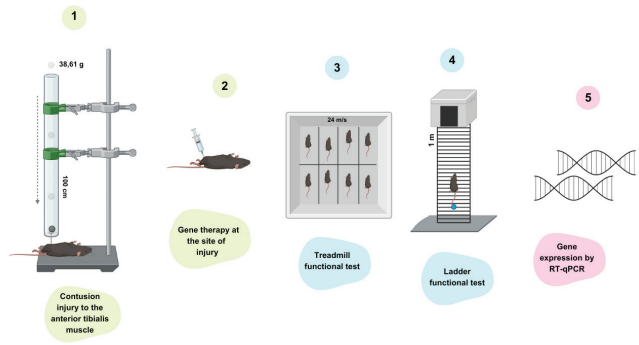
Reducing body myopathy with infantile or early childhood onset is a rapidly progressive, X-linked dominant disorder caused by specific *FHL1* variants in exons 4 and 5 coding for the LIM-2 domain of the Four and a Half LIM domain 1 protein. Intracytoplasmic inclusion bodies containing variant and wild-type FHL1 protein as well as other trapped proteins are forming in skeletal muscle and initially result in a scapuloperoneal distribution of weakness, but rapidly progresses to diffuse hypotonia, contractures, and respiratory failure. Loss of FHL1 causes a milder, X-linked recessive myopathy. This project aims to treat this dominant disorder with a suppression-replacement gene therapy

strategy. The suppression will be achieved by U7 snRNA-mediated exon skipping of *FHL1* exon 3 to result in transcripts that lack the typical translation initiation codon and are predicted to undergo nonsense mediated decay, which is expected to prevent production of both variant and wild-type FHL1. The replacement will contain silent variants resistant to the sequence-dependent U7 snRNA exon skipping, while retaining the functional wild-type amino acid sequence. The current work is focused on determining optimized target sequences to induce exon skipping, which were generated by both rational design (targeting splice donor, splice acceptor, and putative exon splice enhancer sites) and using eSkip-Finder (a machine learning-based web application developed to predict exon skipping efficacy of novel antisense oligonucleotides). To help selection, sequences were initially synthesized as fully PS-2'OMe antisense oligonucleotides and cotransfected into HEK293 cells with a splicing reporter plasmid containing *FHL1* exon 3 with flanking intronic sequence. Skipping efficacy was detected using qualitative RT-PCR. Promising candidates will be tested in cell lines with high FHL1 expression using U7 snRNA cassettes introduced by AAV transduction.

1642. Discovery and Characterization of Novel AAV Capsids with Enhanced Skeletal Muscle Tropism Using Directed Evolution

Adelaida Palla[1], Quan Jin[2], Haley Heusey[1], Frank Li[1], Jimmy Tran[3], Amit Kumar[3], Dora Bodnar[1], Chris Hinckley[4], Ka Ying Hung[2], Samneet Kashyap[2], Aissatou Diallo[2], Emily Rouse[2], Margaret Kelemen[2], Lucia Xiang[2], Aditya Utturkar[2], Misha Chittoda[2], Harini Dhamodaran Sampath[2], Shawn Kyle Bourque[2], Samantha Desmarais[2], Kate Henry[2], Shuyun Deng[2], Wei Tong Chen[1], Davide Gianni[2], Jun Shi[1], Junghae Suh[2], Yuan Yuan[2]

[1]Neuromuscular and Muscle Diseases Research Unit, Biogen, Cambridge, MA,[2]Gene Therapy Accelerator Unit, Biotherapeutic and Medicinal Sciences, Biogen, Cambridge, MA,[3]Nonclinical Safety, Biogen, Cambridge, MA,[4]Translational Cellular Sciences, Biogen, Cambridge, MA



Gene therapy holds considerable promise for treatment of musculoskeletal and neuromuscular disorders. However, low muscle affinity in existing AAV vectors requires high viral doses for systemic delivery, which has been associated with adverse events across clinical trials. Thus, there is a need to identify novel vectors with enhanced muscle targeting to improve gene delivery efficiency with lower doses. By conducting iterative rounds of selection of a RGD peptide insertion AAV library in cynomolgus macaques, we identified AAV capsid variants with enhanced muscle transduction. One such variant, was used to treat cynomolgus macaques with immunosuppressants. This AAV variant led to enhanced muscle transduction compared to AAV9, with minimal safety or pathology findings. In addition, the AAV variant demonstrates acceptable productivity and manufacturability. Importantly, several AAV variants show human and murine cross-reactivity. They mediated efficient skeletal muscle and heart transduction in mice at lower doses compared to AAV9. They also demonstrated enhanced transduction compared to AAV9 in human muscle cells and 3D myobundles. Here we demonstrate these novel muscle-tropic capsids have higher potency than AAV9, which could potentially drive the development of safer gene therapies targeting muscle diseases.

1643. Evaluating the Impact of Soluble TGF-β1 Receptor Expression Controlled by an NF-κB-Inducible Promoter on *In Vivo* Muscle Fibrosis Reduction

Luana De Mambro[1], Leonardo Martins[2], Roberta S. Stilhano[3]

[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil,[2]Department of Medicine, Institute of Medical Biology of Polish Academy of Sciences, Lódz, Poland,[3]Faculdade de Ciencias Medicas da Santa Casa (FCMSCSP), Sao Paulo, Brazil

One of the main challenges in regenerative medicine is the regeneration of skeletal muscle tissue after volumetric loss (VML), in which a persistent inflammatory environment, marked by the activation of fibrotic genes and muscle atrophy induced by the cytokine TGF-β1, leads to extensive fibrotic tissue development. Thus, this study aimed to produce two lentiviral vectors: the therapeutic one, carrying the soluble receptor of TGF-β1 (Lv_NF-κB_sTβRII) and the control (Lv_NF-κB_Luci), both under control of the NF-κB inducible promoter. For this purpose, the vectors were designed and cloned, and subsequently *in vitro* studies were conducted, where C2C12 cells were cultured in cDMEM (supplemented with 10% of fetal bovine serum and 1% penicilin/streptomycin), transduced, and injured with $BaCl_2$, having gene expression evaluated by RT-qPCR. For myogenic differentiation, the cells were cultured in differentiation medium and analyzed by RT-qPCR and immunocytochemistry. In the *in vivo* tests, mice were divided into control groups, injury, and injury with treatment. They were injured in the anterior tibialis muscle by contusion, and Lv_NF-κB_sTβRII was injected to the site of the lesion.

Functional analysis was performed on a treadmill and ladder. Molecular analysis was made by plasma TGF-β1 ELISA and RT-qPCR to assess inflammation, fibrosis, myogenic differentiation, and expression of the soluble TGF-β1 receptor. For statistical analysis, independent t-test, one-way ANOVA, and non-parametric Friedman, Kruskal-Wallis, and Mann-Whitney tests were used in GraphPad Prism 9.0 software. A 95% confidence interval was used for all analyses. In the *in vitro* results, there was an increase in the number of sTβRII copies of 442 times in 24 hours and 67 times in 48 hours among C2C12_NF-κB_sTβRII compared to the control. In addition, there was an increase of 10% in the density of the area marked by MyHC-emb in the cell overexpressing sTβRII and

2.55 times decrease in Pax7 expression. In the *in vivo* results, the injury group showed the lowest performance on the treadmill over 30 days and the lowest average load supported on the ladder, where only 20% of the animals were able to support the group's maximum load (31g), which had the longest average time climbing. Meanwhile, the injury with treatment group showed the best performance on the treadmill and the highest average load supported on the ladder (36g), with 40% of the animals adhering, followed by the control group with 60% of the animals adhering at the same weight. Plasma ELISA showed a reduction of TGF-β1 in the injury and injury with treatment groups after 16 days compared to the control. In the analysis of gene expression by RT-qPCR of muscle tissue, lower expression of NF-κB (0.0477 ± 0.01475) and IL-6 (0.04292 ± 0.02553) was found in the injury group and higher expression of Smad7 (0.07426 (± 0.01778); Pax7 (0.3471 ± 0.05433); MyoD (1.103 ± 0.1209); MyoG (0.9891 ± 0.1932) and sTβRII (1.096 ± 1.049) in the injury with treatment group. Therefore, modulation of the expression of sTβRII by the NF-κB inducible promoter and improvement in muscle regeneration by sequestration of TGF-β1 were found. In addition, the Lv_NF-κB_sTβRII vector demonstrated improvement in muscle function and functional performance of the mice, as well as an increase in the expression of myogenic differentiation markers.

1644. Overexpressing Murine Prg4 and or NFκB-Regulated Il-1ra with High Capacity Adenoviral Vectors (HCAd) by Intra-Articular Injection Improves Motor and Pain Endpoints and Articular Cartilage Maintenance in a Murine Model of Post-Traumatic Osteoarthritis (PTOA)

Zelong Dou[1], Racel Cela[1], Philip Ng[1], Jiansen Yan[1], Ming-Ming Jiang[1], Carolina Leynes[1], Camilla Fernanda Majano[1], Heidi Reesink[2], Matthew Grol[3], Nele A.T. Haelterman[1], Yangjin Bae[1], Brendan H. L. Lee[1]

Osteoarthritis is mainly characterized by loss of articular cartilage, subchondral bone remodeling, inflammation at intra-articular space, synovitis, and pain. The precise molecular mechanism of OA is complex and combinatorial approaches to treatment are likely required. One of the most extensively studied targets for OA therapy is IL1 which can be regulated through modulating IL1 receptor antagonist (IL1RA). Besides, Prg4 loss of function mutation in human patients lead to the camptodactyly-arthropathy-coxa vara-pericarditis syndrome, and the Prg4 knockout mice showed OA-like phenotype in an early stage, suggesting the chondroprotection of Prg4. Local intra-articular injection is believed to be a promising OA treatment option as it can bypass the challenges of systematic delivery. However, even locally being delivered, recombinant proteins and small molecules can be quickly filtered by synovial capillaries and lymphatics, which will significantly decrease the treatment efficacy. In this regard, a greater promise is held by intra-articular delivery of therapeutic transgenes with their sustained local expression after a single injection. We have shown that individually expressed Prg4 and Il1-ra after intra-articular HCAd gene therapy could delay OA progression in small and large preclinical models. This has led to a current phase I clinical trial of intra-articular HCAd5 Il1-RA gene therapy in OA patients (NCT04119687). Given though they target different contributors to OA, we hypothesized that intra-articular delivery of single high capacity adenovirus (HCAd) synergistically overexpressing both chondroprotective murine Prg4 and inflammation inducible Il1-ra would improve joint preservation, compared to their single delivery alone. Using a murine PTOA model generated by destabilization of medial meniscal tibial ligament (DMM) surgery bilaterally we performed knee intra-articular injection of HCAd overexpressing EF1-mPrg4 and NFkB-mIl-1ra with either original or reverse oriented target genes, and the combined NFkB-mIl1ra;EF1-mPrg4, and HCAd0 (control virus without transgenes) at postoperative week 2. At postoperative week 12 behavioral tests including Catwalk and Hot plate were applied for functional readouts, followed by harvesting knee joints for histological, 3-dimensional phase contrast micro-CT analysis, and immunohistochemistry analysis for expression levels of target genes and related inflammation markers. We found that the paw print intensity in HCAd-EF1-mPrg4 treated DMM surgery mice was significantly higher compared to those treated with HCAd0. The hotplate result showed that DMM surgery mice treated with HCAd-NFkB-mIl-1ra had significantly delayed time of response compared to HCAd0 control. Histological and phase contrast micro-CT results revealed comparable treatment efficacy of NFkB-mIl-1ra;EF1-mPrg4 and EF1-mPrg4. In addition, as shown by the undergoing murine PRG4 immunohistochemistry, compared to controls similar amount or more PRG4 expressing chondrocytes with wider distribution were observed in both NFkB-mIl-1ra;EF1-mPrg4 and EF1-mPrg4 treated mice knee articular cartilage, meanwhile we will measure the expression levels of proinflammatory markers. These findings suggested that overexpressing murine Prg4 and Il-1ra in superficial articular chondrocytes and synoviocytes with HCAd, similar to monotherapy, can delay signs of PTOA progression in a surgical mouse model of OA.

1645. AAV-Encoded Soluble PDL1 for Autoimmune Disease Gene Therapy

Wenjun Li[1], Junjiang Sun[2], Susi Feng[1], Chengwen Li[3]

[1]UNC Gene Therapy Center - Chapel Hill, NC, Chapel Hill, NC,[2]University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]UNC at Chapel Hill, Chapel Hill, NC

Autoimmune diseases are a broad range of diseases involving multiple organs that profoundly affects patients' daily activities, mental health, and significantly impacting their life quality and life expectancy. Current treatments for autoimmune disease have limitations in terms of duration, range of relief, as well as affected population. PD-L1, as a checkpoint protein, plays important roles in immune regulation, and has been reported to be highly corelated with the initiation and progression of multiple autoimmune diseases. In this study, we used rheumatoid arthritis (RA) as a platform to investigate the efficiency of PD-L1 in treating autoimmune disease. We have demonstrated that intra-articular injection with wild type PD-L1 improved local inflammation in the RA joints. To optimize the transgene expression and increase therapeutic effect, we have designed an optimized soluble PD-L1(shPD-L1) that was more potent than wild type PD-L1 via AAV vector mediated intra-articular delivery, with a lower dose

needed for arthritis improvement in a collagen-induced arthritis (CIA) mouse model. Since autoimmune diseases involve multiple tissues, to extend the application of PD-L1 for systemic treatment, we further explored the systemic therapeutic effects of adeno associated virus (AAV) encoded shPD-L1 gene therapy in RA. Two weeks prior to CIA induction, AAV8/shPD-L1 were administered intravenously to mice. Notably, CIA mice treated intravenously with AAV8/shPD-L1 exhibited significant improvements in joint inflammation (1.8 ± 1.4 vs 9.9 ±1.3) and paw swelling (2.4±1.4 vs 10.7±2.2) compared to CIA untreated mice, similar to that in naïve mice. Protein levels of shPDL1 remained stable over 7 weeks. Moreover, these mice displayed a slight increase in body weight after AAV8/shPD-L1 treatment when compared to untreated CIA mice. Both total immunoglobulin levels and anti-collagen antibody levels were remarkedly lower in treated CIA mice at day 49 post AAV injection. Serum cytokine analysis revealed reduced levels of pro-inflammatory cytokines IL-1a (65.3±17.1 vs257±49.1), IL-6 (14.3 ±10.6 vs93.5± 51.0), IL-17 (1.8±1.1vs 7.1±5.5), and TNF-a (5.6±2.9vs15.9±6.5) in AAV8/shPDL1-treated mice when compared to untreated mice. The intravenous injection of AAV8/shPDL1 also altered the immune cell profile in the spleen, with treated mice showing reduced spleen sizes, decreased Th2 and Th17 levels, and increased T cell apoptosis when compared to untreated CIA mice, indicating a potential immune regulatory effect of shPDL1. Since AAV liver targeted gene therapy in clinical trials have demonstrated the liver toxicity in 30-50% patients and the expression of PD-L1 in the liver may also impact local immunity. Next, we carried out intramuscular delivery of AAV6 vectors encoding shPDL1. Consistent to AAV8/shPD-L1 liver targeted gene therapy, intra-muscular administration of AAV6/shPD-L1 vectors led to decreased paw swelling, reduced joint inflammation, and lower level of pro-inflammatory cytokines with neglectable levels of viral genome detected in liver. The therapeutic effect from AAV6/shPD-L1 muscular injection was dose dependent. In conclusion, our findings suggest that systemic expression of shPD-L1 from AAV-mediated delivery holds potential as a treatment for RA and other autoimmune disorders. Intramuscular administration of AAV/shPD-L1, in particular, offers an advantageous approach without the concern of liver toxicities.

1646. Development of a Chitosan Methacrylate Hydrogel Platform for Localized and Sustained Gene Delivery to Enhance Cartilage Regeneration in Osteoarthritis

Eunji Lee, Eunhyun Ji, Youjin Kim, Kye Il Joo
Ewha Womans University, Seoul, Korea, Republic of

Osteoarthritis (OA) is a prevalent degenerative joint disease, impacting a significant portion of the global population. Despite its high prevalence, current treatments for osteoarthritis remain inadequate, predominantly providing only symptomatic pain alleviation. Controllable and sustained local gene therapy offers a promising approach to treat osteoarthritis through the direct administration of therapeutic genes to the specific cells. In this study, we designed an injectable chitosan methacrylate (CHIMA) hydrogel platform that enables localized and continuous gene delivery without the need for invasive bone surgeries or implant insertions, aiming to enhance cartilage regeneration. Conventional approaches involving direct injection of gene modalities for local gene therapy are impeded by challenges such as suboptimal transfer efficiency, and short half-life. To overcome these challenges, our approach involves delivering a recombinant adeno-associated virus (AAV) vector which encodes a chondrogenic regeneration factor, through CHIMA hydrogel. CHIMA, a light-inducible mechanically reinforced chitosan, showed low toxicity and facilitated prolonged bioactivity of regeneration factors administrated via CHIMA-mediated AAV. Furthermore, incorporation of AAV into the CHIMA hydrogel encoding genes promoting regeneration, not only reduced the expression of inflammation and pain-related factors but also improved cartilage cell regeneration. The developed CHIMA hydrogel platform holds promise as an innovative approach for treating osteoarthritis by providing a stable and controlled environment for sustained gene delivery, ultimately enhancing the prospects of cartilage regeneration.

1647. Intravenous Delivery of AAV Gene Therapy for the Treatment of SOD1-ALS Provides Broad SOD1 Lowering in NHP

Michael D. Grannan, Tyler C. Moyer, Margaret R. Dalrymple, Ambreen Sayed-Zahid, Xiao Ren, Chiso Egbuchulam, Anupriya Kulkarni, Wenya Yang, Joseph Clement, Jeffrey Thompson, Nilesh Pande, Elizabeth Mellen, Naomi Muse, Crystal Taveras-Cui, Vikram Arora, Chanchal Sadhu, Dinah W. Y. Sah, Mathieu E. Nonnenmacher, Rajeev Sivasankaran, Todd A. Carter
Voyager Therapeutics, Inc., Lexington, MA

Mutations in superoxide dismutase 1 (SOD1) result in progressive motor neuron loss through toxic gain-of-function properties and are responsible for up to 20% of familial amyotrophic lateral sclerosis (ALS), or approximately 2% of all ALS patients in the U.S. Studies evaluating different strategies for SOD1 reduction have demonstrated reduced neuropathology, improved motor behavior, and extension of survival in transgenic mice expressing mutant SOD1. The recent FDA approval of an antisense oligonucleotide targeting SOD1 has further validated SOD1 as a therapeutic target. While approaches to reduce SOD1 have demonstrated varying degrees of efficacy, they are suboptimal in relying on direct CNS administration that fails to achieve the broad, CNS-wide SOD1 reduction thought to be necessary for maximal therapeutic benefit, or systemic administration that requires high doses with associated significant safety considerations. We previously reported the results from a series of in vitro and in vivo studies demonstrating SOD1 reduction following IV delivery of an AAV gene therapy targeting SOD1. In the G93A mouse model of disease, we demonstrated robust SOD1 knockdown throughout the rostral-caudal extent of the spinal cord, significant improvements in motor performance, and survival extension beyond what has previously been reported with intraparenchymal, intrathecal, or intracisternal delivery. In the current studies, we combined a highly potent siRNA against SOD1 with an IV-delivered, blood-brain barrier-penetrant TRACER™ capsid for evaluation in NHPs. Following a 2-month in-life period, we observed favorable biodistribution to the spinal cord and motor cortex which resulted in significant reduction of SOD1 mRNA. The enhanced BBB-penetrance and natural peripheral tissue detargeting inherent to the novel capsid enabled efficacy at a lower dose than typically used in intravenous AAV delivery, resulting in a favorable safety profile. These results demonstrate that the combination of a potent SOD1 RNAi transgene with a novel TRACER™ capsid produces

significant reduction of SOD1 mRNA in critical spinal cord and brain regions impacted in ALS and support its continued development and advancement into the clinic.

1648. High Potency MyoAAV Capsids Enhanced Skeletal Muscle Correction in GSD IIIa Mice

Baodong Sun

Pediatrics, Duke University School of Medicine, Durham, NC

Background: Glycogen storage disease type III (GSD III) is caused by glycogen debranching enzyme deficiency, which leads to pathological accumulation of cytoplasmic glycogen in muscle and liver. We recently reported a gene therapy study using an AAV9 vector to express a bacterial debranching enzyme (pullulanase) from a novel dual promoter, which consists of a liver-specific promoter (LSP) and a ubiquitous CMV enhancer/chicken β-actin (CB) promoter. We demonstrated that the LSP-CB dual promoter effectively suppressed transgene-specific cytotoxic T lymphocyte responses in GSD IIIa mice while allowing sustained pullulanase expression and glycogen reduction in liver, heart, and skeletal muscles. Tabebordbar and colleagues recently developed a class of RGD-motif-containing MyoAAV capsids that transduce muscle with superior efficiency and selectivity over the parental AAV9 capsid in mice and nonhuman primates. In this experiment, we compared two lead MyoAAV capsids with AAV9 for transduction efficiency and therapeutic efficacy in GSDS IIIa mice. **Methods:** An AAV vector carrying the LSP-CB dual promoter and a codon optimized CpG-free pullulanase cDNA (AAV-Dual-Pull$^{CpG\text{-}free}$) was packaged in AAV9, MyoAAV4A, and MyoAAV4E capsids and the resulting viral vectors were intravenously injected into 3-month-old GSD IIIa mice at the same dose ($1x10^{13}$ vg/kg). Six weeks later, muscle functional improvement was evaluated by treadmill and wire-hang tests. Tissues were collected to assess AAV vector biodistribution, pullulanase expression, and glycogen content. Urine samples were collected to analyze disease biomarker glucose tetrasaccharide Glc4 by mass spectrometry. **Results:** In liver, all the three AAV vectors led to a similar level of pullulanase expression and comparable potency in glycogen clearance (**Table 1**). In heart and skeletal muscles, both the MyoAAV4A and MyoAAV4E vectors demonstrated significantly higher treatment efficacy than the AAV9 vector, as determined by enhanced vector transduction efficiencies (AAV genome copy numbers, data not shown), increased pullulanase activities, decreased glycogen contents, improved muscle functions (treadmill and wire-hang performance), and reduced levels of disease biomarker urinary Glc4. The MyoAAV4A vector showed better therapeutic outcomes than the MyoAAV4E vector in general (**Table 1**). **Conclusion:** Our data demonstrated that the two MyoAAV capsids had remarkably enhanced transduction efficiencies in the cardiac and skeletal muscles of GSD IIIa mice, in comparison with AAV9. Follow-up experiments to test effective vector doses and long-term therapeutic efficacy are being conducted. These novel muscle-tropic capsids can also be broadly used for treating other inherited conditions that affect cardiac and skeletal muscles.

Table 1. Biochemical correction and muscle functional improvement in GSD III mice by AAV treatment

		UT	MyoAAV4A	MyoAAV4E	AAV9	WT
Pullulanase activity (mU/mg protein)	Liver	2.11 ± 0.41	39.39 ± 15.23	42.05 ± 7.28	52.6 ± 23.53	1.85 ± 0.88
	Heart	3.18 ± 0.79	238.7 ± 33.5	128.5 ± 40.8	20.53 ± 10.28	2.44 ± 0.30

Data shown are mean ± standard deviation. n= 6 for AAV-treated mice each group, n=5 mice for untreated (UT) and wild-type (WT) control mice. Diaph, diaphragm; Quad, quadriceps; Gast, gastrocnemius.

1649. CRISPR/Cas9-Based Precision B Cell Gene Engineering Coupled with Artificial Intelligence-Guided Protein Design Produces Active and Sustained Levels of Tissue Nonspecific Alkaline Phosphatase for the Treatment of Hypophosphatasia

Monika Musial-Siwek, Sarah Leach, Wayne Bainter, Madison Clements, Swati Singh, Sakshisingh Thakur, Glory Adekanye, Amy Lundberg, Megan L. Brophy, Priyanka Vaishampayan, Timothy Mullen, Connor Malloy, Anja F. Hohmann, Sean Keegan, Sean Arlauckas, Adam Lazorchak, Toshiro Ohsumi, Hanlan Liu, Richard A. Morgan

Be Biopharma, Cambridge, MA

Hypophosphatasia (HPP) is an inherited disorder characterized by defective bone mineralization, caused by deficiency of tissue nonspecific alkaline phosphatase (ALP). ALP is a dimeric zinc-containing metalloenzyme which hydrolyses inorganic pyrophosphate (PPi) and a variety of organic phosphates. Lack of functional ALP leads to elevated levels of PPi, which in turn inhibits bone mineralization, leading to osteomalacia/rickets (soft bones) and can be lethal without treatment. Currently, the only treatment for HPP is enzyme replacement therapy requiring subcutaneous injections 3-6 times per week which is accompanied by injection site reactions including lipodystrophy. B Cells can be engineered to produce a therapeutic protein, and then differentiated into terminally differentiated plasma cells, that secreted the target protein as a B Cell Medicine (BCM). BCMs have many of the attributes of plasma cells; natural longevity (potentially persisting for decades), capacity for high levels of protein secretion (thousands of molecules/cell/sec), the ability to engraft without host preconditioning, and the ability to re-dose, making them an attractive platform for the sustained supply of biologics. We sought to harness the power of BCMs by engineering them to produce sustained levels of ALP, thus offering a potential new treatment option for HPP. In this study, primary human B cells were expanded, precision engineered by CRISPR/Cas9 genome editing with AAV-mediated homology directed repair (HDR) to insert an ALP gene expression cassette into the various loci, including *CCR5*

(a safe harbor locus) and *JCHAIN* (a gene highly expressed in plasma cells). Guided by an artificial intelligence-based ALP protein structure design engine (i.e., AlphaFold2, an optimized version developed for dimeric proteins), protein constructs were optimized for activity and stability by fusing ALP with different Fc fragments (ALP-Fc) coupled with variety of linkers. Engineered BCMs secreted active ALP or ALP-Fc proteins up to 200 ng/1e6 cells/24hr as measured by Legendplex. *In vitro* phenotypic correction with supernatant from ALP or ALP-Fc secreting BCMs (ALP-BCMs) was demonstrated using the MC3T3 cell line mineralization model with robust mineralization observed. To validate our candidates *in vivo*, we have used immunodeficient transgenic mice that express human IL-6 (NOG-hIL6) and have been previously demonstrated to facilitate engraftment of BCMs. Following a single IV injection of ALP-BCM, ALP protein and enzyme activity was detected in mouse plasma from multiple ALP constructs. Importantly, ALP-BCM was well tolerated over the course of the *in vivo* study, with long-term follow-up in progress. In summary, we demonstrated successful production of active ALP *in vivo* coupled with artificial intelligence-guided protein design highlights the therapeutic utility of our BCM platform. The potential therapeutic application of this unique biologic delivery system could afford a novel treatment modality for HPP.

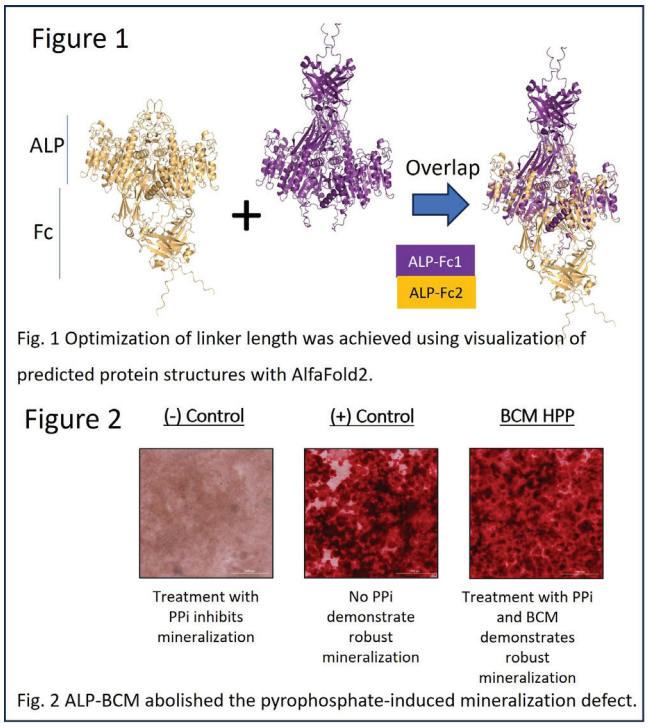

Fig. 1 Optimization of linker length was achieved using visualization of predicted protein structures with AlfaFold2.

Fig. 2 ALP-BCM abolished the pyrophosphate-induced mineralization defect.

Friday Posters: Genetic Disorders of the Blood and Immune System

1650. Novel Lentiviral Gene Therapy for Purine Nucleoside Phosphorylase Immune Deficiency

Robyn Loves[1,2], Weixian Min[1], Matilde Leon-Ponte[1], Arundhati Nair[1], Santhosh Dhanraj[3], Chetan Tailor[3], Eyal Grunebaum[1,2,4]

[1]Developmental and Stem Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada,[2]Department of Immunology, University of Toronto, Toronto, ON, Canada,[3]Tailored Genes, Toronto, ON, Canada,[4]Division of Immunology and Allergy, The Hospital for Sick Children, Toronto, ON, Canada

Background: Purine nucleoside phosphorylase (PNP) deficiency results in impaired purine metabolism and severe T cell lymphopenia. We developed a novel third-generation self-inactivating lentiviral vector (LVV)-based autologous gene therapy, referred to as LVV EFS hPNP. The objective is to test the ability of LVV EFS hPNP to correct metabolic and immune abnormalities in PNP-deficient (PNP-/-) mice. **Methods:** Bone marrow-derived lineage-negative (lin-) cells from PNP-/- mice were transduced with LVV EFS hPNP at an MOI of 50. PNP-/- mice received 6Gy total body irradiation, and were transplanted with 2.0x10^6 LVV EFS hPNP-transuced lin- cells or lin- cells from PNP+/- proficient littermates and followed for 12 or 24 weeks. **Results:** Donor chimerism in the bone marrow and thymus of mice treated with LVV EFS hPNP were 41.8±18.0% and 49.0±35.6%, respectively, which were significantly lower than chimerism following transplants with PNP+/- cells (91.8±7.54% and 98.5±1.48%). Vector copy number was detectable post-gene therapy in the spleen (2.82±5.06), thymus (3.22±5.54), and bone marrow (1.57±2.10). Despite showing lower levels of donor chimerism and large variability in VCN, which may suggest poorer survival and engraftment of cells originating from PNP-/- mice, restoration of PNP enzyme activity was successfully achieved in mice treated with LVV EFS hPNP. PNP enzyme activity measured in the spleen, thymus, bone marrow, and peripheral blood was 79.5±88.5%, 99.5±147.3%, 52.8±55.7%, and 56.1±61.3% respectively, of levels found in PNP+/- mice. Variability in tissue-specific enzyme activity correlated with VCN In the thymus and bone marrow. Further indication for rescue of systemic PNP activity was performed by measurement of urinary uric acid, which was normalized in PNP-/- mice out to 24 weeks post-transplant. Disease correction was also reflected in lymphocyte subpopulations in the thymus of mice treated with LVV EFS hPNP. Notably, the CD4+CD8+ double positive lymphocytes were normalized to percentages observed in PNP+/- mice at 24 weeks post-transplantation (p=0.99), and were significantly improved when compared to PNP-/- untreated mice (p<0.0001). **Conclusions:** This study demonstrates the potential of LVV EFS hPNP to correct enzyme activity in PNP-/- mice. Subsequent testing will investigate functional immune reconstitution and genotoxicity following gene therapy with LVV EFS hPNP.

1651. Development and Characterization of NCG-X Mouse Model for Gene Therapy in Erythroid Disorders

Huiyi Wang[1], Lu Yang[2], Meirong Wu[2], Mengting Wang[2], Xueya Ma[3], Juan Liang[4], Jing Zhao[2], Cuxiang Ju[2]

[1]GemPharmatech Co.Ltd., Nanjing, China,[2]GemPharmatech Co. Ltd, Nanjing, China,[3]GemPharmatech o. Ltd, Nanjing, China,[4]GemPharmate Co. Ltd, Nanjing, China

The NCG-X mouse model, a highly immunodeficient rodent model, has been engineered to address genetic therapies for erythroid-related diseases. With its c-Kit gene mutation, the NCG-X mice exhibit compromised hematopoietic stem cell (HSC) development, creating a bone marrow microenvironment more favorable for engraftment and development of human HSCs. We conducted extensive characterization and demonstrated that compared to its HSC-NCG counterpart, the NCG-X model exhibited human erythrocyte and platelet development in the mouse bone marrow and peripheral blood following human HSC engraftment. Moreover, targeted clearance of host-derived macrophages through Clo-lip treatment facilitated the reconstruction of human erythrocytes and platelets in the peripheral blood of NCG-X mice. Therefore, we believe the NCG-X model offers a unique and advantageous platform for evaluating the efficacy of gene therapies targeting disorders within the erythroid lineage. Its distinctive immune-deficient features, coupled with the observed improvements in erythroid and platelet development, make it suitable for pharmacological exploration and assessment of gene therapy efficacy in the context of erythroid-related diseases. This novel model holds promise for advancing our understanding of gene therapies and pharmacological interventions.

1652. Introducing CRISPR/Cas9 T Cell Pipeline for Highly Efficient Correction of Finnish Founder Mutations in *ADA2*, *AIRE* and *RMRP*

Katariina Mamia[1], Solrun Kolbeinsdottir[2], Anna Komisarczuk[1], Frida Frida Høsøien Haugen[1], Salla Keskitalo[3], Carolina Wieczorek-Ervik[1], Pavel Kopcil[1], Britt Olaug-Lindestad[1], Monika Szymanska[1], Kornel Labun[4], Markku Varjosalo[3], Martin Enge[2], Shiva Dahal-Koirala[1], Emma Haapaniemi[1]

[1]University of Oslo, Oslo, Norway,[2]Karolinska Institute, Stockholm, Sweden,[3]University of Helsinki, Helsinki, Finland,[4]University of Bergen, Bergen, Norway

Emerging CRISPR/Cas9 gene therapy trials demonstrate the therapeutic potential of correcting mutations in defected patient cells. However, as these trials are largely focused on targeting common hematologic diseases, little is known about how to successfully optimize CRISPR for rare primary immunodeficiency disorders (PIDDs). To address this challenge, we developed a CRISPR/Cas9-based T cell editing pipeline that streamlines CRISPR tool discovery for highly efficient and safe correction of mutations in patient T cells. In this study, we focus on correcting mutations in the *ADA2*, *AIRE* and *RMRP* genes to establish, improve and validate the safety of the pipeline, which can now be applied for other relevant PIDDs. Our data demonstrate a rapid and selective expansion of CD3+ T cells from patient and healthy donor peripheral blood mononuclear cells (PBMC) after 8-day cytokine stimulation. CRISPR guide-RNAs (gRNA) for *ADA2*, *AIRE* and *RMRP* were screened in the stimulated patient T cells, and off-targets of selected gRNAs were assessed using genome-wide, unbiased identification of double-strand breaks enabled by sequencing (GUIDE-seq), where no off-targets were identified. To enhance translational potential of the pipeline, we tested multiple strategies to increase homology-directed repair (HDR) and developed an HDR-optimized T cell pipeline that can achieve up to 80% mutation correction levels in patient T cells. Next, we assessed the safety of the pipeline and studied the impact of CRISPR editing at genomic, transcriptomic and proteomic level. First, we performed whole-genome sequencing (PacBio) on corrected cells, and only identified editing at the target site (*ADA2*). Then, we sorted CD3+ patient (ADA2) and HD T cells for Sc-seq analysis. These data demonstrate that nearly all (<90%) of the edits were biallelic and that apart from the target site, CRISPR did not induce significant transcriptomic changes in the cells. Finally, to study protein expression after mutation correction, we performed mass spectrometry analysis on corrected patient (ADA2) cells. We show that corrected patient T cells express ADA2 at levels which correlate with genomic correction. In conclusion, our work demonstrates that the CRISPR/Cas9 T cell pipeline is both efficient and safe and allows for precise custom editing in patient T cells. Furthermore, it has the potential to be converted into a GMP-compatible workflow and scaled up to fit clinical gene therapy needs for PIDD patients.

1653. Advancing X-Linked Agammaglobulinemia Therapy: A Universal Gene Targeting-Based Correction

Hana Y. Ghanim[1], Mara Pavel-Dinu[1], William Feist[1], Robel Fesseha[1], Sofia Elena Luna[1], Matthew H. Porteus[2]

[1]Stanford University, Stanford, CA,[2]Stanford University School of Medicine, Stanford, CA

Primary immunodeficiencies constitute a group of monogenic disorders marked by recurrent infections, autoimmunity, and inflammation. Among these, X-linked Agammaglobulinemia (XLA), predominantly affecting males, results from the inactivation of the Bruton tyrosine kinase (BTK) gene. This condition, if untreated, leads to childhood fatality. The current mainstream treatment, immunoglobulin replacement therapy, while life-sustaining, falls short of being curative, leaving patients vulnerable to respiratory infections and chronic lung disease. In addressing this unmet need, our research focuses on the development of a novel therapeutic approach: a universal gene targeting-based correction. This strategy involves the precise correction of the underlying genetic mutation in a patient's hematopoietic stem and progenitor cells (HSPCs), aligning with endogenous BTK gene regulation and protein expression. Our optimization and implementation of highly efficient gene-targeting tools and methods have yielded over 50% allelic modification at the BTK locus. Importantly, our approach has successfully restored expression levels to near-unmodified levels, establishing the feasibility and efficacy of this cutting-edge therapeutic strategy. Furthermore, our preliminary xenotransplantation studies provide compelling evidence of the successful engraftment of the integrated allele in the bone marrow. Impressively, this engraftment was not only maintained

but exhibited enrichment in the spleen. This observation is particularly intriguing considering existing literature, which suggests a selective advantage for B cells expressing a healthy BTK gene, underscoring the potential therapeutic benefits and the encouraging prospects of our gene-targeting approach. In upcoming studies, we plan to comprehensively characterize BTK-modified cells using highly-sensitive methods, including CyTOF-cytometry by time of flight, single-cell RNA sequencing, and Assay for Transposase-Accessible Chromatin. Beyond advancing XLA therapy, our research holds the potential to unravel novel insights into the pathophysiology of XLA disease.

1654. A Gene-Editing Approach to Study Variants of Unknown Significance (VUS) and Repair Patient Mutations in the Rare Disease Hemophagocytic Lymphohistiocytosis (HLH)

Dror Assa[1,2,3], Elise W. Wolf[1,2,3], Allison J. Bien[1], Srishti U. Sahu[1,3], Alžběta Ressnerová[1,4,5], Ross C. Wilson[1,3], David N. Nguyen[1,2,3]

[1]Innovative Genomics Institute, Berkeley, CA,[2]Department of Medicine, University of California San Francisco, San Francisco, CA,[3]Department of Molecular and Cell Biology, University of California Berkeley, Berkeley, CA,[4]Central European Institute of Technology, Brno, Czech Republic,[5]Mendel University in Brno, Brno, Czech Republic

Hemophagocytic lymphohistiocytosis (HLH) is a rare immunological disease characterized by fevers, cytopenia, and increased inflammatory cytokines' release leading to a life threatening condition. Familial HLH is caused by loss-of-function mutations in genes involved in cytotoxic granule release from immune cells such as $CD8^+$ T cells and Natural Killer (NK) cells. Mutations in the gene *PRF1*, which encodes for the protein perforin, is among the leading causes for familial HLH; however, in many cases gene variants have an unknown effect on its function, and therefore on the disease. Here, we demonstrate using CRISPR/Cas9 combined with homologous-directed repair templates (HDRTs) as a platform to investigate the effects of variants of unknown significance (VUS) on cytotoxic cells' function. We show that introduction of VUS from patients into healthy donor cells followed by enrichment of edited cells leads to a reduction of perforin levels, which is associated with decreased efficiency in a target cell killing assay. Finally, we used base editing in primary human T cells to revert a simulated patient mutation. In conclusion, our study introduces a novel platform for evaluating the impact of VUS on genetic diseases, offering valuable insights into the functional consequences of these variants. Additionally, we present a promising strategy for correcting disease-causing mutations using base-editing techniques.

1655. Targeted Base Editing Models Hematopoiesis and Pathophysiology of VEXAS Syndrome

Martina Fiumara[1], Raffaella Molteni[2], Corrado Campochiaro[3], Guido Pacini[1], Alessandro Tomelleri[3], Elisa Diral[4], Angelica Varesi[1], Alessandra Weber[1], Davide Stefanoni[2], Roberta Alfieri[5], Luca Basso-Ricci[1], Pamela Quaranta[1], Luisa Albano[1], Angelo D'Alessandro[6], Marco Matucci-Cerinic[3], Raffaella Di Micco[1], Alessandro Aiuti[1], Fabio Ciceri[4], Ivan Merelli[1], Lorenzo Dagna[3], Serena Scala[1], Simone Cenci[2], Giulio Cavalli[2], Luigi Naldini[1], Samuele Ferrari[1]

[1]SR-TIGET, Ospedale San Raffaele, Milan, Italy,[2]Division of Genetics and Cell Biology, Ospedale San Raffaele, Milan, Italy,[3]Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Ospedale San Raffaele, Milan, Italy,[4]Unit of Hematology and Stem Cell Transplantation, Ospedale San Raffaele, Milan, Italy,[5]Institute for Biomedical Technologies, National Research Council, Milan, Italy,[6]Department of Biochemistry and Molecular Genetics, University of Colorado, Denver, CO

VEXAS syndrome is a newly described, treatment-refractory, severe, highly prevalent disease caused by somatic mutations in the *UBA1* gene in hematopoietic stem/progenitor cells (HSPCs). VEXAS is hallmarked by vacuoles in myeloid/erythroid precursors and presents with systemic inflammation. About 50% of patients develop hematologic malignancies or myelodysplasia, contributing to the poor prognosis. The pathophysiology and impact of VEXAS syndrome on human hematopoiesis remain elusive. Moreover, the lack of suitable disease models hampers investigation of disease development and preclinical drug testing. Here, we develop *in vitro* and *in vivo* models of VEXAS syndrome by targeted base editing strategies and validate them by multiparametric flow cytometry and multi-omic analyses on VEXAS patients. UBA1 base editing in wild-type human HSPCs installed with >90% efficiency the most common VEXAS mutation. Clonogenic assays of *UBA1*-edited HSPCs revealed an exclusive myeloid output *in vitro* and a significant loss of the erythroid HSPC differentiation potential compared to mock-edited controls. Xenotransplantation of edited HSPCs in immunodeficient mice resulted in a severe reduction in circulating B cells, while NK and myeloid compartments were preserved. Bone marrow (BM) HSPCs were 5-fold lower than in control mice and largely myeloid-biased. Concordantly, while myeloid cells and HSPCs were mainly (>80%) *UBA1* mutated, the lymphoid compartment showed predominance of wild-type alleles. Strikingly, the distribution of *UBA1*-mutant cells across lineages in humanized mice mirrored the composition of our VEXAS patient cohort, where mutant cells accounted for 90% of total myeloid cells/HSPCs and for less than 5% of lymphoid lineages. VEXAS patients' marrow showed unbalanced composition of the HSPC compartment, lower abundance of stem cells, multipotent and lymphoid progenitors, and expanded myeloid populations. This was paralleled by a significant expansion of circulating myeloid-biased HSPCs and immature myeloid cells. Single-cell transcriptomics on the hematopoietic compartment of VEXAS patients harboring different *UBA1*mutations identified specific HSPC populations of VEXAS patients and revealed upregulated stress response and immune activation pathways across VEXAS cell clusters compared with healthy controls. Overall, our data show that base editing-mediated insertion of somatic mutations causing VEXAS

syndrome in wild-type HSPCs phenocopies most features of patients' hematopoietic system. These models will support the dissection of mechanistic bases underlying VEXAS pathogenesis and enable preclinical testing of novel therapies.

1656. Creating High-Quality RNA-Seq Reference Data from ATCC's Verified Cell Lines

Ajeet P. Singh, Rula Khairi, Amy L. Reese, Jade Kirkland, Corina Tabron, Noah Wax, James Duncan, Robert Marlow, Steve King, Ana Fernandes, John Bagnoli, Briana Benton, Jonathan L. Jacobs
Sequencing & Bioinformatics Center, ATCC, Manassas, VA

ATCC®'s authenticated cell lines are vital for biomedical research. Despite the widespread use of RNA sequencing in many studies, a comprehensive dataset that captures the full RNA profiles of these cell lines is not readily available in the public domain. Such a dataset would serve as a reference control for experimental design and guide the selection of appropriate cell line models for specific use cases. Our rigorous RNA sequencing, backed by stringent quality control measures, has led to the development of the ATCC Cell Line Land tool. This tool provides valuable insights into the intrinsic transcriptional patterns and molecular identities of ATCC®'s cell lines, establishing it as a gold-standard reference for researchers.Our sequencing revealed previously unidentified RNA transcripts and regulatory elements, illuminating the cell lines' molecular complexities. A comparative analysis highlighted unique RNA expression patterns, distinguishing between various cell lines, and revealing molecular differences. Notably, this analysis identified variations between derivative and parental cell lines, genetically modified immortalized primary cells and native ones, and healthy primary and cancerous cells. RNA sequencing datasets can integrate with existing genomic and proteomic databases, enabling comprehensive multi-omics analyses and cross-validation of molecular insights. Researchers can utilize the RNAseq data from ATCC Cell Line Land upon receiving cells, saving time, and enhancing experimental clarity. The reference dataset facilitates informed cell line selection and establishes a reliable molecular baseline for experimental controls. Such foundational resources drive advancements in cellular biology, disease modeling, and therapeutic research. Our RNA sequencing framework sets the stage for integrating multi-omics data, exploring cellular responses, and refining molecular characterizations. Collaborative efforts are encouraged to continually update and refine these reference-quality databases, ensuring their relevance and applicability in evolving research landscapes.

1657. The Preclinical Mouse Model for Evaluating Therapeutic Approaches to Hemophilia A

Lingyu Song, Yunlong Jiang, BingZhou Han, Jianming Xu, Hongyu Wang, Xiang Gao
GemPharmatech Co. Ltd, Nanjing, China

Hemophilia A, a hereditary bleeding disorder characterized by deficiency or dysfunction of coagulation factor VIII (FVIII), poses substantial challenges in clinical management. Creating preclinical animal models that accurately mimic the pathological process of human disease is essential for advancing our comprehension of hemophilia A and investigating potential therapeutic approaches. We used the CRISPR-Cas9 system to knock out the region spans exon 16 and 17 of the mouse F8 gene in the C57BL/6J strain, creating the B6-F8-KO mouse model. The reduced expression level of F8 in the mouse liver is confirmed by using primers targeting three different mRNA regions. Quantification of FVIII activity in plasma revealed a significant reduction to approximately 3% of the levels observed in wild-type mice, closely resembling the clinical phenotype of moderate hemophilia A. Additionally, B6-F8-KO mice showed prolonged activated partial thromboplastin time, and increased bleeding volume in the tail-cut experiment. The F8 recombinant protein therapy in B6-F8-KO mice showed improved APTT, indicating promise for the model in evaluating new therapies for hemophilia A.In summary, the B6-F8-KO mouse model serves as a valuable resource for understanding hemophilia A and evaluating innovative therapeutic interventions.

1658. Evolution Directed Gene Engineering (EDGE) Identifies Factor VIII Variants Augmented for Gene Therapy in Hemophilia A Mice

Yani Suber[1], Lucas Van Gorder[2], Julia Chau[1], Kyumin Lee[1], Riley Peng[1], Benjamin Samelson-Jones[1]
[1]Center for Cellular & Molecular Therapies at Children's Hospital of Philadelphia, Philadephia, PA,[2]University of Pennsylvania, Philadelphia, PA

Introduction Emerging clinical trial results across multiple rAAV products for hemophilia A (HA) have questioned the long-term durability of high transgene-produced factor VIII (FVIII) levels. In order to address this limitation, we aimed to identify high activity variants FVIII variants which could provide enhanced hemostatic activity at low stable expression levels. To this end, we developed a novel screening approach Evolution Directed Gene Engineering (EDGE). Our previous studies suggested with coagulation factor IX has not evolved with optimized specific activity (Samelson-Jones et al. Blood Advances 2021). Based on this work, we hypothesized that FVIII similarly has not been optimized for high activity. EGDE utilizes sequence alignment of mammalian orthologues as well as the HA database to identify amino acid positions that have been evolutionary conserved but without missense variants that cause loss-of-function. *Results* EGDE identified FVIII variants with single amino acid substitutions at 12 position which resulted in ≥2-fold enhanced activity compared to FVIII-WT. Multiple amino acid substitutions at K659 (K659M, K659V and K659C) resulted in FVIII variants with up to 6 fold increase in activity. To evaluate if these EDGE-identified variants can enhance HA gene therapy, we administered rAAV8 vectors with B-domain deleted FVIII variants under the control of a liver-specific promoter to CD4/HA$^{-/-}$ mice at a dose of 4 x 10^{12} vg/kg. The transgenes were not codon optimized. After 8 weeks, mice treated with AAV8-FVIII-K569M (n=6) and AAV8-FVIII-K659V (n=4) had a median FVIII activity of 85 U/dL and 63 U/dL, respectively, which was significantly higher than AAV8-FVIII-WT (n=4) activity of 0.5 U/dL ($p < 0.01$) (**Figure**). Transgene expressed K659M and K659V variants also had a higher FVIII specific activity of 84,000 U/mg and 50,000 U/mg respectively when compared to the FVIII-WT of 15,000 U/mg. In a separate experiment, mice treated with 4 x 10^{12} vg/kg of

AAV8-FVIII-K659C also had enhanced FVIII activity levels of 30 U/dL after 14 weeks (n=6) compared to FVIII-WT activity of 5 U/dL (n=5). Further, the HA mice expressing FVIII-K658C normalized their bleeding with a median blood loss of 5 uL/g after tail clip injury (bleeding was not significantly different p=0.5 than WT mice, blood loss was 4 uL/g), while mice expressing FVIII-WT had higher blood loss of 10 uL/g (p=0.03). These results indicate the EDGE identified FVIII variants that enhance rAAV gene therapy for HA. *Conclusions* The EDGE screen can be used to identify single missense mutations in FVIII that result in enhanced specific activity. FVIII variants FVIII-K659M, FVIII-K659V and FVIII-K659C exhibit hyperactivity and improved hemostasis after rAAV gene therapy in mice compared to FVIII-WT. These novel variants have potential to address the current limitations of rAAV gene therapy for HA and EDGE may be helpful for other disease targets.

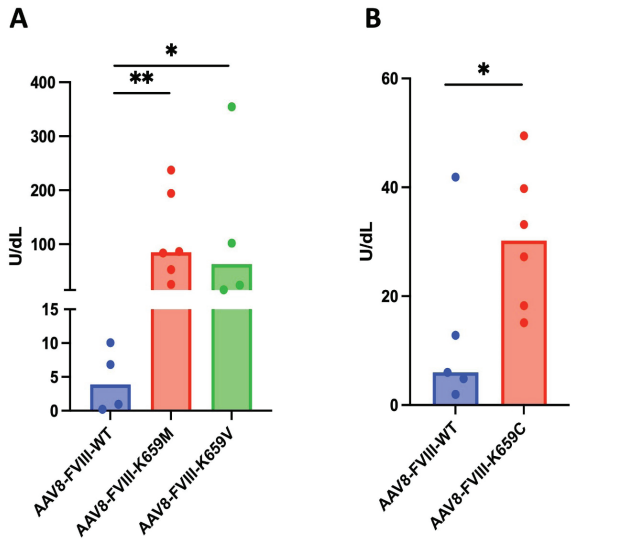

Figure 1. FVIII activity after liver-directed gene therapy of K659 variants in mice. (A) FVIII activity 8 weeks after injection with 4 x 10^{12} vg/kg AAV8-FVIII-WT (n=4), AAV8-FVIII-K659M (n=6) or AAV8-FVIII-K659V (n=4). (B) FVIII activity 14 weeks after injection with 4 x 10^{12} vg/kg with AAV8-FVIII-WT (n=5) or FAAV8-FVIII-K659C (n=6). Bars represent the median and statistical significance was determined by one-tailed Mann-Whitney with p-values ≥ 0.5 considered not significant (ns). 1-4 mice per experiment were removed from analysis because of assumed vector administration challenges based on no detectable FVIII activity or antigen.

1659. Intraosseous Delivery of a Platelet-Specific Factor VIII-Lentiviral Vector to Treat Hemophilia A in a Canine Model

Cameron W. Rementer[1], Timothy C. Nichols[2], Chong Li[3], Xiaohe Cai[1], Ting-Yen Chao[4], Yuanyi Xu[4], Elizabeth Merricks[5], Carol H. Miao[6]

[1]Center for Immunity & Immunotherapies, Seattle Children's Research Institute, Seattle, WA,[2]UNC at Chapel Hill Francis Owen Blood Rsch. Lab., Chapel Hill, NC,[3]Seattle Childrens Hospital, Seattle, WA,[4]Seattle Children's Research Institute, Seattle, WA,[5]University of North Carolina, Chapel Hill, Chapel Hill, NC,[6]Seattle Children's Research Institute, Seattle, WA

Hemophilia A (HemA) is a genetic disease resulting from a factor VIII (FVIII) deficiency. Traditional treatments for HemA are costly and require repeated dosing of replacement protein. Additionally, current AAV-mediated gene therapy generated decreased levels of FVIII over time. We demonstrated previously that intraosseous (IO) gene therapy via delivery of lentiviral vectors (LVs) into bone marrow targeting FVIII expression in platelets successfully treated HemA mice. To facilitate clinical translation, we investigated the treatment of HemA dogs using this approach. An LV vector containing the cFVIII gene was injected into the tibia/iliac bones of 6 HemA dogs (4 in Cohort #1, 2 in Cohort #2). Blood samples were taken at various timepoints post-procedure. For the dogs in Cohort #2, we incorporated several improvements, including performing injections in both the tibia and the iliac bone. Additionally, perioperative hemostasis was performed using bypassing agents to avoid inhibitor formation. All dogs recovered well from the procedure and had blood chemistry values within normal ranges. Expression of cFVIII was examined in platelets and plasma isolated from LV-treated dogs by ELISA and could be detected in platelets with the highest expression at 5-10 mU/10^8 platelets around 1-2 months post-procedure. The improvement of blood coagulation was evaluated by whole blood clotting time (WBCT) and was found to be shortened in multiple time points shortly after IO gene therapy, indicating improved hemostasis. Encouragingly, the dogs experienced fewer bleeding events per year after gene therapy treatment compared to baseline, indicating a partial phenotypic correction. We have established an IO-LV gene therapy protocol to treat HemA dogs successfully with persistent effects of treatment over 2-5 years, including a phenotypic improvement. This represents a potential strategy for gene therapy in HemA patients.

Friday Posters: Epigenetic Editing and RNA Editing

1660. Tunable Transgene Expression Using an ADAR-Mediated Gene Switch

Joseph Silverberg[1], Laura Pereira[1], Daniel M. Cohen[1], Federico Mingozzi[2], Sean M. Armour[1]

[1]Discovery, Spark Therapeutics, Inc., Philadelphia, PA,[2]Former Employee of Spark Therapeutics, Inc., Philadelphia, PA

Adeno-associated viruses (AAVs) are a powerful tool to deliver gene therapies, especially for gene augmentation purposes. However, a limitation of classical expression cassettes is their inability to tune the level of transgene expression post-transduction. The field of gene therapy could benefit from technologies that enable tunable expression of transgenes. One approach to overcome this challenge is to take advantage of gene editing technologies to control the expression of the episomal gene by introducing precise point mutations in the AAV genomes or AAV-derived transcripts. Adenosine deaminase acting on RNA (ADAR) is an enzyme that allows for post-transcriptional editing in both coding and non-coding regions of double-stranded RNA (dsRNA) by editing adenosine-to-inosine (A-to-I). Inosine is interpreted by the ribosome as guanosine (G) during translation, functionally introducing an A-to-G edit. Here, we explore the potential for ADAR to mediate tunable expression of Human Factor IX, hFIX, in the context of AAVs. Within the hFIX transgene sequence, we identified tryptophan codons (TGG) that could be mutated to premature terminating codons (PTC) encoded by an amber stop codon (TAG). One codon, W118STOP, completely inhibited hFIX expression. To edit W118STOP PTC (TAG) back to the native tryptophan codon (TGG) we

designed a trigger RNA for the recruitment of the endogenous ADAR enzyme to enable hFIX expression via an A-to-G point mutation. Huh7 cells transiently co-transfected with W118STOP and trigger RNA achieved expression levels ~40% of wildtype hFIX, whereas those transfected with W118STOP alone had no detectable levels of FIX protein. Sanger sequencing results indicated that ~75% of the mRNA achieved the desired A-to-G edit changing the PTC back to the native tryptophan codon. Incomplete rescue of hFIX expression following editing prompted evaluation of hFIX transcript abundance. The amount of hFIX mRNA in W118STOP was statistically lower than wildtype p=0.0001 and was unaffected by the addition of the trigger RNA. These results demonstrated that our ADAR-based strategy could successfully turn on transgene expression *in vitro*. The ability of an ADAR gene switch to control FIX expression *in vivo* is being investigated using Spark100-ApoE-hAAT FIX AAV vectors. Our work demonstrates the potential to achieve tunable expression of an AAV-delivered transgene using an ADAR-responsive premature termination codon.

1661. Epigenetic Reactivation of γ-Globin Expression as a Novel Curative Option for β-Hemoglobinopathies

Simone Amistadi[1], Letizia Fontana[1], Chiara Magnoni[1], Panagiotis Antoniou[1], Ali Faiq[2,3], Melissa Whitehead[2,3], Claudio Mussolino[2,3], Annarita Miccio[1]

[1]Imagine Institute, Paris, France,[2]Institute for Transfusion Medicine and Gene Therapy, Freiburg, Germany,[3]Medical Center - University of Freiburg, Freiburg, Germany

β-hemoglobinopathies are severe genetic diseases caused by mutations affecting the production of the β-globin chain. Their clinical severity is mitigated by the co-inheritance of mutations that reactivate γ-globin (*HBG*) genes expression and result in elevated production of fetal hemoglobin (HbF) in adults, a condition named hereditary persistence of HbF (HPFH). While the transplantation of allogenic hematopoietic stem and progenitor cell (HSPC) provides a definitive therapy for patients with β-hemoglobinopathies, the frequent absence of a compatible donors demands for alternative strategies such as the transplantation of autologous HSPCs upon gene correction. Targeted nucleases and base editors have been exploited to recreate HPFH mutations and reactivate HbF. However, the unwanted off-target cleavage activity and the genotoxicity associated with these genome editing strategies raise safety concerns for clinical applications. Therefore, novel and safer therapeutic strategies are still needed for the treatment of β-hemoglobinopathies.Here, we investigated the epigenetic regulation of the *HBG* genes to develop novel therapies based on programmable epigenome editing. We aimed at modulating gene expression without altering the underlying DNA sequence. Analysis of epigenetic marks at the *HBG* promoters revealed a distinct pattern of modifications in adult versus fetal erythroid cells. Primary fetal erythroblasts, which express γ-globin, showed enrichment of H3K27ac and H3K4me3 and low DNA methylation, marks typically associated with active transcription. To recreate this epigenetic configuration at the *HBG* promoters in adult cells, we tested CRISPR-based epigenome editors (capable of depositing histone acetylation and removing DNA methylation) in HEK293T, a cell line that expresses low γ-globin levels. These editors reached up to 10^4-fold increase in *HBG* expression with the most effective combination of single guide RNAs spanning the promoter region. We further validated the strategy in HSPCs derived from patients with sickle cell disease, by RNA delivery of the editing components. We observed no alterations between treated and non-treated HSPCs during their differentiation towards the erythroid lineage. In HSPC-derived erythroblasts we observed an increased transcription of *HBG* genes and higher amount of HbF positive cells, as assessed by flow cytometry. Importantly, this correlated with high levels of HbF production (~50%), measured by cation-exchange HPLC, and a substantial correction of the sickling phenotype in mature erythrocytes. Altogether, these results confirmed the crucial role of epigenetic modifications in regulating the β-globin locus and the possibility to reprogram the epigenome to reactivate *HBG* expression and HbF production. In conclusion, this strategy overcomes the genotoxicity risks associated with the use of DNA-cleaving enzymes and offers a safe and effective alternative for the treatment of β-hemoglobinopathies.

1662. Simultaneous Five-Gene Epigenetic Editing to Generate TGF-b and Adenosine-Resistant Allogeneic CAR T Cells

McKensie A. Collins, Laura Kehoe, Avery Houston, Kunza Ahmad, Thijs Udo, Moe Zaker, Scott Clarkson, Benjamin Hallisey, Kendra Bayne, Melissa Pannone, Mary Morrison, Ricardo N. Ramirez, Ari E. Friedland, Pietro Spinelli, Vic Myer, Aron Jaffe, Jamie Schafer

Chroma Medicine, Boston, MA

CAR T cell therapy has generated meaningful clinical responses in patients with CD19+ and BCMA+ hematologic malignancies but cures are limited and patients with solid tumors continue to have poor responses to CAR T. One contributing factor is immunosuppressive molecules in the tumor microenvironment (TME) that limit anti-tumor responses. Soluble factors like adenosine and TGF-b—both well-characterized as drivers of profound immunosuppression—may inhibit the efficacy and durability of CAR T responses. Additionally, the use of autologous cells requires individualized manufacturing which increases cost and restricts availability, with many patients succumbing to progressive disease before receiving treatment. Allogeneic CAR T cells have the potential to address these bottlenecks, but durable responses are limited. Editing of multiple genes (multiplex editing) is necessary to overcome the above limitations but approaches that nick or cut DNA often cause undesired genomic rearrangements. However, epigenetic editing has the potential to durably regulate multiple genes in a single step without cutting or nicking the DNA. This may enable efficient generation of complex cell products such as allogeneic CAR T cells that evade TME-mediated immunosuppressive mechanisms. In this study, activated T cells were engineered via nucleofection with a dCas9-based epigenetic editor and gRNAs to silence the receptors for TGF-b and adenosine: TGFBR2 and ADORA2A. Target expression was durably repressed, as assessed by flow cytometry and RT-qPCR respectively, in single- and dual-target conditions for 35 days through repeat anti-CD3/CD28 stimulations. Next, multiplex-silenced BCMA-targeting CAR T cells were generated and downstream signaling in response to TGF-b or adenosine, cytotoxicity, proliferation, and cytokine production were evaluated following antigen challenge via a BCMA+ cell line. Downstream signaling as assayed via flow cytometry for phospho-SMAD and phospho-CREB showed an ~80% (pSMAD) and ~60% (pCREB) reduction in response to TGF-b

or 2-chloro-adenosine respectively, equivalent to Cas9 knockout controls. Multiplex-edited CAR T cells also had improved anti-tumor potency at multiple effector:target ratios in the presence of TGF-b, and comparable cytotoxic function to unedited CAR T cells under standard culture conditions. Silenced cells were also more proliferative than unedited CAR T cells in the presence of TGF-b following tumor stimulation. IFNg production by silenced cells was uninhibited by TGF-b, while unedited CAR T cells showed a nearly 70% reduction in IFNg production following tumor re-stimulation. As duration of response is an issue for allogeneic products, we believe the inclusion of survival- or potency-enhancing edits with allogeneic modifications addresses a significant unmet need. We combined TME and allogeneic edits, producing cells in which five targets—TGFBR2, ADORA2A, B2M (to reduce MHC class I), RFXAP (to reduce MHC class II), and CD3D/CD3G (to reduce TCR)—were durably silenced in a single step. Expression was repressed at >90% for all five targets for 35 days through two re-stimulations and a 95% reduction in mRNA expression of ADORA2A, highlighting the efficiency of generating a multi-edited cell without genotoxic risk. Simultaneous silencing of five genes demonstrates the multiplexing capability of epigenetic editing and shows the potential to improve allogeneic CAR T cell therapies by rendering the cells resistant to TGF-b and adenosine while maintaining genomic integrity. Chroma's epigenetic editing technology may enable development of the complex next-generation CAR T cell therapies required to improve patient access and overcome biological barriers to success.

1663. Durable *HTT* Silencing Using Non-Evolved dCas9 Epigenome Editors in Patient-Derived Cells

Jennifer Waldo[1,2], Julian A. N. M. Halmai[1,2], Ankita Singh[1,2], Maria N. Florendo[1,2], Jan A. Nolta[2], Kyle D. Fink[1,2]

[1]Ctr. for Interventional Genetics, MIND Institute, Department of Neurology, UC Davis Medical Center, Sacramento, CA,[2]Stem Cell Program, Gene Therapy Center, Institute for Regenerative Cures, UC Davis Medical Center, Sacramento, CA

Huntington's Disease (HD) is an autosomal dominant neurodegenerative disorder caused by a trinucleotide repeat in exon 1 of the Huntingtin (*HTT*) gene. This expansion leads to protein misfolding that causes widespread cellular dysfunction and ultimately leads to neuronal cell death. The advent of nuclease-deficient CRISPR-Cas9 (CRISPR-dCas9) gene regulation technologies allows targeting of the causative gene and subsequent downregulation via fused effector domains that induce heterochromatin at the epigenetic level through DNA methylation (DNMT3A/L) and H3K9me3 deposition (KRAB), blocking transcription. Therefore, we propose using dCas9 epigenetic editing to downregulate *HTT* as a therapeutic approach for HD. *HTT* has large haplotype blocks that allow for allele-specific targeting based upon the presence of heterozygous single nucleotide polymorphisms (SNPs). These SNPs are in genomic regions devoid of NGG PAM sites, a requirement for *sp*dCas9 binding. To address this bottleneck, a screen was conducted of multiple dCas9 variants fused to KRAB and DNMT3A/L with increasingly expanded PAM targeting to initially assess the ability to downregulate total *HTT*. Surprisingly, only *sp*dCas9 was able to significantly knockdown *HTT*, while expanded PAM site variants dxCas9 and dCas9-VQR were less efficient in reducing *HTT* expression. ChIP-qPCR of the *HTT* promoter showed a decrease in the binding efficiency of dCas9 variants, likely leading to the decreased efficiency of *HTT* downregulation. We further investigated DNA methylation changes through reduced representation bisulfite sequencing, showing high on-target increases in DNA methylation and few off-targets. In addition, we demonstrate mitotically stable *HTT* silencing of up to 6 weeks *in vitro* in a rapidly dividing cell line. We then assessed total *HTT* knockdown in HD patient-derived fibroblasts and neuronal stem cells. We identified significant downregulation of *HTT* in our treatment group compared to an unguided control. RNAseq was used to identify differential gene expression between treatment and controls, and gene ontology analysis was performed to identify the rescue of biological processes involved in *HTT* molecular pathogenesis. Off-targets were assessed through overlaying genome-wide changes in H3K9me3 enrichment, dCas9 binding, and differential gene expression. An additional bottleneck is the delivery of large dCas9 epigenome editors to the CNS. Current studies are addressing novel dual AAV and viral-like particle delivery for our identified epigenome editors *in vivo*. This approach holds great promise for those suffering from HD.

1664. Endogenous ADAR Based RNA Editing Therapy for Usher's Syndrome Type II

Pengfei Yuan[1], Huixian Tang[2], Zexuan Yi[1], Gangbin Tang[1], Yongjian Zhang[1], David Gamm[3,4], Divya Sinha[3], Yanxia Zhao[1]

[1]EdiGene Inc., Beijing, China,[2]Peking University, Beijing, China,[3]Waisman Center, University of Wisconsin– Madison, Madison, WI,[4]Department of Ophthalmology and Visual Sciences, McPherson Eye Research Institute, Madison, WI

Usher Syndrome type II (USH2) is a hereditary condition marked by retinitis pigmentosa and moderate to severe hearing loss, primarily resulting from mutations in the USH2A gene. This gene, notable for its substantial size, produces Usherin, a protein essential for the structural and functional integrity of both the retina and inner ear. A prominent mutation in USH2A, c.11864G>A (p.Trp3955*), introduces a premature stop codon, significantly impairing Usherin function. This mutation exhibits diverse geographical prevalence across Europe, with exceptionally high incidence in Slovenia, where 82.5% of USH2A patients possess it. It also accounts for 20% of USH2A patients in Germany. Programmable A to G base editing offers a theoretical solution for correcting this mutation. Beyond CRISPR-based ABE, various ADAR-dependent RNA base editing tools have been developed. These tools leverage adenosine deaminases acting on RNA (ADAR) mediated RNA editing, a widespread eukaryotic cell process where adenosine is deaminated to inosine, which is subsequently recognized as guanosine in splicing or translation, enabling genetic message rewrites. Among these, LEAPER and its advanced version, LEAPER 2.0, facilitate precise, efficient, and enduring RNA transcript editing using engineered circular arRNAs (circ-arRNAs) and endogenous ADAR. Compared to CRISPR-based ABE, LEAPER avoids permanent DNA damage, desirable or otherwise, and potential in vivo immunogenicity. Based on LEAPER RNA editing, we tried to develop therapy for the USH2A c.11864G>A mutation. In this study, we first refined arRNA for high editing efficacy and minimal bystander impact using a mini-reporter system in 293T cells. We then incorporated this arRNA into

AAV and tested it in retinal organoids differentiated from CRISPR-edited iPSCs carrying the homologous c.11864G>A mutation and patient-derived iPSCs with compound heterozygous c.11864G>A. The editing rate reached up to 50% in CRISPR-edited and 35% in patient-derived cases, with minimal bystander effects observed. Since no functional animal disease model exists for the USH2A c.11864G>A mutation, we substituted mouse USH2A gene exon 60 with human Exon 61 harboring the c.11864G>A mutation. This model showed clear hearing loss at high frequency range without affecting vision. LEAPER delivered by AAV effectively alleviated hearing impairment in this humanized mouse model. To further evaluate the editing efficiency and safety in non-human primates (NHPs), we targeted an adjacent adenosine in the NHP USH2A 11864 site as a proxy, administering AAV8-arRNA through sub-retinal injections. Editing at the targeted site achieved up to 40% efficiency in the infected retina, with no safety issues observed over a six-month monitoring period. Collating our findings from the retinal organoid studies, the humanized mouse model, and NHP experiments, we posit that our approach shows significant potential as a therapeutic intervention for the USH2A c.11864G>A mutation.

1665. Evaluating CRISPR Activation Therapy for Pitt-Hopkins Syndrome

Renee Napoliello[1], Katherine L. Lucot[1], Julian Halmai[2], Kyle D. Fink[2]

[1]UC Davis School of Medicine, Sacramento, CA,[2]UC Davis, Sacramento, CA

Introduction: Pitt-Hopkins Syndrome (PTHS) is a genetic intellectual disability with no FDA-approved treatments. PTHS is caused by *de novo* mutations in *Transcription Factor 4* (*TCF4*), which result in haploinsufficiency (expression of a single wild type allele is insufficient for cellular function). *In vitro*/*vivo* studies of rodent and human PTHS models identified *TCF4* as critical for both neuronal development and postnatal function. *Kim et al. 2022* postnatally reinstated *Tcf4* expression in a mouse model of PTHS to fully rescue behavior associated with learning and memory, and partially normalize electrophysiological and molecular markers of neuronal function. It is plausible that restoration of *TCF4* expression could ameliorate symptoms in human cases of PTHS. CRISPR activation (CRISPRa) is a fusion of a nuclease-deficient Cas protein with a transcriptional activator; when targeted to regulatory genomic regions this tool can promote expression of target genes. CRISPRa can be employed to regulate *TCF4* expression by targeting the promoter of *TCF4*. However, the most common and well-characterized iteration of CRISPRa (based on spCas9) is too large to package into a single AAV (Adeno-Associated Virus). This is of concern as AAVs are a favored delivery method for DNA-based therapeutics. AAVs have low immunogenicity, can target specific cell types, and deliver their cargo as a stably expressed nuclear episome. For translational relevance of evaluating CRISPRa to treat PTHS, three methods to circumvent AAV packaging limits were evaluated. These methods were: a dual-plasmid system using the standard spCas9 with a protein intein split fusion, a single plasmid system with the small ortholog cjCas9, and a single plasmid system with the small ortholog cas12f. *Methods:* 23 gRNAs designed for spCas9-based CRISPRa targeting *TCF4* were screened in HEK293 cells. Nine guides were from a dataset based on a predictive algorithm (Horlbeck, et al., 2016) and 14 from the ChopChop software. The gRNA expression plasmid was co-transfected with two plasmids encoding half each of the split spCas9 CRISPRa. qPCR was used to assess changes in *TCF4* expression. Lead gRNAs were selected and the same experiment performed on neural stem cells (NSCs). Twenty gRNAs for cjCas9 and for cas12f (orthologs with AAV-packaging competent CRISPRa constructs) were designed with the CCTop software to target *TCF4*. Transfections of gRNA-expressing and effector domain-expressing plasmid were performed in HEK293s, followed by qPCR. The same transfection with lead gRNAs was performed in neural stem cells (NSCs). *Results:* From HEK293 transfection several spCas9 gRNAs exhibited significant upregulation of *TCF4* using the dual-plasmid method. The lead spCas9 guide was chosen as the gRNA with the greatest TCF4 expression fold change in NSCs. In addition, from HEK293 transfection, several cjCas9 and cas12f gRNAs exhibited significant *TCF4* upregulation, and the lead guide for each ortholog was chosen based on transfection in NSCs, similar to the spCas9 experiments. *Conclusion:* CRISPR activation can significantly upregulate *TCF4* across multiple cell lines. Further, multiple translationally relevant iterations of CRISPRa are effective at targeting TCF4 for activation. In future studies, the three CRISPRa constructs paired with their most potent gRNAs will be further tested via AAV transduction. Multiple PTHS patient-derived neuronal cultures will be treated with the CRISPRa-containing capsids to evaluate potency of *TCF4* upregulation and extent of functional rescue of disease phenotype.

1666. dCasMINI Mediated *ZC4H2* Reactivation in Human Cells

Yomira Palacios, Julian Halmai, Kyle D. Fink

Neurology, UC Davis, Davis, CA

ZC4H2 Associated Rare Disorders (ZARD) is an ultra-rare X-linked intellectual disability caused by a spectrum of inherited and de novo mutations in the *ZC4H2* gene. *ZC4H2* encodes a zinc finger protein that is highly expressed in the brain during early neurodevelopment, yet its direct role in regulating neurodevelopment remains elusive. Female somatic cells undergo random X chromosome inactivation to regulate gene dosage. In X-linked intellectual disability, affected regions such as the brain, result in mosaic cells that express either the wildtype or mutant allele. In mutant-expressing cells, the presence of the second protective X chromosome can be utilized to reintroduce the expression of the healthy silenced gene. Our group was the first to successfully demonstrate the feasibility of reactivating the wildtype allele in mutant loss of function cells of an X-linked neurodevelopmental disorder in female somatic cells. This approach relied on using CRISPR/dCas9 fused to the catalytic domain of DNA methylcytosine dioxygenase TET1 which reactivates expression by active removal of promoter DNA methylation. Although, this tool offers a promising therapeutic approach for X-linked disorders primarily affecting females, packing limitation remains a current problem for therapeutic delivery. In addition, while about 60% of human genes regulate expression through CpG islands in their promoter regions, the *ZC4H2* promoter lacks CpG islands. This highlights the need to explore alternative pathways for gene reactivation, potentially providing a simpler mechanism without the generation of differentially methylated epi-alleles. Recently, a newly engineered miniature CRISPR-Cas system was developed that demonstrated robust gene upregulation of silenced autosomal genes in HEK293T cells when fused to a transcriptional activator

domain (VPR). These results demonstrate the feasibility of gene upregulation from a miniature CRISPR system. Our experiments utilize this improved CRISPR ortholog (dCasMINI) to demonstrate the feasibility of reactivating an X-linked gene in clinically relevant cells in a methylation-independent manner. Electroporation-mediated delivery of dCasMINI fused to VPR has demonstrated gene reactivation of *ZC4H2* in patient-derived B-lymphocytes. Ongoing studies address gene reactivation of *ZC4H2* in iPSC derived Neural Stem Cells (NSC). In addition, RNA collection for mutant and treated NSC have been done to perform RNA sequencing to address rescue of differential expressed genes associated with ZARD. This study can serve as proof-of-principle for other X-linked genes and broaden the therapeutic implication of smaller Cas-mediated programmable transcription.

1667. Gene Therapy Approach for Neurofibromatosis Type 1 via Cell-Specific Epigenetic Editing in Schwann Cells

Adele Guglielmi[1], Max Miller[1], Niraj R. Punjya[1], Ulrika Beitnere[2], Tomas Salter-Cid[1], Claire Caputo[1], Kenneth Sims[3], Kyle D. Fink[4], Henriette O'Geen[1], David J. Segal[5]

[1]Genome Center, UC Davis, Davis, CA,[2]Molecular Biology, Max Delbrück Center for Molecular Medicine, Berlin, Germany,[3]Battelle's Advanced Materials and Energetics Group, Battelle Memorial Institute, Columbus, OH,[4]Institute for Regenerative Cures, UC Davis, Sacramento, CA,[5]Genome Center, UC Davis Genome Center, Davis, CA

Neurofibromatosis type 1 (NF1) is a genetic tumor predisposition syndrome arising from mutations in neurofibromin (NF), a negative regulator of RAS activity. The bi-allelic inactivation of neurofibromin in a subpopulation of Schwann cells (SCs) leads to the occurrence of neurofibromas, the primary cause of morbidity in NF1 patients. The clinical and genetic heterogeneity, the cell and tissue specific symptoms of NF1, together with the complexity of the ubiquitously expressed RAS pathway, require the development of a versatile therapeutic approach to selectively target both the peripheral and central nervous system. Our strategy aims to obtain the gene repression of the downstream mitogen-activated protein kinases MAP2K1-2 in the RAS signaling through a persistent, cell specific epigenetic editing. A synergistic effort has been made to develop, on one hand, a non-viral, cell-type targeted vector carrying a CRISPR-based tool to counteract the effects of the mutated NF, to be tested *in vitro*, and, on the other, a polymer nanoparticle (PNP) delivery system able to vehicle large DNA payloads *in vivo*. We are cloning a single vector housing the SCs specific promoter MPZ(P0), together with the inactivated (dead) form of CRISPR-associated nuclease (dCas9), the DNA methyltransferase (DNMT3A-L) and the repressor KRAB domains, the TdTomato reporter and two MAP2K1-2 guide RNAs, previously screened in Neuro2A cells, for their ability to successfully downregulate the mRNA targets. The generated vector will be initially tested *in vitro* via nucleofection in the murine Schwann cell line. The TdTomato positive cells will be sorted and replated to monitor in time the repression of the two targets MAP2K1 and 2 by qPCR and WB analysis. In parallel, more than 500 PNPs have been synthetized and screened *in vitro* for their DNA loading capability and transfection efficiency. The PNPs biodistribution will be evaluated also *in vivo* in murine models. Ultimately, the final vector will be loaded in the pre-screened top PMPs and delivered *in vivo* to identify the best delivery candidates for their ability to downregulate MAP2K1 and 2 expression in wild type mice.

1669. Accelerating the Discovery of Novel Hypercompact Transcriptional Activators with Machine Learning

M. Zaki Jawaid, T. Blair Gainous, Kavita Jadhav, Aayushma Gautam, Chris Still, Timothy P. Daley, Alexandra Collin de l'Hortet, Dan O. Hart, Robin W. Yeo

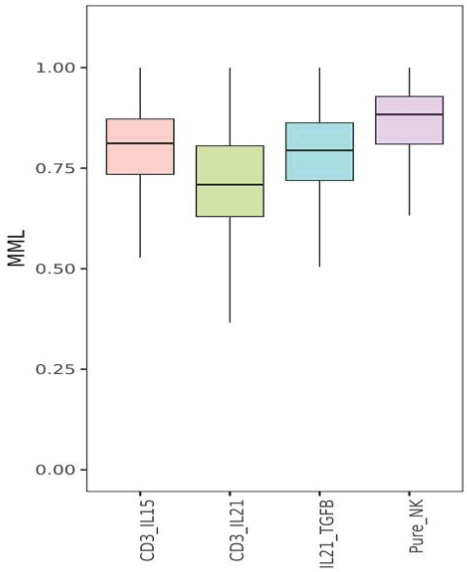
Epic Bio, South San Francisco, CA

Due to the programmability and versatility of CRISPR-Cas systems, gene therapy research is emerging as an increasingly promising strategy to treat genetic disease. However, many genetic diseases, such as those caused by haploinsufficiency, cannot be treated with traditional knock-out based CRISPR gene therapies, since they are caused by allelic loss-of-function. Due to its ability to both activate as well as suppress gene expression, epigenetic editing using CRISPR-dCas systems has the potential to address many genetic diseases that are unsuitable for traditional gene therapies. However, the versatility of epigenetic editing is constrained, especially in the context of gene activation, by the limited number and large size of most modulator peptides, severely limiting their therapeutic utility. To address these limitations, we have built a generative AI platform capable of designing de novo hypercompact modulator peptides with the ability to transcriptionally upregulate a genetic locus. We first collected a large corpus of training data by performing high-throughput screens to discover novel transcriptional activators among peptides derived from human, viral, and archaeal proteomes. We then trained a machine learning ensemble model, composed of a decision tree model and a convolutional neural network, which leverages transfer learning (via large protein language model embeddings) to predict transcriptional activators based on peptide sequence alone. By exploiting a novel sampling algorithm, which we call evolutionary Monte Carlo search, to more efficiently traverse the predicted activator fitness landscape, we used this machine learning platform to generate a library of several thousand hypercompact peptides predicted to be transcriptional activators. We experimentally screened these peptides and validated that our generative AI approach dramatically increased discovery rate (up to 45-fold) resulting in the discovery of hundreds of novel transcriptional activators sharing little sequence similarity with known naturally occurring peptides. We next investigated the evolutionary, biochemical, and biophysical properties of the synthetic activator library, revealing that validated activators consistently lack conserved functional domains but do share certain biochemical features, such as strong negative electrostatic potential. We subsequently selected 10 of our top synthetic activators for further characterization, and assessed their activation strength by screening them at an artificial GFP locus as well as at an endogenous human locus (CD45), comparing their potency to gold standard activators (e.g. VPR, VP64, ···). Additionally, using RNA-seq, we assessed off-target gene expression changes to evaluate the specificity (and thus safety) of on-target transcriptional upregulation using a synthetic activator. These results demonstrate the capability of machine learning to accelerate the discovery of novel functional peptides to expand our toolbox of epigenetic modulators for future therapeutic applications.

1670. Comprehensive Engineering of a CasX-Based Repressor to Create Highly Potent Epigenetic Editors

Jason D. Fernandes, Emeric J. Charles, Ross White, Kirsten A. Reimer, Christopher Duncan-Lewis, Ludmila Lokteva, TC Steven Keller, Shyam Sundhar Bale, Raniel Alcantara-Lee, Ashley T. Wong, Benjamin L. Oakes, Sarah K. Denny

Scribe Therapeutics, Alameda, CA



Epigenetic editing is a powerful and innovative approach to control the expression of disease-associated genes without permanently changing the underlying DNA sequence. Current systems for epigenetic modulation are limited by their large sizes that hinder effective delivery and potency issues that require high doses for efficacious knockdown. Improving these characteristics would require effectively harnessing multifactorial epigenetic machinery to achieve potent and sustained gene perturbation. Here, we leveraged comprehensive engineering approaches to query from tens of thousands of novel compositions to create unique epigenetic repressors based on catalytically-inactive versions of compact, highly engineered CasX (Cas12e) that enable the precise targeting and repression of therapeutic targets in vitro and in vivo. These molecules and subsequent learnings for building epigenetic silencing tools were discovered by testing comprehensive libraries containing tens of thousands of distinct transcriptional repressor domains mined from genomes across the tree of Life. By assessing target knockdown in pooled human cell screens, we were able to identify compact transcriptional repressor domains that were significantly more potent than the widely used repressor domains in CRISPRi. Many of our newly identified domains were significantly diverged from natural human repressor domain sequences and substantially enhanced repression. Tethering the resulting CasX-based repressors (XR) to engineered DNA methyltransferase domains produced optimized Epigenetic Long-Term X-Repressors (ELXR) that achieved sustained and heritable silencing of a therapeutically relevant locus in vivo when delivered via mRNA in a single dose of LNP. Our findings demonstrate that holistic and extensive engineering of CRISPR epigenetic repressors can provide significant benefits in achieving potent and sustained gene repression across multiple in vitro and in vivo systems.

1671. Defining the Epigenetic Signatures of *In Vitro* Expanded NK Cells Used for Cancer Therapy

Megan Zinsky[1], Natalie Holl[2], Ruyan Rahnama[1], Jun Choe[2], Danielle Grace Jones[2], Oscar Martinez[2], Michael Koldobskiy[1], Challice Bonifant[1]

[1]Pediatric Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD

Background: Natural Killer (NK) cells have powerful anti-tumor effect as innate lymphoid cells, especially for acute myeloid leukemia (AML), since myeloid blasts express NK cell activating ligands. NK cells in AML patients have been shown to be dysfunctional; therefore, treatment with adoptive transfer of expanded NK cells is promising. Since large NK cell doses are required for treatment efficacy, NK cells must be activated and expanded after isolation through cell-cell contact and cytokine stimulation. Therefore, NK cells expanded for clinical trials are commonly co-cultured with irradiated K562 "feeder" cells expressing membrane bound IL-15 or IL-21 and 41BB ligand, and then maintained in culture with supplemental IL-2, to sustain an activated phenotype. Recent studies have described improved NK cell anti-tumor functionality by also treating cells *in vitro* with the immunosuppressive cytokine TGFβ. Our goal is to describe the epigenetic signature of NK cells expanded *in vitro* using these techniques. **Hypothesis**: Whole genome profiling of NK cells expanded using clinically relevant manufacturing methods will elucidate global DNA methylation patterns that correlate to optimal NK cell activation and *in vivo* anti-tumor cytotoxicity. **Methods**: To expand human NK cells, CD3+ cells were depleted from human donor peripheral blood mononuclear cells. Remaining cells were co-cultured with: (1) K562.mbIL15.41BBL + IL-2; (2) K562.mbIL21.41BBL + IL-2; (3) K562.mbIL21.41BBL + IL-2 + TGFβ and maintained in culture for 10 days. Each expansion was performed three times. NK cell purity was tested before isolating genomic DNA for whole genome bisulfite sequencing (WGBS). DNA isolated from freshly isolated, non-activated NK cells were included as a control. WGBS libraries were sequenced using 150-bp paired end indexed sequencing and differentially methylated regions were detected using BSmooth and InformME packages. **Results**: For NK cell isolations, mean starting and final NK cell purity percentages were 8 ± 1.6% and 94.3 ± 0.5%, respectively. CD3 depletions were also effective, with mean starting and final CD3+ percentages as 69.9 ± 0.9% and 0.26 ± 0.1%, respectively. The mean fold NK cell expansion measured at day 7 and 10 were not significantly different between activation methods (K562.mbIL15.41BBL: 46.69 ± 15.33, 352.2 ± 204.1; K562.mbIL21.41BBL: 33.65 ± 4.63, 191.1 ± 48.8; K562.mbIL21.41BBL+TGFβ: 41.9 ± 0.77, 200.9 ± 25.96 respectively at day 7 and 10). All data are presented as mean ± SD. Initial data from WGBS and PCA analysis demonstrated global differences in mean methylation level between the four groups. **Conclusions**: We have identified clear differences in global methylation patterns between our NK cells expanded using clinically relevant methodology. We are currently analyzing the gene-specific methylation differences between these cells and seek to identify an epigenomic signature that correlates with optimal anti-tumor NK cell functionality. We plan parallel analysis of transcriptional phenotype using RNAseq and surface protein and receptor expression using multi-parameter flow cytometry. We expect to further identify unique characteristics that define our expanded NK cell products to inform manufacturing plans for future clinical trials.

Friday Posters: Targeted Gene Insertion

1672. From Promoter to Transgene Efficiency: Insights from Promoter Screening in Induced Pluripotent Stem Cells

Kiavash Kiaee, Michael Nehil, Shawdee Eshghi
Ginkgo Bioworks, Inc., Boston, MA

Generating therapeutic cells from iPSCs is an attractive approach to address challenges in precision genome engineering and manufacturing scalability in current cell therapy approaches. Differentiation from a pluripotent state to the desired therapeutic cell involves large scale epigenetic changes and genome rearrangements that can often lead to transgene silencing. In this study we sought to optimize transgene expression in iPSCs by systematically screening promoter in a site-specific manner. We conducted an arrayed screening of commonly used parts of promoters ranging in size between 60 bp to 1200 bp integrated in a site-specific manner into therapeutically relevant loci like TRAC in iPSCs. Surprisingly, widely reported promoters such as EF1a and CMV exhibited minimal expression, in stark contrast to the robust and sustained transgene expression observed with PGK and UbC promoters. Notably, the investigation revealed a discrepancy in transgene expression from the EF1a promoter between plasmid-based and TRAC locus-integrated constructs, suggesting locus-specific silencing of certain promoters.Motivated by the need to enhance our understanding of locus-specific silencing and the differential expression patterns exhibited by widely used promoters, our findings offer key insights for enhancing gene integration strategies and the optimal choice of HDR templates for reliable transgene expression for biotechnology and cell therapy applications.

1673. Efficacy & Safety of AAV9-Mediated *GDAP1* Gene Replacement Therapy in CMT4A Mice

Merve Emecen Sanli, Thomas Dong, Anjala Jiji, Yuhui Hu, Steven J. Gray, Xin Chen
University of Texas Southwestern, Dallas, TX

Charcot Marie Tooth (CMT) manifests as a diverse group of neuropathies with both clinical and genetic variations, encompassing various Mendelian inheritance patterns. Over 1,000 mutations in 80 disease-associated genes have been identified. A small subgroup of hereditary motor and sensory neuropathies in CMT is attributed to mutations in the ganglioside-induced-differentiation-associated protein 1 gene (*GDAP1*). GDAP1-related mutations can be inherited in either an autosomal recessive (AR, more common) or an autosomal dominant (AD) pattern. AR mutations, known as CMT4A, exhibit demyelinating, axonal, or intermediate disease forms. CMT4A leads to an early-onset, severe neuropathy affecting all extremities, often resulting in loss of ambulation in early adulthood (second-third decade). In advanced stages, many of these patients develop vocal cord paresis (unilateral or bilateral) and diaphragmatic weakness. In contrast, AD mutations, termed CMT2K, present with axonal disease and tend to have a more benign course. Since there is no specific treatment and it is a single gene disease, we hypothesized that spinal cord and peripheral nerve delivery of the *GDAP1* gene through lumbar intrathecal (IT) injection during early life can improve disease symptoms in *Gdap1*^{R191X} mice. A codon optimized human *GDAP1* gene driven by a weak ubiquitous promoter was synthesized and cloned into a self-complement adeno-associated viral serotype 9 (scAAV9) vector (AAV9/*GDAP1*). The construct was validated *in vitro* for gene expression following transfection into HEK293 and Lec2 cells. To test the safety of AAV9/*GDAP1* gene therapy, an in vivo safety study was conducted using IT administration of AAV9/*GDAP1* to wild type (WT) mice at postnatal p7-10 with low or high dose. The results showed a significant dose dependent increase in human *GDAP1* mRNA expression in the sciatic nerve. No adverse changes of body weight or survival rate were observed with the treatment. In parallel, to test the efficacy of AAV9/*GDAP1* gene therapy, an *in vivo* efficacy study is ongoing using IT administration of AAV9/*GDAP1* to *Gdap1*^{R191X} mice at postnatal day 7-10 or 120 with low (1.25E11vg), middle (2.5E11vg), or high (5E11vg) dose. h*GDAP1* mRNA expression was dose-dependently increased in the sciatic nerve. All mice undergo behavioral phenotyping involving hindlimb clasping, wire hang, beam walk, digigate, grip strength, and rotarod, as well as nerve conduction velocity (NCV) testing. No significant behavioral phenotypes were observed in the *Gdap1*^{R191X} mice up to 15 months of age, so although no adverse effects on the phenotypes occurred, we could not evaluate the effect of the treatment to alleviate disease-relevant symptoms. NCV test on the *Gdap1*^{R191X} mice demonstrated a decrease in motor nerve conduction velocities (MNCV), which was rescued with the AAV9/*GDAP1* treatment in a dose-dependent fashion at 13 and 19 months of age. Currently, behavioral phenotyping at older timepoints, biomarker analyses using collected sera, and histopathological examination on harvested organs and peripheral nerves are underway to further explore treatment efficacy. In summary, the cumulated data demonstrate that a single dose of IT administration of AAV9/*GDAP1* appears to be

safe and effective in correcting NCV due to GDAP1 deficiency. These results indicate a potential applicability of GDAP1 gene replacement therapy for CMT4A patients.

1674. Integrase-Deficient All-in-One Lentivector Carrying Cas9 Protein, sgRNA & Donor DNA for Directed Chromosomal Knock-Ins

Stanislav Indik, Alex Roser, Dominic Lichtscheidl, Iris Hoger

University of Veterinary Medicine, Vienna, Austria

Here we describe an integrase-deficient lentivector that contains all components necessary for site-directed insertion of viral DNA into mammalian genomes. The vector particles carry the Cas9 protein, together with the viral RNA that serves as a template for the synthesis of the donor DNA containing the transgene(s), the sgRNA-coding region and the sgRNA target site. The DNA produced from the viral RNA in the transduced cells is cleaved together with the chromosomal target site by the co-delivered Cas9/sgRNA. The cleaved DNA is then inserted into the target locus in a homology-independent manner. To prevent cleavage of the vector plasmid (containing the sgRNA target site) during lentivector production, we used an inducible sgRNAi system to control Cas9/sgRNA activity so that sgRNA is present only in the transduced cells. We show that after transduction, the lentivector DNA can be inserted into a predetermined locus in the genome of HEK293 cells. In the most extreme case, we knocked in an 8.6 kb donor containing three transgenes (mCherry, puroR, lacZ). Cultivation of the cells in a medium containing puromycin allowed the enrichment of mCherry-positive cells to >80%. We also used splice acceptor (SA)-containing promoterless donors for insertion into the intronic sites. For example, we inserted a lentivector donor DNA into the last intron of the hspa8 gene to express the HSPA8-mCherry fusion protein. The characteristic cytoplasmic localization of the red fluorescent signal in the transduced cells indicated that splicing was efficiently redirected to the SA site in the insert. The specificity of the insertions and the length of the inserts were confirmed by junction PCR and long template PCR, respectively.

1675. New *In Vitro* Models System for Treat Pitt Hopkins Syndrome

Yanina Tkachenko, Cassandra Dennys, Abuzar Kaleem, Babatunde Ogunlade, Meysam Ganjibaksh, Vera Iakovleva, Shibi Likhite, Kathrin Meyer

Gene Therapy, Nationwide Children's Hospital, Columbus, OH

Introduction: Autosomal dominant mutations in TCF4 cause Pitt-Hopkins syndrome. Pitt-Hopkins syndrome (PTHS) is characterized by intellectual disability, a marked delay in motor development, lack of functional speech and disordered breathing. Understanding upstream regulation of TCF4 expression and transcription is critical to developing therapeutic strategies. TCF4 is a basic helix-loop-helix protein that is broadly expressed especially in the nervous system. It works to regulate gene expression by interacting with other basic helix-loop-helix proteins and either allowing or repressing transcription. With TCF4 being a large gene encoding with many known protein isoforms, is a challenging target for classic gene replacement approaches. Since patients still harbor one healthy copy of the gene, upregulation of TCF4 expression is an attractive alternative approach to gene replacement. Here, we developed a novel gene therapy to enhance the TCF4 expression using an AAV-based targeted U7 small RNA to modulate TCF4 promoter activity. **Methods:** We designed multiple U7 small RNA cassettes targeting different regions of the TCF4 promoter that we predicted to be able to modulate promoter activity. We tested efficacy of the U7 cassettes via transient transfection in HEK293 cells for expression and ability to upregulate TCF4 expression. Next, we generated AAV9 viral particles and verified efficacy in an *in vitro* model system using human PTHS patient cell lines by RT-PCR and immunofluorescent imaging. Functional assays were used to determine the effect of the treatment on cellular health as well. In addition, we used mouse embryonic fibroblasts (MEFs) from a mouse model that expresses the green fluorescent protein under the human TCF4 promoter as an additional model system to further validate our approach. This mouse model will then be used to validate the technology in vivo as a next step. **Results:** We developed a U7 small RNA based technology that was designed to upregulate endogenous TCF4 expression via promoter regulation. We were able to demonstrate increased expression of TCF4 in multiple model systems including HEK293 cells and a novel human patient in vitro model. Importantly, we found upregulated TCF4 levels via RT-PCR as well as immunofluorescence staining. The increased expression of TCF4 also improved the otherwise hampered survival of co-cultured neurons in contact with patient derived induced astrocytes, providing functional evidence of treatment efficacy. Moreover, using mouse embryonic fibroblasts expressing GFP under the control of the human TCF4 promoter, we showed upregulation of GFP expression following AAV9. U7-TCF4 treatment as well in yet another model system. **Conclusion:** We developed a novel U7 small RNA based technology allowing modulating TCF4 promoter activity. Our data indicates efficacy of the approach in HEK293 cells as well as multiple reprogrammed patient cell lines and mouse embryonic fibroblasts expressing GFP under the human TCF4 promoter. Our novel therapeutic strategy is highly promising and could be advantageous over existing gene replacement strategies as it would allow to use the endogenous gene to generate all naturally occurring TCF4 isoforms instead of delivery a single transcript. Our approach could be tailored to delivery via AAV or non-viral systems. As a next step, we will verify efficacy of promoter regulation in vivo. This novel technology allows upregulation of gene expression and could become a promising novel approach for treatment of haploinsufficiencies in general.

1676. Low RT-Based Fidelity in Mouse Hepatocytes: Challenges and Solutions

Maike Thamsen Dunyak, Patrick Hanna, Angela Nan, Mollie O'Hara, Rejina Pokharel, Jenny Xie, Jonathan D. Finn

Tome Biosciences, Watertown, MA

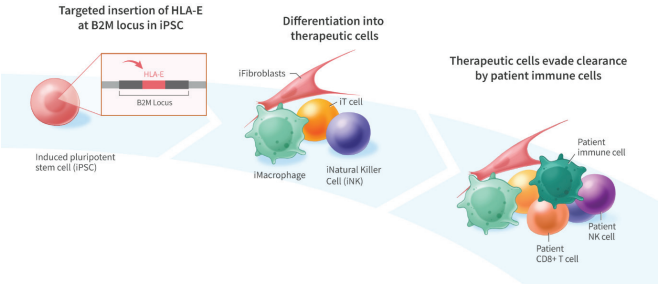
Integrase-mediated programmable genomic integration (I-PGI) utilizes the DNA targeting properties of Cas9 and couples it with the efficient, size-independent DNA integration abilities of large serine integrases (LSIs). This method enables the integration of large pieces of DNA in a site-specific, directional manner that is not dependent on double stranded breaks (DSBs). I-PGI technology can be used to develop gene

therapies for monogenic liver diseases with the potential of a single drug per disease for diseases with a heterogeneous genetic landscape. I-PGI uses a Cas9 nickase (nCas9) with a writing enzyme, such as reverse transcriptase (RT), to write an integrase target site (attB, here called a 'beacon') in a programmed location. Beacon placement (BP) requires a minimum insert length of 38bp which is significantly longer than the majority of edits currently being explored with base and prime editing (<3 bp). After multiple rounds of optimization, we were able to efficiently place beacons with good beacon fidelity (BF) in human cycling cells (HEK293), non-dividing primary human hepatocytes (PHH), and primary cynomolgus hepatocytes (PCH) using transient mRNA delivery and chemically modified attachment guide RNA (atgRNA) pairs.When translating our technology *in vivo* to mice, we observed a surprising result, that despite being able to achieve a high level of editing in mouse hepatocytes following lipid nanoparticle (LNP) delivery of the editing components, that nearly all observed edits were incorrect, leading to very low BF rates. We found that this fidelity issue was also observed *in vitro* in non-dividing primary mouse hepatocytes, was independent of mouse strain, and was also observed in primary rat hepatocytes.To address the mouse beacon fidelity issue, we took two approaches. First, we engineered transgenic mice which had intact beacons in specific locations, allowing us to optimize integrase and DNA template dosing and kinetics. Second, we hypothesized that beacon fidelity in mice is impacted by the non-dividing nature of hepatocytes and can be improved by utilizing cycling hepatocytes. Therefore, we utilized neonatal mice which have a much higher proportion of proliferating hepatocytes than adult mice. Using LNP delivery in neonatal mice, we were able to significantly increase BF. We subsequently have demonstrated that these beacons are functional and have demonstrated functional gene expression after I-PGI mediated targeted integration in a therapeutically relevant target site.In summary, we have identified a previously undescribed challenge when using RT-based editing to write long (~40 bp) sequences in non-dividing mouse hepatocytes. This issue is likely due to DNA repair pathway differences between cycling and non-cycling mouse cells and appears to be limited to rodents, as we can routinely achieve high levels of beacon placement and fidelity in both human and non-human primate hepatocytes.

1677. A Programmable Mammalian Transposon Achieves Accurate Integration of a *CFTR*$_{2\text{-}27}$ Superexon in Human Bronchial Epithelial Cells

Subhrangshu Guhathakurta, Jaclyn M. Kubala, Daniel Pers, Sharmishtha Musalgaonkar, Rupesh Naidu, Lillian Campos, Oleg Iartchouk, Joseph J. Senn, Nancy L. Craig, Joseph J. Higgins

SalioGen Therapeutics, Lexington, MA



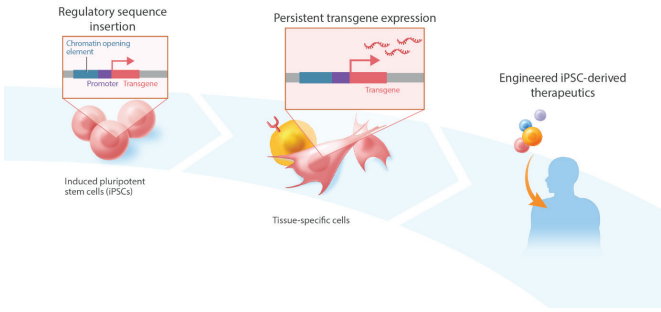
Introduction: Introducing large genes to targeted sites under endogenous regulatory control is ideal in diseases such as Cystic Fibrosis (CF). Recombination systems using DNA DSB-induced HDR have safety limitations. Partial replacement of the CF transmembrane regulator gene (*CFTR*$_{2\text{-}27}$, 4.4 kb) in intron 1 may provide a one-time, curative treatment that restores *CFTR* expression and corrects >97% of downstream mutations. We showed restoration of function using non-viral delivery of our first-generation bioengineered mammalian transposase derived from *Myotis lucifugus (bMLT)* to integrate genes in rodent livers and in retinas of mice and NHPs. The current data uses a second-generation *bMLT* designed to target *CFTR* intron 1 sequences and insert a *CFTR*$_{2\text{-}27}$ cDNA superexon. This process, called Gene Coding, achieves on-target integration, proper splicing, and adequate expression levels without the risk of adverse genomic events. **Methods:** We modified the amino acid sequence of *bMLT* using AlphaFold prediction models and cryoEM structural analyses of *bMLT* bound to DNA. We covalently fused zinc fingers (ZnF) to modified *bMLT* to interact with a recognition sequence near a preferred target site in *CFTR* intron 1 (*ZnF-bMLT*). DNA donor elements contained a splice acceptor site followed by either a GFP reporter or tagged *CFTR*$_{2\text{-}27}$, and a polyadenylation sequence. These sequences were flanked by insulators and *bMLT* terminal inverted repeats. HEK293T cells were lipofected with *ZnF-bMLT*, a *GFP* donor, and an optimized *CFTR* intron 1 landing pad plasmid (*pCFTR*) using the published "find and cut-and-transfer (FiCAT)" reporter assay to analyze targeting efficiency of three *bMLT* mutants. *pCFTR* targeting was confirmed by PCR and Illumina NGS. To assess *CFTR* intron 1-specific targeting efficiency in the human genome, published self-reporting transposon (SRT) methods were used to identify on- and off-target integrations in HEK293T cells after lipofection with an SRT donor and *ZnF-bMLT* (n=8 per group). A tagged promoterless donor (*GFP* and *CFTR-GFP* donor conditions) and *ZnF-bMLT* (n=6) was used to measure targeting efficiency. GFP expression was expected if the promoterless donor was controlled by endogenous *CFTR* regulatory elements. Targeting efficiency was estimated by the percentage of GFP positive cells using FACS and NGS. Wild-type and CF mutant (G542X) human bronchial epithelial cells (16HBE) were transfected and assessed by PCR and ddPCR for proper splicing and genomic integration. **Results:** The FiCAT reporter assay showed >60% integration at the *pCFTR* target sequence and was confirmed in HEK293T cells engineered with multiple artificial *CFTR* intron 1 genomic landing pads containing a specific target sequence flanked by *ZnF* recognition sites. Various *bMLT* mutants reduced off-target insertions by 3-to-4-fold while maintaining on-target insertion efficiency. Importantly, insertions increased in the immediate region of the *CFTR* intron 1 target site by ~100-fold in 16HBE G542X cells using *ZnF-bMLT*. Total off-target integrations decreased by >10-fold when compared to *bMLT* without ZnF fusions. These results confirmed integration in *CFTR* intron 1 of a G542X CF patient cell line using our second-generation *bMLT*. Finally, on-target integration was shown in up to 10% of transfected HEK293T cells when *bMLT* fused to two *ZnF* flanking the *CFTR* intron 1 target site was used as the targeting enzyme. **Conclusions:** The simple and efficient, single enzyme-driven Gene Coding technology presented achieves on-target insertion of the *CFTR*$_{2\text{-}27}$ superexon into the endogenous *CFTR* intron 1 with minimal off-target integrations. This technology has broad therapeutic applications in many genetic disorders that current gene therapies do not address.

1678. Targeted Insertion of HLA-E at the B2M Locus of mRNA-Reprogrammed iPSCs Facilitates the Development of Allogeneic Cell Therapies with Enhanced Safety Features

Elizabeth Belcher[1], Raven Dance Hinkel[1], Christopher B. Rohde[2], Matthew Angel[2], Kyle M. Garland[1]

[1]Eterna Therapeutics Inc., Cambridge, MA,[2]Factor Bioscience Inc., Cambridge, MA

Allogeneic cell therapies derived from induced pluripotent stem cells (iPSCs) are an exceptionally promising class of cellular therapeutic, as they can greatly reduce the manufacturing complexities of autologous and donor-derived allogeneic cell therapies such as scalability, batch-to-batch consistency, and cost. However, host immune cell recognition and clearance of exogenous cells can lead to iatrogenic toxicities and ineffective therapeutic responses. This immune rejection is often caused by CD8+ T cells recognizing foreign HLA-I molecules, while a complete lack of HLA-I expression can result in NK-mediated immune rejection (the "missing self" response). Modulation of HLA class I elements for evasion of clearance by both CD8+ T cells and NK cells has been explored as a strategy to improve *in vivo* persistence. We previously reported generation of iPSCs using an mRNA-based process that avoids the genomic integration and instability risks of DNA and viral reprogramming methods. We also previously reported a novel mRNA-encoded dimerizing gene-editing endonuclease, UltraSlice™ for high-specificity gene editing and demonstrated its use in inactivating β2 microglobulin (B2M), a key component of HLA class I molecules. Here, we report the development of an mRNA-engineered iPSC line developed using UltraSlice™ to express a B2M-HLA-E fusion transgene in lieu of the endogenous B2M gene product to mimic native B2M expression (i.e., upregulation when exposed to proinflammatory stimuli). Using UltraSlice™, we optimized the conditions for insertion of a flexible linker-containing *HLA-E* transgene upstream of the stop codon of the native *B2M* gene in mRNA-reprogrammed iPSCs. Specifically, a single-stranded DNA template encoding a $(GGGGS)_4$ flexible linker and *HLA-E* flanked by 125-nt sequences homologous to the *B2M* locus was co-delivered to iPSCs along with UltraSlice™ mRNA targeting exon 3 of the B2M gene. We found that the sequence of the flexible linker was susceptible to hairpin formation, and initial experiments resulted in insertion of a truncated sequence. We then designed and tested two new linkers with GC content reduced from 83.3% to 71.7% and 61.7% , which increased the theoretical Gibb's free energy from -6.0 to -3.92 and 0.64, respectively. We then analyzed insertion, finding no significant difference in the rate of insertion but observing successful insertion of the full repair template when using the two templates with reduced GC content. These edited populations were plated as single cells to obtain clonal mRNA-reprogrammed iPSC lines that express B2M-$(GGGGS)_4$-HLA-E fusion protein. These cells may prove useful for the rapid development of therapeutics with the potential for increased efficacy and safety owing to the immune-evasive nature of the cells.



1679. Sustained Transgene Expression in Engineered iPSC-Derived Tissue-Specific Cells

Taeyun Kim[1], Raven D. Klee[2], Ismet Caglar Tanrikulu[1], Christopher B. Rohde[1], Matthew Angel[1]

[1]Factor Bioscience Inc., Cambridge, MA,[2]Eterna Therapeutics Inc., Cambridge, MA

Induced pluripotent stem cells (iPSCs) provide an ideal starting point for the generation of gene-edited tissue-specific cells. In particular, engineered iPSC-derived mesenchymal stromal cells (iMSCs) combine the advantages of tissue-derived MSCs (immunomodulation, clinical safety, low immunogenicity, tissue penetration, etc.) with gene editing (e.g., overexpression or knock-out of immunomodulatory factors), and thus, presents a new pathway for the development of cell therapies with higher efficacy and defined modes of action. iMSCs readily overcome the clonality, viability and expandability challenges associated with tissue-derived MSCs and display greater immunomodulation even in their naive form. Engineered iMSCs (EiMSCs) that overexpress transgenic immunomodulatory cytokines could offer further therapeutic potential. Although the overexpression of transgenic cytokines in EiMSCs presents an exciting therapeutic opportunity, transgenic expression can be unstable or silenced during the differentiation of iPSCs to EiMSCs. To enable sustained transgene expression upon EiMSC differentiation, we explored the use of universal chromatin-opening elements (UCOEs) in transgenic cassettes that express green fluorescent protein (GFP) under the EF1α promoter. Cassettes with and without a UCOE were inserted into the adeno-associated virus integration site 1 (AAVS1) safe-harbor locus in iPSCs through the use of mRNA encoding UltraSlice™ gene-editing endonucleases and single-stranded DNA (ssDNA) repair templates. Clonal iPSC lines were isolated by the single-cell deposition of GFP-sorted cells, biallelic insertion into AAVS1 was verified by amplicon sequencing, and GFP expression during differentiation toward EiMSCs was monitored. EiMSC lines all displayed traditional MSC surface markers upon differentiation, but they showed differences in GFP expression: While only ~30% of EiMSCs engineered without a UCOE 6-3 were GFP-positive, use of a UCOE yielded in uniform GFP expression (>99%) that persisted after 10 passages and 2 freeze-thaw cycles. Inflammatory (e.g., IL7 and IL15) and anti-inflammatory cytokines (e.g., IL4 and IL10) are being explored for their opposing, but potentially crucial roles in MSC therapy by directing and enhancing immunomodulation and survival of immune cells to alleviate conditions such as cancer and inflammatory disease, respectively. We therefore applied our established workflow to knock-in expression cassettes encoding either IL7-IL15 or IL4-IL10 fusion proteins into

iPSCs and differentiate them to clonal EiMSC lines. Taking advantage of the high efficiencies obtained for UltraSlice™-mediated knock-ins, clonal iPSC lines were successfully established via single-cell deposition without the use of a reporter system. MSC markers and transgene expression were confirmed in each line upon differentiation, yielding two EiMSC lines that stably express IL7-IL15 or IL4-IL10 fusion proteins. These lines may prove promising in the development of therapies to treat a wide range of diseases.

1680. Site-Directed Integration of Large DNA Sequences into Endogenous Sites in the Human Genome Using Engineered Modular Integrases (MInts)

Friedrich Fauser, Sebastian Arangundy-Franklin, Jessica E. Davis, Lifeng Liu, Nicholas A. Scarlott, Nicola J. Schmidt, Rakshaa Mureli, Danny F. Xia, Luis Rodriguez, Mohammad Qasim, Vishvesha Vaidya, Sarah J. Hinkley, Bhakti N. Kadam, Nga Nguyen, Stephen Lam, Bryan Bourgeois, Adeline Chen, Andrew Nguyen, Patrick Li, David E. Paschon, Gregory D. Davis, Jeffrey C. Miller

Sangamo Therapeutics, Richmond, CA

Introduction: Programmable targeted integration (TI) of large DNA sequences into genomic loci is a highly desirable genome editing modality for development of genomic medicines, agricultural applications, synthetic biology, and basic research. Most methods rely on the induction of a double-stranded DNA break and subsequent integration of the donor via cellular DNA repair pathways such as non-homologous end joining or homology-directed repair. These methods have various limitations associated with the induction of the DNA break itself, as well as their dependency on competing DNA repair pathways. Site-specific large serine recombinases such as Bxb1 have the potential to overcome these limitations. Bxb1 catalyzes precise directional DNA recombination between its attP and attB recognition sites, without the induction of free DNA ends and therefore not relying on any cellular DNA repair processes. However, reprogramming of Bxb1, or other serine recombinases, has not yet been shown yet. To avoid the various therapeutic liabilities of oversized RNA-guiding cargo, we have taken a protein-guided approach and engineered the Bxb1 amino acid sequence directly against new genomic target sites. Here, we demonstrate that engineered Modular Integrases (MInts), derived from Bxb1, can be efficiently retargeted to endogenous sites in the human genome. **Results and Conclusions:** We first integrated the natural Bxb1 attB recognition site into the AAVS1 locus of human K562 cells and demonstrated >80% TI with wildtype Bxb1. An unbiased genome-wide specificity evaluation showed high specificity, but also identified a small number of attB pseudo-sites with detectable levels of TI (<1%). We then developed a directed evolution system to change the molecular specificity of Bxb1 in bacteria. We also established a high throughput system to validate and characterize artificial attB sequences in K562 cells. This allowed us to identify Bxb1 variants that achieved up to ~40% TI at one of the attB pseudo-sites. Encouraged by these results, we evaluated the genome-wide specificity of the most active Bxb1 variants and demonstrated improved specificity compared to wildtype Bxb1. Next, we attempted retargeting of Bxb1 to the first intron of the human AAVS1 gene, a known safe harbor site. We computationally searched for suitable target sites, and then tested them against selected Bxb1 variants. This effort resulted in >50% TI into the AAVS1 locus with minimal to no indels. We also established alternative donor delivery possibilities, such as minicircles or packaging in AAV. Taken together, we demonstrated reprogramming of Bxb1 to a gene-sized locus in the human genome without relying on other gene editing tools to pre-install a natural Bxb1 recombination site at the desired locus. We further de-risked our MInts platform by evaluating its genome-wide specificity, and establishing therapeutically relevant donor delivery strategies, thus showing potential promise for clinical applications.

1681. Metagenomic Discovery and Screening of Novel Recombinase Proteins for Targeted Integration

Joseph Neumeyer, Meng Wu, Shreya Jambardi, Amy Hengyi Zhao, Bradley Taylor, Georgia Giannoukos, Eugenio Marco, Hui Li

Editas Medicine, Cambridge, MA

Current technologies to integrate multi-kilobase (kb) DNA sequences *in vivo* are limited. Some technologies, including retroviruses or transposases, integrate into the host genome through a random manner, raising potential oncogenesis risk and other safety concerns. Other methods mediated by homology directed repair (HDR) are restricted by low integration efficiency *in vivo*, strict dependence on endogenous DNA repair machinery, and lack of feasibility in post-mitotic cells. Here, we explored site-specific large serine recombinases (LSRs) used by phages to integrate large transgenes into bacterial genomes without relying on endogenous host DNA repair machinery. First, through metagenomic data mining, we discovered thousands of potential LSR candidates and reconstructed their cognate DNA recognition sites. Subsequently, we evaluated thousands of LSRs for their efficacy and specificity for targeted integration of large transgenes into the human genome *in vivo* using high throughput functional screening, and discovered hundreds of highly potent LSRs that can integrate into the human genome with a variety of specificity and efficiency. These LSRs could build the foundation to develop novel gene editing technologies capable of knocking in large transgenes *in vivo*, therefore greatly expanding the potential of genetic medicine for more therapeutic indications.

Friday Posters: On- and Off-Target Method Development

1682. INDUCE-seq: Ensuring the Safe Development of Cell and Gene Therapies by Gene Editing

Simon H. Reed, Patrick van Eijk, Felix Dobbs
Broken String Biosciences Ltd, Cambridge, United Kingdom

Advances in genome editing are making it increasingly possible to develop new cell and gene therapies. Synthetic genes and modifications to existing ones can be made in a site-specific manner, while immune-compatible cells created for use in allogeneic patients enable production of 'off-the-shelf' cellular therapies. However, gene editing is a new way of treating disease, requiring new tools to ensure their safe and efficacious design and use in patients. Genome editing comes with risk, including malignant transformation of target cells caused by culturing cells outside the body. Gene editing can directly cause genomic instability resulting in selection for outgrowth of clones with oncogenic mutations. Furthermore, the gene editing tools themselves can cause genomic instability in the form of DNA breaks at sites other than the intended target. Such 'off-target' editing can activate proto-oncogenes, or disrupt tumor suppressors thus driving carcinogenesis. 'Off-target' mutagenesis may also generate neoantigens, triggering autoimmunity, or other types of cellular dysfunction. Furthermore, rare penetrant mutations are now known to confer severe risk of common disease, underscoring the importance of identifying 'off-target' gene editing to assess risk. More precise methods are needed for testing 'off-target' editing during all phases of therapeutic development, including post-treatment follow-up. At present standardised assays to accurately assess the precision of gene editing in cell and gene therapies are lacking. Here, we describe the development and characterization of INDUCE-seq to address this. CRISPR-Cas9-based gene editing of five well-studied genetic targets, including two that have recently been evaluated by regulators, was conducted by two independent industry partners using two different cell-types. On and off-target gene editing was assessed by measuring DNA breaks in the genome using INDUCE-seq and the genetic mutations caused by editing at these locations were subsequently measured using Duplex-sequencing, which sensitively detects rare mutations. The results of this HESI-sponsored validation study will be presented to demonstrate the reproducibility of the assays for measuring intra and inter laboratory 'on-' and 'off-target' editing, the importance of conducting this analysis in the intended cell/tissue targets and the discovery of confirmed off-target gene editing in cells at genomic locations not predictable by *in silico* analysis alone.

1683. High Throughput Single Cell Analysis Workflow for Accurate Measurement of Genotoxicity Arising from Gene Editing Experiments

Saurabh Gulati, Alex Li, Saurabh Parikh, Qawer Ayaz, Indira Krishnan, Charlie Murphy, Lubna Nousheen, Benjamin Miltz, Ben Schroeder, Shu Wang
Mission Bio, South San Francisco, CA

Conflicts of interest: S.G., C.L., S.P., Q.A., I.K., C.M., L.N., B.M., B.S. and S.W. are employees and shareholders of Mission Bio, Inc. Advances in cell and gene therapy (CGT) are transforming the way we treat and potentially cure certain diseases including cancer and rare genetic disorders. Precise gene editing technologies such as CRISPR-Cas9, TALENs, and ZFNs have transcended traditional boundaries, offering novel approaches to rectify genetic anomalies at their source. Despite these advancements, the editing process yields heterogeneous populations where some cells may have undesired outcomes that bear the risk of genome toxicity. Notably, these adverse outcomes include the introduction of structural variants, copy number alterations, or chromosomal translocations. Therefore, the development of efficacious gene therapies hinges on the ability to accurately measure and understand these events. Furthermore, since "cells" are the functional units of gene editing products, it is prudent to measure the co-occurrences of editing results and potential genotoxicity events in a single-cell context.Here, we demonstrate a microfluidics and multiplex PCR based single-cell technology that simultaneously measures the co-occurrence and zygosity of on-target edit, off-target edits, translocations between predicted edit sites, as well as the genomic CNV landscape in over 10,000 cells in parallel. Due to the single-cell resolution, the technology offers a comprehensive view of the heterogeneous editing profile of gene edited products for a proper and fast evaluation of editing outcome and potential malignant events.To evaluate the robustness of this workflow we used a variety of samples with varying levels of adverse effects occurring from multiple gene editing experiments. These samples all had orthogonal results cross validation using bulk NGS (DNA-seq) and rhAMPseq. Using a targeted sequencing panel we measured on and off target editing activity, presence of structural variations, gene editing induced translocation events and genome wide CNVs at a single cell level in these samples. The resulting data was analyzed using a novel bioinformatics pipeline which was developed to accurately measure all of these modalities simultaneously. Our high-throughput single-cell NGS assay represents a significant advancement in gene editing analysis, measuring off-targets, translocations, and genome stability in over 10,000 cells per assay. This technology has proven effective in accurately detecting a diverse range of INDELs from small (1bp) to large genomic alterations (114kbp) in as few as 0.1% of cells. Additionally, we were able to identify translocation events, pinpointing exact breakpoint coordinates even when they occur in less than 0.5% of the cell population.Alongside these capabilities, we were able to simultaneously measure allelic on-target CRISPR editing activity in each cell, providing a comprehensive view of both intended and unintended genetic modifications. This dual functionality not only aids in optimizing gene editing protocols but also offers critical insights for understanding genotoxicity caused due to gene editing experiments and the development of safe, efficacious cell-based therapeutics.

1684. End-to-End Tools and Services for Interrogation of CRISPR-Cas Associated Genotoxicity

Ellen Schmaljohn, Gavin Kurgan, Kyle Kinney, Morgan Sturgeon, He Zhang, Rolf Turk, Garrett Rettig, Ashley Jacobi
Integrated DNA Technologies, Coralville, IA

Identifying and verifying low frequencies of genomic alterations resulting from off-target editing, gRNA synthesis errors, cross-contamination, or other unintended gRNA activity is critical to preventing unexpected genotoxic effects for the gene editing therapeutic community. However, assembling the necessary components and expertise for genotoxicity characterization studies is expensive and labor intensive. To better enable the gene editing community, we demonstrate a series of tools, workflows, and services that can be leveraged to perform genotoxicity characterization of CRISPR reagents. First, we demonstrate an empirical *in vivo* tag-based off-target nomination service rooted in our RNaseH2-dependent amplification technology as a method to generate an off-target list for a target gRNA. Then, we demonstrate how outputs of this service can be fed into rhAmpSeq to identify and classify indels and chromosomal re-arrangements at on/off-target loci with increased effectivity compared to existing methods. Finally, we demonstrate a method to sensitively identify gRNA cross-contamination down to sub-0.1% gRNA contamination levels by leveraging unique NHEJ DNA repair fingerprint information of select gRNAs. Using this method, we demonstrate that editing attributable to a characterized gRNA activity can be identified at frequencies far below detection limits of canonically utilized tools, and we further use this method to characterize the ability of IDT's synthesis platform to prevent cross-contamination reproducibly. From this work, we demonstrate the importance of manufacturing processes in mitigating unintended genomic alterations and present new tooling/services to improve genotoxicity characterization in gene therapy workflows. For Research Use Only. Not for use in diagnostic procedures. RUO23-2134_001 06/23

1685. Limiting Off-Target Effects of CRISPR-Based Products- Guide RNA Sequencing by NGS

Rebecca A. Bova, Christina Kalinyak, Maggie Luce, Brianna McManus, Servane Orozco, Bradley Hasson
BioReliance Corporation (MilliporeSigma/Merk KGaA), Rockville, MD

Gene editing technologies have come a long way in the past several years and with the first product utilizing CRISPR-Cas9 being approved by the FDA in late 2023, this is likely to be an ever-growing market. These highly specific gene editors utilize a CRISPR complex which is shuttled, or guided, to the intended target sequence by a single-guide RNA (sgRNA) molecule. These molecules ensure that the endonuclease makes it to the correct location, this is done by a complementary base-pair sequence on the sgRNA to where the edit should take place (crRNA) followed by a short DNA sequence that is compatible with the specific endonuclease (tracrRNA). These complexes rely on the specificity of the guide RNA to make it to the correct location in the genome for the correct edit to occur. If the specific "on-target" base pair region is not specific and has any inconsistencies like substitutions in nucleic acid sequence, the incorrect part of the genome may be edited creating what is known as an "off-target" event with an unintended effect. These off-target events are closely monitored by additional quality control (QC) assays. To ensure that the guide RNAs and the endonuclease are shuttled to the correct place in the genome, sequence fidelity of the sgRNA is critical. Currently, sgRNA's are QC'ed using mass spec technology which can miss subtle variations in the sequence, especially at low levels. Therefore, a more sensitive means of sequence order identification is required to verify the fidelity of the sequence. Next Generation Sequencing (NGS) using short-read Illumina technology represents a method that can be used to identify sequence variation to a suitable level within the guide RNA, adding to the safety profile and reduction of off-target effects of a gene editor. NGS provides a more sensitive analysis than currently available methods as to the detection of any variants in the sequence which may be missed by analytical methods. By having a more sensitive method this could help product developers reduce the amount of off-target events helping the safety profile of these types of products which are becoming more common in the industry. In this presentation, we will discuss the development of a method using short read NGS technology for sequencing sgRNAs. Method development includes testing of multiple kits as well as sgRNAs from multiple manufacturers. Our testing includes a comparison of two different library kits to overcome the challenges of sequencing short RNA molecules- the first utilizes sequential ligation that adds a pre-adenylated adapter to the 3' end and another adapter onto the 5' end. The other kit is ligation free but incorporates a 3' poly-A tail and extra bases onto the 5' end followed by "template switching". We have seen that both of these kits work well with sgRNAs from multiple different vendors encompassing different sequences as well as different modifications. Successful sequencing of the libraries has generated complete datasets that have not detected variants due to the purity of the nature of the material used for development. During *in silico* testing, we were able to introduce a single base variant and detect it through our validated variant detection bioinformatics algorithm that can detect indels and various variants. Additional testing demonstrates that we have been able to confirm variants present within the sequences down to as little as 1% in the population. We believe that implementing the use of NGS for sequence identity along with other analytical methods would ensure high quality products with minimal off-target editing.

1686. Potency and Off-Target Evaluation of Targeted AID-Mediated Mutagenesis (TAM) Base Editor *In Vitro*

Chunyan He[1], Li Chen[1], Tiangang Yuan[1], Jingsheng Li[1], Guangyuan Xiao[1], Fengpeng Li[1], Yi Dai[2]
[1]SuZhou GenAssist Therapeutics Co., Ltd, Suzhou, China,[2]Peking Union Medical Hospital, Beijing, China

Background DMD is a progressive muscle-wasting disease caused by mutations in the gene encoding the dystrophin protein. Exon 50 skipping can target 4% of DMD patients with large deletions. Until now, there is no drug for those patients. GEN6050 is an intravenously administered DMD exon 50 skipping base editing drug. The exon 50 skipping mechanism of GEN6050 is to modify the IVS50 5'SS in the human DMD gene and result in exon 50 skipping at mRNA level. For exon 50 skipping amenable DMD patients, exon 50 skipping generate a truncated yet in-framed dystrophin protein (**Figure 1**). **Method** Normal iPSCs derived myotubes/cardiomyocytes were treated with GEN6050 for 24hrs. After 7 days drug treatment, the cells were collected for editing window or off-target evaluation. Untreated samples were used as control. Similarly, GEN6050 treated DMD iPSCs derived myotubes or purified cardiomyocytes were collected for efficacy study. **Results** The editing window of GEN6050 was defined as 10 bp upstream to 30 bp downstream of hE50-sgRNA (from +10 to -30 of hE50-sgRNA) corresponding to -24 to +36 bp of dystrophin gene IVS50 5'SS

according to the efficient editing of GEN6050 (MOI=3E5) in normal iPSCs derived myotubes. Dose dependent target site editing, and exon 50 skipping were observed. The exon skipping efficiency is highly correlated with the editing efficiency, confirmed that the exon skipping is caused by efficient DNA modification at IVS50 5'SS. Similarly, dose dependent transgene transcription, target site editing, exon 50 skipping and dystrophin protein restoration were observed in both iPSC-DMD-del51-53 (exon 50 skipping amenable) derived cardiomyocytes and myotubes (**Figure 2**). High exon skipping were observed at the MOI of 1E6 in iPSC-DMD-del51-53 derived cardiomyocytes (80%) or myotubes (90%). Consistent with high exon skipping efficiency, up to 40% (MOI=1E6) dystrophin protein immunofluorescence restoration were observed in both iPSC-DMD-del51-53 derived cardiomyocytes and myotubes, indicating that GEN6050 has the therapeutical potential for exon 50 skipping amenable DMD patients. To assess off-target of GEN6050, we identified less than 5,000 SNV or 1,000 indel sites through WGS data analysis in GEN6050-treated cardiomyocytes (only 3 overlapped indel sites among 3 replicates) with more than 30% on-target editing efficiency using non-treated sample as reference. In parallel, in silicon prediction by Cas-Offinder identified 134,849 (mismatch <= 4, <=3 DNA and RNA bulge) potential off-target sites. There are 22 overlapped sites for the WGS identified SNVs/indel and in silicon predicted sites. Then, partial (top 9 that ranked by significance with carcinogenesis) of the potential off-target sites were validated by target-NGS. No potential off-targets were found in treated normal iPSC derived cardiomyocytes. **Conclusion** In summary, GEN6050 leverages base editing activities to restore the Dystrophin protein in DMD iPSC derived cardiomyocytes/myotubes with low to non-detectable off-target risk. Our results indicate that GEN6050 can provide a potential cure for DMD exon 50 skipping amenable patients.

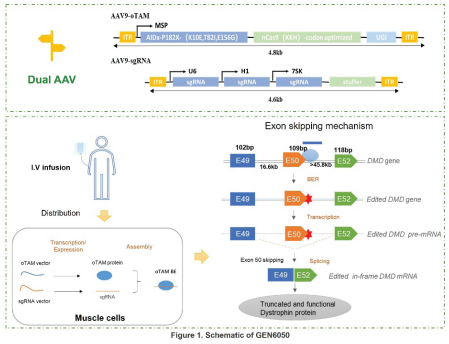


Figure 1. Schematic of GEN6050

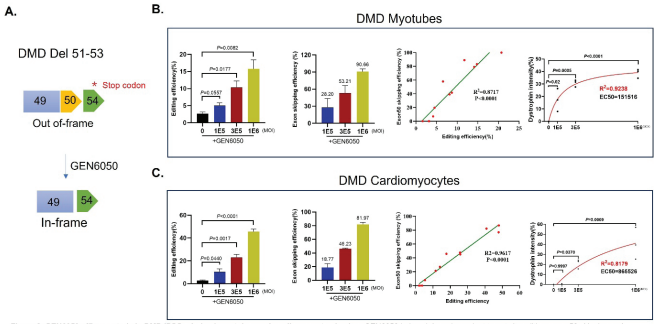

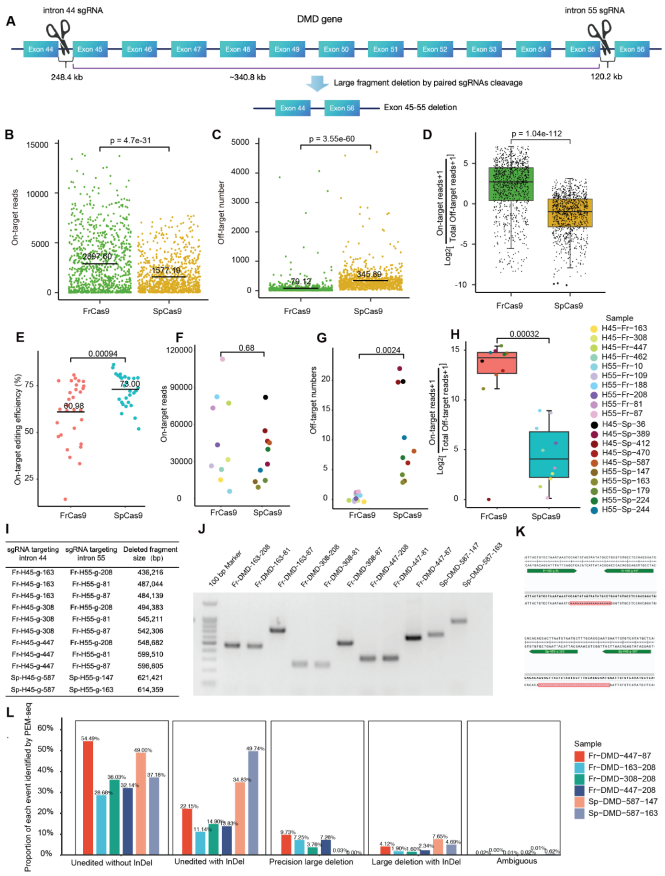

Figure 2. GEN6050 efficacy study in DMD iPSCs derived myotubes and cardiomyocytes *in vitro*. GEN6050 induced dose dependent target site editing, exon 50 skipping and dystrophin immunofluorescence intensity restoration in DMD iPSCs derived cardiomyocytes and myotubes after 7 days drug treatment. The correlation of editing and exon skipping was analyzed with Pearson correlation analysis. The dose dependent dystrophin immunofluorescence intensity restoration was analyzed with non-liner regression model. Data was presented as mean+-SEM, t-test was used for two groups comparison. *P*<0.05 is considered statistically significant. MOI indicates vg/cell.

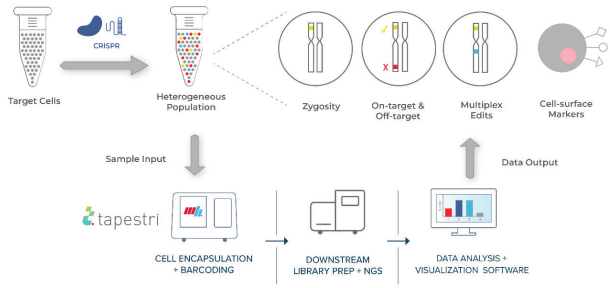
1687. AID-Seq High-Throughput sgRNA Screening Facilitates FrCas9-Mediated Large Fragment Deletion of DMD Exons 45-55

Rui Tian[1], Huabin Lin[1], Zheng Hu[2]

[1]Generulor, Zhuhai, China,[2]Women and Children's Hospital Affiliated to Zhongnan Hospital of Wuhan University, Wuhan, China

Background: Large deletions of exons 45-55 in the DMD gene treat approximately 60% of Duchenne muscular dystrophy (DMD). Current major challenge with this approach is the inefficiency of large fragment deletion and off-target effects. This problem needs to be solved from two dimensions. The first is to use a new efficient CRISPR/Cas that has lower off-target effects. The second is high-throughput sgRNA screening technology to effectively select the optimal sgRNAs that target the DMD intron 44 and 55. **Result: The cleavage efficiency of FrCas9 is equivalent to that of SpCas9, but with extremely low off-target.** We used pooled AID-seq to evaluate the cleavage efficiency and off-targets of our newly identified FrCas9 and the commonly used SpCas9 among 940 DMD sgRNAs targeting DMD intron 44 and 55. Of note, at the same sequencing depth, FrCas9 showed an average on-target read count of 2897.60, surpassing SpCas9's 1577.19 (Fig 1B). Importantly, the average number of off-target sites per sgRNA for FrCas9 was 79.12, almost an order of magnitude lower than that of SpCas9 (345.89, Fig 1C). Moreover, FrCas9 exhibited a significantly higher on:off ratio than SpCas9 (Fig 1D), confirming its enhanced specificity as well efficacy. **Further screen sgRNAs at the cellular level and confirm the high specificity of FrCas9.** We further employed amplicon sequencing and GUIDE-seq to assess on-target cleavage efficiency in vivo. The results showed that the average editing efficiency of FrCas9 in 30 sgRNAs was comparable to that of SpCas9 (Fig 1E, F). However, FrCas9 exhibited significantly fewer off-target effects compared to SpCas9 at cellular level (Fig 1F-H). No FrCas9 off-target was detected at 5 sites, and only one off-target was detected at the remaining 5 sites (Fig 2G). In contrast, SpCas9 showed significantly higher numbers of off-target sites and reads, with multiple off-targets detected per sgRNA (Fig 1F-H). **The screened FrCas9 sgRNA can efficiently and accurately delete the DMD exon 45-55 large fragment.** We further selected six FrCas9 sgRNAs and three SpCas9 sgRNAs for large fragment deletion of DMD exon 45-55. The fragment sizes deleted by paired sgRNAs are detailed in Fig 1I. The presence of small target bands resulting from large deletions of all paired sgRNAs were confirmed by the PCR (Fig 1J) and Sanger sequencing (Fig 1K). PEM-seq was further used to identify editing events by paired sgRNAs. The precise large fragment deletion efficiency of FrCas9 is as high as 9.73%, while that of SpCas9 is only 0.03% (Fig 3L). Additionally, we also calculated the proportion of large deletion accompanied by InDel, which are also useful and safe for DMD exon 45-55 deletion. FrCas9 achieved a 4.12% large fragment deletion efficiency with InDel, while SpCas9 achieved 7.65% (Fig 3L). Furthermore, no off-targets were detected for FrCas9 using the PEM-seq method. **Conclusion:** These results collectively point to the enhanced specificity and efficiency of FrCas9 in the context of large genomic edits, which is crucial for DMD therapeutic applications.



1688. Navigating Heterogeneity in Genome Editing Outcomes Using Single-Cell Analysis

Brittany Enzmann, Saurabh Gulati, Chieh-Yuan (Alex) Li, Benjamin Miltz, Qawer Ayaz, Joanne Nguyen, Shu Wang, Jacqueline Marin, Kathryn Thompson, Benjamin Geller, Benjamin Schroeder

Mission Bio, South San Francisco, CA

Genome editing has emerged as a revolutionary force within the life sciences, wielding transformative potential in applications such as cell and gene therapy development, disease modeling, and functional genomics. Despite the promise of precision of advanced genome editors, editing outcomes remain largely unpredictable. Different cells subjected to the same editing regimen can yield distinct combinations of edits, varying not only across multiple on-target sites but also between on-target and off-target locations. From the perspective of the fundamental biological unit — a single cell — the zygosity disparity (mono-allelic, bi-allelic), heterogeneity in variants (homozygous, heterozygous, compound heterozygous), and their functional impact all contribute to the layer of complexity in the mosaicism of editing outcomes. In addition, different combinations of on-target and/or off-target edits within cells may impact the function and toxicity of edited cells. Moreover, editing efficiencies in mixed cell populations may differ across cells based on cell type or state. Current genome editing analyses primarily rely on bulk methods which provide only an average editing efficiency at the allelic level of a population. The nuanced cell-to-cell variation of edits remains elusive with these traditional approaches. Here, we present compelling evidence that the Tapestri Genome Editing (GE) Solution assesses multi-omic information across 1000s of single cells with high accuracy. To evaluate the single-cell platform's performance in detecting editing events, we used a combination of orthogonally validated CRISPR-Cas9 edited clonal cell lines and pools targeting *PDCD1* and/or *TRAC* genes. Using a targeted panel design strategy for measuring on- and off-target edits, we demonstrate the detection sensitivity and specificity for indels (99.87% and 99.93%) and SNVs (98.71% and 95.27%) with a limit of detection of 0.1% (or, 1 in 1000 cells). This capability enriches the analysis for knockout (KO) and base editing (BE) experiments by providing single-cell information regarding zygosity and the co-occurrence of on- and predicted off-target edits. Additionally, immunophenotypic (cell-surface protein) analysis of edited cells reveals not only differences in editing across cell type/state but also can be used to validate knockouts of cell-surface markers. Additionally, we introduce cell hashing, a method that uses antibody-oligo conjugates (AOCs) against highly expressed cell-surface proteins to enable sample multiplexing. This capability increases the throughput of analysis while lowering reagent cost and processing time. This solution ultimately enables the assessment of cell-to-cell variation in genome editing and provides valuable insights for evaluating the safety and efficacy of cell and gene therapies.

1689. A Fully Integrated and Highly Sensitive Approach to Predicting and Measuring Off-Target Variation in CRISPR Edited Gene Therapy Products

Christopher J. Tompkins[1], Douglas Smith[2]

[1]KromaTiD, Longmont, CO,[2]SequreDx, Waltham, MA

Over the last 6 months, the guidelines and requirements for evaluation of gene therapy product have become clearer and to include the use of orthogonal methods, the effects of genetic variation across target populations, increased levels of assay sensitivity, testing on cell types from target donors, assessment of genomic rearrangements, and evaluation of biological consequence. These guidelines have been further highlighted by recent adverse event findings reported to the FDA. While the cause of these events has not yet been established, one potential cause for these findings is off-target editing. Understanding this association requires measuring all variation of any size and type in gene therapy drug products. We propose a comprehensive and integrated suite of analysis enabling the evaluation of all genomic variation induced by CRISPR editing systems including structural variants formed from recombination of edit site and off-target site double strand breaks. Inherent to our approach is a comprhensive

off-target nomination and biochemical confirmation strategy which allows us to estimate risk to the actual genomes being edited. When paired with unbiased cytogenetic methods and cytogenetic methods using sensitive DNA probes designed to the on-target and confirmed off-target editing sites it is possible to nominate, confirm and test for all edit associated variation, even the low-frequency highly heterogenous variation associated with optimized editing employed in the production of Drug Product. Beyond edit associated variation, this suite of tools can also measure phenomenon such as chromothrypsis, sub-clonal outgrowth, aneuploidy or genomic instability, that may or may not be edit related but poses a risk to patients. By combining best in class methods for nomination, confirmation and routine testing of all classes of variants, this integrated suite of tools meets the needs of guide selection, donor selection, guide characterization, drug product QC and patient testing.

1690. Quantifying Allele-Specific CRISPR Editing Activity with CRISPECTOR2.0

Nechama Kalter[1], Guy Assa[2], Michael Rosenberg[1], Ayal Hendel[1], Zohar Yakhini[2]

[1]The Institute for Advanced Materials and Nanotechnology, The Mina and Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat-Gan, Israel,[2]Arazi School of Computer Science, Reichman University, Herzliya, Israel

The detection and quantification of adverse off-target events is an important component in the field of CRISPR-Cas genome editing. A widespread approach to assessing this risk involves utilizing unbiased detection methods, such as GUIDE-seq, to identify potential off-target sites, followed by targeted amplification of the previously nominated sites (e.g. rhAmpSeq). Allele variance, namely single nucleotide variants (SNVs) or small insertions or deletions (inDels), can alternate the guide-RNA (gRNA) target site or the protospacer adjacent motif (PAM) sequence and thus drastically alter nuclease efficiency. The possible variant-dependent effects mandate precise nuclease activity quantification in an allele-specific fashion. However, currents tools which quantify CRISPR-Cas9 editing activity (EA) using next-generation sequencing (NGS) data, do not quantify editing differences associated with allele variants or are limited to previously known alleles. Hence, we have developed CRISPECTOR2.0, an extension of CRISPECTOR that supports allele-specific quantification of on- and off- target genome-editing. The computational pipeline performs *de-novo* identification of variants and allele phasing, based solely on an unedited sample, and then allocates the treatment reads to their respective alleles. Finally, the software produces an allele-specific inDel report. In addition, the CRISPECTOR2.0 version benefits from the original features developed for the previous version of the CRISPECTOR software package, including (1) precise and sensitive quantification of CRISPR EA through the utilization of a probabilistic Bayesian classifier; (2) confidence intervals (CIs) representing the statistical certainty (now also per allele); and (3) translocation detection feature. To assess CRISPECTOR2.0 performance, we have generated a novel dataset consisting of rhAmpSeq experiments, examining 40 distinct gRNAs in the HEK-293T-Cas9 human cell line. From a total of ~1,500 on- and off- target tested sites, we identified dozens of sites with allele variance, 40% of them not previously reported. Notably, in one off-target site for the gRNA targeting the *CD33* locus, an SNV in the PAM sequence resulted in one PAM-disrupted allele. The PAM-preserved allele had detectable EA (at a level of 0.1%), whereas the second allele was not edited. Interestingly, for certain alleles we detected variations in EA although the SNVs were located more than 10bps away from the cleavage site. This observation implies that EA differences may arise even in the absence of SNVs strictly within the nuclease recognition sequence, and can be attributed to other genomic factors, such as chromatin status or DNA structure. In summary, our software tool, CRISPECTOR2.0, represents significant progress beyond the current gold standard, as it enables reference-free assessment of allele-specific CRISPR-Cas9 EA. This breakthrough paves the way for a more personalized evaluation of both on-target and off-target effects, thereby enhancing the safety and precision of genome editing experiments for therapeutic applications.

1691. Nomination of Genome-Wide CRISPR-Cas9 Cleavage Activity Using rhAmp Technology

Rolf Turk[1], Kyle Kinney[1], He Zhang[1], Thomas Osborne[1], David Wang[2], Garrett Rettig[1]

[1]Integrated DNA Technologies, Coralville, IA,[2]Integrated DNA Technologies, Redwood City, CA

CRISPR-Cas9 nucleases have transformed the genome editing space because of their ease of use and programmability to create targeted double-stranded breaks. The technology has been widely adopted for basic research, in particular for loss-of-function screening applications. In experiments and applications beyond basic research, characterizing and understanding the genome-wide off-target effects (OTEs) becomes increasingly important and remains a significant hurdle. To interrogate off-target activity, many methods have been developed to empirically nominate off-target editing sites, each one with certain advantages and disadvantages. *In cellulo,* tag-based assays, such as GUIDE-seq, provide an advantage in OTE nomination due to a lower false-positivity rate compared to competing *in vitro* nomination methods. To complement GUIDE-seq, we implemented a cellular tag-based assay rooted in our RNaseH2-dependent amplification technology. The rhAmp nomination strategy allows for a high throughout workflow in 96-well plate format, increases OTE amplification, and shortens total hands-on time by implementing single-tube amplification using rhAmp technology. To compare our rhAmp nomination approach to literature precedent, published guides were used with our workflow and compared to sites nominated by GUIDE-seq. Upon identification of OTEs, rhAmp nomination was able to nominate the highest number of OTEs, which enables the design of rhAmpSeq multiplex targeted amplification pools for downstream confirmation studies. We use this opportunity to report the comparison of methods through identification of sites driven by our rhAmp nomination and confirmation of editing with rhAmp amplicon sequencing methods.

1692. Hybrid Deep Learning Approach to Predict guideRNA Editing Efficiency with Low Volume and High Dimensional Data

Rakesh Kappagantu, Pavan Kodamanchili, Nikhil Panchal, Shamik Mitra, Rohini Kalvakuntla, Shoko Iwai, Poulami Chaudhuri

Helex, Inc., New York, NY

The advent of sophisticated gene-editing technologies such as CRISPR/Cas has enabled a plethora of applications including its use in therapeutic settings. CRISPR/Cas9-based editing starts with DNA breaks at the target site complementing the designed Cas9-guide RNA (gRNA) sequence. However, selecting optimal gRNAs for efficient gene editing out of the pool of multiple gRNAs remains a major challenge due to the complexity of parameters affecting the editing efficiency. As a result, machine learning methods have been used to construct tools that predict gRNA activity and help select the optimal ones. Although these tools have advanced significantly, their performance and accuracy remain questionable.Due to the lack of significant publicly available data concerning gRNA activity for CRISPR/Cas9, common issues such as small sample sizes, poor representativeness, data leakage, and/or overfitting issues lower the effectiveness of data-driven solutions. To create an improved tool predicting gRNA's activity, we developed HelexOn, a new hybrid deep learning model for precisely detecting gRNA activity trained on low volume, high dimensional data. Both stacked attention-based multilayer perceptron MLP units (CNN-Att-MLP) and stacked 1D convolutional neural network (1D-CNN) blocks were included in HelexOn. To extract features from the input sequences, we first employed the 1D CNN layer. The average pool layer then assisted in reducing the dimensionality of the features that the 1D CNN had extracted, thereby conserving the crucial information that fastened the model's computational time. Focusing or emphasizing on features that are essential for outcome prediction was made easier by the attention layers. Dropout layers kept the model from overfitting due to low data availability. HelexOn demonstrated a remarkable performance on both training and testing datasets.To generalize and evaluate the effectiveness of our HelexON model, we tested it on publicly available CRISPR/Cas9 edited datasets from different cell lines, including HeLa, HCT116, RPE-1, A375, HL60, KBM-70, HEK293T, Mouse-EL4, MOLM13 and on Endogenous site on K562, HEK293 and Human Embryonic stem cells (H1). We also tested twelve published prediction models for cleavage activities of gRNAs on the above datasets and compared the performance using the Spearman Correlation between the predicted and actual output values as a metric. HelexON demonstrated comparable performance to existing top predictors even with a smaller training dataset. As more data is generated in the future, hybrid deep learning models such as HelexON will significantly outperform shallow neural networks. Such superior models help in precisely predicting gRNA efficiency and advancing the development of CRISPR/Cas9-based gene therapies.

1693. Comprehensive Safety Analysis Using Spatial Genome Organization Data Assures Long Term Safety of Gene Editing

Shoko Iwai[1], Shamik Mitra[1], Nikhil Panchal[1], Kuljeet Sandhu[2], Rakesh Kappagantu[1], Pavan Kumar Kodamanchili[1], Rohini Kalvakuntla[1], Poulami Chaudhuri[1]

[1]Helex, Inc., New York, NY,[2]Biological Sciences, IISER, Mohali, Mohali, India

CRISPR-Cas technology is promising in providing targeted gene editing for therapeutic outcomes. Careful assessment is necessary to ensure its safety as it advances toward clinical applications involving permanent modifications in the genome. Our understanding of how the editing and potential off-targets interact with other vicinity regions in the genome and their consequent short- and long-term effects are under-explored. Recent studies showed the three-dimensional (3D) spatial organization of chromatin in tissues and cells plays a critical role in gene regulation and function. In our previous study, we demonstrated the proximity between on- and off-targets and between off-targets are associated with CRISPR off-target events and translocations. Here, we assessed guide RNA safety for a kidney target by using tissue- and cell-specific 3D spatial organization data. First, target (kidney) and off-target (liver) tissue and cells were identified based on the in vivo non-viral LNP vector biodistribution assay, and corresponding spatial genome data (Hi-C) were retrieved from public repositories such as ENCODE. About 200 primary off-targets were identified based on sequence similarity, chromatin accessibility, and corresponding gene expression at the targeted tissue (kidney) as potential sites that could be edited unintentionally. Over 1,000 secondary off-targets were identified based on the proximity to the target or primary off-targets in the 3D genome space. To assess the risk associated with the off-target sites and assess the safety of the gene editing apparatus, the following steps were performed. Off-target sites were first annotated by locational information (exon, UTRs, intron, intergenic, splice junction, or deep intronic), then searched for any known regulatory elements (miRNA, lncRNA, promoter, enhancer, TF binding, or CTCF binding). For the regulatory elements, the number of genes that the region affects was also examined. Known clinical significance was searched with the corresponding tissue context in ClinVar (https://www.ncbi.nlm.nih.gov/clinvar/). Potential association with cancer was assessed by searching annotated genes of the off-targets against onco- and tumor suppressor genes in the COSMIC database (https://cancer.sanger.ac.uk/cosmic), cancer-related structural variants and fusion genes in the Mitelman database (https://mitelmandatabase.isb-cgc.org/), known chromatin remodeling genes, and known fragile sites. The CRISPR-mediated structural variant risk was assessed by comparing sequence homology and 3D proximity of the sites between target, off-target, and fragile sites. Rare variants were also searched against the gnomAD database (https://gnomad.broadinstitute.org/). An over-representation analysis was conducted to assess pathway-level effects of the primary- and secondary- off-targets. Finally, safety score was calculated for each category and overall safety was evaluated. Considering 3D spatial genome organization in a tissue and cell-specific manner provided a comprehensive view of potential functional and long-term effects as a consequence of CRISPR edits. This approach is essential in developing precision medicine to deliver safer gene editing therapy.

1694. ONE-seq for Variant-Aware Therapeutic Guide Selection

Douglas R. Smith, Alyssa Ferreira, Ashley Lester, Shankar Shankaracharya, Ravindran Ravindran, Vijetha Vemulapalli, Andrew Hollinger, Thomas E. Mullen
SeQure Dx, Inc., Waltham, MA

Choosing a guide RNA with the lowest off-target impact across human populations for therapeutic CRIPSR gene editing is a challenging task. Computational tools for selecting candidate guides can provide rapid results, even across multiple genomes, but their algorithms are unable to accurately predict off-target editing efficiency. Biochemical methods, on the other hand, are able to quantify off-target editing but are limited in their ability to assess population-scale variation. Here, we present an application of the ONE-seq assay (Oligonucleotide Enrichment and Sequencing) for guide selection to identify guides with the lowest potential off-target risk. ONE-seq leverages both computational and biochemical components for a highly sensitive screen of candidate off-target sites across thousands of genomes. The in vitro cleavage data are augmented with biological annotation of off-target sites and classification of ONE-seq scores to enable prioritization of high scoring sites by impact. We applied ONE-seq in a variant-aware manner to identify *in vitro* off-target sites across global human populations for three therapeutically relevant guide RNAs targeting the PCSK9 gene. Comprehensive ONE-seq libraries were generated including sites with up to 6 differences relative to the on-target site that were identified by screening the HG38 reference sequence and over 4000 genomes from the 1000 Genomes and Human Genome Diversity Project data sets. Candidate off-target sites were identified by ONE-seq analysis and classified into multiple tiers based on their ONE-seq editing score and combined annotation concern score. The latter was based on functional annotation including proximity to the on-target sequence, variant effect prediction for a 2-base deletion, genetic constraint (tolerance to loss-of-function variation), potential gene expression impact (ENCODE elements, LncRNAs, and GTEx tissue-specific expression profiles for genic sites), and finally cancer and disease gene hits with associated inheritance information. Of the three guides, PCSK9-1 had by far the lowest number of sites with ONE-seq scores above 0.001 (43 out of 505,370 sites screened) including the lowest number of disease genes with dominant inheritance (2), cancer genes (1), and sites on the same chromosome (0). Of those high scoring sites, two (with ONE-seq scores of 0.15 and 0.002) represented variant off-target sites with high global allele frequency (26% and 17%, respectively) and elevated editing of the variant allele (874-fold and 68-fold, respectively). These variant sites represent multiple alleles of a single gene - ENSG00000232325 (a LncRNA of unknown function) that is expressed at significant levels in reproductive tissues and whole blood, based on GTEx data. This approach has the potential to improve the safety and reliability of guides for therapeutic CRISPR gene editing.

1695. SAFER-Detection for Efficient Interrogation of Rearrangements in Gene-Edited Human Cells

Hongyao Yu, Shankar Shankaracharya, Ricardo Petroni, Vijetha Vemulapalli, Douglas R. Smith
SeQure Dx, Inc., Waltham, MA

Gene editing therapy utilizing programmable nucleases shows great promise for treating genetic diseases, yet its progress is impeded by the risk of off-target editing. An essential criterion for evaluating human genome editing drug products involves the thorough examination of genomic integrity. This comprises the assessment of chromosomal rearrangements, large insertions or deletions, integration of exogenous DNA, and the potential for oncogenicity or insertional mutagenesis. In this study, we introduce Selective Amplification for Efficient Rearrangement Detection (SAFER-detection), a tagmentation and next-generation sequencing based method designed to enable quantitative detection of chromosomal rearrangement breakpoints with single base resolution, which is capable of classifying rearrangements resulting from on-target and off-target editing by programmable nucleases such as CRISPR/Cas and TALENs. SAFER detection using Cas9 with a CCR5 guide RNA readily identified intra-chromosomal deletions, insertions, and inversions between the on-target site (CCR5) and off-target or homologous sites in a nearby homolog (CCR2). Inter-chromosomal translocations between the CCR5 target site and off-target sites on chr1 and chr13 were also captured, and further validated by PCR. SAFER detection exhibits high sensitivity in detecting intra-chromosomal and inter-chromosomal aberrations mediated by off-target activity or by homologous recombination, and is applicable to samples containing low cell numbers. When combined with a sensitive off-target nomination technology such as ONE-seq, SAFER detection provides a valuable method to assess the risk of chromosomal rearrangements in therapeutic genome editing.

Friday Posters: Gene Targeting and Gene Correction New Technologies

1697. Genome Integrity Assessment by Optical Genome Mapping for Research in Cell and Gene Therapy Applications

Alexander Chitsazan, Joseph Estabrook, Andy Wing Chung Pang, Alex Hastie, Alka Chaubey
Bionano, San Diego, CA

Many cell lines and manufactured cell-based products are used in research, such as transformed cell lines for constitutional and oncological research. Cells in culture, or cells that have undergone gene editing can lose genome integrity, often seen as structural and numerical abnormalities, which can result in improper function and even transformation to malignancy. QC methods are critical to identify potentially detrimental events. While karyotyping is used for detecting large-scale DNA rearrangements, it misses many events due to its low clonal sensitivity, low resolution, and dependency on size. Additionally, PCR and targeted sequencing can characterize small variants but are

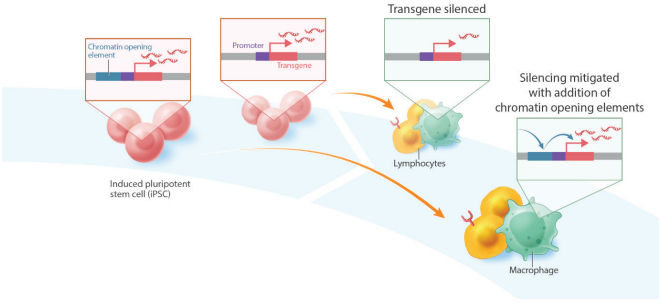
not sensitive to off-target or most structural genomic variants. Finally, while whole genome sequencing can identify small variants genome-wide, it has limited sensitivity with structural variants (SVs) at low variant allele fraction (VAF). Optical genome mapping (OGM) is an unbiased, genome-wide, high-resolution approach that can be used as a single assay alternative to multiple cytogenetic techniques to get a comprehensive view of the genome. To spot clonal variants, 400 Gbp of data is collected from the edited and control samples. A de novo assembly is then constructed, and SVs are called. Afterward, a dual variant annotation pipeline can be used to call differences between the edited and control samples. Alternatively, to discover somatic SVs down to VAFs of 5% or approximately 1% VAF, one can generate 1.5 or 5.0 Tbp of data. Here, a series of in silico simulations was performed to examine the limit of detection of OGM at deep coverage (5.0 Tbp), and the SV analysis workflow was run to detect variants at different known VAFs, down to 1%. The resulting data showed sensitivity to detect at ~1% VAF deletions >50 kbp, insertions >20 kbp, duplications >100 kbp, and translocations. Here, the clonal and somatic workflows were applied to verify the integrity of genomes after cell line immortalization, induce pluripotency, transgene-integration, and gene-editing. This data proves the effectiveness of OGM as a comprehensive solution for genome modification and integrity QC.

1698. Cell-Specific Genome Editing Using Receptor-Targeted Virus Like Particles

Surapathrudu Kanakala[1], Melissa Moy[1], Christopher Ziegler[2], Gopal Naik Nenavath[1], Stephen J. Russell[2]

[1]Imanis Life Sciences, Rochester, MN,[2]Vyriad, Rochester, MN

Clustered regularly interspaced short palindromic repeats (CRISPR)-Cas (CRISPR associated proteins) technology has accelerated the development of gene editing therapies. Enveloped viral and nonviral vectors have shown great promise for delivering CRISPR reagents to ex vivo cultured target cells. However, a major goal for future gene editing protocols is to develop vectors that can directly deliver Cas nucleases with associated guide RNAs to hematopoietic stem cells (HSC) in vivo. Retroviral and lentiviral VLPs (Virus-Like Particles) have recently emerged as attractive vehicles with which to target the delivery gene editing nucleases along with guide RNAs. Here we report the use of our novel VSV-G protein targeting technology to achieve receptor-specific delivery of gene editing ribonucleoprotein complexes using engineered lentiviral VLPs. Untargeted, EGFR targeted and cKit-targeted lentiviral VLPs were generated, each incorporating a Gag-Cas9 fusion protein bound to a single guide RNA targeting the start codon of the DEAD-box helicase 3 (DDX3). Receptor-targeting of the VLPs was achieved by pseudotyping them with VSV-G proteins that had been mutated to destroy their LDL receptor binding activity and further engineered to display epidermal growth factor (EGF) or stem cell factor (SCF) ligands as N-terminal fusions. These retargeted VLPs were shown to specifically deliver their payloads into EGFR-positive or cKit-positive K562 cells (respectively). Deep sequencing (>10,000 reads) of PCR products encompassing the DDX3 target site was used to estimate the efficiency of targeted gene editing of the DDX3 start codon in the transduced K562 cells. On-target editing was readily detected in EGFR-positive, cKit-positive and parental K562 cells transduced with the nontargeted VLP (~18% of reads in each case). In contrast, on-target editing following transduction with the EGFR-targeted VLP was detected exclusively in the EGFR-positive K562 cells (16% of reads). Similarly, on-target editing following transduction with the cKit-targeted VLP was detected exclusively in the cKit-positive K562 cells (79% of reads). Our findings demonstrate the feasibility of achieving cell-specific genome editing through the utilization of receptor-targeted VLPs and highlights their prospective future application for in vivo cell-specific gene editing.



1699. Chromatin Opening Elements Mitigate Silencing of Transgenes During iPS Cell to Macrophage or Lymphocyte Differentiation

Claire Aibel, Abigail Blatchford, Christopher B. Rohde, Matthew Angel

Factor Bioscience Inc., Cambridge, MA

Induced pluripotent stem cell (iPSC)-derived therapies hold potential for increased scalability, broader accessibility, and superior production of genetically identical cells compared to traditional allogeneic approaches. Clonal populations of immune cells expressing therapeutic transgenes can be generated from gene-edited iPSCs. Synthetic promoters are often paired with such transgenes, as they can drive high levels of protein expression and avoid genomic disruption associated with the use of endogenous promoters. However, synthetic promoters can become silenced during differentiation or, conversely, induce expression above a therapeutic range. Therefore, there is a need to engineer regulatory elements that can withstand differentiation and drive clinically relevant levels of a desired protein in multiple therapeutic cell types. We designed novel sequences consisting of a synthetic promoter, EF1α or SFC, and an upstream ubiquitous chromatin opening element (UCOE). We generated iPSC lines containing a GFP reporter under EF1α alone, EF1α with a UCOE (uEF1α), or SFC with a UCOE (uSFC) inserted into the AAVS1 safe harbor locus. The iPSCs were differentiated via static culture into lymphocytes (CD7+) or macrophages (CD14+, CD33+), which displayed expected surface marker expression. We found that uEF1α, compared to EF1α alone, promoted not only higher baseline GFP expression levels in both iPSCs and differentiated cells, but also less differentiation-induced silencing. In iPSCs, the percentages of GFP+ cells were similar (EF1α = 97.9%, uEF1α = 98.1%), but median fluorescence intensity (MFI) among the GFP+ cells was 1.6-fold higher under uEF1α than under EF1α. In the iPSC-derived lymphocytes, the percentage of GFP+ cells was 36.5-fold higher under uEF1α (73%) than under EF1α (2%). Comparison of GFP expression before and after differentiation to lymphocytes indicated that 96% of EF1α cells, but only 25% of uEF1α cells, underwent silencing. Of the GFP+ lymphocytes, the MFI was 7.5-fold higher under uEF1α than under EF1α. In the iPSC-derived macrophages, the percentage of GFP+ cells was 13-fold higher under uEF1α (78%) than under EF1α (6%). These data indicate that, during differentiation to macrophages, 92% of EF1α cells, but only 20% of uEF1α cells, underwent silencing. Of the GFP+ macrophages, the MFI was 2.1-fold higher under uEF1α than under EF1α. Furthermore, we found that the addition of a UCOE did not confer constitutively high gene expression but rather could be modulated through promoter selection to achieve clinically relevant expression levels. uSFC iPSCs were differentiated in parallel with the uEF1α iPSCs into macrophages. The percentage of GFP+ macrophages under uSFC was 17% (compared to 78% under uEF1α), and among the GFP+ population, the MFI was

4-fold higher under uEF1α than under uSFC. These results suggest that pairing a UCOE with a weaker promoter, such as SFC, could be beneficial when lower transgene expression is desired. In summary, we demonstrate novel UCOE-containing regulatory sequences that mitigate silencing during differentiation of iPSCs into lymphocytes or macrophages. These sequence elements may prove useful in engineering cells with functional transgenes encoding therapeutic proteins, and could contribute to the development of effective engineered iPSC-based therapies.

1700. Efficient Ex-Vivo Selection of Gene Edited Hematopoietic Stem Cells by Leveraging on Artificial Transactivators and Lipid Nanoparticle-Mediated Delivery

Samuele Ferrari[1], Martina Fiumara[1], Daniele Canarutto[1], Angelica Varesi[1], Luisa Albano[1], Chiara Gaddoni[1], Erika Zonari[1], Angelo Amabile[1], Angelo Lombardo[1], Bernhard Gentner[1], Pietro Genovese[2], Luigi Naldini[1]

[1]SR-TIGET, Ospedale San Raffaele, Milan, Italy,[2]Dana-Farber Cancer Institute, Boston, MA

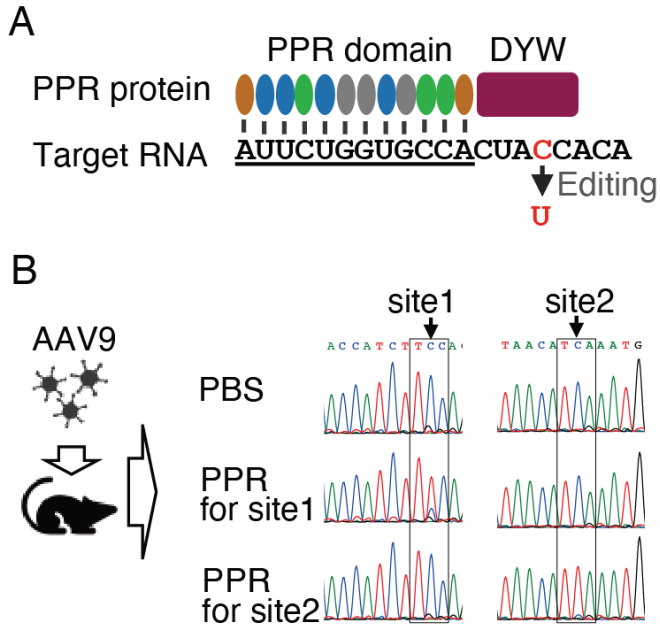
Hematopoietic stem/progenitor cell (HSPC) gene editing by homology directed repair (HDR) holds the promise of precise, targeted integration of a therapeutic transgene in genomic safe harbor loci or *in situ* gene correction of disease-causing genes. However, several hurdles have hindered clinical translation of these strategies in HSPCs, including: i) low HDR editing efficiencies in the rare fraction of long-term repopulating HSPCs; ii) toxicity and loss of stemness potential upon delivery of editing components and ex-vivo culture; iii) safety concerns related to frequent occurrence of unintended, potentially genotoxic, repair outcomes at the nuclease on and off target sites. Here, we tackled these limitations by combining a novel enrichment strategy for HDR-edited HSPCs, clinically compliant culture conditions supporting HSPC expansion, and optimized lipid nanoparticle (LNP)-mediated delivery of RNAs. To enrich for a pure population of HDR-edited HSPCs, we designed a Selection by Means of Artificial Transactivators (SMArT) strategy based on HDR donor templates comprising a selector gene, whose expression is conditional to precise on-target integration and confined to a limited ex vivo processing window. Basal expression of the selector was nearly undetectable given the presence of only a minimal promoter in the template and was induced to actionable level upon transient mRNA delivery of an ArT that binds the genome nearby, but outside, the homology region. This strategy enriched the HSPC product to >80% HDR-edited alleles. Transactivation efficiency, however, was halved in the most primitive HSPCs, suggesting lower permissiveness of this subset to ArT delivery and/or transcriptional activation of the edited locus. PCR drop-off assays on hundreds of single colonies derived from sorted and bulk edited HSPCs confirmed that >95% of the clonogenic, enriched HSPCs carried the intended HDR edit. Moreover, SMArT efficiently purged out HSPC clones bearing on-target long-range deletions from the positive fraction, alleviating the safety concerns related to genotoxic byproducts of editing. Xenotransplantation of SMArT-enriched HSPCs resulted in fully HDR-edited grafts, albeit to a lower human chimerism compared to a control group receiving the same number of bulk unselected cells. As expected by design, selector expression was no longer detectable in the xenografts. By leveraging on a clinically compliant protocol for HSPC culture, and improved LNP-mediated co-delivery of Cas9 nuclease and editing enhancers, we then achieved improved preservation of phenotypically primitive HSPCs and higher HDR efficiency prior to enrichment, further increasing the yield of selectable HSPCs. We anticipate that the combination of SMArT enrichment strategies, optimized culture conditions, and harmless delivery modalities may overcome current limitations and concerns of HDR editing, facilitating its clinical translation.

1701. Precision Editing of PLNR14del Mutation Using a Self-Inactivating, All-in-One AAV Vector to Rescue PLN-R14del-Associated Cardiomyopathy

Emma Xu, Max Levine, Uma Lakshmanan, Melissa Van Pell, Laura Lombardi, Amara Greer-Short, Kathryn Ivey, Timothy Hoey, Huanyu Zhou

Gene Therapy, Tenaya Therapeutics, South San Francisco, CA

The *Arg14del (R14del)* mutation in the *Phospholamban* (*PLN*) gene is a common genetic cause of familial dilated or arrhythmogenic cardiomyopathy. *PLN*'s role negatively regulating sarco/endoplasmic reticulum Ca2+-ATPase (SERCA) in cardiomyocyte calcium homeostasis is disrupted by the *R14del*mutation, leading to both super-inhibition of SERCA activity and PLN protein aggregation. *PLN-R14del*-associated cardiomyopathy has a poor prognosis, high adolescent mortality, limited therapeutic options other heart transplantation, and no therapies that address the underlying genetic cause of the disease Genome editing, particularly with the CRISPR-Cas9 system, has opened avenues for modifying genes associated with genetic disorders, ushering in a potential era of curing and preventing human genetic diseases. *In vivo* delivery of CRISPR-Cas9 components holds promise for treating *PLN-R14del*-associated cardiomyopathy by specifically addressing the *R14del* mutation. Indeed, we previously demonstrated the efficacy of this approach in the *PLN-R14del* mouse model, using an All-In-Oneadeno-associated virus (AAV) vector. However, a significant challenge in gene editing applications is the immunogenicity arising from the bacteria-originated gene editing machinery, along with concerns about off-target events. This becomes pronounced when employing an AAV vector for genome editing, as it results in the continuous expression of the therapeutic transgene, unlike other gene editing methods, such as lipid nanoparticles (LNPs) with only transient expression. Our approach grapples with the distinct challenge of prolonged transgene expression through the AAV vector. To overcome this challenge, we designed a Cas9 self-inactivating editing



system, that achieves high editing efficiency even with transient Cas9 protein expression. We have developed a gene therapy utilizing a single AAV vector to deliver both a self-inactivating Cas9 and *PLN-R14del*-specific sgRNA. Initial testing in patient-specific human induced pluripotent stem cell (iPSC)-derived cardiomyocytes demonstrated precise and efficient editing of the *PLN-R14del* allele without affecting the wild-type *PLN*allele. Further testing in a mouse model at various doses revealed a rescue of heart function in *PLN-R14del* mice to near wild-type levels, along with a significant prolongation of survival. Notably, these positive effects were observed even at low doses in the range of E13 vg/kg with near-complete inactivation of the Cas9 enzyme by four weeks post-viral administration. These preclinical results suggest that *PLN-R14del* gene editing holds promise as a therapeutic approach for *PLN-R14del*-associated cardiomyopathy.

1702. Efficient *In Vivo* C-to-U RNA Editing Using Pentatricopeptide Repeat (PPR) RNA-Binding Proteins

Yusuke Yagi[1], Masaru Ota[1], Takayuki Tamai[1], Mizuho Ichinose[1], Bernard Gutmann[1], Takahiro Nakamura[2]

[1]EditForce, Inc., Fukuoka, Japan,[2]Kyushu University, Fukuoka, Japan

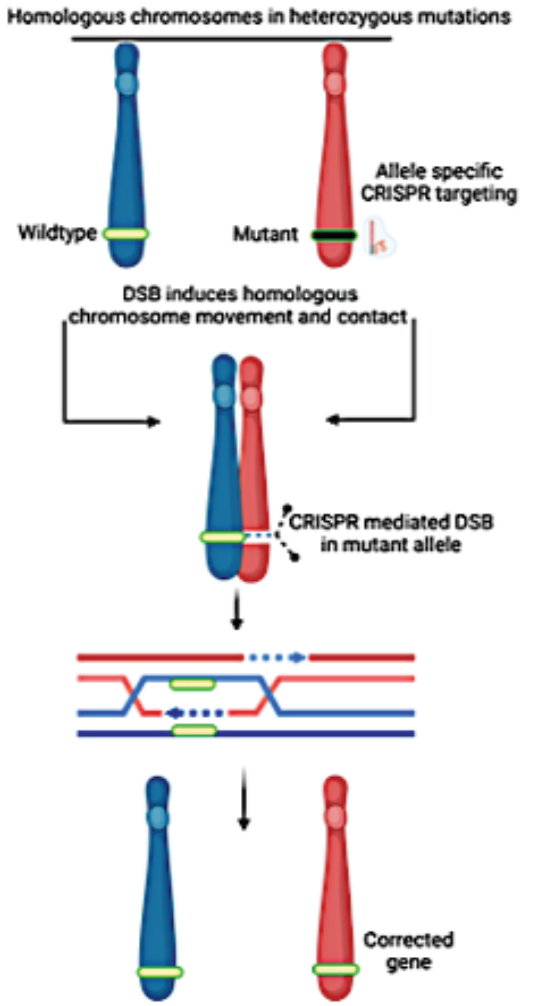
The development of RNA base-editing technologies has predominantly focused on ADAR-mediated A-to-I substitutions. However, efficient *in vivo* C-to-U editing remains relatively undeveloped. Our research pioneered this by harnessing pentatricopeptide repeat (PPR) proteins, which are involved in C-to-U RNA base editing in plants. PPR proteins, characterized by their tandemly repeated PPR motifs, recognize RNA sequences in a manner dictated by a unique PPR code that links specific amino acids within each motif to the corresponding RNA nucleotides (Fig.A). The C-terminus of PPR proteins lies in a domain known as the DYW domain, which resembles deaminase. This domain is known for its role as a C-to-U RNA-editing enzyme in plant chloroplasts and mitochondria. This understanding of the functional structure of PPR proteins provides a scaffold for designing artificial C-to-U RNA-editing enzymes to enable targeted and precise RNA modifications. To develop artificial base-editing enzymes (PPR-editors), we initially analyzed various PPR motif sequences to understand their RNA-binding characteristics. This led to a methodology for designing PPR proteins capable of specifically and accurately binding to various target RNA sequences. Subsequently, we identified a highly active DYW domain in the plant PPR protein family. To evaluate our technology, we designed multiple PPR editors targeting the mouse *Gapdh* gene and assessed their RNA editing efficiency in Hepa1-6 cells. This assessment revealed that up to 40% of the target sites were successfully modified by our PPR editors.To measure the *in vivo* RNA editing activity of the PPR-editor, we incorporated PPR-editor genes into an AAV9 viral vector and systemically administered them to mice. Two months after administration, we isolated total RNA from various organs to measure editing activity. Remarkably, over 70% of the target RNA underwent editing in the muscle tissues, including the gastrocnemius, tibialis anterior, and heart (Fig. B).These findings underscore the potential of our designed PPR editors, delivered via AAV vectors, to achieve high-efficiency RNA editing, heralding a promising avenue for gene therapy. Although the efficacy of PPR technology in editing RNA across different organs remains to be fully ascertained, optimizing the serotype and administration methods could potentially enable targeted delivery of the PPR gene to specific organs.

1703. Systemic AAV-Delivered Base Editing of ACTA2^{R179H} Improves Pupillary Smooth Muscle Cell Contraction in Mice: A Promising Target Engagement Biomarker to Predict Clinical Efficacy

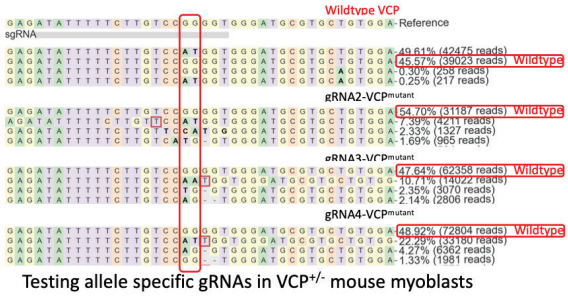
Claire Elyse Fong[1], Elyssa Alber[1], Shruti Gajjar[1], Vijai Krishnan[1], Sabya Das[1], Kangsan Roh[1,2], Christiano Alves[1], Shuqi Yun[1], Lauren Fox[1], Leillani Ha[1], Hannah Stutzman[1], Benjamin Kleinstiver[1,2], Casey Maguire[1,2], Mark Lindsay[1], David Chung[1,2], Patricia Musolino[1,2]

[1]Massachusetts General Hospital, Boston, MA,[2]Harvard Medical School, Boston, MA

Introduction**:** A missense variant in the gene encoding the smooth muscle specific actin isoform α-SMA (ACTA2) at arginine 179 (most commonly replacement by histidine) causes one of the most severe forms of vascular disease and a multisystemic smooth muscle dysfunction syndrome (MSMDS). Children with the disease suffer recurrent strokes, aortic dissections, and death in the first 2 decades of life. Since first described in 2010, most patients can be diagnosed soon after birth by identification of congenital mydriasis (fixed pupillary dilation) caused by loss of smooth muscle cell (SMC) contractility due to the mutant α-SMA. While the ocular phenotypes remain understudied, we have previously shown that gene correction by AAV-delivered CRISPR/Cas base editors can restore vascular function and prevent early neurodegeneration and death in a mouse model of the disease. Here, we studied SMC function in the eye of the mouse and its response to treatment. Methods**:** We have developed a knock-in murine model of MSMDS in which a Cre-inducible mutant allele (*ACTA2*$^{R179H/fl}$) is expressed in heterozygosity once activated by a Cre recombinase driven by the smooth muscle cell (SMC)-specific *Myh11* promoter,



which faithfully recapitulates the human disease. To investigate *in vivo* gene editing mediated by AAV capsid in mice, we customized a Cas9-directed adenine base editor (ABE) and injected mice retro-orbitally at P3 with both AAVPR and AAV9 vectors packaging the VRQR-ABE8e-pegRNA in a split intein design. We imaged the eyes of control, untreated mutant, and AAV9- and AAVPR-treated mutant mice at 8 weeks of age using a Basler imaging system consisting of a high-resolution camera, infrared illumination, and red LED light to observe pupillary reaction to light stimulus. Videos of the eye were captured and resting pupil diameter, degree of pupillary constriction at light stimulus, and degree of recovery dilation after the removal of stimulus were quantified. Results**:** We found that control mice have reliable and quantifiable pupillary reaction to light stimulus while ACTA2^{R179H} mutants showed large, dilated pupils with little to no response. Remarkably, eight weeks following injections, 80% of both AAVPR- and AAV9-treated mice showed decreased resting pupillary diameter resembling that of control mice. Pupillary constriction to light, a direct biomarker of restoration of α-SMA function and therefore SMC contraction, was restored in 60% of AAVPR- and 80% of AAV9-treated mice. These results demonstrate that AAV is capable of transducing SMC in the iris following systemic intravenous delivery and significantly restoring SMC contractility following gene editing. Conclusions**:** Mydriasis and pupillary nonreactivity are hallmarks of MSMDS in humans. Assessment of pupillary response to light, a non-invasive biomarker of SMC target engagement, could guide future clinical studies. Future studies in the mouse model of ACTA2^{R179H} MSMDS will focus on correlating ocular phenotypes to functional and histological analysis of vascular disease and neurodegeneration, which may help identify direct dose-response correlations in their treatment.

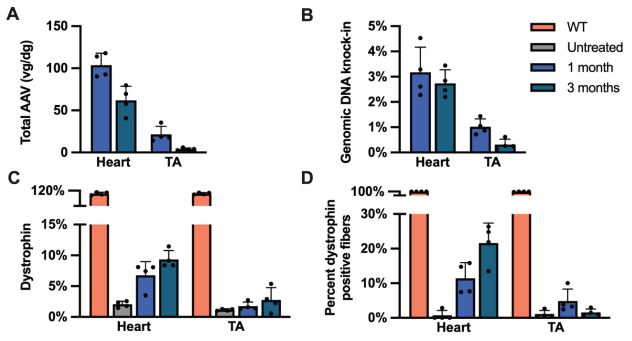


1704. REMEDY, a Novel CRISPR-Based Allele Specific Approach Corrects VCP Mutations without Exogenous DNA Template

Eleonora D'Ambrosio, Yasemin Sezgin, Burcak Ozes, Noushin Saljoughian, Genesis Snyder, Colin Maguire, Joshua Robinson, Jerry R. Mendell, Zarife Sahenk, Meisam Naeimi Kararoudi

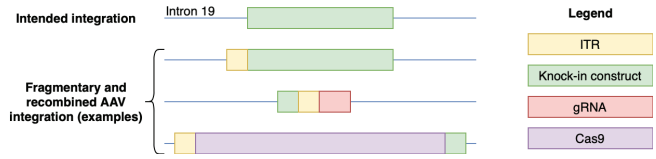
Nationwide Children's Hospital, Columbus, OH

Introduction: Valosin-containing protein (VCP) multisystem proteinopathy (MSP) is a neurodegenerative and ultimately fatal disease. The genetic background of the disease (dominant negative pathology) allows for allele-specific targeting of the heterozygous mutation. *Methods:* We developed a strategy, called REMEDY -REpair of heterozygous Mutations independent of Exogenous Donor template with high efficiencY- to precisely target and correct the mutant allele in VCP-MSP by recruiting the wild-type homologous chromosome as an endogenous template (Figure 1). We screened mutant allele-specific gRNAs to target one of the most frequent mutations in VCP, R155H (c.464G>A). We first tested this approach in patient-derived fibroblasts. We then focused on myoblasts derived from a mouse model of VCP-MSP. After optimizing the electroporation conditions, both patient-derived fibroblasts and mouse myoblasts were electroporated with Cas9/RNP. *Results:* We observed the correction of the mutant allele without an exogenous template. In patient-derived fibroblasts the frequency of the wild-type allele targeted with one of the gRNAs tested increased from 50 to 71%. In mouse myoblasts the frequency of the wild-type allele increased from 50% to 58% (Figure 2). The analyses were done by next generation sequencing and CRISPResso2. *Conclusions:* We observed that 21% of the patient-derived fibroblasts and 8% of the mouse myoblasts had reverted to homozygosity for the wild-type allele. REMEDY has the potential to efficiently repair other diseases caused by heterozygous mutations and without the necessity of an exogenous donor DNA template.



Testing allele specific gRNAs in VCP$^{+/-}$ mouse myoblasts

1705. Gene Editing by Homology-Independent Targeted Integration in Duchenne Muscular Dystrophy is Hampered by Loss of Edited Genomes and Fragmentary AAV Integration



Stefan Nicolau[1], Anthony A. Stephenson[1], Tatyana A. Vetter[1,2], Jessica E. Sarff[1], Gabrielle P. Dufresne[1], Emma C. Frair[1], Kevin M. Flanigan[1,2,3]

[1]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics, Ohio State University, Columbus, OH,[3]Department of Neurology, Ohio State University, Columbus, OH

Background: Duchenne muscular dystrophy is the most common muscle disease in childhood, affecting 1 in 5000 boys. Mutations in the N-terminal region of the *DMD* gene account for 25% of all patients. We previously developed a CRISPR/Cas9-based gene editing system employing homology-independent targeted integration to knock into the endogenous intron 19 of *DMD* a construct consisting of the coding sequence of exons 1-19 under the control of a new promoter. Translation from this new promoter effectively bypasses any upstream mutations and enables full-length dystrophin expression. **Methods:** The gene editing system was delivered to mice carrying an exon 2 duplication using a pair of AAV9 or MyoAAV3A vectors. Biodistribution, editing efficiency, editing outcomes, and dystrophin expression were measured at different time points. **Results:** With both AAV9 and MyoAAV3A, the highest biodistribution was observed in the heart, with significantly lower levels in the diaphragm and tibialis anterior (MyoAAV3A shown in Figure 1A). MyoAAV3A achieved 3-fold higher biodistribution in the heart compared to AAV9, but its performance was similar to AAV9 in skeletal muscles. The highest editing efficiency was 3% in the heart, enabling dystrophin expression levels of 9% of normal (Figure 1B-D). In skeletal muscles, there was a loss of both AAV and edited genomes between 1 month and 3 months post-injection. As a result, there was only a minimal increase in dystrophin expression.

Long-read sequencing identified integration of recombined and fragmentary AAV genomes at the target site, most frequently involving fragments of the inverted terminal repeats (Figure 2). These included both potentially therapeutic and non-therapeutic integrations, and collectively occurred at rates higher than the intended integration outcome.

Conclusion: This gene editing system results in an increase in cardiac dystrophin expression that is expected to be clinically meaningful. Efficiency is lower in skeletal muscles, potentially owing to a combination of vector tropism, immune mechanisms, and turnover of dystrophic muscle. Fragmentary AAV integration may occur at the site of Cas9-induced double-stranded breaks.

1706. Translating AAV-Delivered CRISPR-Cas13 Therapy for FSHD May Require Overcoming Size and Immune Challenges

Manal Ali[1], Afrooz Rashnonejad[1,2], Kate Neal[1], Gerald Coulis[3], Armando Villalta[3], Scott Q Harper[1,2]

[1]Center for Gene Therapy, Abigail Wexner Research Institute, Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics, The Ohio State University College of Medicine, Columbus, OH,[3]UC Irvine, Irvine, CA

Facioscapulohumeral muscular dystrophy (FSHD) is caused by aberrant expression of the toxic *DUX4* gene in muscle, leading to myofiber death and dysfunction. No approved disease-modifying treatments currently exist. We hypothesized that a FSHD treatment should center on *DUX4* inhibition, and we are developing a CRISPR-Cas13-based approach to accomplish this goal. Cas13 has emerged as a potent alternative to Cas9-based genome editing strategies, as Cas13 cuts RNA instead of DNA, thereby reducing potential genotoxicity. In this study we used Cas13b and Cas13d proteins from *Prevotella sp. P5-125* and *Ruminococcus flavefaciens XPD3002* bacterial species, respectively. Cas13b is too large to allow co-packaging of a guide RNA (gRNA) expression cassette in the same AAV genome. The first-generation system required injection of 2 AAVs, one expressing the gRNA from a U6 promoter and a second carrying the Cas13b protein expression cassette. In contrast, Cas13d is sufficiently small to co-package with a gRNA expression cassette in the same AAV. Although Cas13b and Cas13d function similarly, they arise from different bacterial species and utilize different gRNA structures. This necessitated designing two sets of gRNAs targeting *DUX4* mRNA, which we then tested *in vitro* and *in vivo*. We began with Cas13b. Following identification of lead gRNAs using various outcome measures in FSHD cell models, we tested the system *in vivo* using two FSHD mouse models. Following intramuscular injection in a rapidly progressing AAV-based FSHD mouse model, we measured significant *DUX4* mRNA reductions in AAV.Cas13b/gRNA1 co-treated muscles. This knockdown was accompanied by histological improvements, as well as reductions in DUX4 protein, DUX4-activated biomarkers and apoptotic nuclei at early timepoints (2 wks). In our genetic mouse model of FSHD (TIC-DUX4), Cas13b/gRNA1 also reduced DUX4-induced myopathy but protection waned over time. In wild-type mice, loss of Cas13b expression was accompanied by cytotoxic T-cell responses in skeletal muscle, suggesting an immune response to the Cas13b protein. We are now exploring several strategies to overcome this immune challenge, including testing Cas13 proteins from other bacterial species, such as Cas13d. For the smaller Cas13d enzyme, we

designed and tested 50 gRNAs, all of which caused significant *DUX4* knockdown compared to non-targeting controls using several *in vitro* assays. We then selected 3 leads, based on their ability to consistently reduce DUX4 transactivation activity and FSHD biomarker expression, and knockdown DUX4 protein by 80-90% *in vitro*. *In vivo* testing of the potency and durability of single AAV-Cas13d+gRNAs in our FSHD mouse models are still ongoing. We conclude that CRISPR Cas13 is a robust *DUX4* RNA-targeting tool *in vitro* and a promising strategy for *DUX4* mRNA silencing *in vivo*, if immune response challenges can be overcome.

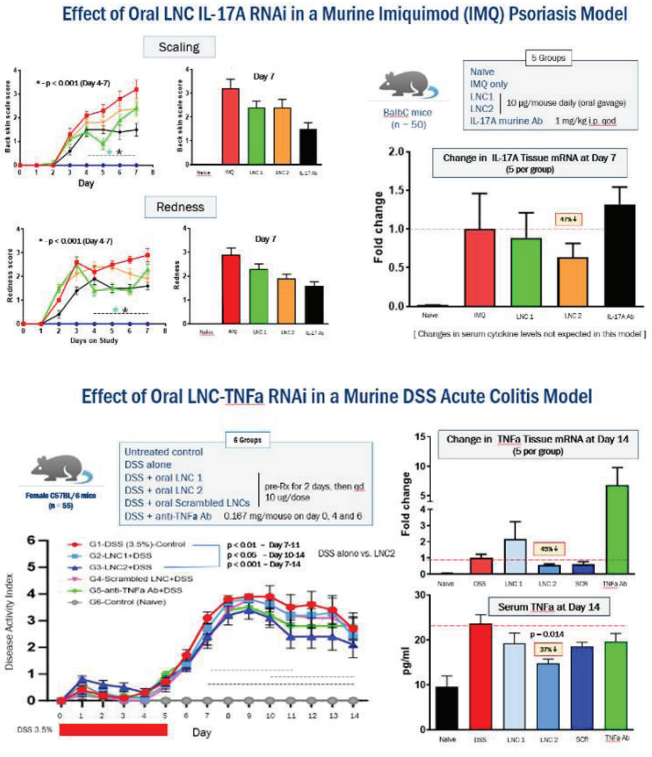
Friday Posters: Oligonucleotide Therapeutics

1708. Development of a microRNA-Based Gene Therapy Platform for Laminopathies

Neel D. Lachhwani[1], Nizar Y. Saad[1,2]

[1]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics, The Ohio State University, Columbus, OH

Laminopathies are a group of genetic diseases caused by mutations in the *LMNA* gene. These are ultra-rare diseases with a prevalence range of 1 in 20 million (i.e., the Hutchison-Gilford Progeria Syndrome) to 1 in 45 thousand (i.e., dilated cardiomyopathy). The laminopathy group of diseases encompasses at least 27 ultra-rare diseases with spontaneous or inherited mutations in the *LMNA* gene. Most of them possessing an autosomal dominant pattern of expression, leading to a spectrum of clinical manifestations affecting various organs, including skeletal muscle, cardiac muscle, connective and adipose tissue. We estimate the number of the autosomal dominant laminopathy patients to be around 20,000 in the US and 500,000 worldwide. To this date, these patients have no approved effective therapies. Therefore, the development of a gene therapy for these diseases is still an unmet need. Due to their ultra-rare prevalence, tackling them, one disease at a time is not a viable model of interest to the biotech industry and private investors, whose support is essential to translate prospective gene therapies to the clinic. Accordingly, we think that the development of a microRNA-based gene therapy platform would make a more compelling and efficient strategy with unified and adaptable framework. This strategy will address commonalities in the design of the gene therapy by using the same miRNA, same target gene (*LMNA*) and delivery vehicle, reducing the cost of toxicology studies. It will also address the treatment of common clinical features i.e., cardiac, muscular and connective tissue abnormalities, streamlining and accelerating the translational process. Hutchinson-Gilford Progeria Syndrome (HGPS) or Progeria is the first disease to be targeted by this strategy. HGPS is an autosomal dominant genetic disease affecting 400 patients worldwide. It is caused by a single C to T substitution in exon 11 of the *LMNA* gene, leading to the formation of a cryptic splice site and the expression of a modified Lamin A nuclear membrane protein isoform called "Progerin". Progerin is toxic and elicits pathology in multiple tissues, leading to premature physiologic aging and eventual death at the current average age of 14 years. Our therapeutic strategy consists of knocking down *Progerin* expression in affected tissues using *Progerin*-targeting microRNAs (miRNAs) that use the RNA interference (RNAi) pathway to silence gene expression. The *LMNA* gene encompasses exons 1-12. Through physiological alternative splicing of the *LMNA* transcript, two isoforms are produced, *Lamin A* and *C*. *Lamin A* encompasses exons 1-12, and *Lamin C*, exons 1-10. The *Progerin* transcript is produced through the activation of a cryptic splice donor site upon the presence of a C>T point mutation at position 1824 (c.1824C>T; p.G608G), leading to a transcript encompassing exons 1-12, but having a deletion of 150 nucleotides in exon 11. Accordingly, our RNAi-based gene therapy aims to target exon 12, knocking down both *Progerin* and *Lamin A* transcripts. Previous studies showed that the absence of lamin A is dispensable. Using a miRNA prediction algorithm, we identified 46 artificially designed miRNAs predicted to target exon 12. To validate target engagement and assess silencing efficiency, we screened these miRNAs in HEK293 cells using a dual luciferase assay in which *Progerin* transcript is expressed. Most miRNAs were able to knockdown *Progerin* and had an inhibition efficiency ranging from 18-60%. *miPRG1*, had the highest inhibition efficiency, reducing by 60% *Progerin* expression. We also tested *miPRG1* in patient-derived fibroblasts and showed similar silencing efficiency. In future steps, we will test *miPRG1* in additional patient-derived fibroblasts and *in vivo* using the $Lmna^{G608G/G608G}$ HGPS humanized mouse model.



1709. Successful *In Vivo* Oral Delivery of Biologically Active and Therapeutic Anti-Inflammatory mRNA-Targeted Oligonucleotides with a Lipid Nanocrystal Delivery Platform

Hui Liu[1], Vinod Ramgolam[2], Jeffrey Bender[2], Miriam Mikhael[1], Amra Tabakovic[1], Tzong-Jen Sheu[1], Partha Samadder[1], Thomas Hoover[1], James J. Ferguson[1]

[1]Matinas BioPharma, Bedminster, NJ,[2]TargetSite Therapeutics, New Haven, CT

Background: There has been little progress in the oral delivery of nucleic acid therapeutics beyond the liver. Matinas BioPharmas' lipid nanocrystal (LNC) platform successfully delivers oral amphotericin-B in patients with cryptococcal meningitis, and other ex vivo work has shown avid LNC uptake by innate immune cells. Prior studies have shown the in vitro efficacy of two mRNA-targeted oligos - one knocking down IL-17A, the other knocking down TNFa. LNC formulations of both have shown greater cytokine knock-down than "naked" oligos in vitro. The present work evaluated the in vivo efficacy of oral LNC formulations of these oligos in two inflammatory disease models. **Methods:** Psoriasis in BALB/c mice was induced with 31.25 mg of 5% Imiquimod (IMQ) applied daily for 6 days. There were 5 treatment groups (n=10/group): untreated controls, IMQ alone, IMQ plus one of two different LNC-oligo formulations administered daily by oral gavage, and IMQ plus anti-IL-17A antibodies. Skin Erythema and scaling was scored daily. The study was terminated at day 7; cytokine mRNA levels in the psoriatic skin lesions were determined by qRT-PCR. Colitis in C57BL/6 mice was induced with 3.5% DSS in drinking water for 5 days. There were 6 treatment groups: untreated controls, DSS alone, DSS plus one of two different LNC-oligo formulations, DSS plus LNC formulated scrambled oligos, and DSS plus a TNFa neutralizing antibody. Daily disease activity scores were measured; animals were

sacrificed at day 14 and serum TNFa and tissue (colon) TNFa mRNA (qt-PCR) were measured. **Results:** In the imiquimod psoriasis model (**Figure 1**) daily oral administration of an LNC formulation of the IL-17A targeted oligo resulted in both knock-down of skin IL-17 mRNA, and significant improvement in clinical parameters of redness and scaling. Similarly, in the DSS colitis model (**Figure 2**), daily oral administration of an oral LNC formulation of the TNFa targeted oligo resulted in reductions of colon TNFa mRNA and significant reductions in serum TNFa levels, as well as significant improvements in disease activity scores. Thus, we have shown successful oral delivery of two RNAi oligos targeting different inflammatory cytokines in two different disease models; with documented biological/molecular activity as well as therapeutic efficacy. **Conclusions:** The LNC delivery platform can successfully orally deliver biologically active (and potentially therapeutic) oligonucleotides targeting key cytokines in inflammatory disease models. While these initial results are promising, there is still some individual heterogeneity of response; future work will be focused on optimizing the LNC formulations to improve delivery efficiency, increase their potency, and extend the application of oral cytokine-targeting oligo therapeutics in other inflammatory diseases. models.

1710. Novel Antisense Therapy to Durably Treat USH2A Patients

Stephanie A. Mauriac[1], Yu-Han Huang[2], Jiahe Jin[2], Jen Phillips[3], Jeremy Wegner[3], Monte Westerfield[3], Karl Koehler[4], Timothy Yu[2], Gwenaelle Geleoc[2]

[1]Otolaryngology, Boston Children's Hospital, Boston, MA,[2]Boston Children's Hospital, Boston, MA,[3]University of Oregon, Eugene, OR,[4]Boston Children's Hospital/Harvard Medical School, Boston, MA

Usher syndrome (USH) is the most common inherited genetic disease of combined deafness and blindness. Mutations in *USH2A* account for half of USH cases. The size of *USH2A* (~15.6Kb) prevents the development of classic gene augmentation therapy mediated by adeno-associated virus (AAV)-based vectors, because it exceeds the capacity of single or even dual AAVs. Thus, we took advantage of an antisense oligonucleotide (ASO) strategy to correct hearing and vision loss in patients living with USH2A. We target an out-of-frame mutation, an *USH2A* founder mutation identified in patients at Boston Children's Hospital, and a major cause of USH in the French-Canadian population. To restore the proper reading frame, we developed a strategy leading to dual exon skip of human *USH2A*. Our hypothesis is that in-frame deletion of two exons in human will result in expression of slightly shorter yet still functional USH2A pseudo-protein. *In silico* analysis was performed using Alphafold2 to predict the 3D structure of both wild-type and pseudo-USH2A protein. We designed ASO sequences based on computational analyses of cis-regulatory sequences predicted to impact splicing. Candidate ASOs were synthesized with modified 2'-O-methyl nucleotides and phosphorothioate backbones. ASOs were either (1) transfected into retinoblastoma cells (WERI-RB1) or (2) applied gymnotically to inner ear and retinal cells derived from human mutant and isogenic iPSCs. We performed RT-PCR to validate ASO-induced *USH2A* dual-exon skipping. To test function, two *ush2a* zebrafish mutant models were generated using CRISPR-Cas9 and sgRNA to mimic (1) the patient's mutation or the (2) dual exon skipping strategy. Phenotype analysis was performed to assess vision (OKR), hearing (acoustical startle reflex), and balance (swimming behaviors) along with histology to assess inner ear and retinal structures. Our exon skipping strategy leads to an in-frame internal deletion of 105 amino acids out of 5202 amino acids. This deletion excises a single fibronectin domain. *In silico* analysis demonstrates the preservation of protein folding properties suggesting that protein function would be preserved. Our data demonstrate successful single and dual exon skip with different combinations and dosages of ASOs. The homozygous zebrafish models with truncating mutations in *ush2a* are viable, fertile and display normal startle response and vestibular behavior, but show a decrease in OKR and loss of Usherin protein localization, consistent with published zebrafish *ush2a* models. Histologic and functional assessments on the dual exon skipping zebrafish model are ongoing. ASOs have great promise as a platform to treat genetic disorders, including Usher syndrome specifically. They are simple to customize to different targets, inexpensive to manufacture, and can be efficiently delivered without special formulation. By demonstrating the high efficiency and safety of this approach, we hope to bring this novel antisense therapy from the bench to the bedside for USH2A patients.

1711. Design and Production of Circular RNAs (circRNAs) with Validated Functional Activity in Cell Models

Nicholas Dreisbach, Isabella Darke, Patrick Magunga, Meemanage De Zoysa, Miranda Yang, Dana Cairns, Stacie Seidel, Austin Thiel, Melissa Carpenter, Cherylene Plewa

ElevateBio, Waltham, MA

The Covid-19 pandemic has highlighted the therapeutic potential of Ribonucleic Acid (RNA) after messenger RNA (mRNA) was

successfully used in vaccines developed to combat the virus. Despite this success, mRNA technology has challenges including reactogenicity, poor stability, and high cost of manufacturing. Circular RNA (circRNA), which is a covalently closed RNA, is being developed to overcome the shortcomings of mRNA to achieve longer therapeutic expression. However, generating circRNAs with low impurities at a large scale has proven to be a challenge in the RNA field. At ElevateBio, we developed a robust and scalable method to produce high quality circRNAs using a Permuted Intron-Exon (PIE)-based construct design. A set of characterization assays were also developed and implemented to ensure the quality of final circRNA products. Initial testing validates the circRNA platform and demonstrates that ElevateBio circRNAs have low toxicity in cells, express robust levels of transgene products and show functional activity in cell models. The current circRNA design and production method are undergoing further development to be used in a range of therapeutic applications both ex-vivo and in vivo.

1712. One-Step Selection of High-Affinity Aptamers Using a Non-Fouling Porous Hydrogel

Yixun Wang, Yong Wang

Biomedical Engineering, The Pennsylvania State University, State College, PA

Aptamers are "chemical antibodies". They have garnered great attention across different fields owing to their economical production and robust structural stability compared to antibodies. However, the discovery of aptamers presents a substantial challenge due to numerous problems related to PCR amplification bias, ineffective partition, and nonspecific binding to the selection matrices. The purpose of this presentation is to discuss a novel aptamer enrichment and selection method - hydrogel for aptamer selection (HAS). In this method, aptamer candidates are loaded into a macroporous polyethylene glycol (PEG) hydrogel that is conjugated with target proteins. After loading, the candidates are allowed to diffuse out of the hydrogel. Low-affinity aptamer candidates are rapidly released from the hydrogel; however, high-affinity aptamers are slowly released. This difference in diffusion is attributed to their difference in the strength of binding to the immobilized proteins. Therefore, different aptamer candidates can be automatically separated during this diffusion-binding process for aptamer enrichment and selection. Methods The macroporous PEG hydrogel was synthesized by cryogelation. The target protein was conjugated to the hydrogel via the standard carbodiimide crosslinker chemistry. After the hydrogel was partially dehydrated, a single-stranded DNA (ssDNA) library was loaded to the hydrogel. The aptamer-loaded hydrogel was incubated in the selection buffer for diffusion. Sixty hours post diffusion, the selection buffer was replaced with a concentrated salt solution to elute the enriched ssDNA library. The enriched library was PCR amplified and purified for next-generation sequencing. The 50 sequences with the most abundant hits were grouped into approximately ten families. One member was chosen from each family for the binding analysis based on multiple assays. Result With thrombin as a model system, we found that the one-step enriched library exhibited a higher affinity than the original ssDNA library (**Fig. a).** An aptamer candidate T.7 exhibited a 1.5 nM Kd value (**Fig. b**). T.7 also showed a high specificity in binding thrombin compared to the other six protein targets (**Fig. c**). The full-length T.7 was further truncated to shorter sequences based on its stem-loop secondary structures (**Fig. d**). Four truncated aptamers exhibited a high binding capability compared to the two most widely used thrombin aptamers -15mer and 29mer that were both selected over ten cycles based on traditional aptamer selection methods (**Fig.e**). Conclusion Therefore, this work has demonstrated a novel HAS method for one-step aptamer enrichment and selection based on a diffusion-binding process in a non-fouling hydrogel matrix. This method is simple, fast, and low-cost. In addition, it does not need the use of sophisticated instruments. This one-step HAS method holds great potential to advance number fields ranging from nucleic acid delivery to biomolecular analysis.

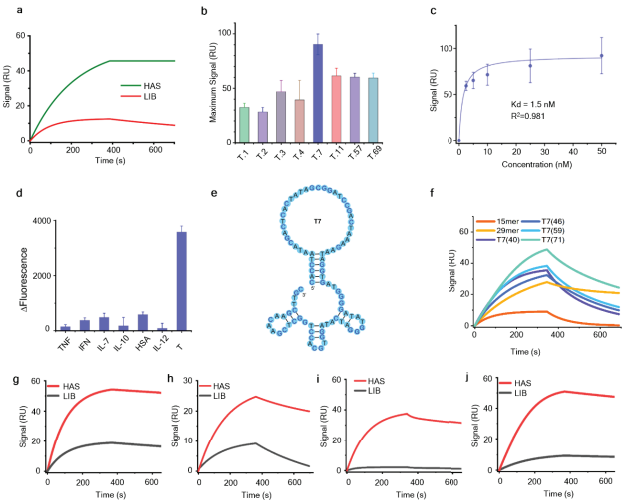


Fig a) Comparison of the initial and enriched library binding affinity. **b)** SPR analysis of nine thrombin aptamer candidates **c)** SPR analysis of T.7's binding affinity. **d)** Evaluation of T.7's binding specificity. **e)** Secondary structure of T.7. **f)** Evaluation of the truncated aptamers using SPR. **g) ~ h)** SPR analysis of enriched library and the initial library in binding to GM-CSF, IL-12, IL-10, and BDNF.

1713. Optimization and *In Vivo* Performance of circVec, a Vector-Based Circular RNA Expression Platform

Eoghan T. O'leary[1,2], Sara Vikberg[1,2], Juan Zhang[1,2], Daisy Hjelmqvist[1,2], Erik D. Wiklund[1], Victor Levitsky[1], Thomas B. Hansen[1]

[1]RnD, Circio AB, Huddinge, Sweden,[2]Clintec, Karolinska Institutet, Huddinge, Sweden

Circular RNA (circRNA) is a class of endogenously expressed non-coding transcripts found in most eukaryotes. In contrast to mRNA, circRNA is resistant to the intra-cellular exo-nucleolytic RNA turnover, which results in increased stability and persistence within cells. With enhanced understanding of circRNA biogenesis and functionality and recent engineering of circRNAs for highly efficient translation of proteins, circRNA is rapidly emerging as a next generation RNA platform that is expected to outperform mRNA-based therapies. Circio is developing a novel spliceosome-dependent expression system, circVec, designed for potent and durable vector-based intracellular production of circRNA, where the circVec cassette design and sequence elements have been optimized for high-yield circRNA biogenesis. Furthermore, to maximize the translation rate of the resulting circRNA, internal ribosomal entry sites (IRESs) have been screened for enhanced protein expression across a panel of cell lines in vitro. The circVec platform is vector agnostic, and we have shown effective expression

from a variety of non-viral and viral DNA vector systems. Here, we show that protein expression from the optimized circVec expression cassette accumulates over time when delivered transiently and reaches 10x higher expression rate compared to mRNA-based vectors one week after transfection. The observed circRNA advantage was consistent in a luciferase reporter mouse model, where the circVec-based system shows significantly enhanced accumulation over time compared to the mRNA benchmark following intra-muscular vector delivery. We therefore propose that the circVec expression platform is a promising new technology for various therapeutic areas requiring high and durable gene expression, such as monogenetic disorders, infectious disease and oncology.

1714. Simultaneous, Multiplex Detection of Sense and Antisense Strands of Therapeutic siRNA Using an Ultrasensitive Electrochemiluminescence Assay

Rohini Datta, Timothy J. Break, Seth B. Harkins, Jeff Debad, Jacob N. Wohlstadter

Meso Scale Discovery, Rockville, MD

Introduction: Small interfering RNA (siRNA) molecules play a key role in gene regulation and therapeutic applications. Currently, there are at least five FDA-approved siRNA drugs, with many more in various stages of the clinical trial pipeline, making their precise detection of paramount importance in preclinical research and translational medicine. Measuring both strands of therapeutic siRNA is essential for optimizing efficacy, ensuring specificity, and addressing safety concerns, including off-target effects and immunostimulation. Most pharmacokinetic assays for the detection of duplex siRNA rely on low-sensitivity formats like LC-MS or singleplex measurements of only the antisense strand (AS) and a separate assay for the sense strand (SS). We sought to develop an assay that can measure both strands of a duplex siRNA, in a single well, with high sensitivity. Methods: Here, we present a rapid and efficient approach for the multiplex detection of both strands of duplex siRNA using an ultrasensitive electrochemiluminescence (ECL) assay. Simultaneous detection of both strands of duplex siRNA in a single well is challenging using existing technologies, since the strands share a high degree of sequence complementarity, leading to cross-hybridization between capture probes and high false positive signals. We address this using specially-designed capture probes, tailored to target the SS and AS strands of siRNA, while eliminating the risk of cross-hybridization. These capture probes are shorter than the SS and AS strands by two or more nucleotides. Shortened probes specific for SS or AS hybridize to their target strands with high stringency in a single well, instead of cross-hybridizing to each other. Any residual probe-probe interactions are also degraded by the added RNases at the free single-stranded RNA sections not covered by the shortened probes. Hybridized probe-analyte complexes are then detected via an RNase protection assay using ECL-based readout. Assay conditions were optimized to achieve reproducible and highly sensitive detection for both siRNA strands. Results: Using this approach, we were able to achieve multiplex detection of duplex siRNA at remarkably low sub-pM concentrations in a single well. The lower limits of detection (LLODs) were 0.15 pM for AS and 0.28 pM for SS strands respectively. Experimentally-determined lower limits of quantitation (LLOQs) were 0.8 pM for both SS and AS strands. We demonstrate the versatility and robustness of this detection strategy in complex biological matrices such as mouse plasma, brain, and liver. Recoveries of high-, mid- and low-spikes in mouse brain and liver tissue lysates ranged between 83% - 118%. In plasma, the assay showed excellent linearity of dilution throughout the dynamic range. Conclusions: This method, combining siRNA strand specificity with highly sensitive ECL detection, represents a significant advancement in siRNA analysis techniques for pharmacokinetic studies.

Friday Posters: Nonviral Therapeutic Gene Delivery and Synthetic/Molecular Conjugates

1716. A Novel, Synthetic DNA Alternative for mRNA Manufacturing

Anjarium Biosciences AG, Schlieren, Switzerland

The emergence of messenger RNA (mRNA) as a transformative platform for gene therapy and vaccine applications, especially in the wake of the COVID-19 pandemic, has ignited a quest for innovations in mRNA production. A pivotal challenge in this space revolves around the choice of a DNA template for in vitro transcription (IVT) to generate mRNA. While bacterial-derived plasmid DNA has been the go-to template, its utilization has presented a significant bottleneck in mRNA manufacturing due to issues of cost, turnaround time, and purity concerns associated with the incorporation of bacterial-derived sequences into the final mRNA product. We have developed a novel, optimized synthetic linear double-stranded DNA with customizable hairpin-ended structures designed to serve as an alternative to plasmid DNA for mRNA production, completely devoid of any bacterial elements. The platform offers unparalleled advantage in terms of scalability, delivering high-fidelity, high-yield, and high-purity DNA within a remarkably brief timeframe. Here we show that our synthetic DNA is a versatile template for in vitro transcription that accommodates a diverse range of mRNA designs, and encompasses variations in length, capping technologies, and degrees of chemical modification. The use of our synthetic DNA for IVT affords significantly higher mRNA yields as compared to conventional plasmid DNA, while exhibiting comparable integrity, purity and levels of dsRNA contaminants. Furthermore, the functional activity of mRNA produced from our novel DNA is equal or superior to benchmark mRNA synthesized from plasmid DNA. The implications of these results underscore our novel DNA as an innovative and robust solution to overcome the bottleneck encountered in mRNA manufacturing.

1717. A Novel, Synthetic DNA for Cell and Gene Therapy Application

Alexander Pekarsky, Luca Distefano, Marco Guarrera, Ivana Pastierikova, David Wilson, Martin Cusack, Anna Krutyholowa, Roxanne Lourman, Fabian Trick, Gustavo Lou, Andreia M. Silva, Ileana Guerrini, Nicolas Meier, Jorge Omar Yanez Cuna, Joel de Beer

Anjarium Biosciences AG, Schlieren, Switzerland

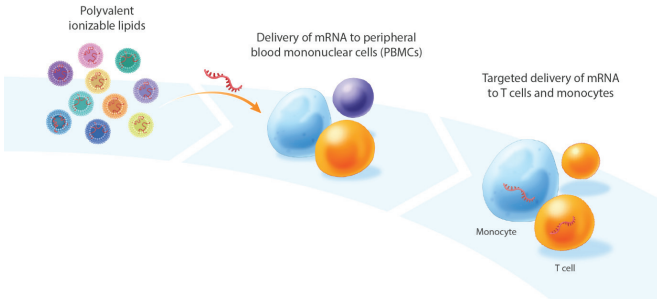
In the last decade, the field of cell and gene therapy has undergone a remarkable expansion with unprecedented growth in research, clinical trials, and therapeutic applications. Central to this transformative development is the increased recognition of DNA as the essential input material. As demand for advanced therapies continues to rise, there is increasing need for efficient and scalable platforms for manufacturing DNA constructs that are used directly as therapeutic agents or as input material for therapeutic products. We have developed a novel optimized synthetic linear double-stranded DNA with customizable hairpin-ended structures (e.g. synthetic and natural inverted terminal repeats) for cell and gene therapy applications. Our proprietary one-pot, enzymatic and cell-free production process has a small footprint, seamless scalability and allows production of synthetic DNA constructs of variable size and sequence complexity without residual bacterial backbone sequences. Additionally, as the generation of the hairpin ends is not sequence specific, the DNA platform allows application-oriented customization of the hairpin structures on both DNA ends. Here, we show that our cell-free, enzymatic DNA production process offers high product purity and flexibility coupled with faster production times and minimal footprint requirements compared to plasmid DNA production process. Additionally, we show the broad versatility of our synthetic DNA for cell and gene therapy applications by demonstrating its use as input for mRNA, recombinant adeno-associated virus, and lentivirus vector production, as well as for use in transgene expression *in vitro* and *in vivo*. Our synthetic DNA is well-positioned to replace plasmid DNA as key starting material for cell and gene therapy modalities.

1718. Non-Viral Gene Editing Solutions for Efficient Cell Therapy Engineering

Lumeng Ye, Fan Zhou, Zhaoyang Mao, Hong Li

R&D Department, GenScript Biotech, Nanjing, China

With the fast progress and deeper understanding of CAR-T cell therapy, finding a better solution other than lentivirus transduction is more requested, to overcome the functional limitation on random insertion, uncontrolled copy number of CAR insertion and to overcome the capacity limitation of GMP lentivirus manufacture. Here we report two non-viral DNA payloads, for highly efficient non-viral cell therapy engineering and manufacture. GenExact™ ssDNA, linear single-stranded DNA produced by proprietary isothermal enzymatic reaction process, with high purity and sequence integrity proved by NGS and HRMS. This high purity single-stranded format DNA payloads also proved with lower cytotoxicity than dsDNA, could facilitate high knock-in efficiency of CAR sequence at specific location when coupled with CRISPR gene editing system, as about 50% at TRAC with CTS (Cas9 Targeting Sequence) modification, and >90% at GAPDH with SLEEK (SeLection by Essential-gene Exon Knock-in) design. For other types of immune cells, GFP knock-in can be achieved as 50% on iPSC and 30% on NK cell as well, and the editing efficiency by HDR (homology-directed repairing) can be further increased by selected chemical compounds. With non-viral CRISPR editing and electroporation process, different kinds of immune cell therapy can be manufactured with more defined design and unified final product. For insertion of large cargo that longer than 5kb, GenCircle™ dsDNA, circular supercoiled dsDNA with minimized backbone (430bp), is designed for large insertion coupled with transposon system. With the reduced backbone size and immunogenicity, GenCircle can be used for the delivery of large cargo without trigger severe cytotoxicity, and can achieve around 60% insertion rate on T cell by dual vector process. This protocol paves the way for non-viral CAR-T manufacture with multiple CAR design and precise modulation with logic control design.



1719. Novel Polyvalent Ionizable Lipids Enable Targeted Delivery of mRNA to T Cells and Monocytes

Ariadna Lubinus, Joseph Pisano, Christopher B. Rohde, Matthew Angel

Factor Bioscience Inc., Cambridge, MA

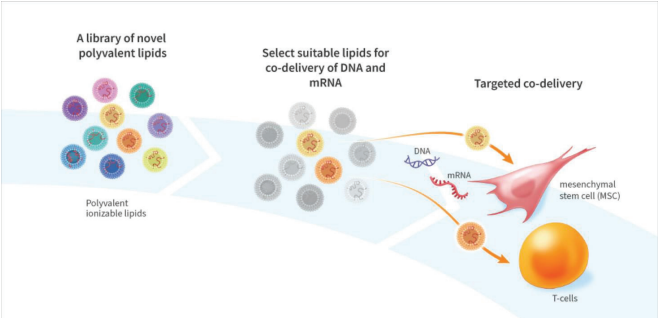
Ionizable lipids are established nucleic acid delivery vehicles capable of delivering mRNA to induce protein expression in target cells. These lipids deliver their mRNA cargo into the cytosol, where it can be directly translated into proteins. As a result, lipid-based mRNA delivery does not carry the risks of mutagenesis that limit the clinical use of both viral vectors and DNA-containing delivery systems. Yet, current lipid-based delivery systems suffer from low transfection efficiency, especially for cell types such as primary cells and immune cells, which are notoriously resistant to transfection due in part to their immune response to foreign nucleic acids and selective uptake of molecules by specialized endocytic machinery. To address this, we designed a library of 4,200 ionizable lipids of which a panel of 84 potential candidate vehicles were synthesized and screened in human peripheral mononuclear cells (PBMCs) and other difficult-to-transfect immune cells including THP-1 monocytes. Human PBMCs were transfected with green fluorescent protein (GFP)-encoding mRNA formulated into complexes with the candidate lipids. 43 of these lipids possess a spermine-derived backbone, a structural characteristic of the ToRNAdo™ Nucleic-Acid Delivery System which has effectively delivered mRNA to a variety of cell types both ex vivo and in vivo. We also tested these lipids on PBMCs that had been exposed to T-cell activators IL-2 and anti-CD3/CD28 antibodies for 72 hrs to mimic innate immune activity in a pathogenic microenvironment. 1.33 ng/uL of GFP mRNA was delivered per 100,000 PBMCs at a lipid:mRNA wt/wt ratio of 3:1. High content cellular imaging and fluorescent microscopy showed peak GFP fluorescence intensity 24-36 hrs after transfection. Flow cytometry was performed 24 hrs after transfection to quantify GFP expression and viability in transfected cells. Of the lipids tested, those containing spermine headgroups and hexyldecanoate ester tails yielded high levels of GFP expression in CD3+ cells with a four- to eleven-fold increase in GFP positive cells relative to Lipofectamine™ 3000. The same lipids transfected THP-1 monocytes at greater than 90% efficiency. Our data collectively indicates that spermine-derived polyvalent ionizable lipids target transfection of mRNA to primary

human immune cells, particularly T cells and monocytes. These novel lipids may prove useful in the development of mRNA therapeutics based on the transfection of immune cells.

1720. Effect of LNP Components on mRNA Mediated Protein Expression of Lipid Nanoparticles in Different Organs

Anitha Thomas, Malathi Anantha, Ruchi Sharma, Cece Nazaripour, Rehan Higgins, Kobe Tickner, Zhengyu Chen, Nikita Jain, Jay Paquette

Cytiva, Vancouver, BC, Canada



Introduction: In recent years, RNA therapeutics have received tremendous attention. To fully realize the potential of RNA therapeutics, lipid nanoparticles (LNPs) have been developed as an efficient delivery system. While LNPs have been widely used for delivery of RNA therapeutics into liver, non-hepatic delivery remains highly challenging. To better understand the mRNA expression of LNPs in different organs, we have evaluated the translation of luciferase encoded mRNA using various LNP systems. **Objectives:** To evaluate the effect of various parameters of compositions constituting LNPs for protein expression in different organs. **Methods:** LNP formulations were manufactured using NanoAssemblr® Ignite with different compositions with Luciferase encoded mRNA. Size and PDI were determined using Dynamic Light Scattering. The encapsulation efficiency was determined using the Ribogreen™ assay. The pKa of mRNA LNPs were measured by TNS assay. Luciferase expression as total flux in various organs were evaluated in vivo and ex vivo using IVIS imaging. Briefly, CD-1 mice were dosed with luciferase encode mRNA LNP intravenously at a 0.1 mg/kg dose. Four hours later mice were injected with D-luciferin and imaged using IVIS. After euthanasia, different organs were dissected for ex-vivo luminescence imaging using IVIS. **Results:** Size of the LNP was reported to be between 60-150 nm with PDI<0.2. The experimental pKa of different ionizable lipids were between 4.9 to 7.4. All LNPs tested demonstrated high luciferase protein expression in the liver. Liver expression levels were comparable to other clinically demonstrated lipids. Conclusions: For ionizable lipids, there is a correlation between overall protein expression and pKa of ionizable lipids. We have also seen that various components in the LNP compositions have implications with respect to protein expression in liver, spleen, and other organs. These parameters affect the biodistribution and translation of the lipid nanoparticles.

1721. A Library of Novel Polyvalent Ionizable Lipids for Targeted Co-Delivery of mRNA and DNA

Joseph Pisano, Ariadna Lubinus, Christopher B. Rohde, Matthew Angel

Factor Bioscience Inc., Cambridge, MA

Lipid delivery systems containing ionizable lipids have entered broad clinical use with the introduction of COVID-19 mRNA vaccines and are now generally considered the gold standard for in vivo mRNA delivery. However, intravenously administered lipid delivery systems are still limited by undesirable toxicity profiles, poor accumulation at in vivo target sites, minimal uptake by cells of interest, and low levels of endosomal escape. To address these deficiencies, we have investigated strategic incremental modifications to the chemical structure of DLinDHS, a key component of the ToRNAdo™ Lipid Delivery System. ToRNAdo™ has shown effective delivery of mRNA to a variety of cell types both ex vivo and in vivo, including mRNA encoding chimeric antigen receptors (CARs) targeting CD19 and the receptor tyrosine kinase like orphan receptor 1 (ROR1), a receptor found on many solid tumor cancers. iPSC-derived macrophages transfected with such mRNA efficiently bound recombinant CD19 or ROR1 and demonstrated improved cytotoxicity towards tumor cells. We hypothesized that combining various structural elements with the polyvalent DLinDHS backbone could lead to improved transfection efficiency and enhanced tissue targeting. In designing the novel lipids, structural characteristics such as biodegradability, lipid tail length, level of branching, branched tail symmetry, and increased hydrogen bonding ability were considered. Ester functional groups were incorporated to increase potential for in vivo biodegradability via hydrolysis by esterases, generating byproducts consisting of functional groups which may be metabolized more readily. Lipid tail design was influenced by length, level of branching, and branched tail symmetry in order to optimize the physicochemical characteristics of the resulting lipid-nucleic acid complexes. Increased hydrogen bonding capacity was achieved through the introduction of hydroxyl substituents, promoting stronger intermolecular association with anionic nucleic acid phosphate groups. Using these principles, we designed 4,200 novel ionizable lipids and synthesized a library consisting of 84 polyvalent ionizable lipids sorted into 11 families. We tested this library for delivery of mRNA to cells and identified candidate vehicles for further development, which will ideally yield an effective and versatile lipid delivery system with potential to enable effective therapies that can positively impact patient outcomes for countless diseases.

1722. Auto-Circulating RNA for Protein Expression

Qianbo Ma[1], Chuanqing Tang[1], Sheng Zhao[1], Xiulian Sun[2]

[1]uBriGene Biosciences International Co., Nanjing, China,[2]uBriGene Biosciences International Co., Suzhou, China

Compared with linear RNA, circular RNA is a closed-loop structure that doesn't require a cap or polyA tail. Without the free ends, circular RNA is resistant to RNA exonucleases, and therefore more stable in cells. At present, the manufacture of circular RNA mostly uses an in vitro circulation strategy by utilizing self-splicing introns from viral or other known genomes, which is often called PIE (permuted introns and exons) based method. Here we reported a linear but auto-circulating RNA (acRNA) produced by *in vitro* transcription with 5' hydroxyl and 3' 2, 3-cyclic phosphate ends formed by the self-cleavage of ribozymes or DNAzyme on both ends. After transfected / delivered into the cell, acRNA can be circulated by the cellular endogenous ligase automatically through a human tRNA splicing mechanism. The auto-circularized RNA is driven by the IRES element to express the coded protein. The results showed that acRNA with different human tRNA stems exhibited different expression activities, indicating different auto-circulating efficiencies of these tRNA stems in cells. To minimize the safety issue raised by using non-human tRNA sequences (like the Tornado system), the acRNA was designed based on the human tRNA stems. An acRNA-LNP-based gene editing system including a spCas9-acRNA was also demonstrated to function well in tested cells. Without the need for capping and polyA tail (for mRNA), or the RNase R digestion and multiple purification steps (for those *in vitro* circulating circRNA, PIE circRNA), the manufacture of acRNA is low-cost when compared to either mRNA or *in vitro* circulating circRNA. Subsequent studies will further optimize the circulating stems to improve the auto-circulating efficiency and transient expression level of the acRNA.

1723. Determination of mRNA Capping Rate and polyA Length by High-Resolution Capillary Electrophoresis

Ye Sun[1], Sheng Zhao[1], Xiulian Sun[2]

[1]uBriGene Biosciences International Co., Nanjing, China,[2]uBriGene Biosciences International Co., Suzhou, China

mRNA therapy has steadily grown to be one of the most popular fields in pharmacological research. It is anticipated to be an efficient treatment for a wide range of illnesses. The *in vitro* transcript mRNA must be capped and have the polyA tail for protein translation in eukaryotic cells. One of the gold standard techniques to measure the rate of capping is to perform RNase H digestion on hybridized RNA with a biotin-labeled DNA probe near 5'-end mRNA followed by purification and mass spectra. A similar analysis can be done to measure the length of polyA. However, these LC-MS-based methods are costly and sophisticated. Here, we introduced a DNAzyme-based high-resolution capillary electrophoresis to quickly and precisely estimate the mRNA capping rate and the length of polyA tail. The site-specific DNAzymes were first screened according to the candidate mRNA sequence near both ends, usually within 5'-UTR and 3'-UTR regions. The selected DNAzyme with enough cleavage activity cut the mRNA near the ends of mRNA, producing small fragments with/without a cap on the 5'-end, or fragments with various lengths of polyA tails on the 3'-end. DNase I treatment was then performed to digest the DNAzyme and the resulting RNA fragments were purified before analyzing by high-resolution capillary electrophoresis (CE) which could distinguish RNA fragments with minimal 1 nt difference. The capped mRNA will produce a 1~2 nt longer CE peak than that of uncapped mRNA. The ratio between the longer peak and the shorter peak of the 5'-end can be used to estimate the mRNA capping rate. On the other hand, the range of the length of the polyA tail can be calculated by the position of peaks of 3'-end cut fragments after subtracting the length of the sequence before the polyA tail and after the cutting site. The DNAzyme-based high-resolution capillary electrophoresis is a cheap, easy-to-use, and accurate method for mRNA quality control for both capping rate and polyA tail length.

1724. Revolutionizing Neurofibromatosis Treatment: mRNA Delivery in Schwann Cells with Lipid-Based Formulation

Nabila Laroui[1,2], Sarah Meresse[1,3], Laura Colar[2], Christophe Delehedde[2], Cristine Gonçalves[1,2], Fabienne Godin[2], Beatrice Vallée[2], Patrick Midoux[1], Helene Benedetti[2], Chantal Pichon[1,2,3]

[1]ART ARNm US55 Inserm, Orleans, France,[2]CBM UPR 4301 CNRS, Orleans, France,[3]Faculty of Sciences and Techniques, University of Orleans, Orleans, France

Neurofibromatosis (NF), an inherited disorder, arises from mutations within the ~8.0 kb coding gene sequence of the NF1 tumor suppressor located mainly in Schwann cells. NF1 hallmark is the development of both benign and malignant nerve sheath tumors including cutaneous neurofibroma (cNF). Currently, cNF treatment is limited to drugs, surgical resections or involves ablation approaches which are invasive and poorly efficient. The only gene replacement therapy work using NF1-GTPase-activating protein-related domain (GRD; an important functional domain of NF1) plasmids and adeno-associated viruses (AAVs) has shown significant progress during pre-clinical studies [1]. However, AAVs have limited capacity in terms of the size of genetic material; around ~ 4.5 kb. In this study, we propose an innovative approach, based on the introduction of the synthetic messenger RNA (mRNA) of NF1 to restore the production of a normal Nf1 protein. The delivery of *NF1* mRNA is much simpler and does not require this nuclear import step as the translation machinery takes place in the cytosol. Most importantly, the *in-situ* expression of Nf1 will allow all post-translational modifications and interactions required for its function. First, we determined and optimized the delivery and expression of mRNA in mutated NF1 cells comprising human Schwann cells (HSCs), fibroblasts and keratinocytes using a range of polymeric and lipid vectors, including our original lipids. With both modified and unmodified mRNA, they achieved the highest transfection rate (~90%), without inducing cytotoxicity. In a remarkable way, intradermal injection of lipid-based luciferase mRNA formulation in human skin explant, a highly relevant organotypic model, demonstrated efficient luciferase expression for up to 5 days, using. In addition, we were able to successfully transfect mutated Schwann cells (*NFI* -/-) with the optimized lipid-based formulation containing GRD mRNA construct enabling the restoration of GRD biological activity. To the best of our knowledge, this study shows for the first time the feasibility of Schwann cells transfection with mRNA GRD-NF1 where the biological activity

will be evaluated on cells and tissue biopsies from neurofibromatosis patients. Thereby, this work will pave the way to a therapeutic paradigm shift based on protein replacement for cutaneous neurofibroma treatment. [1] Bai et al., « Feasibility of Using NF1-GRD and AAV for Gene Replacement Therapy in NF1-Associated Tumors ».

1725. Cargo-Agnostic Lipid Nanoparticles to Correct Cystic Fibrosis Mutations in Airway Stem Cells

Ruth Foley[1], Paul Ayoub[1], Colin Juett[1], Alicia Sanoyca[1], Vrishti Sinha[1], Caroline Cherry[1], Emily Duggan[1], Beate Illek[2], Donald B. Kohn[3], Brigitte Gomperts[1], Steven J. Jonas[4]

[1]UCLA, Los Angeles, CA,[2]UCSD, San Diego, CA,[3]Unversity of California, Los Angeles, Tarzana, CA,[4]University of California, Los Angeles, Los Angeles, CA

Aim: Cystic fibrosis (CF) is a monogenic disorder arising from mutations in the cystic fibrosis transmembrane conductance regulator (*CFTR*) gene that leads to chronic lung infections & respiratory failure. Genetic diseases like CF are appealing targets for gene therapies, but mutation-agnostic gene correction strategies rely on genomic integration of large double-stranded DNA (dsDNA) cassettes that are difficult to package and deliver to target cells. We report the design and testing of a gene therapy strategy that utilizes lipid nanoparticles (LNPs) configured to transport CRISPR/Cas9 payloads designed for site-specific insertion of CFTR in *in vitro* models of the human airway. Methods: LNP formulations were synthesized *via* microfluidic mixing and characterized with dynamic light scattering. We systematically screened LNPs with varying ratios of mRNA encoding Cas9, single guide RNAs (sgRNAs), and donor DNA templates to optimize gene editing in a human bronchial epithelial cell line (16HBE14o-). 16HBE14o- cells stably expressing blue fluorescent protein (BFP) were applied to evaluate editing at the *BFP* locus *via* flow cytometry. In this model, non-homologous end joining (NHEJ)-mediated repair at the locus results in loss of fluorescence whereas homology-directed repair (HDR) can be detected following successful integration of donors designed to convert BFP to green fluorescent protein (GFP). Next, we applied HDR donors designed to insert a *mCitrine* reporter within the endogenous 5' untranslated region of *CFTR* in 16HBE14o- cells to assess whether dsDNA cassettes should be co-encapsulated with Cas9-mRNA and sgRNA in a single LNP or packaged separately. The dsDNA:Cas9-mRNA and nitrogen-to-phosphate (N/P) ratios were systematically varied to improve the integration of a *CFTR*-encoding cassette in 16HBEge-G542x CF mutant cells. Integration of the reporter *mCitrine* and *CFTR*-correction cassettes was measured with digital droplet PCR. Successfully edited 16HBEge-G542x colonies were transferred to TransWell inserts and evaluated in an Ussing chamber to validate restoration of CFTR function. Results: In the presence of an HDR donor, *ca.* 90% NHEJ-mediated repair and up to 35% HDR were observed in 16HBE14o-BFP cells treated with LNPs packaged with BFP editing cargoes. LNPs with a sgRNA:Cas9-mRNA w/w ratio of 1.2:1 achieved the highest overall editing efficiencies. Encapsulation of dsDNA donor cassettes with Cas9-mRNA and sgRNA in a single LNP yielded *ca.* 14% integration of the mCitrine reporter in 16HBE14o- cells compared to *ca.* 10% when the donor was packaged separately. In 16HBEge-G542x cells, LNPs with a dsDNA:Cas9 mRNA w/w ratio of 3:1 demonstrated up to 3.5% integration, compared to <2% integration for 2:1 and 4:1 w/w ratios. Increasing the N/P of the LNPs to 9 further improved CFTR dsDNA integration. Initial validation of *CFTR* dsDNA donors electroporated in 16HBEge-G542x cells restored CFTR-dependent Cl- current to *ca.* 80% of wild-type, confirming functional correction. Conclusion: We demonstrate a LNP platform capable of transporting large gene editing biomolecules to airway epithelial cells that can achieve mutation-agnostic, site-specific correction of *CFTR* in a CF-deficient cell line. These nanotechnologies offer solutions to overcome limitations in the cargo-carrying capacity of existing gene delivery vectors. Our work sets a new precedent for packaging and delivering large dsDNA templates with LNPs that is poised to accelerate progress toward definitive cures for CF and other genetic diseases.

1726. Lung Delivery for Cystic Fibrosis

Miriam L. Greenwood, Hannah Mitchison, Stephen L. Hart

UCL Great Ormond Street Institute of Child Health, London, United Kingdom

Background: Cystic fibrosis (CF) is an autosomal recessive disease caused by mutations in the cystic fibrosis transmembrane conductance regulator (*CFTR*) gene. The dysfunctional CFTR protein leads to thickened mucus, bacterial infections, and reduced lung function. Modulators are effective treatments for many CFTR genotypes, but ~20% of patients remain untreatable. A major obstacle to developing a CF gene therapy is efficacy and safety of lung delivery. Aims: The aim was to compare the transfection efficiencies in different *in vitro* lung models, with respect to uptake and gene expression in response to nucleic acid transfection. As CF involves inflammation of the lung, a further aim was to determine whether delivery exacerbates inflammation. Methods: GFP and luciferase pDNA were packaged into receptor-targeted nanocomplexes (RTNs), comprising liposome, ditetradecyl trimethyl ammonium propane (DTDTMA) and dioleoyl L-α phosphatidyl ethanolamine (DOPE) at a 1:1 molar ratio, and an epithelial targeting peptide, K_{16}-GA-CSERSMNFCG. The cell types transfected were the human bronchial epithelial cells: 16HBE14o-, and primary CF and non-CF basal cells transduced with BMI-1 (CFBE F508del and NHBE). CFBE cells were grown both in submerged culture and in air-liquid interface (ALI) cultures alongside NHBE cells. Interleukin 6 and 8 (IL-6 and IL-8) protein secretion were measured by ELISA as a marker of inflammation. GFP pDNA was labelled with Cy5 using Label IT® to evaluate nuclear uptake and gene expression by confocal microscopy and flow cytometry. Luciferase assays were also utilised to determine transfection efficiency. Results: Transfection efficiency with GFP pDNA was 21.7% in 16HBE cells and 37.1% in CFBE cells, and the uptake efficiency of Cy5-labelled pDNA was 62.4% and 99.1% respectively. ALI cultures demonstrated some successful transfections after two or three consecutive transfections with secretable luciferase when measured from the apical surface. Successful transfection of individual well in ALI cultures correlated with elevated IL-6 and IL-8 levels. There were no significant differences in cytokine levels between CFBE and NHBE cells. In CFBE submerged culture, there was a significant increase in IL-6 (μ = 99 pg/ml compared to 13 pg/ml negative control), but not IL-8 in response to RTN transfection. However, co-transfection with 1000 nM dexamethasone, a glucocorticoid anti-inflammatory, significantly reduced IL-6 to a mean

of 73 pg/ml. Dexamethasone also reduced IL-8 levels. Comparatively, in the 16HBE14o- cell line, IL-6 levels were significantly increased ($p<0.0001$) in transfected cells 24 hours post-transfection but had decreased by 72 hours. However, incorporating dexamethasone into RTNs in 16HBE transfections significantly reduced IL-6 levels from a mean of 1956 pg/ml to 963 pg/ml. Discussion: After comparing different *in vitro* lung models, we found that submerged NHBE and CFBE cells transfect more easily with RTNs than 16HBE14o- cells in both uptake and gene expression efficiencies. In ALI cultures, not all wells achieved successful transfection, likely attributed to substantial mucus production but there was also evidence of an inflammatory response to RTN pDNA transfection, due to increased IL-6 and IL-8, although the effect was transient and can be reduced with dexamethasone, a widely used anti-inflammatory agent. Conclusion: RTN pDNA transfection is highest in primary cells compared to a cell line, and causes an inflammatory response in epithelial cells associated with transfection efficiency but this can be modulated by transient treatment with dexamethasone, a widely used anti-inflammatory agent.

1727. Development of *In Vitro* Transcribed RNA Therapeutics for Cystic Fibrosis

Ruhina Maeshima[1], Aristides D. Tagalakis[1], Drew Weissman[2], Robin J. McAnulty[3], Chris O'Callaghan[1], Deborah Baines[4], Stephen L. Hart[1]

[1]UCL Great Ormond Street Institute of Child Health, London, United Kingdom,[2]University of Pennsylvania, Philadelphia, PA,[3]UCL Respiratory Centre for Inflammation and Tissue Repair, London, United Kingdom,[4]St George's University of London, London, United Kingdom

Background: Cystic fibrosis (CF) is an autosomal recessive rare disease, caused by mutations in the CF transmembrane conductance regulator (CFTR) gene. Absent or nonfunctional CFTR leads to thick, sticky mucus in the lungs, which results in chronic bacterial infection and inflammation. *In vitro* transcribed mRNA has emerged in the last few years as a new approach for CFTR protein replacement therapy, but problems of delivery must be overcome. **Methods:** We have developed novel receptor-targeted nanocomplex (RTN) formulations consisting of liposomes and receptor-targeting peptide for delivery of CFTR IVT mRNA. The RTNs were first optimized in transfections of primary CF bronchial epithelial (CFBE) cells using reporter IVT mRNAs. We then assessed delivery efficiency of CFTR mRNA in CFBE cells at submerged culture and ALI culture and assessed uptake by quantitative reverse transcription polymerase chain reaction and demonstrated protein expression by Western blot. **Results:** We first optimized the RTN formulations, comparing combinations of three cationic liposomes and five peptides for their biophysical properties and transfection efficiency. We identified a novel formulation (size 130 nm, polydispersity index (PDI) 0.28, charge +38 mV) for mRNA delivery that achieved almost 100% cellular uptake efficiency and 90% transfection efficiency. There were no differences in transfection efficiency between primary normal human bronchial epithelial (NHBE) cells and CFBE cells. The same RTN formulation was able to deliver the mRNAs in air-liquid interface (ALI)-cultured cells and mouse lungs. The luciferase expression in mouse lungs was approximately 200 times as high as plasmid DNA encoding luciferase. CFTR mRNA was successfully delivered to NHBE and CFBE cells. In addition, we co-packaged the CFTR corrector VX-809 with CFTR mRNA into RTNs and found that this increased expression of CFTR protein in both NHBE and CFBE cells in submerged culture approximately 2 to 2.5 times. CFTR protein translated from the IVT mRNA was detected by immunoblotting from 4 hours to at least 48 hours after the transfections. CFTR protein expression was also shown in transfections of ALI culture of CFBE cells by functional analysis of ion transport in an Ussing chamber. The change of short circuit current (ΔIsc) in CFBE transfected with CFTR mRNA once, was 10-fold larger than in untransfected cells before and after forskolin was added, and it was approximately 83% of that seen in NHBE. CFBE transfected three times with CFTR mRNA achieved larger ΔIsc than NHBE after CFTR inhibitor 172 was added into the cells. **Conclusions:** CFTR IVT mRNA delivery is a promising novel therapeutic for CF. The flexibility of the RTN formulation allows co-delivery of CFTR mRNA with VX-809, which significantly improved CFTR expression. It can induce the same level of CFTR expression as NHBE in CF cells.

1728. Interleukin-27 (Il-27)-Based Gene Therapy to Reduce Inflammation in Acute Respiratory Distress Syndrome

Grace E. Mulia, Janelle W. Salameh, Marxa L. Figueiredo

Basic Medical Sciences, Purdue University, West Lafayette, IN

Acute Respiratory Distress Syndrome (ARDS) is an acute inflammatory lung injury associated with pulmonary edema and characterized by the presence of alveolar damage and lung stiffness. Globally, about 40% of ICU patients suffer from ARDS, half of which are categorized as severe ARDS with 90% mortality rate. Current therapy is limited to supportive care in the form of mechanical ventilator, which highlights the dire need of targeted therapies. In ARDS, lung injury triggers activation of immune cells, which release pro-inflammatory cytokines aimed at eliminating the cause of injury. Prolonged upregulation of IL-1β, IL-8, IL-6, and TNF-α contribute to macrophage and neutrophil recruitment and accumulation, promoting further release of toxic mediators that perpetuate chronic inflammation and alveolar damage. Therefore, therapies capable of modulating cytokine production while stimulating tissue repair may improve ARDS patients' prognosis. Interleukin-27 (IL-27), a multifunctional cytokine involved in innate and adaptive immunity and in promoting tissue repair, has been hypothesized as a candidate to rebalance an ARDS inflammatory microenvironment. To test this hypothesis, we first established an LPS-induced in vitro model and characterized gene expression responses in lung epithelial cells (BEAS-2B) and macrophages (THP-1). Cytokines typically have short half-lives, thus we utilized a gene therapy approach to deliver IL-27 by transfecting an IL-27-expressing plasmid into human adipose mesenchymal/stromal cells (hASC). Our results showed that IL-27-hASC conditioned media reduces pro-inflammatory cytokine gene expression in LPS-induced BEAS-2B and THP-1, both in monoculture and co-culture settings. We are currently testing our hypothesis in an in vivo model of LPS-induced ARDS, further determining the potential of IL-27 therapy in reducing inflammation in an ARDS model.

Friday Posters: Other Nonviral Delivery

1729. Pulmonary Endothelial Cell- Selective Ionizable Lipid and Biodegradable Polymer-Based Stability Enhanced Nanoshell (SENS™) Technology for RNA Therapeutics

Jihye Han, Seungju Yoo, Kyeongdae Kim, Eujung Kim, Kyuhee Yum, Jongmin Park, Joungpyo Nam, Sojin Lee, Helen Cho

Samyang Biopharmaceuticals, Seongnam, Korea, Republic of

Recent rapid advances in technology of mRNA-based therapeutic has the potential to treat a wide range of uncurable pathologies including infectious diseases, cancers, immune diseases, and genetic disorders. Ionizable lipid nanoparticles (LNPs) have been widely utilized and developed for the delivery vehicles of RNA-based therapeutics but have limited applications due to accumulation in the liver after systemic administration. Systemic delivery of mRNA to target organs in vivo remains the major challenge in the development of mRNA-based therapeutics. Here we report a unique technology termed Stability Enhanced Nanoshell (SENS™) as an RNA delivery platform which contains polymer and proprietary ionizable lipid as essential components. By employing different compositions of lipids and polymers, SENS™ deliver RNAs selectively to various organs by intravenous administration. Lung- selective SENS™ (refers to PulSENS™) enabled selective delivery of RNA to the lung of mice after systemic injection. Importantly, the lung distribution and expression profile of SENS™ translated well in larger species such as rabbits and ferrets that better resembles the architecture of human lungs. Within the lung, mRNA expression was found evenly distributed throughout the endothelial cellular population with minor expression in surrounding immune and epithelial cells in both healthy and fibrosis-induced mouse models. These results suggested a potential therapeutic regimen of PulSENS™ treat pulmonary diseases caused by the dysfunction of multiple cell types. Indeed, bleomycin-induced pulmonary fibrosis were ameliorated after PulSENS™ with therapeutic mRNA administration. Treatment with the PulSENS™ confirms significant decrease in accumulation of fibronectins (FNs) extracellular matrix (ECM) components in the fibrosis mice models. Taken together, SENS™ platform has great potential as translatable therapeutics for the development of RNA therapeutics to treat lung diseases by lung selective delivery.

1730. The Endosomal Escape Vehicle Platform Enhances Lipid Nanoparticle-Mediated Delivery of Genomic Medicines

Nan Cher Flo Yeo[1], Mah Kheirabadi[2], John Buzzo[1], Lucas Bongarzone[1], Pinakin Sukthankar[1], Zekun Li[1], Anushree Pathak[1], Xiang Li[2], Ziqing Leo Qian[1]

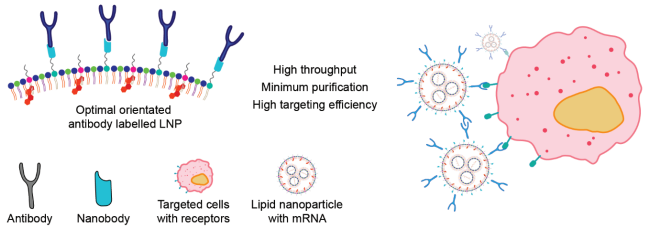
[1]Entrada Therapeutics, Boston, MA,[2]Entrada Therapeutics Inc, Boston, MA

Lipid nanoparticle (LNP) technology has emerged as a promising delivery method for nucleic acids therapeutics, including mRNA vaccines, small interfering RNA and gene editing modalities. Despite tremendous success, LNP delivery platforms still face major challenges, such as limited tissue tropism and poor delivery efficiency due to low endosomal escape. Endosomal escape is especially important for mRNA therapeutics, because different from vaccines, as much as a 1,000-fold higher level of functional protein expression is required to reach a therapeutic threshold. To address these concerns, we have applied our Endosomal Escape Vehicle (EEV™) technology to LNP engineering, with the goal of improving the delivery of genomic medicines. The EEV platform consists of a family of proprietary cell penetrating peptides (CPPs), which has been shown previously to improve intracellular delivery of oligonucleotides in various tissues and cell types. We found that EEV-modified LNP (EEV-LNP) significantly enhanced the efficiency of mRNA delivery and gene editing compared to unconjugated LNP *in vitro*. Through mechanistic studies, we further established the mechanism of uptake for EEV-LNP and indicate its ability to target a broad range of cell types and tissues. Overall, these results indicate the potential of our EEV-LNP platform for improved functional delivery of genomic medicines, with applications in the areas of mRNA delivery and gene editing.

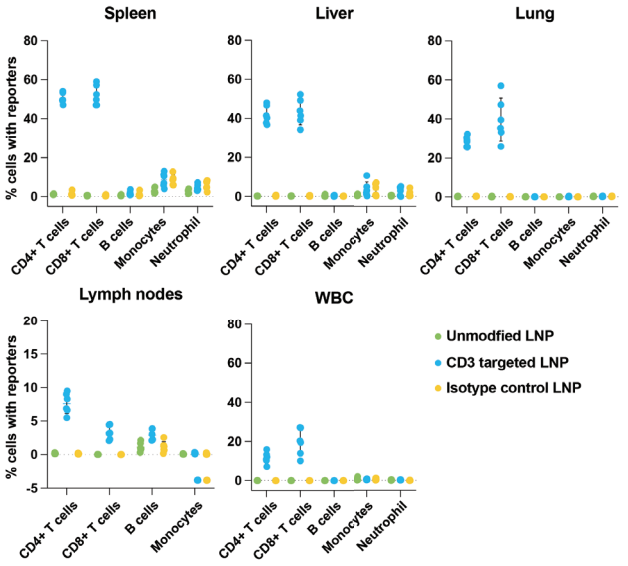
1731. A Platform for RNA-Based and Genomic Cell Engineering: Simplifying Multiplexed Delivery to Human Primary Immune and Stem Cells

Zhihui Song, Sophia Hirsch, Rachel Conover, Athira Pillai, Andrew Laroque, Jacquelyn Hanson, Alec Barclay, Mathias Pawlak, Armon Sharei

Portal, Watertown, MA



Cell therapy has the potential to revolutionize many areas of unmet clinical needs including cancer, degenerative and metabolic diseases, genetic disorders, infection, inflammation and autoimmunity. Both RNA-based and genomic editing technologies (e.g. CRISPR/Cas9) are actively investigated to design cellular therapies with customized functionalities. One of the key advantages of these new technologies is their highly adaptable nature that enables sophisticated cellular engineering, rational design and rapid pursuit of new therapeutic targets. At Portal, we have developed a gentle silicon membrane-based delivery technology that facilitates mechanoporation of cells and can be easily integrated with existing clinical-scale workflows. Our results in primary immune cells using monocytes, T, B and NK cells demonstrate over 80% efficiency and viability of cellular engineering. CRISPR/Cas9 RNPs, mRNAs and siRNAs have been successfully delivered as single cargos or in a multiplexed fashion, demonstrating the potential for either single- or multi-step cell engineering workflows which can address several targets. Furthermore, data in iPSCs and HSCs have also shown significant potential in stem cell engineering and differentiation capabilities. This technology is currently being implemented for research and clinical scale use - including in an integrated Point-of-Care manufacturing system. With continued progress in simplifying cell engineering using both RNA-based and genomic editing technologies, we aim to unlock vast biological potential in the field of cell therapy while simultaneously reducing or even eliminating safety or manufacturing concerns such as inadvertent genome alteration associated with other delivery modalities such as lentiviral vectors.



1732. A Versatile, Receptor-Targeted mRNA/LNP System for *In Vivo* Immune Cell Delivery

Zhe Chen[1], Daniel Yuen[1], Victoria M. McLeod[1], Ken W. Yong[1], Cameron H. Smyth[1], Bruna Rossi Herling[1], Thomas J. Payne[1], Stewart A. Fabb[1], Matthew J. Belousoff[2], Patrick M. Sexton[2], Christopher J. Porter[1], Colin W. Pouton[1], Angus P. R. Johnston[1]

[1]Drug Delivery, Disposition and Dynamics, Monash Institute of Pharmaceutical Sciences, Parkville, Australia,[2]Drug Discovery Biology, Monash Institute of Pharmaceutical Sciences, Parkville, Australia

Efficient and more precise delivery of mRNA is critical to advance mRNA therapies beyond their current use as vaccines. One of the problems lies in its limited targeting ability, namely the off-targeting delivery to bystander cells. This limitation can be overcome by functionalising LNPs with antibodies that target mRNA to the specific cells where it is required. While greatly improving delivery efficiency, antibody modification typically requires complex conjugation and purification methods that lead to poor yields and decreased antibody specificity. To overcome this, we present here a simple method to generate receptor-targeted LNPs, where the LNPs are functionalised with antibodies oriented in their optimal orientation in a process that does not require antibody modification or complex purification (Figure 1). This antibody conjugation strategy leads to protein expression levels >1000 times higher than non-targeted LNPs and >10 times higher than conventional, less optimal antibody functionalization techniques. We have successfully demonstrated the precise delivery of mRNA to T cells via receptor-mediated endocytosis using ex vivo PBMC from healthy donors. We found that by targeting CD3, CD5, and CD7, our targeted LNP can efficiently transfect human primary T cells with minimal delivery to bystander PBMCs. We also successfully advanced this method in vivo, with precise targeting delivery towards T cells. Expression of a reported gene was observed in T cells across multiple organs (spleen, liver, lung, lymph nodes, and circulating blood) with minimal delivery to other immune cells such as B cells, monocytes, and neutrophils. In summary, we have demonstrated a versatile system to engineer LNP with precise delivery to specific cells in vivo. Our targeted LNP system underlines the potential to develop new therapeutic modalities that precisely deliver mRNA cargo to immune cells.

1733. Efficient Scalable Manufacturing of Virus-Like Particles for the Delivery of CRISPR-Cas9 Ribonucleoproteins Using a cGMP-Compliant Electroporation Platform

Tien Nguyen, Peter Gee, Sean Menarguez, Andrew G. Mancini, Marianna Romito, Ashley B. Strickland, Lauren E. Unsworth, Cenk Sumen, Jason Papademetriou, Isabel Daher, James Brady

MaxCyte Inc., Rockville, MD

Genome editing tools such as CRISPR-Cas9 nucleases, base editors, and prime editors hold tremendous promise for treating human diseases by being able to specifically modify a targeted region of the DNA genome. However, there are limited *in vivo* delivery options that are safe, efficient, and transient. Moreover, viral vectors such as AAV are hampered by limited cargo size capacity. Virus-like particles (VLPs) offer a solution to these problems. VLPs are derived from retroviral structural proteins, which can be engineered to specifically package a cargo of interest. They are safer than traditional viral vectors because they lack a viral genome but can utilize the traditional virus delivery machinery to target and enter cells. Recently, VLPs have been reported to efficiently package base editors and prime editors for delivery into mice at therapeutically relevant levels. To realize the potential of VLPs for *in vivo* delivery, alternative methods to scale up their manufacturing will be critical for future clinical applications. Here, we utilized the MaxCyte® ExPERT GTx™, a cGMP-compliant electroporation instrument, to manufacture VLPs— packaged with CRISPR-Cas9 RNPs for genome editing in target cells — in adherent and suspension HEK293 cells. We found that electroporation consistently produced significantly higher yields of functional VLPs compared to a commercially available transfection reagent, with up to a 20-fold improvement when using an optimized electroporation protocol. Furthermore, the production of VLPs using electroporation exhibited favorable production kinetics compared to other transfection methods, enabling a shorter VLP manufacturing process. Finally,

we demonstrated the scalability of VLP production across a 15-fold volume range with minimal re-optimization. In summary, our results show that electroporation is a viable means for consistent, efficient, and scalable manufacturing of VLPs for gene-editing applications and has high promise to address needs for future clinical and commercial VLP manufacturing.

1734. Development of Highly Efficient and Safe mRNA Delivery System for the Treatment of Chronic Liver Diseases: Liver-Selective Ionizable Lipid and Biodegradable Polymer-Based Stability Enhanced Nano Shell (HepaSENS™) Platform Technology

Gooyoung Kim, Jihye Choi, Hyosuk Kim, Hyejin Park, Yisak Kim, Jongmin Park, Joungpyo Nam, Sojin Lee, Helen Cho

Samyang Biopharmaceuticals, Seongnam-si, Korea, Republic of

Lipid nanoparticle (LNP) is a clinically approved delivery system for RNA-based therapeutics, initially developed for siRNA liver delivery and more recently for mRNA vaccine approaches. LNPs have also been shown to effectively deliver mRNA to the liver and various mRNA treatments are in clinical development. Depending on the function of the payload, these systems have facilitated the advancement of treatments for rare genetic disease and acute/chronic liver diseases. Considerable efforts to enhance the potential of these systems by 1) enhancing the target tissue and subcellular cell type selectivity, 2) designing formulations that deliver to different cell types, 3) increasing protein expression efficiency and durability, and 4) improving safety are in progress. Here we report the development of Stability Enhanced Nano Shell (SENS™) as an mRNA delivery platform to overcome these challenges. SENS can effectively deliver mRNA to selective tissues such as liver, lung, and spleen by employing different compositions of novel ionizable lipids and biodegradable polymer. Liver-selective SENS (refers to HepaSENS™) exhibits selective delivery of mRNA to hepatocytes, which are the most prominent and key cell target in variety of liver diseases. HepaSENS™ efficiently delivers mRNA to the liver not only in mice with healthy livers but also in mice with diseased liver by fibrosis. Importantly, different from systems that uses PEG-conjugated lipids, HepaSENS™ does not induce anti-drug antibodies which permits consistent protein expression after each repeat administration. Moreover, to increase the therapeutic index typically seen by traditional LNPs, HepaSENS™ is designed to significantly lower liver toxicity. Human transcription factor gene HNF4A, has been known as a master regulator of the hepatocyte phenotype/metabolism and an effective therapeutic target for the treatment of hepatic disease including liver fibrosis. We compared the efficacy of repeated systemic administration of HNF4 mRNA delivered by HepaSENS™ (HNF4A/HepaSENS™) with that delivered by conventional LNP (HNF4A/LNP) in a thioacetamide (TAA)-induced hepatic damaged mice (TAA-mice) model to overcome liver damage and fibrosis. We confirmed that HNF4 expression is higher in HNF4A/HepaSENS™-treated TAA-mice liver compared to HNF4A/LNP-treated mice liver after repeated systemic administration. Importantly, blood biochemistry (alanine aminotransferase), histology (Sirius red staining), and fibrogenic gene expression profile clearly revealed effective recovery of liver damage and fibrosis in liver of HNF4A/HepaSENS™ -treated mice but not in HNF4A/LNP-treated mice. The data confirmed HepaSENS™ as an advanced hepatocyte-selective RNA delivery system that can be repeat dosed with a high safety profile. To provide new and better treatment options for patients, development of mRNA-based therapeutics using to HepaSENS™ for various liver diseases requiring short and long-term administration are in progress.

1735. Cellular Phenotyping of Non-Human Primate and Mouse Kidney and Liver Following a Novel Targeted Transcutaneous Ultrasound-Mediated Gene Delivery Demonstrates Gene Expression in Clinically Relevant Cell Types

Katie Benthall, Nana Ingram, Margarita Krivega, Julia Poniatowski, Ivan Krivega, Bert Frederich, Surabhi Rao, Victor Foster, Barry Campbell, Adel Alonso, Glenda Arauz, Celia Ortiz, Oliver Chen, Dhruv Bole, David Kim, Elizabeth Del Greco, Charlotte He, Anagha Rao, David Satyadi, Zoya Gluzman-Poltorak, Steven B. Feinstein, Ken Greenberg

SonoThera, Inc., South San Francisco, CA

Introduction: Robust delivery of genetic payloads to the kidney and liver remains a significant challenge for the development of safe and effective genetic medicines. Current limitations include the ability to 1) achieve durable episomal gene expression in a safe, titratable, and redosable manner, 2) deliver large DNA payloads (>5kb), 3) bypass endosomal and cytoplasmic immune recognition and effectively transit the nuclear envelope, and 4) achieve targeted transgene expression in clinically relevant cell types. Transcutaneous ultrasound-mediated gene delivery (UMGD) is a noninvasive *in vivo* gene delivery approach that may overcome the key delivery challenges facing genetic medicines. SonoThera is developing a novel ultrasound-guided nonviral gene therapy platform based on UMGD that allows selective targeting of specific organs and tissues within the body in a safe, redosable, durable, and titratable manner. A body of literature suggests UMGD may be an effective approach for transgene delivery into various organs, however relatively few studies have been performed to analyze the biodistribution of payload delivery and expression. Methods: To evaluate the potential of UMGD for safe and efficient transgene delivery to the non-human primate and mouse kidney and liver, we developed a technology platform utilizing novel acoustic profiles, next-generation genetic payloads, and FDA-approved ultrasound components. The delivery process involves intravenous co-administration of nucleic acid payloads (e.g. DNA or RNA) and ultrasound contrast agents (a.k.a microbubbles), coupled with targeted application of externally applied ultrasound energy to guide the DNA into specific tissues via sonoporation. To perform cellular phenotyping following sonoporation in mouse and non-human primate preclinical models, we developed three orthogonal assays, namely HALO analysis of RNAscope stained tissue slides, single nucleus RNA-seq, and immunohistochemistry. Results: Upon systematic investigation of multiple mice and NHP liver tissue samples, we confirmed that our novel UMGD platform enabled delivery of genetic payloads to hepatocytes and liver sinusoidal endothelial cells (LSECs) following liver targeting. In the mouse and NHP kidneys, we identified podocytes, tubular epithelial, and

endothelial cells as major targets for UMGD-mediated genetic payload delivery. Furthermore, we confirmed robust delivery and expression of genetic payloads in the polycystic kidney of a mouse ADPKD disease model (Nek8^{jck}). Conclusion: These biodistribution data establish a novel UMGD platform as an effective approach for non-viral delivery of genetic medicines to the most clinically relevant cell types in the liver and kidney.

1736. ARMMs as Non-Viral Vehicles that Enable *In Vivo* Functional Delivery of Cas9 to Disrupt NLRP3 in Kupffer Cells and Ameliorate Acute Liver Injury

Mike Thomas, Ryan von Kleeck, Qiyu Wang, Emmanuel Appiah, Carson Semple, Lucy Sun, Pearl Moharil, Komal Vyas, Chou-Wei Chang, Shu-Lin Liu, Qin Yu, Joseph F. Nabhan

Vesigen Therapeutics, Cambridge, MA

Acute liver injury (ALI) can be initiated through a variety of stimuli and is often the initial trigger to multiple chronic liver diseases. The NLRP3 inflammasome plays a central role in ALI to exacerbate liver disease pathogenesis thus making NLRP3 a potential target for therapeutic intervention. In this study, the non-viral delivery vehicle ARMMs (ARRDC1-mediated microvesicles) were loaded with Cas9 and gRNA targeting NLRP3 and were administered intravenously in a CCl4-induced mouse model of ALI. This resulted in up to 60% genomic editing of NLRP3 in liver tissue-resident Kupffer cells. Liver damage was assessed 24 hours post-administration of CCl4. Notably, we observed significantly diminished %TUNEL+ staining in the tissue sections of ARMM-treated mice compared to control treated mice. Flow cytometry analysis of harvested non-parenchymal cells from dissected liver tissue revealed significantly greater cell viability of cells isolated from ARMM-treated compared to control-treated mice. Circulating liver enzymes ALT and AST were also monitored in this study. In conclusion, we demonstrate that ARMMs efficiently deliver the gene editing complex (Cas9/gRNA) to disrupt NLRP3 expression in a large proportion of Kupffer cells and yield diminished liver inflammation in a mouse model of ALI. Our data suggest ARMMs as a superior vehicle for precise gene editing in renewable immune cells, such as macrophages, and as a therapeutic strategy for multiple inflammation-related disorders of the liver, including fibrosis.

1737. Novel Biodegradable Lipid Nanoparticles (LNP) for Co-Encapsulation of Complex Nucleic Acid Payloads for *In Vivo* Genome Editing

Alicia Davis, Lijun Huang, Ling Li, Khalid Hajj, Mu Li, Sang Jun Lee, Fernando L. Espinoza, Eliana Estrada, Stephanie Kearney, Kevin Johnson, Tuyen Nguyen, Thien Le, Chris Deng, Oscar Alvarez, Brian Sloat, Michael Bennett, Joshua Rychak

Poseida Therapeutics, San Diego, CA

Our Cas-CLOVER™ Gene Editing System comprises a next-generation nuclease able to achieve precise genomic edits with exceptionally high fidelity. Ensuring that the targeted genomic edits occur in the desired tissue, in particular to avoid genomic alterations that would be heritable, is of key importance for this class of gene therapy. This requirement for high organ specificity presents a challenge to conventional delivery platforms. Here, we present the results of our efforts aimed at developing a lipid nanoparticle capable of robustly co-encapsulating and delivering the Cas-CLOVER payload (consisting of a single mRNA and two gRNAs) to liver, while avoiding uptake in gonads. A novel class of biodegradable ionizable lipids was discovered and characterized as part of this effort, and methodical formulation optimization studies were performed to understand how LNP formulation and process parameters influence *in vivo* biodistribution and performance. We first aimed to discover novel ionizable lipids capable of supporting robust encapsulation and delivery of the multi-component Cas-CLOVER payload. A library of novel diamine lipidoids was designed, synthesized, formulated, and screened for delivery of a luciferase mRNA. The highest-performing lipidoid was explored using design-of-experiment (DoE) modelling to generate a panel of LNPs that were evaluated in adult mice by BLI and by measuring cytokine release. We observed a promising formulation parameter space, though subsequent studies revealed this lipidoid demonstrated unacceptably long residence time in the liver. Structure-activity relationship studies were conducted to accelerate liver clearance while preserving potency and liver tropism. One resulting ionizable lipid with ideal clearance characteristics was selected and further explored in an *in vivo* formulation discovery campaign. We conducted a DoE formulation optimization campaign using Cas-CLOVER mRNA and gRNAs specific for mouse *Pcsk9* (as a tooling locus). The model evaluated four formulation variables (% ionizable lipid, % phospholipid, % DMG-PEG, and lipid-to-payload ratio), and each run was evaluated in mice. A formulation able to reproducibly encapsulate the Cas-CLOVER payload components and mediate *Pcsk9* editing with high potency was identified from the DoE model. Benchmarking studies demonstrated superior potency and tolerability for this LNP formulation using the Cas-CLOVER nuclease. The formulation was subsequently transferred from the benchtop microfluidic/dialysis process to one utilizing scalable unit operations, and successfully scaled up by 10X. This work resulted in the generation of a novel ionizable lipid and LNP formulation capable of supporting application of the Cas-CLOVER nuclease for liver-directed genome editing. These results demonstrate the utility of rational design, chemical syntheses and formulation optimization when seeking to deliver complex nucleic acid payloads.

1738. Inhibition of IFNAR-JAK Signaling Enhances Tolerability and Transgene Expression of Systemic Non-Viral DNA Delivery

Cameron Baptista, Sujata Senapati, Mike Minnier, Matt Walsh, Sean M. Armour, Pedro J. Cejas

Spark Therapeutics, Philadelphia, PA

Lipid nanoparticles (LNPs) have demonstrated great potential for non-viral delivery of nucleic acid therapeutics, with mRNA delivery used for vaccines and siRNA to treat genetic disease. There is considerable interest in applying LNPs to therapeutic delivery of DNA (DNA-LNPs) to achieve long-term gene expression for a broad range of genetic diseases. A significant obstacle to systemic DNA-LNP delivery is the potential for acute inflammatory responses, which present

significant safety concerns and potentially limit therapeutic transgene expression. However, the mechanisms and immune signaling pathways underlying DNA-LNP-triggered inflammatory responses are not well characterized. We employed gene-targeted mouse models and identify cGAS-STING and IFNAR as major molecular mediators of acute inflammation triggered by systemic DNA-LNPs. cGAS-STING activation induces expression of numerous JAK-STAT cytokines, and we show that treatment of mice with JAK inhibitors, ruxolitinib or baricitinib, significantly improves tolerability to systemically delivered DNA-LNPs. Further, specific inhibition of IFNAR signaling significantly enhances DNA-LNP tolerability and transgene expression. Therefore, utilization of JAK inhibitors or IFNAR blockade present potentially useful approaches to improving safety and efficacy of non-viral DNA delivery for gene therapy.

1739. Human Organoids for Optimization of LNP Mediated Targeting of Non Parenchymal Patient Liver Cell Types

Tobias Raabe[1], Jilian Melamed[1], Mohamad-Gabriel Alameh[1], Andy Liu[2], Drew Weissman[1]

[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[2]School of Engineering and Applied Science, University of Pennsylvania, Philadelphia, PA

Background and Rationale: Lipid nanoparticles (LNPs) have emerged as pivotal tools in gene therapy and drug delivery, epitomized by the success of mRNA LNP-based COVID-19 vaccines and the FDA-approved LNP-mediated gene therapy for transthyretin amyloidosis. However, most intravenously administered LNP's target hepatocytes, limiting their potential applications. Targeting non-parenchymal liver cells, which are crucial mediators in liver diseases, poses a significant challenge and urges the development of effective LNP strategies. Since mouse models of LNP targeting are often unable to predict optimal LNPs for use in humans, and primate models are time consuming and expensive, we reasoned that targeting human liver derived organoids with LNPs may be helpful to efficiently and systematically develop clinically relevant LNPs for nonparenchymal liver cells. **Experimental Setup:** We incorporated two excipient lipids with candidate myeloid tropism - as determined by mouse studies - into LNPs, in the hope to effectively modulate cellular distribution away from patient hepatocytes and towards patient liver myeloid cells. We employed non alcoholic steatohepatitis (NASH) patient liver - derived organoids in co-culture with primary human macrophages and tested the two types of candidate myeloid tropic LNP preparations under several culture conditions. To asses myeloid targeting capacity of the candidate LNP types we co-transfected them with known hepatotropic LNPs. To directly and simultaneously visualize both hepatotropic and candidate myelotropic LNPs in the co-cultures we formulated the hepatotropic LNPs with GFP mRNA and the candidate myelotropic LNPs with tdTomato mRNA. **Results:** Detailed quantitative analysis of immunofluorescence images revealed that our candidate myelotropic LNPs are indeed myelotropic compared to the LNPs with known hepatocyte specific tropism. Importantly, we also show that organoid-macrophage co-culture media composition is a major determinant of the degree of myelotropism and especially the remaining capacity to target hepatocytes. We show that our system has the capacity to directly test the effect(s) of media components such as ApoE, serum and others on our candidate LNPs myeloid specificity. Importantly, even under optimal media conditions our candidate myeloid tropic LNP formulations targeted unexpectedly only about 50% of all primary human macrophages. We are currently improving our myeloid specific LNPs which includes investigating if our candidate myeloid specific LNPs target only specific subtypes of human macrophages. **Conclusions:** Co-cultures of primary human myeloid cells with patient liver derived organoids have the capacity to precisely assess LNPs patient liver cell type specific tropism and to optimize LNP formulations to direct them toward non parenchymal patient liver cells and away from patient hepatocytes. Combining advanced LNPs and patient liver organoids holds the potential to revolutionize targeted gene therapy and drug delivery, paving the way for precision medicine in the treatment of liver diseases.

1740. Kidney-Targeted Non-Viral Gene Delivery Using a Novel Noninvasive Transcutaneous Ultrasound Delivery Platform Enables Redosable, Titratable, and Durable Gene Expression in Healthy Mice and NHPs, and Polycystic Kidneys Mouse Model

Bert J. Frederich, Surabhi Rao, Victor Foster, Barry Campbell, Adel Alonso, GLenda Arauz, Celia Ortiz, Oliver Chen, Charlotte He, Elizabeth Del Greco, Anagha Rao, David Satyadi, Dhruv Bole, David Kim, Katie Benthall, Margarita Krivega, Julia Poniatowski, Ivan Krivega, Zoya Gluzman-Poltorak, Steve Feinstein, Kenneth Greenberg

Sonothera Inc, South San Francisco, CA

Introduction: Gene delivery to the kidney remains a significant impediment to the development of genetic medicines for renal diseases. Transcutaneous ultrasound-mediated gene delivery (UMGD) presents a noninvasive *in vivo* gene delivery approach that may overcome the key delivery challenges facing genetic medicines. Despite a body of literature supporting the effectiveness of UMGD in introducing transgenic DNA into target organs, a comprehensive understanding of the efficacy, durability, and safety in healthy and diseased kidneys has yet to be established. SonoThera is developing a novel ultrasound-guided nonviral gene therapy platform based on UMGD that allows selective targeting of specific organs and tissues within the body in a safe, redosable, durable, and titratable manner. Methods: To evaluate the potential of UMGD for safe and efficient transgene delivery to the kidney, we developed a technology platform utilizing novel acoustic profiles, next-generation genetic payloads, and FDA-approved ultrasound components. The delivery process involves intravenous co-administration of nucleic acid payloads (e.g. DNA or RNA) and ultrasound contrast agents (a.k.a microbubbles), coupled with targeted application of externally applied ultrasound energy to guide the DNA into specific tissues via sonoporation. In vivo bioluminescence imaging of firefly luciferase reporter gene expression was evaluated using an IVIS imaging system at multiple timepoints in kidneys of wild type mice and a mouse model of polycystic kidney disease ($Nek8^{jck}$) following UMGD. Mouse and monkey kidney tissues were analyzed for reporter gene presence and expression. Multiple clinical and molecular safety assessments were evaluated in mice and monkeys using established methods. Results: The delivery of next-generation

non-viral genetic DNA payloads via UMGD resulted in rapid, robust, durable, redosable, and dose-responsive transgene expression in wild-type mouse kidney. Durable gene expression with no loss of signal was observed beyond 9 months following a single treatment in mice. Additionally, in a mouse model of polycystic kidney disease (Nek8^{jck}) exhibiting advanced cystic pathology, UMGD resulted in significant microvascular perfusion, efficient gene delivery, and robust expression in cystic structures. Reporter gene presence and expression were detected in the analyzed mouse and NHP kidney tissues. Safety assessments including clinical observations, blood urea nitrogen, creatinine, and a proinflammatory cytokine panel indicate an excellent tolerability and safety profile following single and repeat treatments in mice and monkeys. These findings hold potential significance for the application of this technology in genetic medicines for multiple types of kidney diseases. Conclusion: This study positions a novel UMGD platform as a promising strategy for *in vivo* transgene delivery using next-generation non-viral genetic payloads, thereby laying the foundation for the development of future genetic medicines for renal diseases.

1741. Next-Generation DNA-Based Delivery of Therapeutic Proteins Using MYO Technology: Preclinical Results on Incretins Receptor Agonists

Linda Sasset, Marek M. Drozdz, Andrew D. Cameron, Delcora A. Campbell, Debnath Maji, Xin Yao, Carleigh Sussman, Andy T. Thompson, Robert Miller, Rachel Liberatore

RenBio, New York, NY

Therapeutic proteins, a large class of drugs including antibodies, hormones, and enzymes, have seen a substantial increase in both clinical development and use across many disease areas. However, significant drawbacks continue to limit access to many of these drugs, and can include: i) high manufacturing costs; ii) administration via time-consuming intravenous infusions; iii) frequent dosing, sometimes even daily; iv) requirements for low temperature storage, hindering the ability to get therapeutics to large numbers of people, a problem amplified in low and lower-middle income countries. MYO Technology™, a DNA-based platform for the delivery of therapeutic proteins, was developed to overcome these barriers. The MYO Technology platform consists of therapeutic-encoding plasmid DNA (pDNA) and a proprietary medical device for the intramuscular injection of pDNA, followed by the delivery of very short electrical pulses to the muscle tissue surrounding the injection site. These pulses promote the *in vivo* electroporation of muscle cells and uptake of pDNA, leading to production and secretion of the therapeutic protein, and ultimately uptake into peripheral circulation.MYO Technology™ offers several advantages over standard delivery of therapeutic proteins, in part because pDNA manufacturing is a simpler and less specialized process as compared to protein manufacturing, and pDNA is very stable and lacks most cold chain requirements. Furthermore, administration using MYO Technology takes just a few minutes, and the serum level of a therapeutic protein can potentially be maintained for many months, perhaps even years, without the need for redosing. A subclass of therapeutic proteins that have recently come to prominence are incretin (GLP-1, GIP) receptor agonists (IRAs). IRAs are emerging as powerful glucose control and weight loss drugs, used for the treatment of type 2 diabetes (T2D) and obesity. The FDA-approved drugs semaglutide (Ozempic/Wegovy) and tirzepatide (Mounjaro/Zepbound) are very potent molecules but have a short half-life, requiring weekly administration by subcutaneous injections. Moreover, since their effects rapidly disappear once the treatment ends, T2D and obese patients may have a life-long dependency on IRAs, and this requirement for weekly injections can negatively affect the quality of life and the adherence to therapy, as well as create a significant financial burden.Here, we present our preclinical studies on delivery of IRAs with MYO Technology. Animal proof-of-concept studies demonstrate that expression of MYO Technology-delivered IRAs is pDNA-dose dependent and remains stable for several months or longer in vivo. Importantly, MYO Technology-produced IRAs are functional and efficacious in stimulating weight loss in animal models of diet-induced obesity.Through significant improvements in administration frequency, MYO technology has the potential to dramatically improve quality of life and therapy adherence among T2D and obese patients. Furthermore, MYO Technology has the potential to present the same advantages when applied to other therapeutic proteins with short half-lives.

1742. Risks and Benefits of Multiplexed Gene-Editing Strategy for Generation of Hypo Immune Universal Pluripotent Stem Cell Platforms for Off-the-Shelf Cell-Based Therapeutic Applications

Miguel A. Tellez[1], Joe Geraghty[1], Luis Borlado[1], Saumyaa Saumyaa[2], Noorul S. Sheikh Farid[2], Gargi Roy[1]

[1]Biopharmaceutical Development-Cell Culture and Fermentation Sciences, AstraZeneca, Gaithersburg, MD,[2]Safety Sciences, AstraZeneca, Gothenburg, Sweden

We seek the development of allogeneic regenerative cell therapy products to make cell therapies accessible to wider patient populations. But this approach requires the product to escape immune system activation to obtain a sustained therapeutic benefit. We and others have shown that major histocompatibility complex (MHC) class I and II removal prevent T-cell recognition, however this approach requires the expression of cloaking genes on the cell surface to avoid elimination by natural killer (NK) cells and macrophages. Herein in a single electroporation-based gene editing step, we generated hypo immune universal human embryonic stem cells (hESCs) by knocking out MHC-I and MHC-II genes and inserting NK cell and macrophage evasion molecules in beta-2-microglobulin and CIITA loci respectively, utilizing a non-viral transgene delivery in combination with synthetic guide RNA and Cas9-mediated double strand DNA breaks. This single electroporation strategy significantly reduced the number of cell passages and timeline required for the establishment of clonal hypo immune hESCs, resulting in the reduction of overall timeline for generation of gene-edited lines by 3 months, as compared to a multistep editing approach. Among the clones screened, 38% contained site-specific knock-ins, expressed high levels (>90%) of pluripotency markers with normal karyotype and were able to efficiently differentiate into the three germ layers. Interestingly, 1 of 3 clones evaluated by

long-range whole genome analysis (optical genome mapping) showed no post-editing structural and copy number variations across the genome. Overall, when multiplex gene editing is used in tandem with clonal expansion, there is no observed excessive risk of chromosomal translocations, but rather is balanced by the reduced risk of genomic instability as observed in extended passages of stem cells.

1743. Polycistronic Modified mRNA Encoding Epigenome Rejuvenating Oct4, Sox2 and Klf4 Factors for Genome-Safe Rejuvenation of Age-Defective Kidneys from Life-Supported Organ Donors

Daniel Chevallier[1], Roger Bertolotti[2]

[1]Department of Urology and Kidney Transplantation, University Hospital of Nice, Nice, France,[2]Faculty of Medicine, University of Nice-Sophia Antipolis, Nice, France

Breakthrough retinal rejuvenation has been recently achieved by others upon AAV-mediated ectopic expression of 3 Yamanaka factors (Oct4, Sox2 and Klf4: OSK) in mouse retinal ganglion cells. Unlike the full set of Yamanaka factors (OSKM, M: cMyc), polycistronic OSK transduction has been shown to maintain cellular identity while restoring youthful DNA methylation patterns and relevant transcriptomes, consistent with the described promotion of axon regeneration and reversion of vision loss in aged and glaucoma mice. Such a stable in vivo epigenetic gene therapy achievement relies on an hit-and-run protocol in which transient expression of the long-lasting AAV-OSK transgene is under the control of doxycycline, thereby prompting us to devise a genome-safe strategy based on intra-vitreal delivery of short-lived nucleoside-modified mRNA (modRNA). Importantly, similar rejuvenation results have been recently published for mouse kidney with the above AAV-OSK vector, a result that could broaden the availability of kidney transplants upon applying our above protocol to rejuvenate kidneys from aged donors. Indeed, the shortage of kidney grafts is such a dramatic burden that we have transplanted kidneys from an 80 years-old donor. Of course, therapeutic rejuvenation will most likely target patient's organs themselves in a non-distant future. However, such a clinical translation requests costly time-consuming trials with large animal models. Therefore, rejuvenating age-related defective donor kidneys during the transplantation process stands as an exciting option because we believe that delivery of OSK modRNA before transplantation can be efficient enough to induce significant post-transplantation rejuvenation while avoiding potential OSK mRNA hazards to the patient himself. Indeed, under our proposed modRNA transfection protocol, safety hazards are mainly restricted to the allogeneic graft, thereby securing a positive benefit/risk balance. Our approach is thus discussed in terms of genome-safe rejuvenation of aged kidney transplants mediated by delivery of synthetic OSK mRNA modified by N1-methylpseudouridine as a substitute for uridine and optimized with appropriate capping, 3'/5'UTRs, improved coding sequence and poly(A) tail. Kidney delivery of such purified modified polycistronic OSK mRNA will rely either on lipid nanoparticles or on a citrate-saline formulation. Of note, as described by others, hydrodynamic delivery of DNA/mRNA to the kidney has been shown to be effective on mice/rats as long as it is performed on the clamped renal vein (with synergistic renal artery clamping) or on the renal pelvis. Hydrodynamic delivery appears to be perfectly fitted to the rejuvenating trial since it can be done in situ, before transplantation, on the kidneys from aged organ donors maintained under life support. Design optimization of the synthetic modRNA will be done while the compassionate use of early transfected donor kidneys will be consistent with the acute dramatic organ shortage. Importantly, we believe that kidneys from life-supported donors can accommodate several courses of mRNA transfection before transplantation, thereby easing the optimization of the rejuvenation process under compassionate conditions. Thus, the idea is to reduce kidney organ shortage upon epigenome rejuvenation of kidneys from aged organ donors maintained under life support, first upon compassionate conditions, then under optimized rejuvenation conditions of donor kidneys. Our proposed compassionate clinical trial is now ready for evaluation.

1744. Nanoparticles in the Biomimetic Extracellular Matrix Coated on the Cell Surface Remotely Regulate Gene Expression

Kyungsene Lee, Brandon Davis, Xuelin Wang, Yong Wang

The Pennsylvania State University, University Park, PA

The regulation of gene expression is critical to various applications. In this study, we introduce a novel approach for nanoparticle (NP) immobilization on the cell surface for cell regulation utilizing an ultrathin biomimetic extracellular matrix as a nanocapsule for carrying nanoparticles (CN2). This biomimetic extracellular matrix not only encapsulates cells but also carry gene-regulating nanoparticles. Encapsulated cells demonstrate sustained high viability and normal metabolic activity. By employing gold nanoparticles as a model, we found that exposure to light induced a transient temperature increase, activating the heat shock protein 70 (HSP70) promoter and modulating the expression of reporter genes. Given the versatility of the biomimetic nanocapsule for decoration with various nanoparticles, CN2 emerges as a promising platform for the regulation of gene expression and cell functions. Methods: Oligonucleotides used in this study were purchased from Integrated DNA Technologies (Coralville, IA). The DNA initiator was introduced to the cell membrane through lipid insertion. The combination of biotinylated DNA monomer 1 and alginate-conjugated DNA monomer 2 resulted in the formation of a DNA template through hybridization chain reaction. The decoration and stability of nanoparticles facilitated by CN2 on the cell surface were assessed using confocal microscopy and flow cytometry. In vivo imaging system demonstrated the successful transfection of a heat-inducible HSP70 promoter-based DNA plasmid into mesenchymal stem cells (MSCs) under laser irradiation. ELISA and in vitro wound healing assays revealed improved VEGF secretion from CN2 engineered MSCs with the HSP70-VEGF plasmid. Laser speckle contrast imaging on the chicken chorioallantoic membrane model study demonstrated enhanced angiogenesis in the CN2 group compared to other groups. Results: Confocal laser scanning microscopy and flow cytometry results demonstrated the formation of CN2 on the cell surface. CN2 stably retained NPs on the cell surface with minimal dissociation and internalization. Cell viability assays and cytokine array results demonstrated that CN2 did not compromise cellular behaviors of the host cell. MSCs transfected with heat-inducible HSP70-luciferase DNA plasmid showed significantly increased luminescence after laser

irradiation, demonstrating the stimulated luciferase expression from the plasmid. Kinetics analysis demonstrated that the expression of protein was time post laser irradiation dependent, with showing plateau after 12 hours. ELISA results showed the more than 3-fold increase in HSP70-VEGF plasmid transfected group after laser irradiation compared with other groups. Cells were transplanted on the chicken chorioallantoic membrane and blood flow was analyzed. CN2:VEGF group showed significantly increased blood flow after laser irradiation with showing over 270% increase. Conclusions: CN2 synthesis on the cell membrane represents a promising approach for nanoparticle immobilization on the cell surface for gene regulation. Nanoparticles can be displayed at the vicinity of encapsulated cells. This system offers a facile means to regulate cellular functions, including gene expression. The results show versatility and generality of CN2 in encapsulating any cell type while carrying single or multiple nanoparticles. Consequently, CN2 is a promising technique leveraging the features of both polymeric nanocoating and inorganic NPs, presenting a novel pathway for advancing cell-based applications, such as stem cell delivery for regenerative medicine, immune cell delivery for immunotherapy, and cell-mediated nanoparticle delivery for cancer treatment.

1745. Highly Efficient Non-Viral Gene Editing of Unactivated Human T cells and Hematopoietic Stem and Progenitor Cells Using Microfluidic Transfection

Eric Ouellet[1], Manreet Chehal[1], Ulrike Lambertz[1], Elinor Binson[1], Tina Liao[1], Gil Paik[1], Phillip Chau[1], Kevin Chen[1], Bob Dalton[1], Allen C. Eaves[1,2], Sharon A. Louis[1], Andy Kokaji[1]

[1]STEMCELL Technologies, Inc., Vancouver, BC, Canada,[2]Terry Fox Laboratory, Vancouver, BC, Canada

Ex vivo gene editing of primary cells presents great potential for investigating molecular drivers of disease and development of new therapeutics. The increasing variety of bioactive molecules used in these studies continue to push the limits of traditional intracellular delivery methods. Non-viral delivery represents an attractive approach to limiting the risks of insertional mutagenesis associated with viral delivery, but some methods, including electroporation, can be accompanied by increased cell loss and altered cellular physiology. Therefore, careful considerations must be made in selecting the best approach that provides high efficiencies and minimal unwanted cellular perturbations. Mechanoporation has been shown to safeguard critical cell quality attributes including viability, phenotype and function. The CellPore™ Transfection system is a mechanoporation-based system that relies on rapid controlled cell deformation within microfluidic channels to generate temporary pores for direct cytosolic introduction of materials. In this work, we describe the implementation of the CellPore™ technology workflow for genetic manipulation of human unactivated T cells and CD34+ hematopoietic stem and progenitor cells (HSPC). By evaluating the interplay between the delivery of fluorescent dextrans and impacts to cell viability under varying system pressures, the transfection efficiency can be optimized for various biological cargos, including mRNA and CRISPR Cas9 ribonucleoproteins (RNP). Our study first applied this method to optimize the delivery of Cas9 RNP complexes targeting either *B2M* or *TRAC* genes in unactivated T cells from healthy donors. After 2 or 6 days of culture, T cells were analyzed for MHC-I or TCRαβ marker expression, respectively. *B2M* editing resulted in 73.6 ± 4.0% knockout of MHC-I (mean ± SD; n = 12) and 93.9 ± 1.0% knockout of TCRαβ for *TRAC*-edited donors (n = 3). Overall viability for all edited donors remained high (80.3 ± 4.1%; n = 15). Importantly, we further demonstrated that transfection via CellPore™ safeguarded the unactivated T cell phenotype, evidenced by low CD69 activation marker expression (0.8 ± 0.3%; n = 6) and baseline secretion levels of several pro-inflammatory cytokines, including IL-2 (0.11 ± 0.09 pg/mL) and IFNγ (0.14 ± 0.03 pg/ml; n = 3). In contrast, electroporation resulted in elevated levels of CD69 marker expression (41.2 ± 8.4%; n = 6) and proinflammatory cytokines (77.6 ± 23.5 pg/mL IL-2; 8.9 ± 3.5 pg/mL INFγ; n = 3). Finally, the ability for unactivated T cells manipulated by CellPore™ to undergo similar activation and expansion compared to unmanipulated samples is shown. Likewise, we investigated the ability to genetically manipulate cord blood-isolated CD34+ HSPCs via CellPore™ transfection. After two days of culture in StemSpan™ medium, HSPCs were harvested, transfected with Cas9 RNP targeting *B2M*, and returned to culture for an additional 4 days. Editing of *B2M* resulted in 80.6 ± 3.1% knockout of MHC-I (n = 15) in the long-term repopulating hematopoietic stem cells (CD34+CD90+CD45RA-) within the bulk CD34+ HSPC population. Furthermore, a 14-day colony-forming unit (CFU) functional assessment of the edited HSPCs showed minimal impact to their proliferation. These results underscore the important considerations that need to be made when choosing a suitable intracellular delivery method for genetically manipulating primary cells. In this capacity, these results provide a demonstration of a non-viral delivery approach that enables high cellular engineering efficiencies with minimal impacts to downstream cellular function.

1746. Suspension Cell-Based Production and Scalable Purification of Engineered ARMMs as a Platform for Non-Viral Therapeutics

Steven Greenway, Alysia Bryant, Ishaan Tiwari, Zachary Shelnitz, Leah Gens, Adam Francoeur, Arian Pushka, Kristin Luther, Gary Hao, Joseph Nabhan

Vesigen Therapeutics, Cambridge, MA

Extracellular vesicles (EVs) are currently being evaluated as promising platforms for non-viral delivery of therapeutic payloads. The clinical development of EVs is hampered by the challenges in manufacturing of therapeutic-grade material at scale. Here, we report an efficient and scalable platform tailored for production of a specific class of EVs, ARRDC1-mediated microvesicles (ARMMs). During process development, each unit of operation was systematically evaluated for the selection of the optimal reagent, instrumentation, and parameters. The upstream process is comprised of a specific class of transfection reagent for enhanced ARMMs yield, low-shear rocking platform bioreactor, and primary clarification by continuous centrifugation. The downstream process entails tangential flow filtration followed by mixed-mode size exclusion chromatography or monolithic anion exchange chromatography. The platform enables the production of ARMMs loaded with therapeutic molecules including CRISPR/Cas, base editors, mRNA, or short hairpin RNA (shRNA). The final products show high purity, consistent size distribution and payload concentration, as well as functional payload delivery in both in vitro

and in vivo experiments. Our data establishes robust and scalable production and purification processes for ARMMs with multiple payloads. These advances support the potential to utilize these processes for manufacturing of ARMMs for clinical trials.

1747. Regulatory Strategy to Maximize Success Potential of Gene Therapy & Rare Diseases

Mridula Shukla

Poseida Therapeutics, San Diego, CA

The rapidly changing field of Gene Therapies promises several innovative treatments for rare diseases. Given that approximately 80 percent of the 7,000 known rare diseases are caused by a single-gene defect, there has been increased research in developing cell and gene therapies to treat rare diseases. However, several challenges hinder these efforts, including the high cost of bringing these drugs to market, unique manufacturing and supply chain challenges, pricing and reimbursement, and our current limited understanding of disease pathology and progression. In this presentation, we will discuss how we can downplay the complexities associated with gene therapies by employing the optimal regulatory strategy. Questions that will be covered in this presentation include. Q1: Recent trends in gene therapies and key challenges given the complexity & high cost of gene therapy development Q2: Discuss strategies to develop gene therapy products in a cost-effective way Q3: How gene therapy can be impactful for Rare diseases Q4: Successful and Proven Regulatory Strategies to expedite the development of GT drugs Q5: Recent announcements from the FDA on Project OWS-RD & BCGT Plug-n-Play approach Q6: Benchmarking of regulatory pathways for gene therapy drugs Q7: Inflection point and evolving trends in Gene Therapy

1748. Gene Editing in Liver Towards the Treatment of Life-Threatening Cardiovascular Diseases: POC for Efficient *In-Vivo* Genome Editing/Base Editing Using Lipid Nanoparticle Library

Anitha Thomas, Mehar Gayatri Namala, Nikita Jain, Zhengyu Chen, Leanna Lee, Malathi Anantha, Sams Sadat, Tony Wu, Ruchi Sharma, Eric Wu, Jay Paquette

Cytiva, Vancouver, BC, Canada

Introduction: The transformative potential of CRISPR-Cas9 gene-editing technologies, including CRISPR-Cas9 base editors (ABE, CBE), in modifying human genes has paved new path for genomic medicines. This, along with the renaissance of the LNP field hold enormous potential in enabling gene medicines. Efficient gene editing workflows and enabling tools for in vivo and ex vivo gene editing are required to advance genomic medicine innovation. Scarcity of well characterized fit-for-purpose lipids that are suitable for CRISPR-Cas9 gene-editing technologies continue to be a problem in advancing many genomic medicine applications. In this study, we present the development of novel ionizable lipids as functional excipients for designing vehicles for delivering CRISPR-Cas9. We evaluated the genomic medicine potential towards the treatment of life-threatening cardiovascular diseases. **Methods:** The robust LNP delivery system utilized our proprietary lipids and compositions for editing *TTR* and *PCSK9* genes in rodent models. Guide RNA (sgRNA) and messenger RNA (Cas9 or ABE 8.8m) were co-formulated in LNPs using NanoAssemblr® Ignite. Size and PDI were determined using Dynamic Light Scattering. The encapsulation efficiency was determined using the Ribogreen™ assay. Cas9-TTR LNPs and ABE 8.8m-PCSK9 LNPs were administered intravenously into CD-1 and C57BL/6 mice, respectively, at 2-3 mg/kg dose. Serum was collected 7 days post injection and analyzed for *TTR* and *PCSK9* levels through ELISA. Further, we have done NGS sequencing to evaluate editing levels. **Results:** Size of the LNPs were reported to be between 50-140 nm with PDI<0.2. PNI LNPs showed significant editing of the mouse transthyretin (*TTR*) gene and proprotein convertase subtilisin/kexin type 9 (*PCSK9*) gene in the mouse liver, resulting in approximately 75% and 80% reductions in serum protein levels, respectively, following a single administration of 2mg/Kg LNPs. The robust LNP delivery system used in this current study demonstrated exceptional biodegradability and high tolerability, at efficacious doses tested. It has been shown earlier that ABE-cas9 show off-target editing even with-in the targeted locus. Novel LNPs showed precise base editing of PCSK9 locus without having off targeting effects. Overall, we demonstrated successful gene editing and base editing of *TTR* and *PCSK9*, respectively, in rodents. **Conclusions:** Our proprietary lipid and or LNP compositional library can be used to efficiently deliver CRISPR/Cas9 components. We achieved clinically relevant levels of in-vivo genome editing of TTR and PCSK9 targets as examples. These findings highlight the potential of our lipid library as a highly effective and promising platform tools for genome editing.

1749. Sonogenetic Modulation of Cellular Activities for Treatment of Neurological Disorders

Subrata Batabyal[1], Sanghoon Kim[1], Michael Carlson[1], Darryl Narcisse[1], Adnan Dibas[2], Samarendra K. Mohanty[1]

[1]Nanoscope Technologies LLC, Bedford, TX,[2]Nanoscope Technologies, Bedford, TX

PURPOSE: While electrical modulation of neuronal activity in the central and peripheral nervous systems using neuroprosthetic has shown therapeutic benefits in restoring sensory and motor function in various neurological disorders, it is challenged by complexity due to invasive implantation surgeries and non-specific stimulation. It has been demonstrated that ultrasound can modulate cellular activities with or without the use of exogenous microbubbles or genetic mechano-sensitization. However, the requirement of high-intensity ultrasound poses a challenge in miniaturization for neuroprosthetic applications. By sensitizing specific neurons toward ultrasound using engineered mechanosensitive channels (EMC), low-power sonogenetic simulation provides a potential alternative therapeutic modality to achieve cell-specific stimulation for improving the treatment of various neurological diseases. METHODS: Using pressure-clamp electrophysiology, we have screened several mutated mechanosensitive channels derived from different microbial species that are heterologously expressed in HEK293 cells. Sensitization of cells with EMC was achieved either by viral or non-viral methods. In-vivo expression of EMC in the central nervous system was achieved by AAV delivery. Sonogenetic stimulation of EMC-expressing neurons was carried out by ultrasound

with varied intensity to determine the threshold for activation. The activation was evaluated using electrical measurements *in-vitro* and *in-vivo*. The impact of ultrasound-evoked electrical activities in EMC-sensitized neurons was evaluated for modulating different sensory functions. RESULTS: By molecular engineering, the activation threshold of EMC was significantly reduced compared to wild-type microbial mechanosensitive channels. Our studies show robust EMC expression in the cellular membrane (assessed by analysis of mCherry reporter) leads to activation in response to low-intensity ultrasound (0.2 MPa). In-vivo stimulation of EMC-sensitized neurons by low-intensity ultrasound led to statistically significant ($p<0.05$) activation measured by electrophysiology compared to non-treated controls. Sonogenetic stimulation of the EMC-sensitized brain led to efficient neuromodulation, as assessed by behavioral assays. CONCLUSION: EMC sensitization of specific neurons via genetic targeting combined with external ultrasound stimulation elicited functional responses in multiple animal models. The advancement of this sonogenetic approach will lead to a new treatment approach for debilitating neurological disorders.

1750. Chandipura Viral Glycoprotein (CNV-G) Promotes Gectosome Generation and Enables Delivery of Intracellular Therapeutics

Xuedong Liu[1], Xiaojuan Zhang[1], Quanbin Xu[1], Zeyu Liu[1], Brandon Black[1], Saheli Ganguly[1], Jayson Ball[2], Michael E. Harland[2], Samuel Blackman[3], Stephanie Bryant[3], Kristi Anseth[3], Linda Watkins[2]

[1]Biochemistry, University of Colorado-Boulder, Boulder, CO,[2]Psychology & Neuroscience, University of Colorado-Boulder, Boulder, CO,[3]Chemical and Biological Engineering, University of Colorado-Boulder, Boulder, CO

Achieving cell type-specific delivery of biologics and overcoming the challenge of delivering large macromolecules through endosomal barriers remain significant hurdles in the field of biomedicine. Previously, we developed a versatile approach for delivering proteins and ribonucleoproteins (RNPs) to both in vitro cell cultures and in vivo mouse liver tissue using specially engineered vesicles known as "Gectosomes." These Gectosomes are designed to co-encapsulate the vesicular stomatitis virus G protein (VSV-G) with bioactive macromolecules through split GFP complementation. Our method enables active cargo loading into these Gectosomes, resulting in improved cargo delivery efficiency and simplified purification processes. While VSV-G Gectosomes have broad cellular tropism, for specific therapeutic applications, it is often desirable to have Gectosomes with more restricted cellular tropism and cell type specificity. In this study, we evaluated a subset of viral glycoproteins from a diverse range of viruses for their ability to stimulate the production of Gectosomes and the intracellular delivery of encapsulated cargos. We made a significant discovery that the expression of the viral glycoprotein CNV-G, derived from the human neurotropic pathogen Chandipura virus in 293T cells, significantly shifts the production of extracellular vesicles (EVs) towards CNV-G Gectosomes. Compared to VSV-G Gectosomes, CNV-G Gectosomes exhibit enhanced cell-type selectivity, demonstrating effectiveness in primary cells and tumor cell lines, with a notable preference for neuronal cells. Further investigations revealed that CNV-G Gectosomes enter cells independently of the Low-Density Lipoprotein Receptor (LDLR), which is essential for VSV-G entry. Additionally, CNV-G Gectosomes respond differently to pharmacological modulators. Using a split GFP and chemical-induced dimerization system, we demonstrated that CNV-G Gectosomes can be adapted to deliver various intracellular cargos designed to modify the genomic sequence of target cells or respond to external stimuli, both in vitro and in the brains of mice in vivo. Pharmacokinetics and biodistribution analysis further support the potential of CNV-G Gectosomes as a highly effective programmable macromolecular delivery platform for intracellular therapeutics. Consequently, Gectosome technology holds promise for the treatment of rare human diseases by enabling targeted gene therapy.

1751. One-Step Production of Cas9-Based Precision Gene Editors for *In Vivo* Delivery

Colin D. Robertson[1], Alexandros Poulopoulos[2]

[1]Pharmacology and UM-MIND, University of Maryland School of Medicine, Pikesville, MD,[2]Pharmacology and UM-MIND, University of Maryland School of Medicine, Baltimore, MD

As precision genome editing technologies advance, it is important to broadly consider applications that may benefit patients suffering from genetic diseases. Given the long path towards approval for therapeutic gene editing, a more immediate clinical need might be met through the use of these precision editors to efficiently model disease. Our previous work has demonstrated the use of prime editing in vivo to model an individual rare epilepsy variant in a wild type background. Because gene editing approaches now boast extremely flexible design requirements, allowing efficient and precise modifications spanning an impressive range of sizes, most genetic variants could similarly be targeted. Our work has previously been limited to delivery of plasmids in utero, restricting the target tissues and breadth of impact. Here, we describe an updated system for producing custom Cas9-based ribonucleoproteins (RNPs) in one step in *E. coli*. We assess these RNPs for efficiency and precision in vitro and in vivo assays targeting multiple genomic loci. These RNPs alleviate previous restrictions to our disease modeling platform, decrease the potential for off-target and unintended edits, and allow for higher efficiency editing while providing the possibility of on-demand whole animal editing. This approach could allow for rapid, personalized disease modeling, providing patients with a population of preclinical surrogates tailored to their own genetics, a pseudo n-of-1 trial that could be used to screen approved medications and inform evidence-based medicine for patient treatments. This approach is not limited to any specific tissues, targets, or model organisms, and each variable can be tailored to the disease, condition, and patient.

1752. Co-Quantifying Surface Targeting Antibody and Nucleic Acid Payload of Lipid Nanoparticles by Single Nanoparticle Analysis

Sixuan Li[1], Yizong Hu[2], Jinghan Lin[1], Hai-Quan Mao[1], Tza-Huei Wang[1]

[1]Johns Hopkins University, Baltimore, MD,[2]Massachusetts Institute of Technology, Cambridge, MA

Introduction: Lipid nanoparticles (LNPs) are one of the leading approaches to deliver nucleic acid therapeutics in a wide range of applications, including genetic vaccines, gene editing, regenerative

therapies, etc. To achieve a desired tissue or organ-specific treatment, especially extrahepatic delivery, active targeting by decorating the LNP surface with targeting ligands has been extensively investigated [1]. However, it remains challenging to effectively leverage the rational design of this mechanism due to the lack of tools to characterize ligand configurations on LNPs, which is critical to understand and control the delivery specificity and efficiency of the targeted LNPs. Existing methods provide an estimated average ligand quantity on LNP at best. Here, we describe a technique using a microfluidic-based, single-particle analysis, termed cylindrical illumination confocal spectroscopy (CICS), to achieve statiscally robust and absolute quantifications of targeting antibodies on the surface of LNPs and nucleic acid payloads encapsulated within LNPs. This technique can unveil the heterogeneity of surface ligand density and mRNA payload at a single particle level and provide key information to assess nanomedicine targeting. **Methods:** We adopted our recently developed CICS platform and the LNP characterization protocol [2] to examine the LNPs with fluorescently labeled Cy5-pDNA, and TopFluor-PC lipids and conjugated with Alexa 546 labeled IgG antibody (Ab) by maleimide-thiol chemistry. A DLin-MC3-DMA-based benchmark LNP formulation was formulated by rapid mixing at pH 4, dialyzed against PBS at pH 7.4, and purified after antibody conjugation. **Results:** Antibody conjugation was verified by an approximate 20 nm increase in LNP size measured by DLS, and a 12 mV decrease in zeta potential (**Fig. 1a**), while maintaining a narrow polydispersity index (~0.2) and high DNA encapsulation efficiency (~95 %). The 3-color labeled Ab-conjugated DNA LNPs were screened at the single nanoparticle level by CICS; and the single particle fluorescence coincidence was analyzed to classify 6 LNP subpopulations including Ab-DNA-LNPs, non-Ab DNA-LNPs, Ab-empty-LNPs, non-Ab empty LNPs, unencapsulated DNA and unconjugated Ab. Three Ab to maleimide-PEG molar ratios were used for the conjugation reaction, and we found more DNA-encapsulated LNPs were conjugated with Ab compared to empty LNPs by around 30% consistently across the 10-fold Ab range (**Fig. 1b**). Fluorescence deconvolution analysis was performed to quantify the Ab surface density and DNA payload on single LNP particles. The ligand surface density distribution follows a Poisson distribution (**Fig. 1c**) and the average ligand number increases at higher antibody input (**Fig. 1d**), while the DNA payload distribution follows a lognormal distribution and the payload remains the same before and after conjugation (**Fig. 1e**), suggesting the different LNP assembly and ligand conjugation mechanisms. **Conclusions:** The CICS platform and the single particle assay characterize targeting antibody-functionalized lipid nanoparticles and quantify the surface density and distribution of ligand and nucleic acid payload simultaneously. This technique provides a powerful single nanoparticle analysis tool to facilitate further optimizations of LNPs aiming for more homogeneous payload loading and surface antibody presentation. **References:** [1] Nat. Rev. Mater. 8(4): 282 (2023). [2] Nat. Comm. 13 (1): 5561 (2022).

(c) Antibody quantification and ligand quantity per LNP distribution. (d) Number of Ab per LNP, including both DNA encapsulated and empty LNPs. (e) DNA payload distribution in DNA encapsulated LNPs before and after conjugation.

1753. In Utero Systemic LNP mRNA Delivery Targets the Fetal Brain and Permits Diffuse Gene Editing

Marco D. Carpenter, Rosa Choi, Nicole Kus, Andrew Mudreac, Alanis Perez, Hooda Said, Mohamad Gabriel Alameh, William Peranteau

Children's Hospital of Philadelphia, Philadelphia, PA

No curative therapies exist for the 1% of children affected by genetic diseases of the central nervous system (CNS). Often the pathogenesis of these diseases begins before birth and is irreversible. CRISPR-Cas9 gene editing provides a unique opportunity for a single dose cure if the target cell type and organ are reached. Unfortunately, therapeutic CNS gene editing is limited by the diversity of cell types in the brain, the limited regenerative capacity of neurons and, the impenetrable blood-brain barrier (BBB) which prevents access of systemically delivered gene editing therapies. Non-viral ionizable lipid nanoparticles (LNPs) have emerged as a safe and effective means of mRNA for the correction of genetic liver diseases but they have not been shown to deliver mRNA to the brain following intravenous delivery. In addition to mitigating disease pathology before its onset, in utero gene editing via LNP delivery may take advantage of fetal developmental properties to facilitate delivery of therapeutic editing technology to the brain following systemic delivery. To address this hypothesis, we screened three LNP formulations loaded with CRE recombinase mRNA in a GFP reporter mouse, via intravenous delivery at three developmental stages: fetal, neonatal, and adult. All mice were harvested 4-6 weeks following injection and GFP expression in the brain was quantified using flow cytometry and immunohistochemistry using markers for specific cell types (neurons, endothelial cells, microglia, astrocytes, and oligodendrocytes) and other organs. We identified one LNP (LNP1) with efficient mRNA delivery to endothelial cells (~50%), macrophages (75%) and neurons (5%) in mice who were injected in utero when compared to mice injected as neonates or adults which demonstrated no editing in endothelial cells or neurons. These data suggested the fetal environment has distinct biological features that enhance mRNA delivery via LNPs to the brain. We then applied these findings and used LNP1 to assess CNS gene editing in a mouse model of Friedreich Ataxia (FRDA). FRDA is a neurodegenerative disease in which propagation of

GAA repeats in the frataxin gene results in decreased frataxin protein expression. Gene editing to excise the triplet repeat is one potential therapeutic approach that has been suggested. LNP mediated systemic delivery of SpCas9 mRNA and gRNA targeting the triplet repeat to gestational day 14 FRDA fetal mice result in low level editing in the brain. These initial studies provide a foundation for an in-utero gene therapy approach for FRDA. In conclusion, we leverage our discovery related to basic fetal biology and its influences on LNP-mRNA delivery to develop clinically relevant CNS therapies.

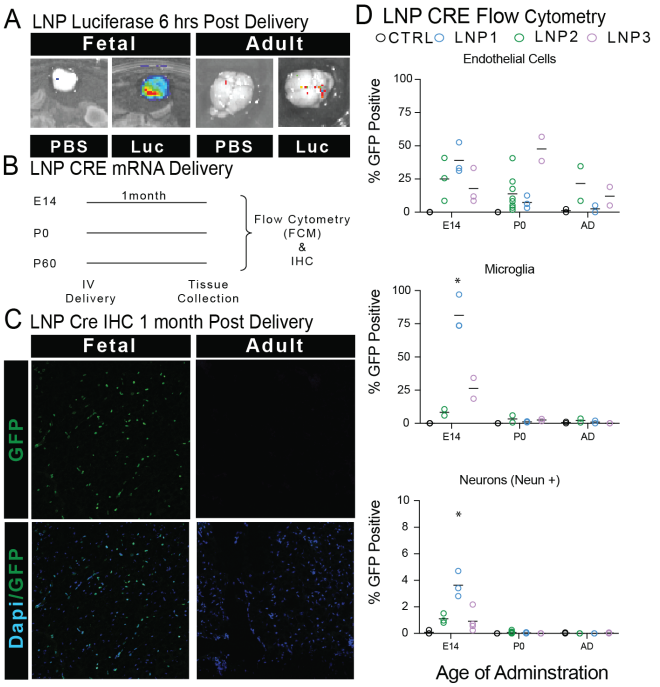


Figure 2. LNP containing mRNA is efficiently delivered to the brain following in utero but not adult IV administration. A) In utero delivery of LNP1-Luciferase mRNA targets the fetal brain. LNP1-Luc mRNA translation is undetected in the adult brain. B) Mice were injected IV with LNP1-3 at E14, P0 or P60 (adult) and tissue was collected for analysis 1 month following injection C) LNP1 efficiently delivers CRE mRNA to the fetal brain. LNP1-CRE mRNA translation is undetected in the adult brain. Sun1GFP is expressed in the nucleus following successful recombination with CRE. Nuclei stained with DAPI. Brain and liver were collected for IHC 1 month post LNP delivery D) In utero delivery of LNP-CRE mRNA targets fetal brain endothelial cells, Microglia and neurons in the brain parenchyma. Editing quantified by Flow Cytometry as percent GFP positive (edited). Two-way ANOVA compares CRE recombinase mRNA delivery in utero vs adult across 3 LNP formulations. P< 0.05. n = 2-9

1754. Engineered Virus Like Particles VLPs Transverse Immune Cells *In Vitro*

Priya Dhole[1], Natalie Correa[1], Isai Leguizamo[1], Michael Kuipa[1], Abubakarr Koroma[1], Matthew R. Gardner[1,2]

[1]Microbiology and Immunology, Emory University, Atlanta, GA,[2]Medicine, Emory University, Atlanta, GA

During the replication of viruses, apart from virus progeny, virus-like particles (VLP) are also generated randomly by selfassembly of viral proteins during infection or by in vitro protein expression. These particles are devoid of proper genetic material, which makes them replication and infection-deficient. Owing to their simultaneous property of mimicking the parent virus and inability to cause disease in the host, VLPs are a viable choice for wide application in the field of gene therapy. Many documented scientific annals have accumulated the usage of VLPs in delivering an array of drugs, peptides, and nucleic acid to the target cell. Advances in the retrovirus research field have helped researchers to use natural HIV-derived VLPs for carrying cargo inside the cells. A unique feature of retroviruses is that they contain the Gag polyprotein, which is capable of self-assembly into VLPs without requiring any other viral protein. Here we describe the production and application of targeted VLPs for various receptors on B and T lymphocyte-derived cell lines. We pseudo-typed an array of different VLPs by co-transfecting human embryonic kidney 293 (HEK-293) with different plasmids combinations, encoding monoclonal antibodies against CCR5, CD4, CD3, CD19, and CD20 receptors on T-lymphocytes and B lymphocytes. All the generated VLPs had luciferase tagged NL4-3delta(env), a full-length proviral DNA construct without a functional env gene, and vesicular-stomatitis virus G (VSV-G) as a fusogenic component. VSV-G is modified to knock out binding to natural receptors, thus only fusing in cells where the VLP enters through specific receptor targeting. VLPs generated in this manner had greater efficiency at entering cells than VLPs produced using a modified Sindbis virus glycoprotein that was modified to bind to monoclonal antibodies targeting similar receptors. Initial results showed targeted VLPs were capable of entering immortalized T and B cell lines like Sup-T1, Jurkat, and Raji cells. We are currently evaluating targeted VLPs for their efficiency in entire primary T and B cells. Overall, targeted VLPs can serve as a useful gene therapy tool, especially for delivering cargo to specific cells without entering off-target cell types.

1755. Pharmacokinetics and Distribution of Lipid Nanoparticle Formulations of mRNA in Gonadal Tissues in Rat and Monkey

Sherry A. Weppler, Merete L. Eisenhardt, Thomas C. Chamberlain, Ying K. Tam, Sean C. Semple

Acuitas Therapeutics, Inc., Vancouver, BC, Canada

With the increasing use of lipid nanoparticles (LNP) for gene-editing and other RNA-based therapeutics, a detailed understanding of LNP distribution is essential to support the safety assessment of these therapeutics and to identify cell types for further investigation of on- and off-target editing. The distribution and persistence of LNP components in gonadal tissue is of particular interest, given the potential for chemical and/or biological effects of LNP components on reproductive status. To address these questions, we have evaluated the pharmacokinetics and distribution of different mRNA-LNP formulations in cynomolgus monkeys and Wistar Han rats, with emphasis on distribution into testes and ovaries. mRNA localization and persistence within tissues and cells was evaluated by *in situ* hybridization, and ionizable lipid and PEG-lipid levels in plasma and tissue were quantified by LC-MS/MS or MALDI-MS. Distinct plasma pharmacokinetic (PK) profiles and large differences in plasma exposure of the ionizable lipid were observed in monkeys for the three different LNP compositions evaluated; however, the PK profiles of the PEG-lipid component of each LNP formulation were nearly identical, consistent with the intended exchange of the PEG-lipid out of the LNP in vivo. Ionizable lipids, PEG-lipid and mRNA were detected mainly in liver, spleen and adrenal glands for all three LNP, and much lower levels of ionizable lipids were detected in ovaries and testes, which further decreased to near the limit of detection by 14 days after dosing. Low levels of mRNA payload were also detected in ovaries and testes, with most of the signal present for only 24 hours post-dose and declining

rapidly thereafter, consistent with mRNA degradation. In ovaries, mRNA was observed mainly in the stroma and in thecal and granulosa cells surrounding the follicles, while in testes, mRNA was detected mainly in connective tissue cells between seminiferous tubules. Importantly, no mRNA was detected within oocytes or spermatogonia at any timepoints, for any of the formulations. These results illustrate that, despite a range of LNP plasma exposures examined, mRNA-LNP components were observed only at low levels in gonadal tissues, and there was no evidence of uptake into germline cells of rats or monkeys.

Friday Posters: Cancer - Oncolytic Viruses

1756. Dual Tumor-Responsive Liposome System Enables Effective Systemic Treatment of Breast Cancer Using Oncolytic Adenovirus

A-Rum Yoon[1], Yuebin Zhao[1], Chae-Ok Yun[2]

[1]Hanyang University, Seongdong-Gu, Korea, Republic of,[2]Hanyang University, Seoul, Korea, Republic of

To improve the efficiency of tumor-targeting systemic delivery of adenovirus (Ad), a dual tumor-targeting liposomal system composed of lipid decorated with epidermal growth factor receptor (EGFR) targeting peptide (GE11) (GE11-DOPE) and a pH-responsive sulfamethazine-based polymer (PUSSM)-conjugated phospholipid (DOPE-HZ-PUSSM) was complexed with Ad (Ad/LP-GE-PS). The replication-incompetent Ad (dAd) complexed with a dual tumor-responsive liposome system (dAd/LP-GE-PS) showed higher transduction efficiency than naked Ad in EGFR-positive cancer cells. Similarly, oncolytic Ad co-expressing short hairpin RNA (shRNA) against Wnt5 (shWnt5) and decorin complexed with dual tumor-responsive liposome system (oAd/LP-GE-PS) induced potent pH-responsive and EGFR-specific breast cancer cell killing. Importantly, systemically administered oAd/LP-GE-PS was shown to accumulate more effectively in EGFR-overexpressing breast xenograft tumor tissue compared to naked oAd, oAd encapsulated in control liposomes lacking tumor-targeting moieties (oAd/LP) or oAd encapsulated in EGFR-targeted liposomes (oAd/LP-GE). Liposome-based systemic delivery of oAd resulted in significantly attenuated hepatic sequestration of the virus compared to naked oAd, ultimately attenuating the induction of hepatotoxicity and lethality associated with systemically administered Ad. Taken together, this systemic delivery of oAd using dual tumor-targeted liposomes may be an effective and safe strategy for the treatment of EGFR-overexpressing breast cancer.

1757. Multifaceted Immunological Response by Combination of Dendritic Cell Therapy with Oncolytic Adenovirus-Based Nanohybrid System

In-Wook Kim[1,2,3], A-Rum Yoon[1,2,3], JinWook Hong[4], Dayananda Kasala[1], Chae-Ok Yun[1,2,3,4]

[1]Department of Bioengineering, Hanyang University, Seoul, Korea, Republic of,[2]Hanyang Institute of Bioscience and Biotechnology (HY-IBB), Hanyang University, Seoul, Korea, Republic of,[3]Institute of Nano Science and Technology (INST), Hanyang University, Seoul, Korea, Republic of,[4]GeneMedicine CO., Ltd, Seoul, Korea, Republic of

To reprogram the immunosuppressive tumor milieu and augment DC-based anticancer immune response, here we investigated polymeric nanocomplex incorporating an oncolytic adenovirus (oAd) expressing antitumor cytokines and arginine-grafted bioreducible polymer with PEGylated paclitaxel (APP) in combination with adoptively transferred DC. The nanohybrid system (oAd/APP) in combination with DC (oAd/APP+DC) induced higher expression level of therapeutic gene over oAd/APP or DC monotherapy in tumor tissues, resulting in higher level T cell and activated DC infiltration. oAd/APP+DC was also shown to effectively promote the migration of DC to secondary lymphoid organs, such as tumor draining lymph nodes and spleen, in comparison to either monotherapy. Effective migration of DCs to the secondary lymphoid organs following oAd/APP+DC treatment led to more robust tumor-specific T cell immune response over the respective monotherapy. oAd/APP+DC-treated mice possessed lowest percentage of immunosuppressive regulatory T cell in tumor infiltrating lymphocyte and splenocyte populations compared to other treatment groups. Taken together, combination of gene therapy, cell therapy and drug delivery nano system effectively overcome immunosuppressive tumor microenvironment, leading to potent and synergistic antitumor immune response.

1758. Tumor Microenvironment-Responsive Nanohybrid for the Controlled Release of Therapeutics

Dayananda Kasala[1], A-Rum Yoon[1,2,3], Jinwoo Hong[4], Chae-Ok Yun[1,2,3,4]

[1]Department of Bioengineering, Hanyang University, Seoul, Korea, Republic of,[2]Institute of Nano Science and Technology (INST), Hanyang University, Seoul, Korea, Republic of,[3]Hanyang Institute of Bioscience and Biotechnology (HY-IBB), Hanyang University, Seoul, Korea, Republic of,[4]Gene-Medicine, Seoul, Korea, Republic of

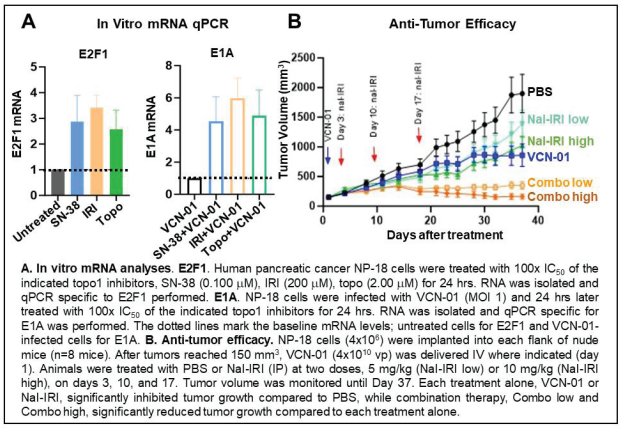
To improve the synergistic efficacy induced by oncolytic adenovirus (oAd) and paclitaxel (PTX), a reactive oxygen species (ROS)-responsive supramolecular hydrogel (mPEG-*b*-PCL-DPMP/α-cyclodextrin (DPMP-hydrogel)) has been newly designed. Here, we demonstrated that ROS-responsive DPMP hydrogel system can effectively prolong the biological activity of both oAd and PTX in ROS-rich tumor microenvironment to induce potent antitumor effect. DPMP-hydrogel loaded with oAd and PTX was shown to degrade over the span of one week period *in vivo*. Both oAd and PTX released from DPMP hydrogel were shown to retain their biological activity, thus exerting superior antitumor efficacy up to 19 days after single administration

in subcutaneous H460 xenograft tumor model compared with oAd and PTX combination therapy in absence of hydrogel delivery system or respective monotherapy, simultaneously enhancing intratumoral delivery efficiency of oAd and PTX in a ROS-rich tumor microenvironment.

1759. Efficacy of Third-Generation Oncolytic Herpes Virus G47Δ Combined with Immune Checkpoint Inhibitors in Renal Cell Carcinoma Models

Kenichi Sasaki[1], Yuta Takeshima[1], Miwako Iwai[1], Hiroshi Fukuhara[2], Haruki Kume[3], Tomoki Todo[1]

[1]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan,[2]Dept. of Urology, Kyorin Univ. School of Med., Tokyo, Japan,[3]Dept. of Urology, Faculty of Med., The University of Tokyo, Tokyo, Japan



G47Δ (teserpaturev) is a third-generation oncolytic herpes simplex virus type 1 (HSV-1) recently approved in Japan as a new drug for malignant glioma. As a result of its oncolytic activity, G47Δ elicits systemic antitumor immunity, therefore works collaboratively with other cancer immunotherapies. Renal cell carcinoma (RCC) is known to be relatively immunogenic, and immune checkpoint inhibitors (ICIs) are frequently utilized for metastatic RCC. In this study, we aim to investigate the efficacy of G47Δ combined with ICIs and to apply the evidence towards clinical settings. In immunocompetent mice harboring subcutaneous RCC tumors, intratumoral injections of G47Δ and systemic administrations of ICIs were both significantly more efficacious than controls, and the combination therapy was more efficacious than either monotherapy. Analysis of intratumor immune response showed a marked decrease in the proportion of regulatory T cells (Tregs) among CD4-positive cells in the combination treatment group, resulting in a significant increase in the CD8+/Tregs ratio. These results suggest that the combination therapy exhibits high efficacy for RCC via effective remodeling of the immunosuppressive tumor microenvironment.

1760. Enhanced Anti-Tumor Efficacy of Combination Therapy with the Oncolytic Adenovirus, VCN-01, and Liposomal Irinotecan in a Human Pancreatic Mouse Xenograft

Maria Maliandi[1], Paz Moreno[1], Ramon Alemany[1,2], Manel Cascallo[1], Sheila Connelly[3], Ana Mato-Berciano[1]

[1]Theriva Biologics, S.L., Barcelona, Spain,[2]Immunotherapy and Virotherapy, ProCURE Program, Catalan Institute of Oncology (ICO), Barcelona, Spain,[3]Theriva Biologics, Inc., Rockville, MD

VCN-01 is a clinical-stage oncolytic adenovirus engineered to replicate selectively in cancer cells with an aberrant RB1-E2F pathway. The VCN-01 E1A promoter is modified by inclusion of eight E2F1 binding sites and a 24-bp deletion that promotes viral transcription in cells with elevated free E2F1 and renders the virus replication-deficient in RB1-functional, normal cells. Here, human pancreatic cancer cell lines were exposed to topoisomerase I (topo1) inhibiting chemotherapeutics, irinotecan (IRI), its active metabolite, SN-38, and topotecan (topo; see Figure A). Notably, in NP-18 cells, E2F1 mRNA was increased ~3-fold compared to untreated cells, and E1A mRNA was boosted ~5-fold in cells treated with VCN-01 + topo1 inhibitors compared to VCN-01 alone. These data suggest topo1 inhibitor-mediated elevations in E2F1 increase VCN-01 transcription. Based on these promising in vitro results, potential synergy of VCN-01 plus the liposomal formulation of IRI (nal-IRI) was tested in animals bearing subcutaneous human pancreatic tumors . After tumors were established, indicated animals were treated with a single IV dose of VCN-01 ($4x10^{10}$ vp) or PBS (day 1). Designated animals in each group were then treated with either PBS or nal-IRI (IP) on days 3, 10 and 17. In animals with NP-18 tumors, treatment with VCN-01 or Nal-IRI alone at both the 10 mg/kg and 5 mg/kg doses resulted in significant tumor growth inhibition compared to PBS (see Figure B). Importantly, combination therapy with VCN-01 + nal-IRI at either dose displayed significantly reduced tumor growth compared to each treatment alone. qPCR analyses performed on tumors collected at end of study confirmed the presence of viral genomes and E1A mRNA suggesting intratumoral viral replication and indicating ongoing transcriptional activity of VCN-01. Preliminary analyses suggest that combination therapy with VCN-01 + nal-IRI has a tolerable toxicity profile. These data are consistent with the hypothesis that topo1 inhibitors increase cellular E2F1 protein expression resulting in upregulation of the modified VCN-01 E1A promoter thereby enhancing viral gene expression and improving anti-tumor efficacy. The combination of VCN-01 + topo1 inhibitors, such as Nal-IRI, may demonstrate improved efficacy in the treatment of human pancreatic cancer.

A. In vitro mRNA analyses. E2F1. Human pancreatic cancer NP-18 cells were treated with 100x IC_{50} of the indicated topo1 inhibitors, SN-38 (0.100 μM), IRI (200 μM), topo (2.00 μM) for 24 hrs. RNA was isolated and qPCR specific to E2F1 performed. **E1A**. NP-18 cells were infected with VCN-01 (MOI 1) and 24 hrs later treated with 100x IC_{50} of the indicated topo1 inhibitors for 24 hrs. RNA was isolated and qPCR specific for E1A was performed. The dotted lines mark the baseline mRNA levels; untreated cells for E2F1 and VCN-01-infected cells for E1A. **B. Anti-tumor efficacy.** NP-18 cells ($4x10^6$) were implanted into each flank of nude mice (n=8 mice). After tumors reached 150 mm^3, VCN-01 ($4x10^{10}$ vp) was delivered IV where indicated (day 1). Animals were treated with PBS or Nal-IRI (IP) at two doses, 5 mg/kg (Nal-IRI low) or 10 mg/kg (Nal-IRI high), on days 3, 10, and 17. Tumor volume was monitored until Day 37. Each treatment alone, VCN-01 or Nal-IRI, significantly inhibited tumor growth compared to PBS, while combination therapy, Combo low and Combo high, significantly reduced tumor growth compared to each treatment alone.

1761. Investigating the Potential of Oncolytic Adenovirus-Mediated Immunotherapy in the Neoadjuvant and Metastatic Settings for Pancreatic Cancer

Kazuho Inoko, Shuhei Shinoda, Kari Jacobsen, Masato Yamamoto, Julia Davydova

Department of Surgery, University of Minnesota, Minneapolis, MN

Background: Pancreatic ductal adenocarcinoma (PDAC) remains one of the most common and lethal cancers. Even in patients with localized and resectable PDAC, upfront surgery often fails to eradicate this disease mainly due to micro-metastases. Accordingly, neoadjuvant therapy (non-curative treatments before surgery) is becoming the de facto standard of care for this population with the intent of reducing postoperative recurrence. On the other hand,

patients with metastatic PDAC are ineligible for surgery, and instead receive systemic chemotherapy to prolong survival. However, these efforts have thus far not led to major improvements in survival. Furthermore, despite breakthroughs in cancer immunotherapy, its efficacy is limited in PDAC. In the current study, we investigated the potential of a replication competent oncolytic adenovirus (OAd) as an immunotherapeutic strategy for PDAC in both neoadjuvant and metastatic settings. **Methods and Results:** We used the immunocompetent Syrian hamster model, which is permissive to OAd replication and provides an advantage in simulating OAds behavior in humans. We employed a type 5 adenovirus with the RGD-fiber and no therapeutic transgenes (Ad5-RGD) to better investigate the intrinsic ability of OAd to induce immunogenic cell death (ICD). We first evaluated the cytotoxicity and immunostimulatory responses induced by Ad5-RGD in a hamster PDAC cell line, PGHAM-1, which harbors a KRAS mutation (G12D), the most common oncogene in PDAC. Ad5-RGD showed efficient replication and cytotoxicity in hamster PDAC cells, while increasing the level of extracellular ATP, suggesting the potential to induce ICD. We then evaluated *in vivo* immunomodulatory activities of Ad5-RGD in the neoadjuvant setting. Hamsters were subcutaneously inoculated with PGHAM-1 cells. After tumor establishment, the tumors were simply resected in the upfront surgery (control) group. In the neoadjuvant OAd group, the tumors were treated with intratumoral injection of Ad5-RGD ($2.5x10^9$ pfu/injection) every two days for a total of three injections and were surgically resected three days after the final injection. After 31 days from the initial treatments, the hamsters in both groups were rechallenged with the same PDAC cells, mimicking micro-metastasis after surgery. Compared to the upfront surgery group, the neoadjuvant OAd treatment showed significant tumor growth inhibition in the rechallenged tumors, resulting in complete tumor regression in 33% of animals and significantly improved survival. We further evaluated *in vivo* systemic efficacy of Ad5-RGD. Hamsters bearing subcutaneous PGHAM-1 tumors on both flanks were treated intratumorally with PBS or Ad5-RGD as above in one of the two tumors. Compared to the PBS group, localized OAd treatment showed significant tumor growth inhibition not only in the injected tumors, but also in the non-injected distant sites, resulting in complete tumor regression in 60% of animals and significantly improved survival. Notably, all the surviving animals from both settings completely controlled the further tumor challenges over > 300 days. The cytotoxicity assay with splenocytes collected from these long survivors showed significantly higher killing of PGHAM-1 target cells compared with splenocytes from naïve hamsters, indicating the establishment of a long-lasting antitumor immune memory response. **Conclusion:**This is the first study to demonstrate the potential of OAd to induce systemic, long-lasting antitumor immune responses in replication-permissive, immunocompetent PDAC models in both neoadjuvant and metastatic settings. These findings provide far-reaching implications for the use of OAd for patients with PDAC at all stages.

1762. Inhibition of c-MYC in Hepatocellular Carcinoma via AAV8 Mediated Gene Transfer

Isaiah L. Reeves[1,2], Stephen M. Winston[1,2], Yunyu Spence[1], Dongli Hu[1], Chris Morton[1], Andrew M. Davidoff[1,2]

[1]Department of Surgery, St. Jude Children's Research Hospital, Memphis, TN,[2]Graduate School of Biomedical Sciences, St. Jude Children's Research Hospital, Memphis, TN

Inhibiting the key transcription factor MYC has long been a goal of cancer therapy due to the central role of MYC in human cancers, although, it has yet to be accomplished clinically. Hepatocellular carcinoma (HCC) is the most common liver malignancy in adults and the second most common liver tumor in children and is often associated with MYC deregulation. The mini protein Omomyc has been shown to induce tumor regression in a variety of cancer types by preventing the heterodimerization of c-MYC with its obligate binding partner MAX, thus preventing its transcriptional activation. but questions about in vivo peptide toxicity and efficacy remain. Due to the natural strong liver tropism of AAV8, we hypothesized that targeted delivery of Omomyc using the AAV platform will be much more efficacious and limit off target toxicity. Expression of Omomyc in HCC cell lines *in vitro* by transient transfection and doxycycline induced expression induced an 8-20 fold inhibition of proliferation depending on cell type, including G2 cell cycle arrest (about 50%) in the high c-MYC expressing cell line Hep3B. We have also demonstrated a 2-fold induction of autophagy, measured via mCherry-GFP-LC3 levels in HCC cell lines with a direct correlation to the amount of c-MYC expressed in these cell lines. Autophagosome formation was also observed via electron microscopy and immunofluorescent microscopy. When combined with conventional therapeutics like the multi-kinase inhibitor sorafenib, Omomyc induces autophagy another 20%. Additionally, Omomyc results in significant levels of cell death (20-60%), in direct correlation with the level of c-MYC protein expression. Our preliminary data suggests that this could be due to induction of autophagic cell death, with high levels of a necrotic phenotype observed via Annexin-V staining. Treatment of HCC with recombinant AAV8 with vector genomes encoding Omomyc results in a profound cytostatic effect (2-7 fold lower proliferation rate), and very strong cytotoxicity when combined with sorafenib, leading to high levels of cell death in Hep3B cells. We have also demonstrated a potential synergistic effect of combining autophagy inducing compounds like sorafenib and mTOR inhibitors being able to increase transduction efficiency by approximately 50-60% in our HCC cells lines as well as enhanced cytotoxicity. We have also demonstrated the efficacy of recombinant AAV delivered Omomyc *in vivo* by inhibiting tumor growth and prolonging mouse survival when combined with sorafenib. Taken together, our data suggest that our novel AAV8 delivery of Omomyc has the ability to inhibit cellular proliferation, induce autophagy, and induce cell death in HCC which may prove to be a novel therapeutic approach for the treatment of HCC, especially when combined with conventional therapeutics.

1763. Treatment Effect of CD133-Targeted Oncolytic Adenovirus for Colorectal Peritoneal Metastases in a Preclinical Model

Mizuho Sato-Dahlman, Praveensingh B. Hajeri, Kari Jacobsen, Brandon Hitchcock, Masato Yamamoto
University of Minnesota, Minneapolis, MN

Introduction: Colorectal cancer (CRC) is the third most common cause of cancer-related death in the US. While the death rate has been gradually decreasing for the last 20 years owing to advances in screening and treatments, its local recurrence and distant metastasis rates are still disappointingly high. Peritoneal metastases (PM) are a common type of metastatic spread in CRC, and occurs in approximately 10 to 15% of patients with CRC. From a patient's perspective, the presence of PM is not considered curable unlike resectable liver or lung metastases. Despite significant progress in the development of new chemotherapies, the survival of patients with PM remains poor. Therefore, development of novel therapeutic approach for PM is critically important to improve the prognosis of patients with advanced CRC. A growing body of evidence suggests that expression of CD133 is reported to highly correlate with metastasis, recurrence, and treatment resistance in CRC patients. We therefore hypothesize that development of novel approach that eliminating CD133-positive cells leads to suppression of metastasis and recurrence, and provide more effective treatment of PM in CRC patients. **Methods:** We used CD133-targeted oncolytic adenovirus to eliminate CD133-positive cells. We generated CD133-targeted OAd (CD133-OAd) by using our adenovirus-based library screening system. We evaluated the target specificity of the virus *in vitro* and *in vivo* analysis. For *in vitro* analysis, we used binding assay and cell killing assay with CD133-positive or CD133-negative CRC cell lines. As a proof of concept, the *in vivo* therapeutic potential of the CD33-OAd was investigated in a mouse peritoneally metastatic colon cancer model with luciferase-labeled CD133-positive human CRC cells (HCT116-Luc). HCT116-Luc cells were inoculated intraperitoneally into mice, and treatment started 5 days post cell inoculation. On day 6, mice with tumors were divided into 4 groups: PBS intraperitoneal (i.p.) injection (200ul, every week for 3 weeks), wild-type Adenovirus type 5 (Ad5-WT), CD133-OAd, and integrin-targeted OAd (RGD-OAd) i.p. injection (1×10^{10}vp/200ul, every week for 3 weeks). All mice were monitored by IVIS imaging once a week to confirm and track tumor growth. **Results:** Binding and cell killing assay confirmed that the CD133-OAd selectively infected CD133-positive cells and lysed them efficiently. *In vivo* anti-tumor assay demonstrated that CD133-OAd significantly suppressed the peritoneal metastasis of HCT116-Luc cells on day 28 after initial treatment compared to administration of PBS or RGD-OAd. The survival of mice with PM of HCT116-Luc cells was significantly increased by treatment with CD133-OAd compares with PBS, Ad5-WT, or RGD-OAd treatment. Interestingly, Adenovirus type 5 (Ad5-WT) showed anti-tumor activity, and its level was comparable with CD133-OAd. However, Ad5-WT injected mice started to show severe toxicity and die from around 21 days after initial viral injection. At necropsy of Ad5-WT injected mice, all of the mice showed abdominal adhesion. H&E staining of liver indicated that leukocyte infiltration into liver parenchyma and especially around blood vessels. Further analysis of toxicity of Ad5-WT is ongoing and will be presented. **Conclusions:** Intraperitoneal administration of CD133-OAd has therapeutic potential to suppress the peritoneal metastasis in mouse model without significant toxicity, resulting in prolonged survival.

1764. Harnessing Viral-Mediated NIS Expression to Enable Imaging of Colorectal Cancer Tumors

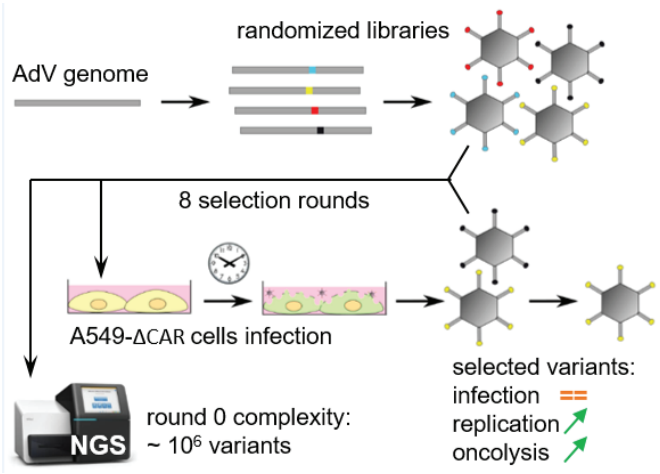
Stacey Wilber, Sacha Robert, Margarita V. Romanenko, Kazuho Inoko, Julia Davydova, Christopher J. LaRocca
University of Minnesota, Minneapolis, MN

Introduction: Patients with advanced and metastatic colorectal cancers often have limited therapeutic options, especially if they do not respond to conventional treatments such as chemotherapy or surgery. In these scenarios, new therapeutic approaches are needed, and oncolytic viruses represent novel agents that have the potential to enable innovative treatment regimens. Methods: Our group has generated an oncolytic adenovirus which expresses the sodium iodide symporter (OAd-NIS) as a function of viral replication. The vector was thoroughly tested *in vitro* across multiple human colorectal cancer cell lines (LoVo, SK-CO-1, WiDr) to evaluate transgene expression and cytocidal effects. Additionally, to evaluate the ability of the OAd-NIS virus to facilitate imaging of human colorectal tumors, small animal PET/CT was utilized to visualize radiotracer uptake. Results: The OAd-NIS virus is based upon the ΔE3 NIS backbone structure (that has been previously described) and also employs the Ad 5/3 chimeric fiber to optimize binding and transduction in human colorectal cancer cells. Our prior work in pancreatic cancer demonstrated that viral constructs with deletions of the Adenovirus Death Protein (ADP) provide for increased *in vitro* NIS expression. In all three colorectal cancer cell lines, we compared vectors both with and without ADP and anti-human NIS antibody staining demonstrated much stronger NIS expression in ADP-deleted vectors. LoVo cells were utilized to establish subcutaneous tumors in the flanks of athymic nude mice, which were subsequently inoculated with the OAd-NIS virus ($5x10^{10}$ pfu / tumor). Radiotracer (^{124}I, 0.25 mCi) was administered via intraperitoneal injection and PET/CT images were acquired with the Sofie G8 system. Evaluation of the cross-sectional images demonstrated avidity within the flank tumors, thereby confirming the ability of the OAd-NIS vector to enable transgene expression in human colorectal cancer tumors. After harvesting the tumors, viral copy number analysis and NIS staining confirmed strong *in vivo* viral replication and NIS expression within the tumors. Conclusion: The OAd-NIS virus demonstrates transgene expression across multiple colorectal cancer cell lines and in murine models. It highlights the potential of viral-mediated NIS expression to enable radionuclide-based imaging for colorectal cancer. Future studies will examine the potential therapeutic effects of combining the OAd-NIS virus with radioactive iodine (^{131}I) in colorectal cancer models. This preliminary data highlights the potential of OAd-NIS to serve as a theranostic (*thera*peutic and dia*gnostic*) agent for colorectal cancer and supports the pursuit of additional testing toward clinical translation.

1765. High Potential of a Novel oHSV-1 Vector Encoding Immune Factors for Cancer Therapy

Junmei Zhang[1], Wei Ma[1], Zhao Gao[2], Gang Zou[2], Jim Zhen Wu[2], Qiong Zhou[1]

[1]WuXi AppTec, Shanghai, China,[2]Ark Biopharmaceutical, Shanghai, China



Oncolytic immunotherapy, a virus-mediated therapeutic modality, is emerging as a novel and promising anticancer therapy, especially for patients with cancers resistance to other therapeutics. Oncolytic viruses can directly lyse cancer cells and indirectly elicit antitumor immunity in the tumor microenviroment. Recently, oncolytic herpes simplex virus (oHSV) has been extensively explored and widely used in clinical. oHSV has exhibited great potential in anticancer applications with its advantages of natural tumor affinity and high capacity for insertion of a therapeutic gene(s). However, there are significant technical challenges in the genetic manipulation of the large virus genome, such as the complexity of the viral genome, potential impacts on viral fitness and replication, and unpredictable effects on the host immune responses. To facilitate the genetic manipulation of the oHSV vector, we have established bacterial artificial chromosome (BAC) and CRISPR systems for genetic modifications of oHSV. The BAC and CRISPR methods can complement each other and may be applied to different genetic modifications. The two-method approach can be used for accelerating the development of novel oHSV-1 and other large genome virus vectors. Using the BAC and CRISPR systems, we generated a novel oHSV-1 vector with the deletion of viral neurovirulence factor ICP34.5 for improving the safety while maintaining the robust virus replication capacity. We also introduced an immunostimulatory factor and an immune checkpoint antibody into the oHSV-1 vector at a novel insertion site for enhancing the antitumor immunity. The recombinant oHSV-1 had the same level of replication efficiency as the parental virus and exhibited greater than 90% killing effect on SK-MEL-28, HepG2 and LN-Cap cell lines at 96 h post infection in cell-based assays. The recombinant oHSV-1 was further evaluated in mouse tumor models. In the mouse model of human melanoma SK-MEL-28 cell the recombinant oHSV-1 displayed the inhibition of tumor growth in a dose dependent manner, and almost completely eliminated tumor at a dose of 1×10^7 pfu/mouse. The available results indicate that the oHSV-1 vector has high potential in exploring genetically modified oHSV-1 products for the treatment of cancer. Currently we are conducting additional studies for further improvement and characterization of the novel oHSV-1 vector.

1766. Development of Enhanced Oncolytic Vectors by Adenovirus Directed EVOlution (ADEVO)

Erwan Sallard[1], Julian Fischer[2], Nissai Beaude[1], Arsalène Affes[1], Eric Ehrke-Schulz[1], Wenli Zhang[1], Katrin Schröer[1], Adrian Westhaus[3], Marti Cabanes-Creus[4], Leszek Lisowski[4], Zsolt Ruszics[2], Anja Ehrhardt[1]

[1]Department of Human Medicine, Center for Biomedical Education and Research (ZBAF), Witten/Herdecke University, Witten, Germany,[2]Faculty of Medicine, University of Freiburg, Freiburg, Germany,[3]GENETHON, Evry, France,[4]Children's Medical Research Institute, Westmead, Australia

Directed evolution is a vector development method consisting in the generation of random vector variants libraries, followed by the selection of improved variants fitting selection criteria. Directed evolution yielded few successes in Adenovirus vector (AdV) development until now, mainly due to difficulties in constructing large random libraries. Meanwhile, AdVs clinical applications are still hampered by the predetermined tropism of natural adenoviruses. To overcome this challenge, we hypothesized that validated vector retargeting technologies like peptide insertions can be incorporated into the AdV toolbox. Here we designed novel Adenovirus Directed EVOlution (ADEVO) protocols for AdV retargeting, based on random peptides insertion in the exposed HI loop of the fiber knob domain, and used them to increase the oncolytic efficiency of several AdVs. As a proof-of-concept, AdV genome libraries were constructed by recombination of random oligonucleotides in the fiber gene, following three distinct protocols. Vector libraries were generated following genome libraries transfection in HEK293 cells, and selected by serial passaging on A549-ΔCAR cells that are non-permissive for natural human adenovirus type 5 (Ad5), with the goal of identifying variants able to infect and lyse these cells efficiently. Library complexities were estimated by NGS variant calling and capture-recapture population size modeling. Crystal violet was used to stain live cells in oncolysis assays. All three ADEVO protocols enabled the construction of high complexity libraries, with up to 8.7e5, 9.6e5 and 1.7e5 unique variants in each initial vector libraries, which is an approximate 100-fold improvement compared to previously published AdV libraries. After 8 rounds of selection by serial passaging of the replication-competent vectors, the non-functional variants containing stop codons had been eliminated, and the most highly enriched variants were recloned and purified. Interestingly, they did not display enhanced or more specific transduction but intensified and accelerated replication and cell lysis in all tested tumor cell lines. This is consistent with the selection criteria given, that was the efficient completion of full replication cycles. The mechanisms of this so far unsuspected involvement of the fiber protein in stages of the AdV replication cycle other than receptor binding are currently being investigated. Finally, the selected inserts were applied to the fiber proteins of Ad34 and Ad35-based replication-selective oncolytic vectors to increase their therapeutic index. ADEVO, our novel directed evolution workflow for Adenoviruses, facilitates the generation of highly diverse variant libraries and the selection of improved vectors with user-friendly protocols. Besides the development of enhanced oncolytic AdVs, we expect that this technology can be applied to other vector features and contribute to a wide range of clinical applications.

1768. Genetically Engineered Oncolytic Measles Virus with Pro-Apoptotic Gene of Human Origin: Its Mechanistic Basis for Selective Killing of Triple Negative Breast Cancer Cells

Alok Kumar[1], Subbarao Naidu[2], Maitreyi Syamala Rajala[1]

[1]School of Biotechnology, Jawaharlal Nehru University, New Delhi, India,[2]School of Computational and Integrative Sciences, Jawaharlal Nehru University, New Delhi, India

Breast cancer is the second most leading cause of cancer related deaths worldwide including India. Types of breast cancer include ductal carcinoma *in situ*, invasive ductal carcinoma, inflammatory breast cancer, and metastatic breast cancer. Triple negative breast cancer (TNBC), a subtype comprises of 15-20% of all breast cancers is an aggressive one with poor prognosis. Currently available treatments such as tamoxifen and trastuzumab based therapies are targeted towards estrogen receptor positive (ER+) and human epidermal growth factor receptor 2 (Her2/neu) positive tumours. TNBC being negative for ER, PR (progesterone receptor) and Her2/neu is insensitive to endocrine therapy and targeted molecular therapies leading to recurrence and metastasis. Thus, new therapies are being developed to target TNBC; one such therapy is the use of engineered viruses which is rapidly evolving and holds great promise as a potential treatment for various cancers including breast cancer. Our earlier studies reported the development of a genetically engineered measles virus armed with BNiP3, a pro-apoptotic gene of human origin and its selective anti-proliferative effects in TNBC cells. In this study, we sought to understand the mechanistic insights of oncolytic measles virus induced selective killing of TNBC cells using bioinformatic tools and experimental studies. Upon comparison of TNBC *vs*. non-TNBC cells and TNBC *vs*. non-TNBC tumor tissues using the available data bioinformatically, five hub genes were identified to be involved in tumor development and progression in both the data sets. Of which, β-catenine was observed to be the most significant one. As β-catenine is known to be over expressed in invasive tumors and its correlation with poor prognosis, the regulatory role of oncolytic measles virus on β-catenine pathway was investigated. The results had shown reduced expression of β-catenine in TNBC cells compared to non-TNBC cells following oncolytic virus infection at transcript and protein level by real time PCR and western blot analysis respectively. Further experiments had demonstrated the significant inhibition of its downstream targets Cyclin D1, matrix metalloprotease 7, c-JUN, CD44 and Ki67 which are involved in cell proliferation and invasion. Second reason for selectively was observed to be an efficient internalization of virus into TNBC than non-TNBC cells as the expression of CD46 receptor being used by the engineered virus for internalization is high in TNBC cells. This led to the increased expression of BNiP3 protein as well in TNBC cell. Our bioinformatic studies inclduing protein-protein docking had shown the strong interaction between BNiP3 and anti-apoptotic protein BCL2 speculating that this interaction may release BCL2 bound pro-apoptotic protein Bax to induce apoptosis. Third possible reason for the selectively was observed to be the interaction between one of the virus proteins, 'V' protein with Stat1/2, a transcriptional factor required for transactivation of interferon stimulatory genes. As the virus 'V' protein expression would be more in TNBC cells following infection, its interaction with Stat1/2 may inhibit the expression of antiviral interferon stimulatory genes facilitating efficient replication of oncolytic measles virus subsequently induction of apoptosis in TNBC cells. Further studies are ongoing; based on our preliminary results, the above three mechanisms are likely to be regulated by oncolytic measles virus for selective killing of TNBC cells signifying its potential to be a novel therapeutic agent to selectively target TNBC.

1769. A Novel Virotherapy Vector Engineered for Tumor Selective Transgene Delivery Following Intravenous Administration: TROCEPT

TROCEPT is a novel tumor selective, lytic, virotherapy vector engineered to remove all natural tissue tropisms and reach the tumor following intravenous (IV) delivery. This addresses the main limitation of other viral vectored therapies: sequestration in normal tissues and rapid clearance by the liver which reduces the amount of therapy which is delivered to the point of need. This results in the requirement for local delivery to the tumor. TROCEPT has been further engineered to specifically infect cancerous tissues positive for αvβ6 integrin, a molecule expressed on most carcinomas. The TROCEPT platform can be loaded with transgenes to enable *in-tumor* production of powerful therapeutic drugs. The lead program, TROCEPT-01 (ATTR-01), enables tumor-localized expression of high concentrations of an immune checkpoint inhibitor. Herein, we demonstrate that TROCEPT-01 is safe and tumor selective in pre-clinical models, *in vitro* and *in vivo,* and that αvβ6 integrin is a tumor

selective target in human tissues. Our studies show that TROCEPT-01 is selectively infectious for tissues which are αvβ6 integrin$^+$ and does not replicate outside of cancerous cells. *In vivo* models support a favorable, tumor specific, biodistribution of the TROCEPT vector. We go on to demonstrate delivery of TROCEPT-01 to the tumor following intravenous administration. Finally, we show that infection with TROCEPT-01 results in expression of functional immune checkpoint inhibitors. TROCEPT-01's tumor selective transgene delivery and *in-tumor* production of immune checkpoint inhibitors enables high concentration immunotherapy doses, specifically in the tumor. This will address undesirable off-target toxicities associated with checkpoint therapy, potentially increasing efficacy, and patient tolerance. Additionally, several pre-clinical studies have demonstrated that oncolytic viruses can induce anti-viral immunity against infected tumor cells, recruiting cytotoxic T cells and other pro-inflammatory cell types. Thus, TROCEPT enabled delivery of checkpoint inhibitors has the potential to generate a synergistic effect, first attracting and activating T cells, and then enabling tumor-localized production of checkpoint inhibitors to boost anti-tumor T cell responses and increase response rates. TROCEPT has the potential to deliver new and powerful therapeutic drugs for in-tumor treatment of cancer following intravenous deliver. TROCEPT-01 is currently undergoing IND/CTA-enabling studies and is expected to enter First In Human studies in late 2024 in multiple solid tumor indications.

1770. Preclinical Toxicology Assessment of Intracranial Administration of an Oncolytic Measles Virus Strain Armed with *H. pylori* Neutrophil-Activating Protein Prior to Phase I Trial in Glioblastoma Patients

Kim Viker[1], Susanna C. Concilio[1], Susan M. Clark[2], Steven Robinson[3], Roy Dyer[4], Naomi Gades[5], Jenny Pattengill[6], Ianko D. Iankov[2], Evanthia Galanis[3]

[1]Molecular Medicine, Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]Oncology, Mayo Clinic, Rochester, MN,[4]Immunochemical Core Laboratory, Mayo Clinic, Rochester, MN,[5]Comparative Medicine, Mayo Clinic, Scottsdale, AZ,[6]Animal Histology Research Core, Mayo Clinic, Scottsdale, AZ

Introduction: Glioblastoma (GBM) is the most common malignant brain tumor in adults and has a dismal prognosis with a median survival of 14-18 months despite multimodality treatment. Engineered measles virus (MV) strains based on the attenuated MV Edmonston (MV-Edm) vaccine platform have demonstrated significant efficacy against GBM models. A recently completed first-in-human clinical trial using a carcinoembryonic antigen expressing MV strain (MV-CEA) in recurrent GBM has demonstrated safety and biologic activity. To further increase the immunomodulatory potential of oncolytic cell death, we engineered MV to express an immunostimulatory transgene, the secretory form of the neutrophil-activating protein (NAP) of *H. pylori*. MV-s-NAP resulted in curative anti-tumor effect in syngeneic orthotopic murine GBM models, which can be enhanced by the addition of immune checkpoint inhibitors. This study was designed to evaluate the safety of intracranial administration of MV-s-NAP in MV-replication susceptible transgenic IFNAR KO-CD46Ge mice in preparation for clinical translation.**Methods:** Forty-eight (24 males and 24 females) 5-to-6-week-old measles-immunized IFNAR KO-CD46Ge mice were used in this study. MV immunization status in this toxicology study mimicked the patient population in the proposed trial. Mice were stratified into 3 groups with 16 mice per cohort. Treatment with MV-s-NAP at "Low Dose" (1 x 10^4 $TCID_{50}$) or "High Dose" (1 x 10^5 $TCID_{50}$) or vehicle control on day 1 and repeated on day 5.The highest proposed total virus dose administered to the mice in this study was 2 x 10^5 $TCID_{50}$ MV-s-NAP (divided in two equal doses). By direct brain weight conversion, this would be approximately equivalent to 7 x $10^8$$TCID_{50}$ in an adult human, which exceeds the maximum proposed dose in the human trial. Body weight and clinical signs of toxicity were monitored daily. Hematology, plasma chemistry, plasma cytokines, gross pathology, and histopathology of major organs were analyzed on days 4, 8 (early timepoints), 28(intermediate timepoint), or 56 (late timepoint). Biodistribution of MV-s-NAP genomes was assessed by qRT-PCR. **Results:** Intracranial treatment with MV-s-NAP did not impact body weight in either males or females and none of the mice experienced toxicity or clinically adverse health effects. No difference between control and treated animals was observed in complete blood counts, plasma chemistry values (including liver and kidney function), or proinflammatory cytokines at any time point. MV genomes were only detected by qRT-PCR on day 4 in the brain tissue of two animals that received a single high dose injection: these findings were not associated with histopathologic changes and were deemed to be residual from Day 1 administration. All remaining tissues tested at all time points for animals that received either one or two injections of either Low Dose or High Dose MV-s-NAP were negative for MV. Histopathologic findings for all tissues were within normal limits. Of note, no cytopathic effect, inflammation, or other abnormality was observed in the histologic examination of the injected mouse brains. **Conclusion:** Intracranial delivery of MV-s-NAP was well tolerated with no significant toxicity being observed following direct administration in the brains of MV-replication susceptible transgenic mice. This outcome supports the safety of the MV-s-NAP platform for clinical oncolytic virotherapy of GBM. This study was supported by NIH grant RO1CA258239.

1771. A Novel Immunocompetent, Adenovirus-Permissive Model to Analyze the Oncolytic Potential and Anti-Tumor Immunity of Human Adenovirus Against Metastatic Breast Cancer

Sacha Robert[1], Natasha Ivelisse Roman[2], Kazuho Inoko[1], Margarita V. Romanenko[1], J. Michael Mathis[3], Julie Ostrander[4], Julia Davydova[1]

[1]Surgery, University of Minnesota, Minneapolis, MN,[2]Pharmacology, University of Minnesota, Minneapolis, MN,[3]Health Science Center, University of North Texas, Fort Worth, TX,[4]Medicine, University of Minnesota, Minneapolis, MN

Breast cancer remains a formidable challenge necessitating innovative therapeutic approaches. This study addresses the imperative for new breast cancer therapeutics and focuses on the potential of human adenovirus (Ad) in this context. Recognizing the limitation of predictive immunocompetent animal models due to the inability of human adenovirus to replicate in them, we introduce a novel hamster

syngeneic model developed to assess the oncolytic potential and anti-tumor immunity of human adenovirus against metastatic breast cancer. Our "Mammary INtra Ductal" (MIND) model, utilizing the HMAM5 cell line, a chemically-induced hamster luminal breast cancer cell line, offers a unique combination of orthotopic, immunocompetent, and human Ad-replication-permissive features. This surpasses existing non-Ad-permissive immunodeficient rodent models, enhancing relevance and utility. To enable comprehensive tracking of tumor growth and metastasis, Luc-ZsGreen-HMAM5 cells were employed for bioluminescence imaging using the IVIS® Spectrum *in vivo* imaging system. Real-time visualization 24 hours post-cell injection validated successful tumor establishment within the model. Tumor progression, dependent on injected cell quantity, revealed a 50% and 100% tumor engraftment rate with 200,000 and 800,000 HMAM5 cells, respectively. The rate of tumor growth was notably faster in hamsters injected with 800,000 cells as opposed to those injected with 200,000 cells. Histological analyses confirmed the connection of tumors to the mammary fat pad, with estrogen receptor-positive staining validating the luminal molecular classification of the tumors. Metastatic potential was observed post-mortal by enlarged lymph nodes (including para-aortic and inguinal nodes), indicating the need for further histological characterization to distinguish between inflammation and metastasis. *In vitro* analysis of binding and oncolysis assays revealed the enhanced responsiveness of HMAM5 cells to human Ad modified with an RGD-fiber, contrary to Ad5 and Ad5/3 counterparts. Subsequent pilot *in vivo* experiments with repeated Ad5-RGD-WT injections demonstrated significant tumor growth inhibition compared to untreated tumors, showcasing the efficacy of human adenovirus to replicate in this model. Following analyses will confirm viral spread and replication within tumors and validate cell trafficking in lymphatic nodes using Luc-ZsGreen-HMAM5 cells. Upcoming plans include immunological profiling, combinatorial therapy investigations with adenovirus and estrogen therapy, such as Tamoxifen, and abscopal effect experiments. Overall, the success of establishing this orthotopic syngeneic breast cancer hamster model, underscored by its demonstrated Ad-replication permissiveness with RGD-fiber, provides a platform for comprehensive safety and efficacy evaluations of human adenovirus, contributing to advancements in breast cancer therapeutics.

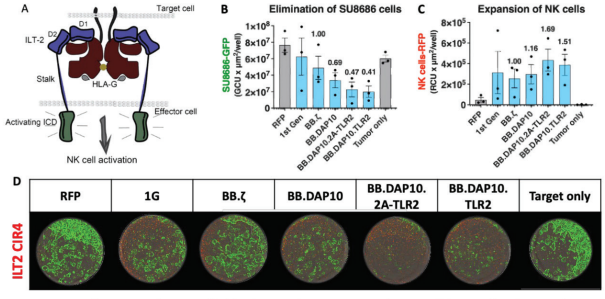
1772. An RNA-Based Platform to Facilitate Arming of Oncolytic Picornaviruses

Kyla A. Boyd, Caitessa G. Venables, Velia Penza, Rebecca Nace, Autumn J. Schulze

Mayo Clinic, Rochester, MN

Oncolytic virotherapy is the use of viruses to treat cancer. Clinical data indicates that oncolytic vectors have limited therapeutic efficacy compared to preclinical studies. This has led to arming viruses via the addition of transgenes largely focused on immune stimulation or chemotherapeutic combination as well as the use of repeat dosing regimens. However, genetic arming is not ideal for all viruses and systemic repeat dosing may be hindered by development of neutralizing antibodies. Picornaviruses are small positive-sense RNA viruses with a limited packaging capacity and cannot be efficiently armed with many therapeutically relevant genes, such as cytokines, via gene insertion. To date, several picornaviruses have been explored in clinical trials, and have resulted in a modest boost to overall survival in patients treated. Immune-related signatures have been observed in some responders versus non-responders providing prospective therapeutic combinations. Therefore, we hypothesize that rational arming of picornaviruses will boost their therapeutic effect and further improve patient outcomes. We have developed an RNA-based oncolytic platform for mengovirus, a murine picornavirus, based on the delivery of synthetic RNA genomes (iRNA) via lipid nanoparticles (LNPs), which may facilitate repeat intravenous dosing while expanding opportunities for targeting based on nanocarrier modification. This platform also augments our capacity to explore novel arming mechanisms. Here we describe an optimized microRNA-targeted Mengovirus iRNA construct, MC_0R, deliverable via LNP. The specific infectivity, translation, and cytotoxicity of the iRNA were comparable to an untargeted construct *in vitro*. To assess therapeutic efficacy, mice bearing MPC-11 subcutaneous tumors were treated with vehicle, empty LNPs or LNPs containing mengovirus iRNAs and tumor volume was monitored. All mice in the MC_0R-LNP treated group showed tumor regression, significantly improved overall survival, and viremia. Further confirmatory *in vivo* studies are ongoing. Overall, we observed that mengovirus iRNAs delivered by non-viral vectors are safe and can have a therapeutic effect. This capsid independent delivery opens opportunities for initial and repeat dosing that can bypass toxicity and immune neutralization. Our results support the continued development of MC_0R as an RNA-based oncolytic virus platform and allow exploration of combining RNA-based therapeutics with our oncolytic iRNA formulation, studies that are currently ongoing.

Friday Posters: Cancer - Targeted Gene and Cell Therapy



1773. Chimeric ILT Receptors (CIR) Coupled with Novel and Potent Costimulatory Domains Efficiently Direct Natural Killer Cells to Eliminate HLA-G Positive AML and Solid Tumors

MyLinh T. Duong, Jihyun Park, Raphael Ognar, Simon Wain-Hobson, Joseph Henri Bayle

NKILT Therapeutics, Houston, TX

Background Human leukocyte antigen (HLA)-G directs immunosuppression by binding to ILT2 in lymphoid cells and ILT4 in myeloid cells via ITIM signaling motifs. HLA-G expression is low or absent in normal tissues, except for the cytotrophoblasts in the placenta during pregnancy. However, about 50% of cancers derepress HLA-G as a mechanism to evade immune attack. To effectively target the multiple structural isoforms of HLA-G, we developed an approach utilizing ILT2 and ILT4 as engagers and linking them with intracellular signaling domains to create chimeric ILT receptors or CIRs that drive activation of Natural Killer (NK) cells. *Methods* $CD56^+$ NK cells isolated from PBMCs (up to 5 donors) were activated with IL-15, IL-2 and a feeder-free cocktail of an immobilized cytokine and activating ligand and transduced with γ-retroviruses directing expression of various CIR-containing vectors together with soluble IL-15 and a ΔCD19 marker. After 8 days of expansion, CIR- or CAR-NK cells were

cocultured with GFPffluc-expressing tumor cell lines with or without transgenic HLA-G G1, G2 and G5 isoforms or primary human cell types. Cytotoxicity of CIR-NK cells was determined by reduction of GFP fluorescence or luciferase activity and supernatants were analyzed for IFN-γand TNF-α release. Transduced NK cells were labeled with nuclear-RFP for measurement of expansion in coculture. *Results* CIR (ILT2 or ILT4.4-1BB.ζ) constructs were efficiently and stably expressed in NK cells (>80% $CD19^{+}$) and induced HLA-G-specific killing of AML and solid tumor cells relative to mock-transduced cells. In cocultures against THP1 and KG1 target cells expressing exogenous G1, G2 or G5 isoforms, CIR-NK cells displayed enhanced target cell killing in 2 and 7-day assays relative to mock-transduced effector cells (Mock = 1.47E6 ± 4.9E5 vs. CIR = 5.7E5 ± 6.0E5 in coculture against KG1-HLA-G1). To improve cytotoxicity and persistence of CIR-NK cells, a screen of >45 novel intracellular costimulatory molecules to replace 4-1BB.ζ resulted in several potent candidates. Notably, ILT2 or ILT4 CIR fused to 4-1BB.DAP10 and TLR2 constructs achieved approximately 70% greater tumor cell killing and 2-fold greater expansion over 4-1BB.ζ counterparts. Further, in serially repeated cocultures in which tumor cells were added up to 4 times every 2 days, the ILT4.4-1BB.DAP10-2A.TLR2 CIR-NK cells eliminated more than 60% of Molm13 tumor cells (4-1BB.ζ = 3.96E7 ± 5.37E6 vs. 4.1BB.DAP10.2A-TLR2 = 1.45E7 ± 3.34E6), expanded more than 2-fold relative to CIR-NK cells containing 4-1BB.ζ (4-1BB.ζ= 1.49E5 ± 5.72E3 vs. 4.1BB.DAP10.2A-TLR2 = 3.26E5 ± 5.1E4) and was accompanied by 2-fold higher IFN-γ secretion (4-1BB.ζ = 15.3 pg/ml ± 1.1 vs. 4.1BB.DAP10.2A-TLR2 = 35.5 pg/ml ± 3.58). We validated the safety profile of ILT2 and ILT4 CIR-NK cells against more than 15 primary human cell types populations from PBMCs and CIR expression did not induce targeting against normal tissues relative to mock-transduced NK cells. *Conclusions* The use of natural receptors (ILT2/4) to target HLA-G permits pairing of the ILT receptors with the multiple immunosuppressive HLA-G isoforms thereby circumventing a mechanism for target escape often observed in CAR-directed therapy. We demonstrated that engineered CIR-NK cells, coupled with potent intracellular costimulatory domains, can convert HLA-G expression in cancer cells from an inhibitor of immune surveillance into a practical target for anti-cancer therapy.

1774. Adeno-Associated Virus-Mediated Expression of Rituximab for the Treatment of Central Nervous System Lymphoma

Marcela S. Werner, Otto D. Cerqueira, Lama Abdullah, Jillian Roamer, Jenny A. Greig, James M. Wilson

Gene Therapy Program, University of Pennsylvania, Philadelphia, PA

Introduction: Central nervous system lymphoma (CNSL) is a group of rare incurable malignancies that originate in the brain or spinal cord (primary CNSL) or from systemic disease that metastasizes to the CNS (secondary CNSL). Up to 95% of CNSL cases arise from B-cell non-Hodgkin lymphoma (NHL). Although there is a lack of consensus, the 5-year survival rate for patients diagnosed with CNSL is <30%, and the overall survival from diagnosis is estimated to be <7 months for patients aged 70 years or older. Rituximab, a human/murine chimeric anti-CD20 monoclonal antibody, is part of the standard of care regimens for the treatment of indolent and aggressive forms of B-cell NHL. However, rituximab has low bioavailability in the CNS because of the intrinsic properties of the blood-brain barrier. In this study, we established a model for rituximab expression mediated by adeno-associated virus (AAV) vectors (AAV.Rituximab) for direct CNS delivery to bypass the blood-brain barrier and maximize the effectiveness of rituximab against B-cell CNSL. Methods and Results: We evaluated four different codon-optimized versions of AAV.Rituximab in healthy *Rag1* knockout (*Rag1*$^{-/-}$) mice following intracerebroventricular (ICV) delivery of $1x10^{11}$ genome copies (GC) of vector per animal. Treatment was well tolerated, and no signs of toxicity were observed. We selected the top codon-optimized version of AAV.Rituximab based on enzyme-linked immunosorbent assay results, which showed an average expression of 102 ng rituximab/mg total protein in saline-perfused brain tissue homogenates and 815 µg rituximab/mL in serum by day 30 after treatment. Rituximab identity was confirmed via mass spectrometry analysis, and heavy- and light-chain expression was confirmed via Western blot using brain tissue homogenates from ICV-treated mice. We evaluated the DNA and RNA biodistribution in brain and liver tissues of these animals by quantitative PCR; results confirmed successful CNS transduction and transgene expression. Because of vector leakage into the systemic circulation, vector transduction and transgene expression also occurred in the liver of *Rag1*$^{-/-}$ mice injected ICV with AAV.Rituximab. Tumor challenge experiments using human lymphoma cell lines (Ramos, Oci-ly3, and Daudi) implanted into the brain parenchyma of adult *Rag1*$^{-/-}$ mice demonstrated that ICV treatment with $1x10^{11}$ GC/mouse of the lead codon-optimized AAV.Rituximab candidate delayed tumor progression and increased overall survival in all xenograft models tested compared with control groups injected with AAV.Isotype antibody vector control. Conclusions: These preclinical findings highlight the potential of direct CNS delivery of AAV-based gene therapy to achieve sustained expression of therapeutic monoclonal antibodies such as rituximab for the treatment of B-cell CNSL.

1775. Gene-Edited Hematopoietic Stem Cells to Enable Next-Generation CAR-T Cell Therapy for the Treatment of AML

Julia Etchin[1], Yonina Keschner[1], Mariana Silva[2], Hillary Hoyt[2], Matthew Ung[3], Nathan Manalo[4], Juliana Xavier-Ferrucio[4], Amanda Halfond[1], Julia DiFazio[1], Michelle Lin[4], Julian Scherer[2], John R. Lydeard[1], Tirtha Chakraborty[5]

[1]Discovery and Molecular Engineering, Vor Biopharma, Cambridge, MA,[2]Cancer Immunotherapy, Vor Biopharma, Cambridge, MA,[3]Quantitative Biology, Vor Biopharma, Cambridge, MA,[4]Preclinical and Translational Biology, Vor Biopharma, Cambridge, MA,[5]Vor Biopharma, Cambridge, MA

Acute myeloid leukemia (AML) is a hematologic malignancy characterized by the abnormal clonal expansion of leukemic blasts. The lack of cancer specific antigens (Ags) coupled with heterogenous expression of the disease has made the treatment of AML difficult. Targeted therapies, such as CAR-Ts and the CD33-directed therapy gemtuzumab ozogamicin have shown significant anti-leukemic activity in both preclinical and clinical studies of AML but are hampered by severe myelotoxicity due to on-target, off-tumor activity. We developed an approach of genetically ablating biologically dispensable target Ags from hematopoietic stem cell grafts, thereby restricting the Ag expression to AML cells and enabling subsequent targeted therapy without risk of on-target off-tumor toxicities. Here, to identify and prioritize AML target Ags to address the challenge of heterogeneous AML expression we created a comprehensive multi-modal single cell expression atlas quantifying the intensity and (co)expression patterns of leukemic blast cells. In an assessment of 28 paired diagnosis and relapse patient bone marrows (BMs), we profiled ~80 candidate Ags (by applying RNA sequencing with surface Ag feature barcoding (>450,000 total cells)). Among the top target Ags based on ranking of average surface expression across all blasts in each patient are CD33 (currently under clinical evaluation (NCT05984199, NCT04849910)) and CLL-1. A promising AML target candidate, ADGRE2/EMR2, is among the top 25 highest surface expressors in both diagnosis and relapsed samples. Encouraged with the consistent expression levels, we developed ADGRE2-directed CAR-T cells. Novel ADGRE2-specific binders were identified and activation, cytokine secretion and potent killing against the ADGRE2$^+$ MOLM13 AML cells but not ADGRE2-lacking cells was confirmed. However, healthy BM and peripheral blood flow cytometric (FC) analysis showed that ADGRE2 is also expressed on hematopoietic stem and progenitor cells (HSPCs) and myeloid lineages, suggesting that editing may be necessary to protect healthy graft from subsequent off-tumor targeting. Human genetic data of ADGRE2 null individuals provide compelling evidence for biological dispensability (https://gnomad.broadinstitute.org/). To validate these null natural variants (NVs), we utilized a HEK293T-based system. Protein quantification of 7 predicted NVs showed surface and complete or partial intracellular protein loss in 5 NVs. Of those validated, two NVs that exhibited surface loss with reduced intracellular protein levels are found in conserved isoforms. We next utilized the adenine base editing (ABE) approach to knock out *ADGRE2* in HSPCs, observing >90% editing with a corresponding surface protein loss. Pharmacology studies using NSG mice showed no impact of ADGRE2 deletion in HSPCs on long-term 16-week engraftment and multilineage differentiation as compared with unedited cells and maintained editing. To enable combinatorial targeting of ADGRE2, we simultaneously ablated *ADGRE2* and *CD33* in HSPCs, observing >90% editing at both loci with consequent protein loss of both targets and no impact on myeloid cell differentiation. In conclusion, our data provide a discovery framework for prioritizing AML targets based on expression patterns throughout disease progression. Paired with multiplex genome editing to reduce the toxicity to healthy donor graft, this may enable administration of combinatorial therapeutics with reduced on-target, off-tumor toxicity for AML patients.

1776. Pegenzileukin, a Selectively Pegylated IL-2 Analog, Enhances Anti-Tumor Function of NK Cells without Activating Regulatory T Cells

Anna Oja[1], Nada-Katarina Kasic[1], Ieva Cesonyte[1], Katarzyna Franciszkiewicz[2], Loreley Calvet[2], Sukhvinder Sidhu[2], Andre Kunert[1], Robert Igarashi[1]

[1]Oncology Research, Sanofi, Amsterdam, Netherlands,[2]Oncology Research, Sanofi, Vitry, France

Adoptive cell therapy using natural killer (NK) cells for cancer treatment is attractive due to their anti-tumor activity, their high safety profile, and feasibility of using NK cells "off-the-shelf". K-NK cells, NK cells expanded using plasma membrane particles (PM21) from K562-mb21-41BBL cell line, have high anti-tumor activity against a range of tumor types. IL-2 promotes NK cell proliferation and survival. While use of IL-2 showed early promise in oncological clinical studies, the high toxicities and non-specific engagement, particularly to promote Treg cell activation, has limited its clinical use. Pegenzileukin (SAR444245) is a synthetic IL-2 that is selectively pegylated and preferentially binds the IL-2 receptor β/γ complex, but not the α receptor. This allows for selective activation of effector CD8+ T cells and NK cells with diminished Treg cell activation. Thus, pegenzileukin shows reduced activation of Treg cells and limits their deleterious effects as compared to IL-2. PBMCs and K-NK cells were stimulated with pegenzileukin to investigate the activation of the different immune cell populations. K-NK and CD8+ T cells can be selectively activated by pegenzileukin to cause activation and proliferation. Stimulation of K-NK cells with pegenzileukin maintains their viability for at least 2 weeks in vitro and increases K-NK cell numbers in vivo in mice. Importantly, pegenzileukin does not cause aberrant cytokine production by K-NK cells in the absence of tumor cells, and likely would not increase the risk of graft-vs-host or host-vs-graft when used as a clinical combination, albeit a clinical study is required to demonstrate this hypothesis. Furthermore, pegenzileukin enhances K-NK cell cytotoxicity up to 13-fold compared to no cytokine treatment. In vivo administration of pegenzileukin together with K-NK cells improves tumor control and correlates with higher numbers of K-NK cells in peripheral blood. Thus, a combination therapy of adoptive K-NK cells and pegenzileukin has the potential to significantly improve pharmacokinetics of K-NK cells and enhance pharmacodynamics for cancer therapy.

1777. Exploring BAFF-R as a Novel Target for Chimeric Antigen Receptor T-Cell Therapy in Chronic Lymphocytic Leukemia

Yan Luo[1,2], Yaqing Qie[1], Martha Gadd[1], Shuhua Li[1], Tanya Hundal[1], Hemant Murthy[3,4], Roxana Dronca[3], Mohamed A. Kharfan-Dabaja[3,4], Hong Qin[1,2,3]

[1]Regenerative Immunotherapy and CAR T- Translational Research Program, Mayo Clinic, Jacksonville, FL,[2]Department of Cancer Biology, Mayo Clinic, Jacksonville, FL,[3]Department of Internal Medicine, Mayo Clinic, Jacksonville, FL,[4]Blood and Marrow Transplantation and Cellular Therapy Program, Mayo Clinic, Jacksonville, FL

Tremendous benefits have been reported by a significant number of patients who have received chimeric antigen receptor (CAR) T-cell therapy against B-cell malignancies. With the passage of time and accumulation of surveillance data, a new set of challenges have been identified with the observations of antigen-escape relapse and of variability in patient responses to the treatment. Chronic lymphocytic leukemia (CLL) is an example of a refractory disease in which CD19 CAR T-cell therapeutic success has not been realized. In this study, we explored the use of B-cell activating factor receptor (BAFF-R) targeting CAR T-cells as an alternative immunotherapy for CLL. BAFF-R-mediated signaling regulates B lymphocyte development and survival and is expressed almost exclusively on B cells and most human B-cell lymphomas and leukemias. The finding of universal BAFF-R expression on CLL positions it as an ideal target for developing CAR T-cell therapy against CLL. Our data demonstrated that BAFF-R CAR T-cells elicited antigen-specific cytotoxicity against both CLL cell lines and primary CLL tumors isolated from patients. Given that CD19 antigen-escape is a major factor leading to release after CAR T-cell treatment, we explored the potential of using the BAFF-R CAR T-cell therapy to address this unmet need. A CD19-deficient CLL model was generated by genetically knocking out CD19 expression on the MEC-1 human CLL cell line. As expected, CD19-deficient MEC-1 cells showed resistance to CD19 CAR T-cells; however, BAFF-R CAR T-cells demonstrated potent cytotoxicity against these tumor cells, supporting our hypothesis that BAFF-R can be targeted for CD19 negative tumors. Finally, we validated the therapeutic efficacy of BAFF-R CAR T-cells in an autologous experiment setting using CLL patient samples. We successfully generated patient-derived BAFF-R CAR T-cells using a limited amount of blood samples from three CLL patients and demonstrated the cytotoxicity of these CAR T-cells against autologous CLL tumors. All our proof-of-principle data highlight BAFF-R-targeting CAR T-cell therapy as a novel therapeutic approach for CLL patients who have failed all options including CD19 CAR T-cell therapy.

1778. Molecular Shielding of CD52 Retains Expression, Anti-Phagocytic Don't Eat Me Function and Protects from Alemtuzumab-Mediated Depletion

Anna Camus[1], Emiel Ten Buren[1], Laura Garcia-Prat[1], Brault Julie[1], Valentin Do Sacramento[1], Sophie Lackner[1], Rosalba Lepore[2], Benedetta Romeo[1], Mathilde Testut[1], Klin Daniel[1], Izabela Durzynska[3], Saniye Yumlu[1], Stefanie Urlinger[1]

[1]Cimeio Therapeutics, Basel, Switzerland,[2]University Hospital and University of Basel, Basel, Switzerland,[3]Ridgeline Discovery, Basel, Switzerland

Targeted immunotherapies such as monoclonal antibodies aim to eliminate transformed or dysregulated cells expressing a specific target antigen and are highly effective in the treatment of various hematologic diseases. E.g., Alemtuzumab is approved for treatment of CD52+ malignancies as well as multiple sclerosis and is clinically assessed in reduced intensity conditioning and for lymphodepletion prior to administration of CAR-T cells. These novel applications raised the interest in engineered cell products with resistance to Alemtuzumab, which is usually achieved by CD52 knock-out (KO). CD52 is found on most cells of the lymphoid lineage as well as on monocytes and macrophages. Mature CD52 is a highly glycosylated 12-mer peptide, which is GPI-anchored to the cell surface and acts as a regulator suppressing inflammatory responses. This implies that CD52 KO on T cells will not be functionally inert and thus influence the activity and exhaustion of CD52 KO lymphocytes. Here, we shield CD52 from Alemtuzumab binding by introducing by a single amino acid (aa) substitution. This minimally invasive approach combined with careful selection of the substitution preserved expression and function of the engineered protein. From the determination of the Alemtuzumab epitope through a comprehensive mutagenesis screen three key residues emerged, which were predicted to retain GPI anchoring and glycosylation. By detailed binding assays and glycosylation profiling we identified two aa substitutions fully shielding CD52 from Alemtuzumab binding with limited impact on the glycosylation pattern. Primary T cells, HPSCs and cell lines were genetically engineered using base editing for both shielding variants. Engineered CD52 variants lose binding to Alemtuzumab, while binding of a control CD52 antibody remains unchanged, demonstrating expression levels comparable to unedited cells (Fig. 1a). We confirmed shielding of CD52 variants in antibody-dependent cytotoxicity (ADCC) assays with cells overexpressing either WT or CD52 variants. Due to similar processing of CD52 and CD24, we speculated that CD52 also inhibit phagocytosis. Indeed, CD52 KO primary T cells are phagocytosed at significantly increased levels when exposed to macrophages compared to CD52 WT T cells. Importantly, this was not observed with T cells expressing CD52 shielding variants (Fig. 1b), which also showed expression of phenotypic T cell markers and activation capabilities comparable to WT T cells. In analogy to what we have shown for targeted immunotherapies paired with engineered CD123[1], CD117 and CD45, we successfully shielded CD52 from Alemtuzumab binding by single aa substitutions while maintaining expression and biochemical properties. Moreover, our data is the first indication that CD52 can act as a novel don't eat me signal and single aa substitutions in CD52 retain this anti-phagocytic function. Further studies need to verify

increased in vivo persistence of engineered lymphocytes as compared to CD52 KO cells and thus being a superior alternative to CD52 KO approaches. 1 Marone, R. et al., J Exp Med. 2023

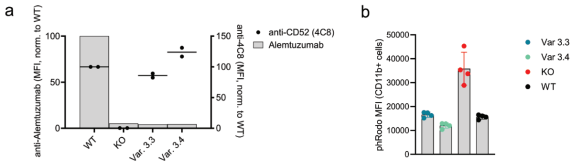

Figure1: Characterisation of shielded primary human T cells. T cells were either base edited cells for the shielding variants or to generate knock outs and sorter for loss of Alemtuzumab binding by low cytometry.
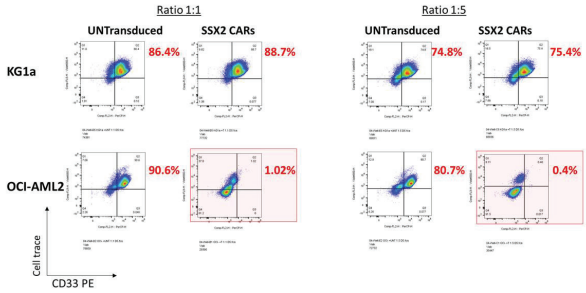
a) Shielded variants completely loose Alemtuzumab binding while binding of the control CD52 antibody 4C8 remains unchanged. This demonstrates expression levels comparable to unedited cells. b) Median fluorescence intensity of phRodo dye in the macrophage (CD11b+) population was measured by flow cytometry analysis after 2 h incubation with CD52 WT, KO, Var 3.3 or Var 3.4 edited primary T cells previously stained with phRodo dye.



1779. Development of a Novel Cell Therapy Targeting SSX2 for Acute Myeloid Leukemia

Achouak A. Achour

Cancer Research Center, Children National Hospital, Washington, DC

Background: Acute Myeloid Leukemia (AML) is the most common leukemia in adults and the second most common leukemia of childhood. Disease relapse is still a leading cause of death in these patients. With the success of CD19-CAR-T cell therapies for Acute Lymphoblastic Leukemia (ALL), novel T-cell therapeutics are also being explored for AML. Hence, we hypothesize that gene engineering T cells to target the tumor associated antigen Synovial Sarcoma X Breakpoint 2 (SSX2) will elicit potent anti-leukemia effects. **Objective:** To determine whether a novel T-cell product engineered to express a chimeric antigen receptor (CAR) targeting the HLA A2-restricted SSX2 epitope 41-49 will have anti-leukemia activity in vitro and in vivo. **Methods:** To achieve this goal, we developed a novel CAR which recognizes the 41-49 epitope of SSX2 in an HLA-A*0201 restricted manner, similar to the recognition of a TCR. To confirm a lack of off-target specificity of the CAR, we screened $SSX2_{41-49}$ peptide expression in HLA-A2+ healthy tissues and primary AML blasts by flow cytometry and immunochemistry (using bone marrow biopsy sections from AML patients with healthy donor control peripheral blood samples). We also tested the functionality of SSX2-CAR-T cells against AML cell lines by performing a co-culture assay using HLA A2-positive (OCI-AML2) and HLA A2-negative (KG1a) AML cell lines as targets. $SSX2_{41-49}$ CAR T versus control unmodified T cells were evaluated in this model in the absence of cytokines. Subsequently, to assess the anti-tumor activity of $SSX2_{41-49}$ CAR T *in vivo* we established an AML model in NSG mice. Mice were intravenously injected with HLA-A2 + (OCI-AML2) and HLA-A2 - (KG1a) AML cell lines expressing FFLuc. Upon confirming tumor engraftment by bioluminescence imaging (BLI), mice received a dose of $10x10^6$ cells/mouse of $SSX2_{41-49}$ CAR T-cells or control unmodified T-cells at day 7 after tumor injection. Leukemia burden was monitored weekly using BLI. Peripheral blood and splenocytes were analyzed every 2 weeks to track the CAR-T. **Results/discussion:** Screening of SSX2 expression confirmed high $SSX2_{41-49}$ peptide expression in HLA-A2 positive AML cells only. *In vitro*, $SSX2_{41-49}$ CAR-T demonstrated enhanced cytolytic activity, at both 1:1 and 1:5 effector: target ratios, exclusively against the HLA-A2 + OCI-AML2 cells (range 80-98%), In contrast, no cytolytic activity was observed against the HLA-A2 - KG1a cells (range 1-20% cytotoxicity) (**Figure**1). Our *in vitro* studies confirmed robust specificity and efficacy of $SSX2_{41-49}$ CAR-T cells. In a xenograft model, $SSX2_{41-49}$ CAR-T demonstrated modest anti-leukemic activity (after 3 weeks of tumor injection) with no acute infusion-related toxicities. To increase potency, combination therapy with the DNA methyltransferase (DNMT) inhibitor, 5′-azacitidine (AZA) was explored. Early study showed increase expression of $SSX2_{41-49}$ in HLA-A2 + OCI-AML2 cells (from 10% to 35% after 5-AZA treatment). **Future studies** will combine $SSX2_{41-49}$ CAR T with 5 AZA treatment one week after tumor injection to enhance $SSX2_{41-49}$ expression and tumor kill. Ultimately results from these studies will complete the IND-enabling studies needed to translate this novel treatment to the clinic.

Figure1. T cells expressing a $SSX2_{41-49}$ CAR eliminate exclusively Cell trace+ CD33+ THP-1 cells *in vitro*.

1780. Engineered Receptor Provides Inducible Signal 2 and Signal 3 Costimulation to Augment TCR-Based Cell Therapies of Cancer

Mansi Narula, Johannes Englisch, Azlann Arnett, Tadahiro Honda, Maksim Mamonkin, Norihiro Watanabe

Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX

Cellular immunotherapy using natural and engineered TCR-based T cells produces versatile and highly sensitive tumor targeting in preclinical models. However, their activity in a clinical setting is limited due to the lack of costimulatory signaling and cytokine, which reduces functional persistence of T cells and their clinical benefit. Engineered constitutive cytokine signaling helps boost T-cell persistence but comes with a risk of accelerated T-cell exhaustion or uncontrolled proliferation. We *hypothesized* TCR-based therapies can be enhanced by integrating physiologic costimulatory Signal 2 and a conditional Signal 3 resembling natural cytokine signaling. To test this hypothesis, we created a panel of engineered receptors with an extracellular domain derived from a 4-1BB ligand (4-1BBL) and intracellular domains emanating signaling from cytokine receptors. Upon antigen recognition and TCR stimulation in T-cells, these dual-stimulatory receptors engage 4-1BB, which is transiently upregulated on T-cell surface, thus producing Signal 2 with physiologic intensity and timing. Additionally, 4-1BB engagement activates intracellular signaling of the engineered receptor producing temporary Signal 3 to further aid in costimulation and survival of activated T-cells. We found a specific costimulatory receptor configuration comprising 4-1BBL linked with an intracellular domain of cMPL (a thrombopoietin receptor) produced highest activity in our models. When tested in T cells expressing a chimeric T-cell receptor (cTCR) targeting a leukemic antigen, co-expression of our engineered receptor on these cells produced 25-fold higher expansion than unarmed cTCR T cells,

in a 9-day tumor coculture assay. Similarly, when expressed on T cells redirected with leukemia-specific T-cell engager, the costimulatory receptor improved cell expansion by 35-fold, indicating the benefit is not limited to engineered TCRs. Mechanistically, the engineered costimulatory receptor induced strong STAT3 and STAT5 activation downstream of cMPL, concomitant to 4-1BB expression in activated T cells. Finally, a single injection of the engineered receptor armed cTCR T-cells mounted robust expansion and durable persistence in the absence of exogenous cytokines in a mouse xenograft model of human leukemia, in which unarmed cTCR T cells had only transient anti-tumor activity. These results suggest the application of the newly developed costimulatory receptor could be extended to diverse TCR-based therapies, to overcome the limited cell persistence.

1781. Targeting TdT for Highly Selective Therapy of Acute Lymphoblastic Leukemia

Pan Yin[1], Norihiro Watanabe[1], Zhang Ding[2], Xinya Liu[3], Mark Yarmarkovich[3], Alexey Stepanov[2], Maksim Mamonkin[1]

[1]Baylor College of Medicine, Houston, TX,[2]The Scripps Research Institute, San Diego, CA,[3]NYU Grossman School of Medicine, New York, NY

CAR T cells targeting pan-B cell antigens produce robust responses in patients with B-cell acute lymphoblastic leukemia (B-ALL) but often induce concurrent B-cell aplasia which requires additional management. Similar targeting of pan-T cell antigens to treat T-ALL could induce dangerous T-cell aplasia with associated immunodeficiency that is harder to compensate than the loss of B-cells. Targeting antigens highly restricted to leukemic cells with minimal presence on normal tissues can help overcome unwanted ablation of the critical immune cells. Terminal Deoxynucleotidyl Transferase (TdT) is expressed in the majority (>80%) of T-cell and B-cell ALL and is commonly used as a diagnostic marker. Normal expression of TdT is restricted to lymphocyte progenitors undergoing somatic rearrangement of antigen receptors and is absent in mature lymphocytes or primitive and committed progenitors. A recent study showed TdT-derived peptide on HLA-A2 can be recognized by a TCR which effectively redirects CD8+ T cells to eliminate leukemia. We hypothesized TdT/HLA-A2 targeting can be improved by utilizing a specific single-chain variable fragment (scFv) which could be used instead of a TCR to activate both CD4+ and CD8+ T cells for optimal anti-tumor effect. Using phage display, we identified a human scFv that selectively recognizes a TdT peptide complexed with HLA-A2. Structural modeling of the scFv-HLA/TdT interaction showed three potential hydrogen bonds formed between CDR regions of both heavy and light chains of the scFv and the TdT-derived peptide in the HLA-A2 groove. Notably, due to low antigen presentation, T-cells expressing an scFv-based CAR produced limited cytotoxicity against leukemic cells. However, a chimeric TCR (cTCR) with a TdT-specific scFv replacing either alpha or beta variable region enabled strong cytolysis of HLA-A2+ TdT+ cell lines NALM-6, BV173 and TALL-1. As expected, TdT cTCR T cells showed no activity against TdT+ HLA-A2- cell line CCRF-CEM and TdT- HLA-A2+ cells THP-1, GDM-1, and Loucy. Disruption of surface HLA Class I expression in BV173 by CRISPR/Cas9 editing abrogated their recognition by TdT cTCR T cells. Further, TdT cTCR T cells elicited no detectable cytotoxicity against normal autologous HLA-A2+ peripheral blood T- and B-cells unlike control CD19 CAR T cells that produced robust killing of peripheral B cells. In a mouse xenograft model of human B-ALL (BV173), a single injection of TdT cTCR co-expressing a costimulatory receptor produced complete elimination of detectable leukemia with 100% survival of all animals for the duration of the experiment (>60 days). Finally, we created a bispecific T-cell engager (BiTE) using the TdT/HLA-A2 specific scFv. Normal T-cells were effectively redirected to recognize and eliminate B-ALL and T-ALL cell lines BV173 and TALL-1 in the presence of soluble TdT BiTE. These results suggest TdT+ B-ALL and T-ALL can be effectively targeted by both cellular and biologic immunotherapy without ablating normal lymphocytes.

1782. Engineered *ortho*IL2-CAR T Cells Generated Using Viral Vector-Free, Three-in-One Nonviral CRISPR-Based Technology Demonstrate Enhanced Antitumor Activity in a Murine Model of Leukemia

Qian Zhang[1], Yihao Wu[1], Jingyi Yang[1], Eric Nigel Ebenezer Anand Manoharan[1], Tyra Wentz[1], Alvin Yu[1], Kevin Zhou[1], Morgan Hresko[1], Leon Su[2], Daniel Ryan[3], Christopher Garcia[2], Michael Milone[1]

[1]Upenn, Philadelphia, PA,[2]Stanford University, Stanford, CA,[3]Agilent Research Labs, Santa Clara, CA

Our previous studies have shown that an orthogonal IL-2 and IL-2Rβ system offers a potent approach to enhance CAR-T therapy. *Ortho*CAR T cells can be produced by transferring CAR and oIL2Rβ genes into T cells through a viral gene delivery system like lentivirus or retrovirus. However, this process carries with it the risks of variable transgene expression and oncogenesis due to random integration of transferred genes into the T cell genome. To address these challenges, we engineered *ortho*CAR T cells by combining multigenic-editing strategies, CRISPR/Cas9-mediated gene knockout (KO) and HDR-mediated gene knock-in (KI) to direct CAR integration into the IL2 locus. The IL2 gene locus was selected as the CAR target site to disrupt expression of the native IL2, which is functionally replaced by the orthogonal system and would be expected to also prevent the effects of CAR T-cell-derived IL2 on endogenous Tregs that depend upon this cytokine. IL2 KO and CAR KI were achieved with an efficiency of 46% (range 30 - 65%) using a 2nd generation, anti-CD19 CAR with 4-1BB and CD3ζ signaling domains in a donor DNA containing a CBh promoter with 650 bp homology arms flanking the CRISPR/Cas9 cut site within the IL2 gene. Sequencing confirmed the expected knock-in of the transgene as well as > 96% IL2 KO efficiency that was also associated with reductions in IL-2 production by the edited CAR T cells following antigen stimulation. The Prime Editing 3 (PE3) system was used to convert endogenous wildtype IL2Rβ to orthogonal IL2Rβ using a transfection of a PE3-encoding in vitro transcribed mRNA, Prime Editing guide RNA (pegRNA), and nicking sgRNA (ngRNA). This approach was able to achieve an editing efficiency of 71% (range 54-89%). This tandem engineering strategy not only results in more uniform CAR T expression, but also demonstrated *ortho*IL2-enhanced antitumor activity in vivo using immunodeficient NSG mice xenografted with NALM-6 (leukemia) model. Unexpectedly, control T cells bearing the IL2 KO with CAR KI were also highly functional in vitro and in vivo with activity that more rapid and potent than

conventional CAR T cells made by lentiviral transduction. This was associated with reduced tonic CAR signaling in the edited IL2-CAR19 T cells compared to the conventional CAR19 T cells. Our results indicate that the IL2 gene is dispensible for CAR T cells, and a virus-free tri-genome editing workflow has the potential to enable rapid and flexible manufacturing of precisely engineered CAR T cell products to advance CAR T cell immunotherapy.

1783. SynNotch-Gated CARs Enhance Specificity, Promote Persistence, and Reduce Toxicity in AML

Shawn Barman, Samy Leon Jambon, Jainping Sun, Sakunthala Muthugounder, Yong-Mi Kim, Shahab Asgharzadeh, Chintan Parekh, Babak Moghimi
CHLA/USC, Los Angeles, CA

Background and significance: Despite advances in modern chemotherapy and bone marrow transplantation, the outcome for patients with relapsed and refractory pediatric acute myeloid leukemia (AML) remains very poor. While CAR-T immunotherapy has proven extraordinarily effective in treating lymphoblastic leukemia, its success in treating AML is yet to be realized. A lack of tumor-specific antigens in AML and the risk of toxicity have hindered the development of AML-specific CAR-T cells. Additionally, current AML CARs in clinical trials often lack T-cell persistence and have failed to demonstrate effectiveness. We have engineered logical gated CAR-T cells targeting a combination of CD33 and CD123 in AML to address the lack of tumor-specific antigens. These gated CAR-T cells are designed to deliver precise killing against dual-positive tumor cells while sparing normal tissues expressing individual targets. **Methods**: We engineered gated CAR-T cells to express CD123 through a CD33 synthetic receptor and used in vitro coculture, cytokine release, and cytotoxicity assays to evaluate their effectiveness against AML cell lines and patient-derived xenografts (PDXs). Subsequently, we employed immunocompromised murine models of AML to assess their efficacy in vivo and utilized humanized mouse models to evaluate hematopoietic toxicity. **Results**: Our findings demonstrate that CD33-gated CD123 CAR-T cells effectively eliminate AML in vitro and in vivo, particularly against AML cell lines and in PDXs. Unlike constitutively expressed CD123 CARs, the CD123 CAR expressed via the CD33 SynNotch circuit preserves hematopoietic stem cells (HSCs), reducing the risk of on-target off-tumor hematopoietic toxicity. These gated CAR-T cells also show enhanced resilience to exhaustion, an improved memory profile, and increased proliferation potential. Notably, the moderated CAR signaling within this circuit further prevent cytokine release syndrome, addressing a major limitation in CAR-T dose escalation and enhancing overall efficacy. **Conclusion**: Precision SynNotch gated CAR-T cells targeting a combination of CD33 and CD123 in AML that prevent hematopoietic toxicity and demonstrate superior T-cell phenotype, are positioned to overcome significant shortcomings of current AML CAR-T cell therapies.

Friday Posters: Challenges to Immunological Responses to Therapeutic Interventions

1784. Reducing Cas9-Specific Immune Responses Through the Self-Inactivating CRISPR (SiC) System in the Canine DMD Model

Bryan Hu[1], Yongping Yue[1], Xiufang Pan[1], Matthew J. Burke[1], Keqing Zhang[1], Jin Han[1], James A. Teixiera[1], Sandeep R. P. Kumar[2], Roland W. Herzog[3], Dongsheng Duan[1,4,5]
[1]Department of Molecular Microbiology and Immunology, School of Medicine, University of Missouri, Columbia, MO,[2]Department of Pediatrics, Indiana University, Indianapolis, IN,[3]Department of Pediatrics, IU School of Medicine, Indianapolis, IN,[4]Department of Chemical and Biomedical Engineering, College of Engineering, University of Missouri, Columbia, MO,[5]Department of Neurology, School of Medicine, University of Missouri, Columbia, MO

Adeno-associated virus (AAV)-mediated CRISPR Cas9 editing holds great promise in treating Duchenne muscular dystrophy (DMD). However, previous studies have shown that Cas9 immunity drastically reduces the number of edited muscle fibers, impeding successful treatment. Thus, there is an urgent need to minimize Cas9-specific immune responses for AAV CRISPR therapy. One approach is to impose a transient expression of the Cas9 protein. This can be achieved through a self-inactivating CRISPR (SiC) system. Co-delivery of a gRNA that specifically targets the Cas9 expression cassette can abrogate the expression of the Cas9 protein, thereby becoming self-inactivating. Many groups have generated different self-inactivating CRISPR systems to reduce off-target editing. However, it is unclear whether this approach can be purposed to reduce Cas9-specific immune responses. Here, we evaluated dystrophin restoration and Cas9-specific immune responses using the SiC system in Welsh corgi muscular dystrophy (WCMD) and labrador retriever muscular dystrophy (LRMD) dog models of DMD. WCMD and LRMD dogs carry intronic insertions in the *DMD* gene. We previously designed and selected the best mutation-specific gRNAs for each model. We adopted the SiC-V2-Cas9G7 gRNA that targets a sequence in the SpCas9 genome from Kelkar et al. (Mol Ther 28:29-41, 2020). The self-inactivating gRNA was packaged either within an alkaline phosphatase (AP) reporter cassette or included as part of the therapeutic gRNA cassette. We produced AAV8 vectors and co-injected intramuscularly in one WCMD dog and two LRMD dogs. For the WCMD dog study, we co-injected the CK8.SpCas9 vector, the WCMD gRNA vector, and the AP.SiC gRNA vector at the dose of 1 x 10^{13} vg/muscle/vector. For the LRMD dog study, we co-injected one dog with the CK8.SpCas9 vector, the LRMD gRNA vector, and the AP.SiC gRNA vector at the dose of 1x10^{13} vg/muscle/vector. We co-injected the other LRMD dog with the CK8.SpCas9 vector, the LRMD gRNA. SiC gRNA vector, and an AP reporter vector at the dose of 1x10^{13} vg/muscle/vector. All vector mixtures were injected into three muscles of each dog. All injected dogs were placed under a twelve-week high-dose prednisolone immune suppression as previously published. The WCMD dog was euthanized at 3 weeks post-injection. LRMD dogs

were biopsied at 3 and 6 weeks post-injection and euthanized at 12 weeks post-injection. Plasma, serum, and PBMCs were collected every week from one day before injection till termination. We are currently processing and evaluating the tissues collected from the study. We will report our results at the annual conference (Supported by NIH).

1785. Transgene-Directed Immunological Investigations into Immune-Mediated Myositis Following Delandistrogene Moxeparvovec Gene Therapy

Sohrab Khan[1], Hélène Haegel[2], Andreas Hollenstein[2], Christoph M. Wandel[2], Damon R. Asher[1], Danielle A. Griffin[1], Emanuel Palatinsky[1], Stefanie Mason[1], Rachael A. Potter[1], Ida Moeller[1], Susan T. Iannaccone[3], Craig M. Zaidman[4], Louise R. Rodino- Klapac[1]

[1]Sarepta Therapeutics, Inc., Cambridge, MA,[2]F. Hoffmann-La Roche Ltd, Basel, Switzerland,[3]University of Texas Southwestern Medical Center and Children's Health, Dallas, TX,[4]Department of Neurology, Washington University in St. Louis, St. Louis, MO

Introduction: Delandistrogene moxeparvovec is a recombinant adeno-associated virus rhesus isolate serotype 74 vector-based gene transfer therapy, designed to compensate for absent functional dystrophin in Duchenne muscular dystrophy (DMD) by delivering a transgene encoding delandistrogene moxeparvovec micro-dystrophin, an engineered protein retaining key functional domains of wild-type dystrophin. As of January 2024, delandistrogene moxeparvovec is approved in the USA, UAE, and Qatar for the treatment of ambulatory pediatric patients aged 4 through 5 years with DMD with a confirmed mutation in the *DMD* gene. Two cases of immune-mediated myositis (IMM) were reported in ENDEAVOR (SRP-9001-103; NCT04626674), an open-label, Phase 1b, multi-cohort study of delandistrogene moxeparvovec. Case 1 occurred in a 9-year-old patient with a deletion of exons 3-43 of the *DMD* gene, 35 days post-dosing, and Case 2 occurred in a 7-year-old patient with a deletion of exons 8 and 9 of the *DMD* gene, 29 days post-dosing. Both patients experienced muscle weakness and received immunosuppressive treatment, including high-dose corticosteroids and tacrolimus. We conducted a clinical and immunological investigation to better understand the antigenic determinants of IMM events in these two patients. **Methods:** An interferon-γ enzyme-linked immunosorbent spot (ELISpot) assay was used to detect T-cell responses to delandistrogene moxeparvovec micro-dystrophin peptide pools. An *in silico* tool was used to determine micro-dystrophin peptide binding with human leukocyte antigen class I (HLA-I) or human leukocyte antigen class II (HLA-II) molecules corresponding to the patients' specific HLA allele combinations. **Results:** ELISpot analysis suggested that IMM resulted from T cell-mediated responses directed against specific delandistrogene moxeparvovec micro-dystrophin peptides corresponding to exons 8 and 9 (Case 1) and exon 8 (Case 2) of the *DMD* gene. *In silico* analysis of HLA presentation suggested a high risk of immunogenicity for peptides derived from exons 8 and 9 of the *DMD* gene. **Conclusions:** These results are consistent with clinical trials of other investigational DMD gene therapies suggesting that patients with deletions in regions of the *DMD* gene overlapping those expressed in a given microdystrophin may be at an increased risk of IMM following gene therapy. Future work may provide a better understanding of risk factors to mitigate safety concerns in patients with potentially higher-risk *DMD* mutations.

1786. A Novel Quantitative Methodology for Profiling Anti-AAV Antibodies: Insights from a Pilot Study in SMA Type I Patients Receiving Zolgensma

Tomas Baldwin[1], Ivan Doykov[1], Pierpaolo Ala[2], Nikki Cornell[2,3], Mariacristina Scoto[2,3], Giovanni Baranello[2,3], Haiyan Zhou[1], Francesco Muntoni[2,3], Kevin Mills[1], Wendy Heywood[1]

[1]Genetics and Genomic Medicine, University College London - Institute of Child Health, London, United Kingdom,[2]Developmental Neurosciences, University College London - Institute of Child Health, London, United Kingdom,[3]Great Ormond Street Hospital, London, United Kingdom

Adeno-associated virus (AAV)-based gene therapies have emerged as a promising strategy the treatment of rare diseases. However, a significant hurdle remains in the form of the common prevalence of anti-AAV antibodies in the population. There is currently no consensus in methodologies for the assessment of anti-AAV antibodies, with options ranging from semi-quantitative ELISAs to *in vitro* and *in vivo* neutralisation assays. Whilst informative, there is significant variability between outputs, leading to a call for a more quantitative approach. In this study, we present an innovative fully quantitative methodology designed to assess anti-AAV antibody response using multiplexed targeted proteomics. Through a pilot investigation involving 20 spinal muscular atrophy (SMA) patients and 10 healthy controls, we evaluated changes in the immune complex binding to AAV9 capsid (VP1-3) both pre and post AAV9-based gene therapy and correlate our findings with reported adverse events. Our findings reveal longitudinal shifts in the composition of the immune complex binding AAV9, characterized by a significant increase in the prevalence of IgG1 binding ($p<0.0001$), with IgG1 titer increasing for up to 6 months post infusion in some patients. Additionally, alterations in IgG2 binding were observed ($p<0.001$), highlighting the dynamic nature of the immune response to AAV9-based interventions. Additionally, varying levels of seroprevalence of anti-AAV9 antibodies was identified in 40% of the healthy control group ($p=0.0025$), emphasizing the significance of understanding baseline immunity in the general population. The implications of our methodology extend beyond the specific patient cohort studied, providing a valuable tool for enhancing our understanding of AAV seroprevalence in diverse populations. Crucially, the quantitative nature of our methodology allows quantitative isotype specific cutoff values before the AAV administration, and the monitoring of patients' immune responses over time, allowing . These quantitative determination could be important to assess the relevance of "below" qualitative threshold AAV determination for the long term efficacy and toxicity, and could provide a very sensitive methodology for assessing the impact of immunosuppression for re-administration of AAV-based gene therapies.

1787. Impact of Serotype Switching on Intra-Articular Administration of High Capacity Adenovirus Vectors on Transgene Expression

Jiansen Yan[1], Camilla Majano[1], Zelong Dou[1], Yangjin Bae[1], Masataka Suzuki[2], Amanda Rosewell[2], Racel Cela[1], Carolina Leynes[1], Ming-Ming Jiang[1], Philip Ng[1], Brendan Lee[1]

[1]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX,[2]Center for Cell and Gene Therapy, Baylor College of Medicine, Texas Children's Hospital, Houston, TX

High Capacity Adenovirus (HCAd) vector-based intra-articular gene therapy has completed phase I clinical trial in osteoarthritis (NCT04119687). However, the impact of pre-existing Anti-Ad5 adaptive immunity resulting from natural infection on joint transduction and transgene expression remains unknown. Given the chronic nature of osteoarthritis progressing over many decades, multiple administrations of vectors may be required to sustain therapeutic benefits, potentially inducing new anti-vector immunity after the initial intra-articular administration. To address this issue and circumvent the preexisting immunity, we explored the the use of adenovirus vectors with different capsid serotypes. First, we evaluated the ability of different serotype vectors to mediate joint transduction in wild-type FVB/NJ mice through intra-articular injection of high capacity adenovirus 5 (HCAd5), HCAd1, HCAd2, and HCAd6 expressing luciferase. Consecutive detection of luciferase activity by IVIS demonstrated effective transduction in joint tissues and constant transgene expression over time for all HDAd serotypes. Intra-articular re-injection with HCAd5-LacZ at 16 weeks after the first injection in wild-type mice showed decreased transduction when using the same serotype vector, whereas re-administration of different serotypes of HCAd improved transduction as demonstrated by LacZ staining of knee joints. To mimic natural immunization, wild-type FVB/NJ mice were immunized with two intramuscular injections of first-generation serotype 5 Ad, followed by intra-articular administration of HCAd5, HCAd1, HCAd2, and HCAd6 expressing LacZ. Our findings revealed that preexisting Anti-Ad5 immunity resulting from immunization reduced HCAd5 vector transduction and transgene expression after intra-articular administration, while switching the serotypes to HCAd2 and HCAd1 improved transgene expression. These findings offer valuable insights into strategies for overcoming immunity against adenoviruses, potentially improving the effectiveness of HCAd vector-based intra-articular gene therapy for knee joint diseases such as in post-traumatic osteoarthritis.

1788. Rituximab Extends Duration of Efficacy of AAV-hLDLR in Reducing LDL-C in Cynomolgus Monkeys

Sijia Huang[1], Zhikui Gao[1], Simian Li[1], Yiting Liu[2], Guang Qu[1,2], Lixin Jiang[1,2]

[1]NGGT (Suzhou) Biotechnology Co., Ltd., Suzhou, Jiangsu, China,[2]NGGT, Inc, Walnut Creek, CA

Introduction: Familial hypercholesterolemia (FH) is mostly caused by a defect in the gene encoding low-density lipoprotein receptor (LDLR). Massive elevations in serum cholesterol levels are observed in homozygous FH patients (HoFH). When left untreated, this genetic disorder of cholesterol metabolism can lead to premature atherosclerosis, cardiovascular disease (CVD) and often death at a very young age. We developed NGGT006, a liver-targeting AAV-hLDLR vector and demonstrated that it restored the uptake of LDL-cholesterol (LDL-C) from peripheral blood by expressing WT human LDLR (hLDLR) protein on liver cell surface. However, in WT cynomolgus monkeys, a single injection of NGGT006 reduced serum LDL-C level for a short time. Then serum LDL-C returned to the baseline level. Associated with the declined effect in LDL-C reduction, antibodies against hLDLR were detected, as well as the significant increases of liver enzymes aspartate aminotransferase (AST) and alanine aminotransferase (ALT), suggesting the activation of immunity and liver toxicity. This study explored the effect of immunosuppression mediated by Rituximab, an anti-CD20+ B-cell monoclonal antibody in WT cynomolgus monkeys with NGGT006 administration. **Method/Result:** Four WT AAV8 neutralizing antibody (NAb) negative cynomolgus monkeys were randomly divided into NGGT006 group and combination of Rituximab/NGGT006 group, with 2 animals in each group. Rituximab was administered by intravenous injections at 20mg/kg at day -3, 18, and 71, followed by NGGT006 at 5×10^{13}vg/kg at day1. Levels of liver enzymes, AST and ALT, serum LDL-C, lymphocyte subsets (CD45+CD19+) and anti-hLDLR antibodies were monitored. In NGGT006 only group, a transit reduction of serum LDL-C level was observed for 5 weeks. In contrast, treatment of NGGT006 combined with Rituximab maintained the reduced LDL-C level for at least 24 weeks till the anatomy point. No significant increase in AST or ALT was detected. Consistent with the profound depletion of CD45+ CD19+ B-cells, no increase in anti-hLDLR antibody was observed. **Conclusion:** These data show that immunosuppression by Rituximab may result in a prolonged effect of LDL-C reduction and decrease hepatotoxicity mediated by AAV-hLDLR in non-human primates (NHPs). This study supports the clinical deployment of Rituximab in the setting of AAV-mediated LDLR gene transfer for treating HoFH.

1789. Characterization of the Immune Response to Adeno-Associated Virus Vectors in the Central Nervous System of an Ovine Model

Nathan K. Yingling, Ashley Harkins, Hector Ribeiro Benatti, Meghan Blackwood, Motahareh Arjomandnejad, Toloo Taghian, Sarah Nath, Darcy Reil, Heather L. Gray-Edwards, Allison M. Keeler-Klunk

UMass Chan Medical School, Worcester, MA

Background: Adeno-associated virus (AAV) stands out as a prominent gene delivery system. Despite AAV's relatively low immunogenicity, host immune responses remain an impediment to widespread AAV application in gene therapies. These challenges require special consideration when targeting the central nervous system (CNS) due to its unique immunologic nature. As such, research into understanding the immune response to AAV in the CNS is warranted. In an ongoing CNS-directed AAV clinical trial, the induction of systemic capsid-specific immune responses and concurrent increases in the inflammatory cytokine, CXCL10, within the cerebral spinal fluid (CSF) were observed suggesting the recruitment of inflammatory cells to the CNS. To further understand these findings, we investigated the

immune response to AAV gene therapy after CNS-directed delivery in a sheep model. **Methods:** Lambs were assigned to either, an AAVrh32.33 conjugated to secreted embryonic alkaline phosphatase (SEAP) (n=2) or a PBS control (n=1). Bilateral thalamic injections were performed, with treated lambs receiving 4.8E12 vg in 175ul per thalami and control sheep receiving 175ul of PBS per thalami. Baseline assessments included physical and neurological exams. Blood and CSF collection were performed before vector administration. Animals were then monitored for 6 weeks by clinical and neurological exams, and blood and CSF analysis. Animals were terminated at 6 weeks, and tissues were collected for immunohistopathological and vector genome analyses. **Results:** Treated lambs exhibited neurological signs, including ocular strabismus, hind limb weakness and disordered proprioception. One treated lamb was noted to have eating disturbance, leading to weight loss and termination on week 4. No neurological signs were noted in the control animal. Treated lambs showed decreases in body mass by their endpoint. As expected of growing lambs, the control increased its weight by 25%. Liver function tests were unremarkable, except for a transient increase in AST levels observed postoperatively in all animals, which normalized by week 1. Analyses in both serum and CSF of treated lambs demonstrated early and sustained increases in SEAP transgene expression, with treated lambs showing a 4.3 to 5.6-fold increase in average relative light units (RLU) in the CSF when compared to serum levels at endpoint. No transgene expression was seen in the control lamb. Serum CXCL-10 analyses showed no differences between AAVrh32.33 lambs and the PBS control, however, CSF CXCL-10 concentrations increased on weeks 3 and 5 in the treated lambs and remained elevated when compared to the control. One treated animal had a positive ELISPOT response at endpoint. **Conclusions:** These findings provide a model for understanding responses observed in clinical trials and developing immune-modulating strategies to allow for safer and more effective therapies. Our results underscore the complexities of AAV immunogenicity in the CNS and could help us further understand both local and systemic immune responses to AAV gene therapy in the CNS. Forthcoming studies will encompass flow cytometry from peripheral mononuclear blood cells isolated from peripheral blood and whole brain tissue, immunohistochemical analysis, AAV vector biodistribution, IFN-γ and PDL-1 concentrations of the CSF and serum.

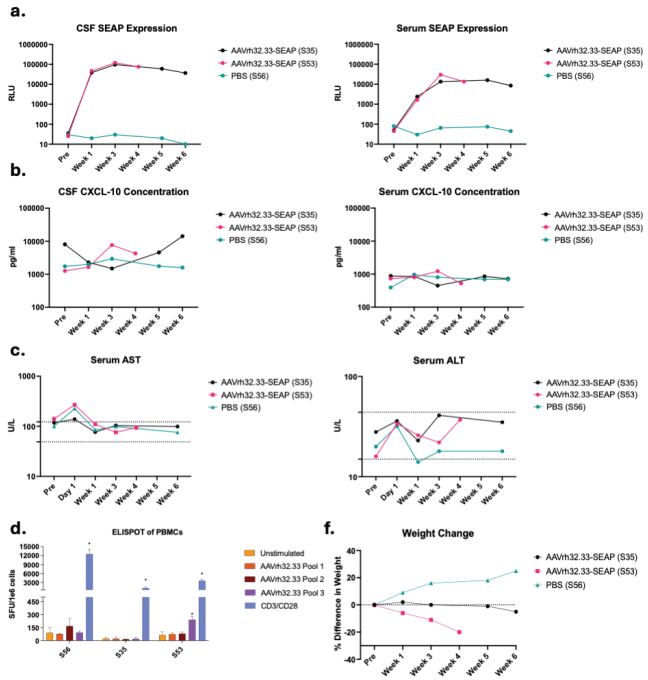


Figure 1. (a) ELISA results of CSF & Serum SEAP transgene expression. (b) CXCL-10 assay results in CSF & Serum. (c) AST and ALT lab results. (d) ELISPOT results from PBMCs collected at endpoint (* indicates significant response). (f) Changes in weights, interpreted percent change from "pre" timepoint baseline.

1790. Safety and Feasibility of Parenchymal Re-Dosing of AAV2-hAADC into Non-Human Primate

Anitvir S. Taunque, Matthew T. Rocco, Allison Clark, Akhila Dandamudi, Kaya Ceyhan, Meika Travis, Vikas Munjal, Krystof Bankiewicz, Lluis Samaranch

Neurological Surgery, The Ohio State University, Columbus, OH

Gene therapy has shown exciting and promising results in multiple clinical trials across the globe. However, the current paradigm in the field portrays it to be a one-time administration; several studies report a significant post-injection adeno-associated virus (AAV) vector-specific immune response. While this holds true for most systems within the body following systemic delivery, the brain is an immune-privileged organ with the potential to circumvent inflammatory responses depending on the delivery platform. In this study, three non-human primates (NHP) received an initial injection of AAV2-hAADC (human aromatic L-amino acid decarboxylase) within the left thalamus. After 7 months, an identical second dose was given in the contralateral thalamus. Animals were necropsied four months after the second injection and brains were processed for histology. Serum, CSF, and PBMC samples were collected periodically to assess humoral immunity, while brain sections were stained to analyze vector distribution, transgene expression, and cell-mediated responses. No significant cage-side findings were observed in any of the animals during periodic in-life neurological assessment. Whole blood chemistry showed no hematological abnormalities or signs of liver, kidney, or electrolyte dysfunction at any of the examined time

points. Immunohistochemistry assessment of brain sections showed transgene expression in both infused thalami, suggesting no AAV2 or transgene neutralization. Histopathologic analysis showed no brain edema, perivascular cuffing, interstitial cellular infiltration, or cytotoxic response, supporting the absence of an ongoing active cellular immune response. IgG and IgM serum levels remained near the baseline levels for the duration of the study. CSF and serum neurofilament light chain levels also support the same conclusion. We believe this data supports the hypothesis that a second brain parenchymal dose of AAV2 is well-tolerated and opens the opportunity to explore the clinical implications of brain parenchymal AAV2 redosing.

1791. A Study of the Immunogenicity of Cas9 in the Developing and Mature Mouse Central Nervous System

Robert Duba-Kiss[1], David R. Hampson[1,2]

[1]Department of Pharmacology & Toxicology, University of Toronto, Toronto, ON, Canada,[2]Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada

Adeno-associated virus (AAV) gene therapies are being assessed as potential treatments for a variety of neurological genetic disorders. Some AAV therapies in development rely on the expression of proteins which are not endogenously produced by the patient, such as Cas9 nucleases used in gene editing. A drawback of such strategies is the risk of triggering an inflammatory immune response directed against the exogenous polypeptide, in this case a prokaryotic protein. AAV therapies for some neurodevelopmental disorders may require the treatment of newborns or infants who have immature immune systems; it is generally thought that they exhibit weaker immune responses compared to older children and adults. Inflammatory responses against foreign transgenes might therefore be mitigated by early postnatal vector administration. This study seeks to elucidate differences in the immune response to Cas9 expressed in the CNS between newborn and mature mice, with the goal of determining whether early postnatal expression of Cas9 results in lower inflammation and toxicity compared to adults. AAV-Cas9 was administered to the CNS of early postnatal mice via intracerebroventricular injection and to adult mice via intra-cortical injection; the degree of neurotoxicity and inflammation elicited in each cohort was quantified one-month post-treatment. Several key controls were included in our study. Analyses of neuroinflammation were also performed three months after neonatal treatment to assess whether any degree of immune tolerance to Cas9 observed at the 30-day post-injection time point is maintained after full maturation of the mouse brain and immune system. The results have implications for the use of non-self proteins in gene therapies for neurodevelopmental and other disorders. This research is supported by the Canadian Institutes of Health Research.

1792. Immunocompetent hiPSC-Based 3D Models to Study Innate Immune Response to Gene Therapy Vectors

Catarina Monteiro Gomes[1,2], Gabriela Silva[1], Stephan Holtkamp[3], Mark Trautwein[3], Daniel Simão[1], Paula Marques Alves[1], Catarina Brito[1,2]

[1]IBET, Oeiras, Portugal,[2]Instituto de Tecnologia Química e Biológica António Xavier, Oeiras, Portugal,[3]Bayer AG, Wuppertal, Germany

Background and novelty: Recombinant AAV (rAAVs)-based gene therapies for central nervous system (CNS) disorders face significant challenges due to host immune responses. Astrocytes and microglia initiate innate immune responses in the CNS, eliciting neuroinflammation. Nonetheless, a thorough understanding of the molecular mechanisms driving and sustaining glial cell activation remains elusive, particularly due to the scarcity of human cell models depicting the neuro-immune axis. Here, we present an innate immunocompetent 3D cell model that recapitulates neuroinflammatory hallmarks and propose it as a platform for the preclinical development of viral vector-based therapies. **Experimental approach:** hiPSC-derived neural progenitors were cultured as neurospheres in perfusion stirred-tank bioreactors (STB, 200 mL) and differentiated into neurospheroids (iNSpheroids) composed of neurons, astrocytes, and oligodendrocytes, as previously reported. hiPSC-derived microglia cells (iMGLs) were co-cultured with iNSpheroids, optimizing the medium composition and cell ratios. To assess rAAV immunogenicity and increase throughput, a miniaturized and parallelized STB system (15 mL, Ambr15) was used. iNSpheroids were challenged with inflammatory factors (e.g., TNF-α, LPS), and rAAV2 and rAAV9, candidates for gene therapy due to broad tropism and ability to cross the blood-brain barrier, respectively. **Results and discussion:** iMGL in iNSpheroids displayed morphofunctional plasticity (ameboid to ramified) and expression of microglia proteins (e.g., TMEM119 and P2RY12). Detection of phagolysosome-like structures containing MAP2-positive neurite fragments suggested physiological synaptic pruning. Upon exposure to proinflammatory stimuli, TIC (TNF-α, IL-1α, and C1q) or LPS plus IFNγ, iNSpheroids upregulated neuroinflammatory genes (e.g., IL-6 and CXCL8) and secreted inflammatory cytokines/ chemokines (e.g., CXCL8, and CCL2), all hallmarks of neuroinflammation. iNSpheroids exposed to rAAV2- and -9 had 20-40 % eGFP-positive cells, with negligible contribution from microglia and differences in neuron/ astrocyte tropism. Neuroinflammatory responses to rAAV9 were milder than to prototypical stimuli. iNSpheroids upregulated IL-6, CXCL8, and TNF. Notably, iMGL-iNSpheroids displayed downregulation of these inflammatory mediators, suggesting a protective effect of iMGL. Altogether, we report the human iNSpheroids model as a useful preclinical model to dissect CNS-specific neuroinflammatory mechanisms and viral vector immunogenicity, paving the way to accelerate the development of gene therapies.

1793. A Half-Life Extended IgG Protease with Reduced Immunogenicity to Enable Efficient *In Vivo* Gene Transfer and Vector Readministration

Maximilian M. Sauer, Benjamin Dutzar, Emily Frazier, Kui K. Chan, Daniel Farrell, Gavin Robertson, Andrew Jerome, Yifan Song, Eric Tarcha, Erik Procko

Cyrus Biotechnology, Seattle, WA

Adeno-associated virus (AAV) neutralizing antibodies (nAbs) are prevalent in humans and block AAV vector-mediated *in vivo* gene transfer and vector re-administration. Hence, AAV nAbs remain a major challenge for AAV-mediated gene therapy. Strategies to overcome this challenge often include immunosuppressives or plasmapheresis and are not effective for efficient nAb removal. The immunoglobulin G (IgG) degrading enzyme IdeS from Streptococcus pyogenes is clinically approved for transplantation patients and can cleave AAV nAbs. However, the immunogenicity of this bacterial enzyme and its short *in vivo* half-life limit its efficacy. Here, we employed computational protein design to engineer IdeS variants with reduced immunogenicity and extended *in vivo* half-life. First, in a cell culture assay, IdeS was processed by antigen-presenting cells and IdeS peptides displayed on HLA class II (HLA-II) were isolated and identified by mass spectrometry. Using machine learning algorithms trained on large data sets of HLA-II-bound peptides, mutations predicted to decrease HLA-II affinity were then introduced into the major HLA-II epitopes that we had identified. The mutations were validated biochemically to reduce peptide affinity for HLA-II and thus reduce T cell immunogenicity. Second, we introduced N-glycosylation sites into the IdeS sequence to shield B cell surface epitopes, creating hyperglycosylated drug candidate CYR241. In addition to reducing reactivity against anti-IdeS antibodies in serum from donors with recent strep infections, IdeS glycosylation also resulted in an extended *in vivo* half-life, which we further improved by generating a human serum albumin (HSA) fusion variant (drug candidate CYR212). CYR241 and CYR212 demonstrate similar endopeptidase activities and specificities as wild-type IdeS. Pharmacokinetic-pharmacodynamic studies in rabbits reveal that CYR241 and CYR212 deplete IgG for more than 5 and 12 days respectively, in contrast to short-lived, wild-type IdeS (2 days), resulting in a significantly improved therapeutic window in which antigen-binding IgG fragments have been cleared but full-length IgG has yet to rebound. In ongoing experiments, CYR241 or CYR212 administration in mice passively immunized with human intravenous Ig (IVIg), which inhibits gene therapy due to anti-AAV nAbs, enables efficient liver gene transfer by AAV vectors. In conclusion, our results provide a framework to overcome the challenge of pre-existing nAbs to AAV gene therapy allowing repetitive gene transfers with high efficiency.

1794. A Simple, Rapid and Robust Bioluminescent Assay for Detecting Anti-AAV Neutralizing Antibodies in Serum Samples

Brock F. Binkowski[1], Morten Seirup[1], Trish Hoang[2], Marjeta Urh[1]

[1]Promega Corporation, Fitchburg, WI,[2]Promega, Fitchburg, WI

Adeno-associated viruses (AAVs) are widely used vectors to deliver transgenes for gene therapy. Individuals with pre-existing immunity to AAVs are less likely to benefit from gene therapy owing to the presence of neutralizing antibodies (NAbs) that reduce cellular uptake. Widespread, pre-existing immunity in human and animal subjects increases the need for sensitive assays to detect NAb activity in serum samples, allowing drug sponsors to identify candidates for enrollment in clinical trials or patient eligibility. Here we describe a cell-based transduction inhibition (TI) assay utilizing NanoLuc® luciferase, an enzyme engineered to be extremely bright and structurally stable. The superior brightness of NanoLuc® (~150-fold brighter than firefly luciferase) enables the sensitive detection of NAb activity using low MOI values (100 - 1,000) and short incubation times (≤24 hours). The assay is tolerant to high levels of human serum, allowing dilutions as low as 1:3, and luminescence is measured following addition of an add-mix-read (homogeneous) detection reagent (Bio-Glo-AAV). We screened 1:3, 1:10 and 1:20 dilutions of human serum samples using low MOI values to demonstrate the influence of sample dilution on hit rate. We also compared head-to-head with the analogous approach using firefly luciferase as the reporter, and we validated use of thaw-and-use HEK293 cells. Taken together, this rapid, highly sensitive and reliable assay enabled by NanoLuc® AAV reporter technology precisely measures NAbs against AAVs in both human and animal serum.

Friday Posters: Immune Targeting and Approaches with Genetically-Modified Cells and Cell Therapies

1795. Dual Targeting of Drug-Resistant Liver Cancer: Integrating HSP90 Inhibition with Multikinase Inhibitor Chemotherapy and GRP78-CAR-NK Immunotherapy

Youssef Sabha, Sajjan Rajpoot, Chih-Hsiung Chen, Xuening Wang, Dongfang Liu

Pathology and Laboratory Medicine, Rutgers University-New Jersey Medical School, Newark, NJ

Drug resistance represents a major obstacle for cancer therapy, which makes hepatocellular carcinoma (HCC) difficult to treat. Drug resistance emerges when tumors have genetic changes leading to tumor evolution. The mutations in the genome cause drug-resistant cancers to have a growing number of misfolded proteins that make the proteome unstable. Tumors utilize heat shock proteins such as Heat Shock Protein 90 (HSP90) or Glucose Regulated Protein 78(GRP78), to stabilize misfolded proteins allowing cells to survive and evolve in drug-resistant cancers. By inhibiting HSP90, we make the tumor cells susceptible to drug therapies (i.e., multikinase inhibitors). Strikingly, when HSP90 is inhibited, surface expression of GRP78 increase on tumor cells allowing for precise targeting as a tumor antigen. Futhermore, HSP90 inhibition has strong effects on both the intracellular proteome through regulation of VEGFR2 signaling and surface proteome by regulation of the Heat Shock Response. Immunotherapies are growing in popularity because of harnessing the power of immunity systems instead of intracellular pathways that are targeted using chemotherapies, radiotherapy, and surgery. Natural Killer (NK) cells, are soldiers that survey the body,

killing tumor cells, dysfunctional cells, aged cells, or virally infected cells. However, tumor cells can thwart NK action through immune evasion. Our lab has recently developed Chimeric Antigen Receptor-Natural Killer (CAR-NK) therapies to target liver cancer by precise tumor detection and killing. While CAR-NK therapies have shown success in blood cancers, challenges persist in treating solid tumors such as HCC and pancreatic cancers, resulting in suboptimal outcomes. This study proposes a unique approach to enhance specific CAR-NK immunotherapy with a combination of HSP90 inhibitor chemotherapy to target the drug-resistant HCC. We used a novel "kick and kill" model whereby we "kick" the tumor cells to be sensitive to immune cells and then "kill" the tumor using CAR-NK cell therapy with enhanced cancer detection and killing. We hypothesize that inhibition of HSP90 function will improve precise GRP78-CAR-NK targeting and killing of drug-resistant HCC. To achieve this, we used high-throughput assays to evaluate the "kick and kill" model on cells derived from tumors, followed by testing efficacy of the combination therapy in various mouse models. We found combination chemotherapy and GRP78 targeting CAR-NK suppressed HCC growth in vivo and in vitro. Ultimately, this study uncovers a novel role for HSP90 in NK cell killing of tumors and how that enhances CAR-NK therapy treatment of solid tumors. This study also pushes the boundaries of traditional clinical targeting of HSP90 to synergize with novel CAR-NK immunotherapies.

1796. Unlocking CAR T Cell Activity Against Metastatic Osteosarcoma Using RNA-Based Nanoparticle Vaccination

Paul Castillo[1], Ruixuan Liu[1], Elizabeth Ogando-Rivas[1], Arnav Barpujari[1], Dingpeng Zhang[1], Hector Mendez-Gomez[1], Xiaojie Ma[1], John Ligon[1], Duane Mitchell[1], Jianping Huang[2], Elias Sayour[2]

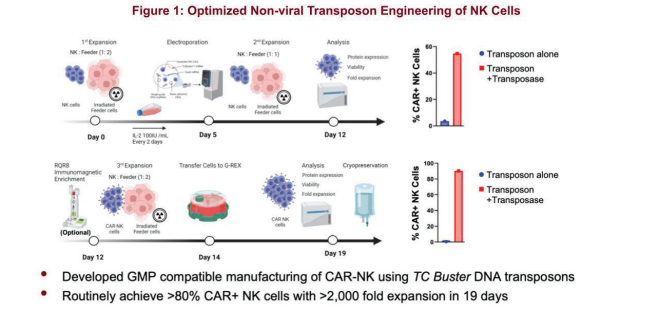
[1]Pediatrics, University of Florida, Gainesville, FL,[2]University of Florida, Gainesville, FL

Background: Metastatic osteosarcoma (OSA) has a dismal prognosis despite novel targeted therapies, including CAR T cells. Unleashing CAR T cell therapy against poorly immunogenic cancers requires new technologies that activate the tumor microenvironment (TME), while inducing CAR T cell migration, proliferation, and persistence into tumor to sustain tumor-specific immunity. We have developed tumor RNA-loaded nanoparticle (CD70-encoding RNA-NP) vaccines to overcome CD70-specific CAR T cell limitations in OSA. **Methods:** Using two murine solid tumor models (K7M2 osteosarcoma and B16F0 melanoma, in Balb/c and C57Bl/6 background) highly metastatic to lungs, we implant K7M2 and B16F0 intravenously (i.v.). We subsequently generated NPs complexed with RNA encoding for CD70 antigen and control vaccine (GFP RNA). RNA-NPs are administered intravenously beginning on day 5 post-tumor implantation and day 7, 14 & 21. Mouse CD70-specific CAR T cells are manufactured after activation of T cells with CD3 and CD28 antibodies for 2 days. CAR T cells are ready for use in downstream experiments 2 days after pMSGV8-mCAR transduction and cells were injected (i.v.) on day 6. **Results:** In preliminary data, we show that intravenous administration of CD70-encoding RNA-NPs rapidly recruit CD70-directed CAR T cells into tumor stroma unlocking their activity in two immunocompetent aggressive lung metastatic tumor models. Interestingly, regression of CD70-expressing tumors associates with CAR T cell mobilization out of peripheral blood and into reticuloendothelial (RES) tissues (i.e., lung, and spleen), a phenomenon that correlates with upregulation of vaccine-induced type I interferon (IFN) and activation of CCR2 pathway. In addition to the CAR T-mediated antitumor killing, an antigen spreading phenomenon was observed. The long-term survival benefit (150 days) provided by this approach reached 70-80% in both models compared with 0-10% of control groups. **Conclusions:** Based on these findings, we hypothesize that tumor trafficking and persistence of CD70 CAR T cells depend on coordinated cytokine/chemokine signaling that can be ignited through intravenous RNA-NP vaccination. RNA-NPs in combination with CAR T cells prolong long-term survival of mice bearing these aggressive tumor models which was not only mediated by CAR T cells but also by activation of endogenous adaptive immunity. Future studies include the evaluation of this approach in large animal models prior to translation into first-in-human clinical trials.

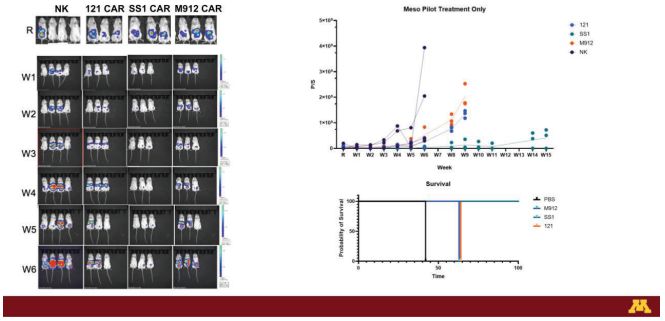
1797. Generation of Monocytes and Macrophages from CD34+ Cord Blood Cells for Cell Therapy

Katherine Brempelis, Jared Pudiwitr, Carrie Stoltzman, Erika von Euw, Colleen Delaney

Deverra Therapeutics, Seattle, WA



Introduction: Solid tumors are challenging targets for existing cell therapies due to poor infiltration of the tumor mass by immune cells and immunosuppression in the tumor microenvironment (TME). Current approaches to overcome these challenges have had limited success and there are still no FDA-approved cell therapies for solid tumors. In addition, autologous cell therapies are expensive, patient-dependent, and can require weeks to produce limited cell numbers. To address these issues, we developed an *ex vivo* process to expand and differentiate CD34+ cells into monocytes and macrophages, cell types that traffic to and persist in solid tumors. Furthermore, these cells can be engineered to resist immunosuppression in the TME and to recruit immune effector cells, providing an off-the-shelf cell therapy option with the potential to revolutionize the treatment of solid tumors. **Methods & Results:** We optimized three consecutive phases of *ex vivo* culture conditions to generate macrophages from pooled cord blood-derived CD34+ hematopoietic stem and progenitor cells (HSPCs): 1) expansion of CD34+ HPSCs using a proprietary culture process, 2) continued expansion and differentiation of cells into monocytes, and 3) terminal differentiation of cells into macrophages. Monocytes and macrophages were phenotypically characterized using flow cytometry and functional *in vitro* assays, including cytokine release and phagocytosis assays. From each starting CD34+ HSPC, we generate up to 400,000 differentiated progeny cells which are ≥80% CD14+CD11b+ monocytes (at the end of Phase 2) or macrophages (at the end of Phase 3). These myeloid cells phagocytose *Staphylococcus aureus* bioparticles and release cytokines in response to LPS stimulation, and our macrophages express canonical markers including CD40, CD86, HLA-DR, and CD206. **Conclusions:** Our proprietary *ex vivo* culture platform produces therapeutically relevant numbers of functional monocytes and macrophages for use as allogeneic off-the-shelf cell therapies. We are currently assessing the effects of cryopreservation as well as targets and strategies to genetically engineer these cells to drive anti-tumor immune responses while resisting the immunosuppressive TME.



1798. Armored CAR-NK Cell Therapy for Ovarian Cancer

Joshua B. Krueger, Jae Woong Chang, Young Vue, Alexandria Gilkey, Timothy Folsom, Ethan Niemeyer, Joseph Skeate, Beau Webber, Branden S. Moriarity

University of Minnesota, Minneapolis, MN

Immunotherapy with chimeric antigen receptor (CAR) expressing NK cells engineered via viral vectors has shown exceptional efficacy against hematologic cancers in clinical trials. This method, however, is limited in cargo capacity and large-scale manufacturing for clinical use is cost-prohibitive. We have addressed these shortcomings by engineering CAR-NK cells using non-viral transposon engineering that can be paired with CRISPR/Cas9 editing simultaneously. We believe that this approach avails opportunities that will allow researchers to address some of the more difficult solid tumor cancer types. Here, we developed a CAR-NK therapy with specific advantages to killing mesothelin positive ovarian cancers which tend to form solid tumors, a new area for CAR NK cells. We started by testing 3 different mesothelin binders named SS1, 121, and M912. Our transposon vector also encodes for secretion of the cytokine IL15 for increased persistence of the CAR NK cells. The SS1, 121, and M912 CAR NK cells with soluble IL15 (Armored-NK) were tested in vitro and in vivo. No CAR variant stood out as a clear winner during the in vitro testing so all three proceeded into a pilot in vivo study. In this experiment, NSG mice were engrafted with a mesothelin high tumor cell line, A1847, engineered to expressLuciferase. A1847 cells were injected 14 days prior to the Armored CAR NK injection. Both tumor cells and Armored CAR NK cells were delivered via intraperitoneal (IP) injection.At week 6, control mice, 121 treated, and m912 treated mice had tumors beginning to grow exponentially. The SS1 CAR seemed to be controlling tumor growth. This trend continued for 3 more weeks as the SS1 treated mice did not see significant tumor growth while all other mice in the study had to be euthanized due to tumor burden. SS1 mice survived long term with the only detectable tumor being a mass that grew at the injection site, outside of the IP space. With these results we have decided to continue with the SS1 CAR and plan to test additional edits to these cells before attempting a phase 1 clinical trial. The two other modifications that were described in our pre-IND filing is a knockdown or knockout of the CISH gene, an immune checkpoint inhibitor as well as expression of a TGFb dominant negative (DN) receptor. The TGFbDN receptor is able to sequester TGFb, a cytokine often in the tumor microenvironment, which normally suppresses immune function. The binding of this cytokine to a dominant negative receptor will prevent its normal activation on NK cells. We believe these edits will push NK cells into being a viable treatment for solid tumors.

1799. Iterative Engineering of Polarization-State Responsive Synthetic Promoters for Autonomous Control of Macrophage Polarization Logic

Frances Liu[1], Michelle Hung[1], Assen Roguev[1], Magdalena Cichewicz[1], Yin Yin Chong[1], Cesar Juarez[1], William Hendriks[2], Jessica Haverkamp[2], Mark Tomishima[3], Timothy K. Lu[4], Russell Gordley[1], Philip Lee[5]

[1]GeneFab, LLC, South San Francisco, CA,[2]Blue Rock Therapeutics LP, Cambridge, MA,[3]BlueRock Therapeutics LP, New York, NY,[4]Senti Biosciences, Inc, South San Francisco, CA,[5]GeneFab, LLC, Alameda, CA

Introduction Macrophages are plastic cells capable of sensing microenvironmental cues and are generally polarized to either a pro-inflammatory (M1-like) or anti-inflammatory (M2-like) state. Macrophages can contribute to disease progression in both autoimmune disorders and cancer when polarized to a pathological state (M1 or M2, respectively). Here, we leveraged macrophages' innate ability to sense extracellular anti-inflammatory signals to design and build highly discriminatory M2 polarization-state specific promoters. We then paired these promoters with candidate polarization state master regulators for autonomous control of macrophage polarization logic. **Methods** Five rounds of promoter engineering were performed to optimize for the best M2-polarization state-specific promoters. This included 1) bioinformatic mining of native enhancer sequences from ATAC-Seq data, 2) minimal promoter engineering, 3) functional mapping of regulatory regions with mutational variants, 4) rational redesign of native enhancer elements, and 5) combinatorial rearrangement of elements from multiple enhancer families. Synthetic

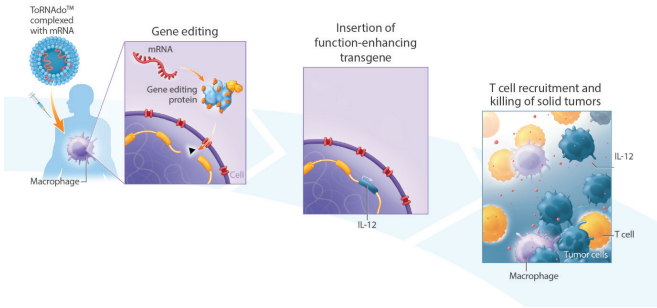
promoters were paired with fluorescent reporters in lentiviral vectors and individually transduced into primary human derived macrophages and then polarized. State-specific promoter activity was assessed by fluorescent activity compared to the elongation factor 1 alpha short promoter (EFS) as a constitutive control promoter. Top M2 state-specific promoter candidates were then paired with candidate master regulators to create synthetic gene circuits to "sense" polarization state and "respond" by driving macrophage phenotype. Macrophage polarization phenotype was assessed using multi-color flow cytometry and cytokine expression. **Results** We designed synthetic enhancer-based promoters with >10-fold M2-specificity over the M1 state and >100-fold specificity over the M0 state, but they were <15% of the strength of EFS. To increase promoter strength, we reengineered the core promoter which increased promoter strength by >10-fold while maintaining high levels of M2-state specificity. From functional mapping of regulatory regions, we redesigned the synthetic promoters to achieve >800% of the strength of EFS with >150-fold M2 specificity over the M1 state and >40-fold specificity over the M0 state. By combining regulatory elements from multiple enhancer sequences, we achieved >100-fold M2 specificity over both M0 and M1 states with promoter strength ranging from >200-400% of EFS. When pairing an M2-state specific promoter with a cytokine-based M2 master regulator, we engineered an autocrine positive feedback loop thereby locking the cells into an M2-like state. We alternatively used these same M2 state-specific promoters to drive M1-associated transcription-factor based master regulators. In this case, the cells switched towards a pro-inflammatory phenotype in the presence of immunosuppressive cues. **Conclusions** We have built an iterative promoter discovery platform capable of being applied to the discovery of novel extracellular cue-responsive promoters in many cell types. We used this platform to discover promoters specific to the M2 polarization state in macrophages. We also demonstrated modularity of these state-specific promoters with multiple payload types (e.g., cytokines and transcription factors) which enabled us to build gene circuits that control macrophage polarization phenotype to either "lock" the cells in a pre-determined state or "switch" it from one polarization state to another.

1800. PSMA/NKG2DL Tandem CAR T-Cells to Overcome Antigen Heterogeneity and Improve Anti-Tumor Efficacy Against Prostate Cancer

Jennifer Bolsée, Benjamin Violle, Thuy Nguyen, Céline Jacques-Hespel, Eytan Breman

R&D, Celyad Oncology, Mont-Saint-Guibert, Belgium

Background: Chimeric antigen receptor (CAR) T-cell therapies have shown remarkable success in treating hematological malignancies. However, demonstrations of efficacy in solid cancer indications have been limited so far, largely due to antigen heterogeneity, antigen loss or modulation, and inadequate T-cell function. Hence, design of multispecific CAR T-cells, targeting several cancer antigens simultaneously, might be envisaged as one of the best options to overcome antigen heterogeneity in solid cancers. NKG2D ligands (NKG2DL), are a group of 8 stress-induced ligands expressed by virtually all cancer types and absent from normal healthy cells. These therefore represent an attractive approach for multispecific CAR T-cells in large panel of cancer indications, including prostate cancer. Methods: To improve CAR T-cell efficacy against prostate cancer, we designed a prostate specific membrane antigen (PSMA)/NKG2DL tandem CAR T-cell candidate that encompasses the extracellular domain of the natural NKG2D receptor fused to an anti-PSMA scFv. Functionality of the PSMA/NKG2DL tandem CAR T-cells was evaluated in cocultures with cells expressing the main antigen (i.e. PSMA and NKG2DL) or not (only NKG2DL) and was compared to the functionality of single-targeting CAR T-cells. Results: We show here that PSMA/NKG2DL tandem receptor was highly expressed and that T-cells expressing this tandem were able to secrete IFN-γ against prostate cancer cell lines expressing, (LNCAP cells and PC-3 PSMA, PSMA+) or not (PC-3 WT cells, PSMA-) the principal target antigen. In addition, our results demonstrate that PSMA/NKG2DL tandem CAR-T cells proliferated and eliminated PSMA+ and PSMA- prostate cancer cells *in vitro*. Finally, upon chronic antigen stimulation with HeLa cells overexpressing PSMA, PSMA/NKG2DL tandem CAR T-cells were able to control tumor cell growth and proliferate as efficiently as PSMA single-targeting CAR T-cells. Conclusions: Our *in vitro* data indicate that PSMA/NKG2DL tandem CAR T-cells are an attractive approach to overcome antigen heterogeneity and improve anti-tumor efficacy in prostate cancer. In addition, by targeting stress-induced targets rather than lineage specific targets, the issues with antigenic heterogeneity/modulation may be avoided. Additional *in vivo* studies will be performed to validate *in vitro* results obtained so far.



1801. iPSC-Derived Macrophages Engineered to Express IL-12 Enhance Cancer Cell Killing of a Multi-Cell Type Therapeutic Platform

Ian Hay, Abigail Blatchford, Claire Aibel, Christopher B. Rohde, Matthew Angel

Factor Bioscience Inc., Cambridge, MA

The immunologically cold microenvironment of solid tumors limits the ability of immune cells to infiltrate and attack cancer cells. The systemic injection of potent cytokines such as interferon gamma (IFNγ) and interleukin 12 (IL-12) have shown tumor shrinkage in mouse models, but have faced challenges in human clinical trials due to dose-limiting toxicities. Myeloid cells, including macrophages, can deliver cargo to the solid tumor microenvironment. However, autologous macrophages are limited by their resistance to genetic engineering, limited expansion potential, cost of characterization and the limited quantity of cells attainable via leukapheresis. Bioreactor-based differentiation of induced pluripotent stem cells (iPSCs) into macrophages can overcome the limitations of autologous macrophages, enabling the generation of large numbers of well characterized, genetically identical, engineered macrophages. Here, we present iPSC-derived macrophages engineered to overexpress IL-12 for delivery to the tumor microenvironment. Bi-allelic knockout of the beta-2-microglobulin gene ($B2M^{-/-}$) is designed to reduce alloreactivity of transplanted iPSC-derived macrophages. $B2M^{-/-}$ iPSC-macrophages transfected with mRNA encoding both IL-12 subunits joined by a self-cleaving peptide (IL-12 P2A) or a flexible linker (IL-12 fusion) resulted in the production of 20 and 40 ng/mL of the IL-12 p70 heterodimer, respectively, as assessed via ELISA 24 hours after transfection. Both IL-12 mRNA constructs resulted in similar levels of IFNγ production when co-cultured with PBMC-derived T cells (17 ng/mL for IL-12 fusion and 15 ng/mL for IL-12 P2A) with no detectable IFNγ in the absence of IL-12 mRNA or T cell co-culture, indicating functional bioactivity. The co-culture

of B2M$^{-/-}$ iPSC-derived macrophages with allogeneic PBMC-derived T cells did not upregulate T-cell activation markers CD25 or CD69, as assessed via flow cytometry, suggesting a lack of host-vs-graft-type immunoreactivity of the B2M$^{-/-}$ iPSC-derived macrophages, a feature of importance for durable adoptive cell therapies. When IL-12-mRNA transfected iPSC-derived macrophages were co-cultured with PBMC-derived T-cells and a GFP-expressing ovarian adenocarcinoma cell line SK-OV-3 at a 10:1 effector to target ratio for 72 hours, cancer cell killing was significantly greater when compared to non-transfected iPSC-derived macrophages, as assessed by real-time fluorescence imaging (p=0.03). Engineered iPSC-derived macrophages offer a path to repolarize the tumor microenvironment and translate the clinical success of T cell immunotherapies targeting hematologic cancers to solid tumors, which comprise 90% of cancer cases. Here we show a scalable platform for producing iPSC-derived macrophages engineered to express the potent immunostimulatory protein IL-12. Engineered iPSC-derived macrophages may thus prove useful for the development of therapies designed to deliver biologics previously limited by toxicity or bioavailability directly to the tumor microenvironment.

1802. A Dermal Fibroblast Derived Human Induced Pluripotent Stem Cell (hiPSC) Line That Efficiently Differentiates into NK Cells

Vivek Chandra, Lindsay Bailey Steinitz, James Pierpoint, Jenny Yang, Garrett Wong, Erik Willems

Thermo Fisher Scientific, Carlsbad, CA

Natural killer (NK) cells are specialized cells of the immune system that play critical roles in innate and adaptive immunity. Their ability to target and kill tumor cells have made them a promising candidate for the next generation of cell-based immunotherapies. NK cells, like T cells, can be engineered to express chimeric antigen receptors (CARs) to improve targeting the cancer cell of interest. NK cell therapies have the potential to use as an allogenic therapeutic with main advantages being reduced cost and greater accessibility to patients. The use of primary NK cells to reach expansion requirements for manufacturing has proved difficult, and their genetic engineering is more challenging compared to other immune cell types. However, human induced pluripotent stem cells can be utilized to generate a nearly endless supply of NK cells and their genomes can be engineered easily. Here, we report the generation of a human induced pluripotent stem cell (hiPSC) lines with the intent to identify iPSC lines that are amenable to NK differentiation. We identified that one of the hiPSC lines derived from human dermal fibroblasts, which was normal in a variety of pluripotency and genomic stability assays, efficiently differentiates into NK cells. These NK cells express functional NK cell markers, and we also demonstrate that these hiPSC differentiated NK cells are functional by different cell-based assays like target cell killing and cytokine release assays. In summary, we have identified iPSC lines and a differentiation workflow that enable efficient generation of functional iPSC-derived NK cells.

1803. Nanobody-Based CAR Targeting of an Endogenous Retroviral Envelope for the Treatment of Glioblastoma

Saliha Majdoul[1], Wenxue Li[2], Kevon Sampson[2], Kari Wilson[1], Deepa Seetharam[3], Anandani Nellan[1], Ashish H. Shah[3], Avindra Nath[2], Naomi Taylor[1]

[1]National Cancer Institute, Center for Cancer Research, Pediatric Oncology Branch, National Institutes of Health, Bethesda, MD,[2]National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD,[3]Department of Neurosurgery, University of Miami School of Medicine, Miami, FL

Glioblastoma multiforme (GBM), identified as grade IV astrocytoma, is the most common malignant brain tumor and is highly aggressive. Despite surgical resection, radiotherapy, and chemotherapy it has a poor prognosis with a median survival time of 14-16 months. Thus, it is critical to develop new therapeutic strategies for these patients. We recently showed that the human endogenous retrovirus HERV-K (subtype HML-2), normally silenced in non-malignant cells, is reactivated in GBM and contributes to the maintenance of glioblastoma stem cells, enabling tumor regrowth. Furthermore, the HML-2- envelope (Env) is expressed at high levels at the surface of GBM tumors compared to healthy brain tissue, making it an attractive target for the development of a chimeric antigen receptor (CAR)-based immunotherapy strategy. We first developed an HML-2 Env-specific nanobody through the screening of a synthetic humanized VHH phage display library and used epitope fingerprinting to map binding to a non-linear epitope in the Env surface unit domain. This nanobody was then incorporated into CAR constructs harboring either 4-1BB or CD28 costimulatory domains. Notably, HML-2 Env-targeting CARs were efficiently expressed at the surface of transduced primary T cells and exhibited high induction of both IFN-γ and IL-2 cytokines in response to HML-2 Env+ GBM at multiple effector:target ratios. Moreover, HML-2 Env CAR-T demonstrated high *in vitro* cytotoxicity, as assessed by cellular impedance assays. These promising results highlight the strong potential for a HML-2 Env-targeting CAR T-cell therapeutic approach for the treatment of GBM. S.M. and W.L. are co-first authors. A.H.S., A.N. and N.T. are co-senior authors.

1804. Repeated Antigen Stimulation Mediated Exhaustion, Not Fratricide, Drives B7H3 CAR-NK Cell Dysfunction in Glioblastoma Multiforme

Kajal Chaudhry[1], Nethaji Muniraj[1], Joshua L. Terao[2], Ashley Geiger[1], Ehsan Dowlati[3], Haili Lang[1], Eric S. Yvon[2], Matthias Holdhoff[4], Rick Jones[4], Barbara Savoldo[5], Michael D. Keller[1], Conrad Russell Y. Cruz[1], Catherine M. Bollard[6]

[1]Children's National Hospital, Washington, DC,[2]The George Washington University, Washington, DC,[3]Department of Neurosurgery, Georgetown University Medical Center, Washington, DC,[4]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD,[5]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[6]The George Washington University, Bethesda, MD

Glioblastoma multiforme (GBM) is a devastating brain cancer with a uniform poor prognosis for patients with relapsed/refractory disease. We have evaluated allogeneic "off the shelf" NK-cell-based immunotherapies against GBM in pre-clinical models. We hypothesized that redirecting NK-cell specificity to the tumor-associated antigen B7H3 using a chimeric antigen receptor (CAR) would enhance the potency of NK-cell products against GBM. We showed that B7H3-CAR-NK products elicited robust killing against GBM cells (89.73±2.44 % @20:1 E:T ratio) in vitro. However, CAR-NK products failed to show a significant effect on the survival in the U87 MG *in vivo* model compared to untransduced NK cells (P>0.05). Hence, we interrogated multiple mechanisms, including B7H3 antigen upregulation/trogocytosis, TGF-β mediated suppression, and NK cell exhaustion. First, we observed that CAR-NK and untransduced NK cells (Un-NK) cells upregulated B7H3 antigen on activation. We knocked out (KO) the B7H3 antigen on NK cells to avoid B7H3 antigen upregulation and associated fratricide, however, we failed to see any significant fratricide in KO-CAR-NK cells compared to control CAR-NK products. Second, we confirmed that trogocytosis-mediated transfer of B7H3 antigen to CAR-NK also did not mediate significant fratricide in Trog+ve CAR-NK compared to Trog -ve CAR-NK cells. Third, we identified that TGF-β secreted by GBM rendered CAR-NK cells dysfunctional with significant downregulation of activation receptors, including NKG2D (68.14%±6.92% downregulation; p<0.05), which markedly reduced NK cell cytolytic ability. To overcome TGF-β immune suppression, we co-transduced NK-cells to express the B7H3-CAR and the TGF-β-DNR (72.21% ± 23.05%). Co-expression of TGF-β-DNR and B7H3-CAR on NK cells preserved their cytolytic function and activating receptor expression in the presence of TGF-β in vitro. Co-transduced DNR.B7H3-CAR-NK-cells lysed 85.45 %±3.05% of U87-MG cells in the presence of TGF-β in comparison to 80.89% ±14.84% in its absence (E:T ratio 20:1; p>0.05). However, DNR.B7H3-CAR-NK cells failed to enhance murine survival in the U87 MG *in vivo* model. To understand the CAR-NK product failure we used a repetitive tumor stimulation method, which recapitulates the in vivo model better. Using this model, we confirmed that Un-NK and B7H3 CAR-NK cells have limited serial killing ability compared to B7H3 CAR-T cells. NK cells showed functional exhaustion post stim 2 with significantly decreased proliferation, reduced IFN-γ and TNF-α secretion, and diminished cytolytic activity (p<0.05) compared to B7H3 CAR-T cells. Therefore, we next evaluated whether supplementing with IL-15 could rescue CAR-NK cells from exhaustion. We observed that by adding IL-15, CAR-NK and Un-NK serial killing were comparable to B7H3 CAR-T cells. In sum, we conclude that B7H3 CAR-NK cell dysfunction is related to NK cell exhaustion in response to repetitive antigen stimulation, which can be overcome with local IL-15 delivery. Our next step is to validate this approach in vivo, If successful, we will evaluate CAR-NK products engineered to resist TGF-β and secrete IL-15 in the clinical setting for patients with relapsed/refractory GBM.

1805. Novel Costimulatory Domain Improves CAR-M Activity Against Tumors

Sumiti Jain, Kevin Carbajal, Kilsoo Jeon, Anastasya Birger, Grace Reynolds, Prasanna Ekambaram, Beatrice Breckheimer, Jessica Gorczynski, Warren Anderson, Adam Pecoraro, Matthew Esquivel, Max Richter, Matthias Schroff

Inceptor Bio, Raleigh, NC

Myeloid cells, unlike other immune cells such as T cells or NK cells, are known residents in the solid tumor microenvironment (TME). In the absence of checkpoints and in proinflammatory conditions, myeloid cells (particularly M1 macrophages) are known to be capable of direct phagocytosis of tumor cells and can present tumor-associated antigens to the host immune system. However, the immunosuppressive conditions within the TME restrict and limit the anti-tumor response of tumor associated macrophages (TAMs), including their ability to recruit and activate other immune cells against the tumor. Engineered CAR-Monocytes can serve a unique function in cell therapy by bridging a key gap in the treatment of solid tumors. We are developing an autologous engineered CAR-M cell therapy product targeting Glypican-3 (GPC3) to treat hepatocellular carcinoma (HCC). The CAR serves a dual purpose as a homing 'GPS' signal for trafficking directly to the tumor site, and for directing phagocytosis specifically at targeted tumor cells. We have designed a proprietary CAR molecule (M83 CAR) which contains a macrophage-specific costimulatory domain that significantly increases the phagocytosis function of the CAR-M cells. Furthermore, we have demonstrated that the M83 CAR-M cells are not inhibited by the prevalent CD47 checkpoint ('do not eat me' signal expressed on tumor cells), which is known to restrict myeloid function in the TME. Effective phagocytosis of engineered CAR-M cells is central to subsequent mechanisms of actions that can elicit robust anti-tumor immunity against patient-specific neoantigens. However, the first barrier to overcome is effective infiltration of engineered CAR-M into the tumor from the periphery. We have demonstrated that our engineered CAR-Monocyte drug product can successfully home to the targeted tumor specifically, from the periphery. Subsequent *in situ* differentiation of CAR-monocytes into CAR-macrophages (M1) enables robust tumor cell phagocytosis, the central mechanism that can result in the following series of events: 1) proinflammatory shift in the TME milieu, 2) recruitment of innate and adaptive immune cells, 3) activation of T-cells against tumor neo-antigens. This is a unique outcome of the CAR-M mechanism of action that is not capitulated by CAR-T or CAR-NK cells. Leveraging and further enhancing CAR-M function could lead to the rejection of the tumor and its metastases, particularly in combination with other immune-modulating therapies.

1806. Evaluating mRNA-Based Multi-Antigen Targeting CAR T Cell Therapy Against Glioblastoma

Oula Dagher[1], Avery D. Posey[1,2]

[1]Systems Pharmacology and Translational Therapeutics, University of Pennsylvania, Philadelphia, PA,[2]Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA

Glioblastoma multiforme (GBM) is the most common and aggressive primary brain malignancy, characterized by heterogenous antigen expression and very low survival rates post standard therapy. Chimeric antigen receptor (CAR) T cell therapies are immune cells engineered *ex-vivo* via viral transduction, gene-editing and integration, transposition, or mRNA incorporation and exert potent target-specific anti-tumor cytotoxicity. Due to the complex tumor heterogeneity and self-renewal capacity of glioma stem cells, localized intracranial delivery of CAR T cells engineered to target multiple GBM associated antigens have been investigated both preclinically and clinically and have demonstrated better remission profiles as compared to single antigen targeting CAR T cells. However, most anti-glioma CAR T cells investigated have been engineered via viral transduction for constitutive expression of CAR molecules, which introduces risks of off-tumor toxicities and the perpetuation of neurotoxicity in GBM patients. Here, we hypothesize that the combination of surgical resection with multivariant targeting of glioma antigens via mRNA-based CAR T cells would provide a safe and efficacious translational platform for treating GBM patients. Using two separate mRNA incorporation strategies, we have utilized a "one-day" CAR T cells production protocol and evaluated whether treatment of tumors derived from U87-GM cells with pooled mRNA-based CAR T cells (CARPool) or mRNA-based CAR T cells expressing multiple CARs (MVCAR) targeting IL13Rα2, HER2, and/or EphA2 would elicit effective anti-tumor efficacy. We utilized real-time eSight imaging and impedance analysis, flow-cytometry based analysis, and ELISA to compare best-in-class combination of multi-antigen targeting CAR T cells against a heterogenous pool of single-antigen null U87 glioma cells (U87KO-pool) *in vitro*. The efficiency of our single-scFv mRNA-based CAR T cells was initially validated by the target-specific cytotoxicity of U87 cells that express the target glioma antigen as well as increased CAR T cell proliferation and IFNγ secretion, and lack of cytotoxicity of target-null U87 cells. Notably, triple-targeting CARPool or MVCAR T cells elicited superior efficacy against U87KO-pool as compared to single- or dual-targeting CAR T cells, at low E:T ratios *in vitro*. We utilized glioma xenograft mouse models in NSG mice undergoing partial tumor resection to evaluate the efficacy of localized delivery of triple-targeting mRNA-based MVCAR or CARPool. We created a resection cutoff criterion that maintains only minimal residual disease and used this criterion to subdivide mice within each group based on resection intensity (desired or undesired). Our preliminary data from the resection model shows that CAR T cell treated mice undergoing "desired resection" had higher survival rates as compared to their counterparts in "undesired resection" subgroups. Significance: Multivariant targeting of glioma associated antigens with mRNA-based CAR T cell therapies provide an easily translational platform for the management of GBM patients undergoing surgical resection and help counteract solid tumor evasion mechanisms. Additionally, the one-day protocol for transient CAR expression in mRNA-based CAR T cells is expected to generate a safer and faster alternative to traditional CAR T cells undergoing standard manufacturing.

1807. cGMP-Grade MAD7 TARGATT™ Master iPSCs for Allogenic Cell Therapies

Ruby Tsai[1], Alfonso Farruggio[2], Simon Wu[3], Lin Jiang[4]

[1]CEO and President, Applied StemCell, Inc., Milpitas, CA,[2]Head of Research and Development, Applied StemCell, Inc., Milpitas, CA,[3]Associate Director, Project Management, Applied StemCell, Inc., Milpitas, CA,[4]Production/GMP Cell Products, Applied StemCell, Inc., Milpitas, CA

Induced pluripotent cells (iPSCs) for site-specific DNA-fragment knock-in are essential for developing and manufacturing the next generation of cell therapeutic products. Traditional genome editing technologies, such as CRISPR/Cas9 systems, can be used to establish stable knock-in cell lines; however, transgene size can be limited, and substantial licensing fees are required to move the engineered cell line into product development and manufacturing. To generate a ready-to-use cGMP-grade iPSC line for site-specific gene of interest (GOI) knock-in, we adapted the TARGATT system by integrating an attB landing pad into the Hipp11 locus (H11) by MAD7 in a cGMP-grade iPSC line, and isolated desired clones harboring the landing pad, which then were confirmed by Sanger Sequencing. With an established cGMP-grade TARGATT iPSC line, we then inserted a single copy of RFP construct at the H11 locus to verify efficiency of knock-in (insertion) as well as expression robustness and the ability of engineered iPSCs to be differentiated into natural killer (NK) cells (iPSC-derived NK cells). Our data demonstrates that the TARGATT system can be particularly useful for cancer immunotherapy applications. For example, unique therapeutic genes (such as CAR constructs) can be inserted in the cGMP TARGATT Master iPSC line for differentiating into NK cells or T cells that could potentially be utilized to fight various serious human diseases.

1808. Exploring Adenovirus Type 35 as Oncolytic Virus in Combination with NK-Cell Therapy as a Novel Concept in Cancer Treatment in Respiratory Disease

Luca Scarsella[1], Wenli Zhang[2], Serge C. Thal[3], Anja Ehrhardt[1], Malik Aydin[4]

[1]Witten/Herdecke University, Witten, Germany,[2]Witten/Herdecke, Witten, Germany,[3]Helios University Hospital Wuppertal, Wuppertal, Germany,[4]Faculty of Health, Department of Human Medicine, Witten/Herdecke University, Witten, Germany

Oncolytic therapy using adenoviruses (Ad) presents a promising approach for the treatment of solid tumors, as evidenced by multiple clinical trials. Besides oncolytic viruses, also Natural killer (NK) cells are becoming a central role in CAR-based cellular immunotherapy against malignancies. However, the potential synergistic implications of combining adenoviral oncolytic therapy with NK cell-mediated immunity remain insufficiently studied, although NK cells demonstrated robust anti-viral and -tumor activity. While there are indications in the literature that Ad5-based vectors carrying Ad35 or Ad37 fibers may transduce NK cells, a comprehensive analysis of a broad spectrum of

human Ads on primary NK cells is lacking. Therefore, our primary aim was to identify optimal Ad vector candidates and investigate the role of NK cells in the context of Ad transduction. To address this objective, we investigated different recombinant Ad vectors (n=11) from different species containing a dual-reporter cassette in the E3 region of the Ad genome, encoding a green-fluorescent protein, a nano-Luciferase, and a neomycin resistance gene. To monitor the transduction efficiency in cells following 24 hours of cultivation, we conducted luciferase assays and quantitative PCR to measure transduction efficiencies and viral progeny in the supernatant. PBMCs were isolated through centrifugation and subsequently NK cells were isolated. A co-culture model involving Ad35-infected A549 cells and primary NK cells was established to analyze the impact of oncolytic therapy on NK cell cytotoxicity. Our investigations revealed that Ad35 from species B using CD46 as its primary cell entry receptor, and Ad37, derived from species D using GD1a glycan as an entry receptor, exhibited the highest transduction efficiencies in PBMCs obtained from healthy donors. Subsequently, we identified Ad types with optimal tropism for NK cells, with Ad35 as the most suitable for viral transduction using 2000 and 5000 viral particles per cell (vpc) for NK cell infection (p=0.0286). Furthermore, Ad35 demonstrated potent oncolytic activity in A549 cells, resulting in robust cell lysis 3 days post-infection (p=0.0001). To understand the role of NK cells during Ad transduction, co-culture experiments using primary NK cells were performed. These experiments revealed the presence of Ad virion in the culture medium produced by infected A549 cells and we detected infected NK cells. We hypothesize that the infection of NK cells was the result of viral progeny derived from infected A549 cells, which led to infection of NK cells. Moreover, an LDH assay indicated an increase in LDH secretion (20 %) as a marker of cell toxicity in the co-culture medium, particularly when A549 cells were pre-transduced with Ad35, which was in sharp contrast to uninfected A549 cells. Flow cytometry analyses of Ad-specific surface receptors on NK cells post-infection revealed a decrease of CD46 expression (18 %) in comparison to uninfected NK cells, while CAR expression remained constant. In conclusion, our findings demonstrate that Ad35 effectively transduces NK cells and exerts a rapid oncolytic effect in A549 cells, making it a promising candidate for both oncolytic and cell-based viral therapies. In the subsequent steps, we will focus on human lung tumor samples and the molecular analysis of alterations in NK cells after Ad35 vector application.

1809. Characterization of Allogeneic Engineered Human "Tissue-Tregs" with Immune Suppression and Tissue Homing Capabilities for Treatment of Acute Inflammatory Diseases

Yash Agarwal, Priya Saikumar, Maegan E. Hoover, Guoping Deng, Madison Milaszewski, Carlos E. Frias, Abigail Doherty, Scott Hussell, Rebecca Brunette, Marko Repic, Tiffany F. Chen, Thomas Wickham, Payam Zarin

GentiBio, Cambridge, MA

FoxP3+ Regulatory T cells (Tregs) orchestrate immune tolerance, thus preventing life-threatening autoimmunity, while maintaining tissue homeostasis and promoting repair following tissue damage. Tissue-resident Tregs appear to have a highly specialized gene expression program that enables the simultaneous activation of the anti-inflammatory and pro-repair functions. Adoptive transfer of allogeneic tissue Tregs could prove effective in patients with acute inflammatory conditions such as Acute Respiratory Distress Syndrome, acute kidney injury, or acute ischemic stroke where only a swift intervention could be useful, necessitating an "off-the-shelf" therapeutic that could ameliorate disease within hours. However, while the repair program has been well characterized in murine models, the understanding of tissue Tregs in humans is limited. Here, we engineer tissue Tregs from bulk CD4+ T cells with enhanced tissue-homing and suppression. Further, we demonstrate the effectiveness of allogeneic Tregs when transferred into a mouse model of acute lung injury. Engineered human regulatory T cells (EngTregs) were generated from CD4+ T cells using CRISPR-Cas9 to knock-in a strong promoter at the *FOXP3* gene locus to stabilize *FOXP3* expression and express a chemically inducible IL-2 signaling complex (CISC). This promotes rapamycin-activated IL-2-like signaling only in the engineered cells, thus enabling enrichment of FoxP3+ cells in the culture process. To impart a tissue-Treg phenotype, we overexpressed a 'tissue-Treg' associated protein in EngTregs. We found that the final product (Tissue EngTregs) had a robust Treg phenotype as measured by high expression of key Treg-associated proteins such as FoxP3, CD25, CD39, HLA-DR, TNFRII and more, and increased suppression of proliferation of a polyclonal pool of effector T cells relative to control mock-engineered cells. Tissue EngTregs also upregulated several chemokine receptors (CCR4, CCR5, and CCR8) that would enable chemokine-dependent homing to inflamed tissues and demonstrated modulation of tissue repair. When exposed to an acute inflammatory cytokine milieu, tissue EngTregs also respond by rapid sequestration of several inflammatory molecules (e.g. TNFα, IL-2, IL-4, IL-33) *in vitro*. Therefore, Tissue EngTregs have significant potential for the treatment of acute inflammatory diseases. As proof-of-principle we also evaluated the efficacy of allogeneic surrogate murine Engineered Tregs (mEngTregs) in an LPS induced model of acute lung injury. mEngTreg treated animals showed significantly improved disease outcome and lower levels of inflammatory cytokines such as IFNγ and TNFα in the bronchoalveolar lavage (BAL). Also, mEngTregs were found to effectively home to the site of pulmonary inflammation, and resemble endogenous Tregs in expression of key markers such as FoxP3, CD25, ST2 and CCR4. Overall, these data are supportive of the potential for developing a potent off-the-shelf engineered Treg cellular therapy for human acute inflammatory disease.

1810. Preclinical Development of KYV-201, an Investigational Allogeneic Anti-CD19 CAR T-Cell Therapy for Autoimmune Diseases

Ashley Mahne[1], Brandon Kwong[1], Joseph Cheng[1], Jessica Wang[1], Jesus Banuelos[1], Peter Starokadomskyy[1], Soo Park[1], Candice Gibson[1], Shouvonik Sengupta[1], Simone Sandoval[1], Jazmin Bravo[1], Jeanne Flandez[1], Shairaz Shah[1], Amanda Goodsell[1], Yong Zhang[2], Ian Miller[2], Birgit Schultes[2], Tom Van Blarcom[1]

[1]Kyverna Therapeutics, Emeryville, CA,[2]Intellia Therapeutics, Cambridge, MA

Background: Autologous anti-CD19 CAR T cells show early clinical evidence of safety and efficacy for the treatment of numerous autoimmune diseases (Schett G. *Lancet*. 2023). Allogeneic CAR T cells have the potential to further address drug supply for the substantial B-cell driven autoimmune disease population with advantages that include scalability, removal of the need for patient apheresis, and reduced treatment wait times. Emerging data in autoimmune disease trials suggests long-term CAR T-cell persistence is not required as patients have achieved long-term remissions (>1 year) despite B-cell compartment reconstitution within months (Schett G. ACR 2023). This suggests persistence-associated limitations of allogeneic CAR T cells observed in oncology (DiNofia AM. *Nat Rev Clin Oncol.* 2021) may not apply to the same extent to autoimmune disease. KYV-201 is an investigational allogeneic anti-CD19 CAR T-cell therapy for B-cell-driven autoimmune diseases. KYV-201 combines the same fully human anti-CD19 CAR construct as KYV-101, an autologous CAR T-cell therapy being studied in lupus nephritis, systemic sclerosis, myasthenia gravis, and multiple sclerosis, with a differentiated allogeneic platform developed by Intellia Therapeutics involving selected CRISPR/Cas9-mediated gene edits (Blarcom TV, *CAR TCR Summit. 2023;* Taubmann J. EULAR 2023*)*. These edits intend to avoid GvHD by removing the endogenous TCR and provide immune evasion to prolong CAR T-cell persistence by removing key cell surface proteins involved in host recognition of an allogeneic cell product. *Objectives*: To generate preclinical data supporting advancement of KYV-201 to first-in-human clinical studies. *Methods*: CAR-mediated and target-dependent activity of KYV-201 against both CD19$^+$ target cell lines and primary B cells was demonstrated with in vitro cytotoxicity, cytokine production, and proliferation studies, as well as with an in vivo xenograft model. Functionality of the immune evasion edits was demonstrated by in vitro assays modeling host T and NK-cell-mediated rejection mechanisms. Genotoxicity concerns of the product were assessed through chromosomal translocation, karyotyping, and cytokine independent growth assays. *Results*: KYV-201 demonstrated CAR-mediated and CD19-dependent cytotoxicity, cytokine production and proliferation against the human CD19$^+$ NALM6 cell line. In vivo, KYV-201 effectively controlled growth of a CD19$^+$ NALM6 xenograft in a dose-dependent manner. In co-culture with allogeneic T and NK cells, KYV-201 mitigated allogeneic recognition and rejection responses. In co-culture with allogeneic healthy donor PBMCs, KYV-201 eliminated primary B cells and proliferated in a CAR-dependent manner (Figure 1), avoiding rejection by alloreactive T cells and NK cells. Genotoxicity assays revealed minimal levels of translocations or chromosomal abnormalities by ddPCR and karyotyping, and a lack of transformation by cytokine independent growth assays. *Conclusion*: The preclinical data generated for KYV-201 demonstrates the functionality and safety necessary to advance to first-in-human studies, bringing the promise of allogeneic CD19 CAR T cells for autoimmune diseases closer to fruition.

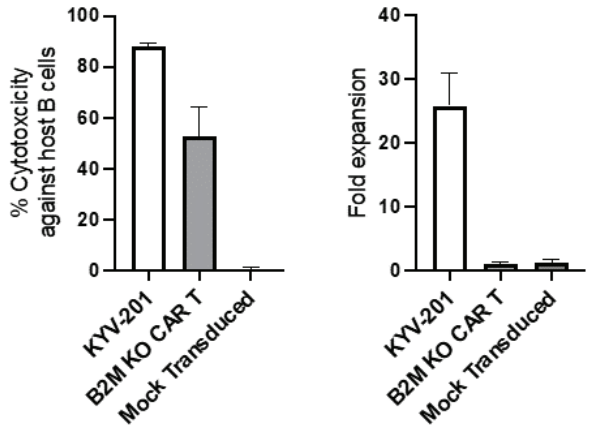


Figure 1. KYV-201, CAR T cells lacking HLA Class I (B2M KO CAR T cells), or mock transduced T cells were co-cultured with allogeneic PBMCs for 6 days at a (CAR) T cell:PBMC ratio of 1:30. KYV-201 demonstrated CAR-mediated cytotoxicity against primary B cells that was higher than that seen with B2M KO CAR T cells (left panel). KYV-201 expanded following CAR-mediated activation, in contrast to B2M KO CAR T cells that were mostly eliminated by the end of co-culture (right panel).

1811. A Novel Approach to Target Autoreactive B Cells Using ADAMTS13-Derived Chimeric Auto-Antigen Receptors (CAARs) T Cells in the Context of Immune-Mediated Thrombotic Thrombocytopenic Purpura (iTTP)

Roman H. Khadka[1], Kalpana Parvathaneni[2], Jennifer Hoffmann[1], Ezgi Tezer[1], Morgan Hresko[1], Don L. Siegel[1], Vijay Bhoj[2]

[1]Center for Cellular Immunotherapy, University of Pennsylvania, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA

Background: Immune-mediated thrombotic thrombocytopenic purpura (iTTP) is a severe form of thrombotic microangiopathy caused by autoantibodies directed against ADAMTS13 (disintegrin and metalloproteinase with thrombospondin motifs) which functions as von Willebrand factor (vWF) cleaving protease. Accumulation of ultralarge vWF during iTTP is characterized by microvascular thrombi, focal neurological symptoms and ischemic multi-organ injury leading to high degree of fatality in absence of interventions. While existing strategies to manage iTTP including plasma exchange offer transient benefit, there is frequent relapse in patients highlighting the need for more robust and sustained therapies to tackle both the autoantibodies and contributing autoreactive B cells. **Objective:** To address this gap, we utilized a novel approach to target ADAMTS13-specific B cells using chimeric auto-antigen receptors (CAAR) T cells as therapeutic approach for iTTP. **Methods:** We generated CAARs employing different combinations of ADAMTS13 domains as extracellular targeting domains. We also created a panel of target B cell-like Nalm6 cell lines expressing iTTP patient-derived autoantibodies. ADAMTS13-CAAR T cells were tested for efficacy and specificity using co-culture assay with Nalm6 target cells *in-vitro*. In vivo experiments utilized Nalm6 targets in a murine xenograft model to test the efficacy of ADAMTS13-CAAR T cells compared to a non-specific CD19-targeted CAR T

(CART-19). We further assessed the ability of ADAMTS13-CAARs to target polyclonal patient B cell using a serum adsorption assay. **Results:** ADAMTS13-CAAR T cells exhibited specific cytotoxicity against Nalm6 cells-expressing human iTTP autoantibodies. We additionally observed robust IFN-gamma secretion and degranulation as measured by CD107a expression in ADAMTS13-derived CAAR T cells. Importantly, we demonstrate using xenograft murine model that CAAR T cells are capable of persisting and targeting B cells expressing autoantibody specific to human-ADAMTS13. Adsorption of iTTP sera with ADAMTS13-CAAR T cells significantly depleted autoantibodies compared to adsorption with control non-CAAR T cells ($p<0.05$, t-test). **Conclusions:** We have successfully demonstrated ADAMTS13-based CAAR T cells can eliminate pathogenic B cells. Hence, CAAR-based T cell approach has significance and potential applications to ameliorate thrombotic microangiopathy in iTTP

1812. Engineering Tregs with a CAR, Phenotype Lock™ and Synthetic Cytokine Signaling Improves Their Potential as a Cellular Therapy for Various Immune Conditions

Sim Tung, Bethany McCloskey, Somayya Manzoor, Mahnoor Irfan, Julieta Karegli, Joanne Anstee, Marco Romano, Yasaman Shahrabi, Amy Billman, Evanthia Nikolopoulou, Jenny McGovern, Daniela Penston, Nathalie Belmonte, Marc Martinez-Llordella, Tracey Lodie

Quell Therapeutics, London, United Kingdom

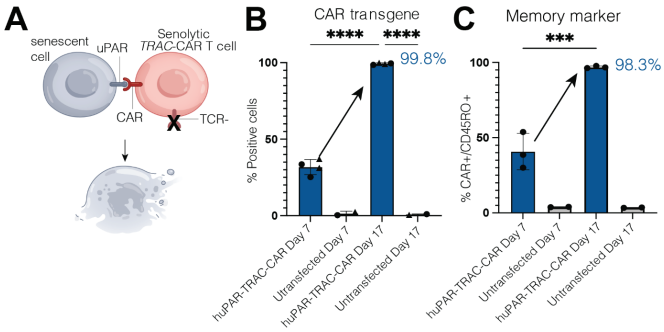
Regulatory T cell (Treg) therapy is a promising new approach to induce immune tolerance in organ transplantation and autoimmunity. Some of the limitations of polyclonal Treg cell therapy include lack of specific targeting, the loss of stability and limited durability. Chimeric antigen receptors (CARs) are recombinant fusion receptors that can redirect Tregs to recognize desired target antigens. FoxP3 is a hallmark marker and an essential master transcription factor of Tregs which controls numerous genes responsible for Treg phenotype, stability and function. Tregs require the crucial IL-2 cytokine for their generation, survival, expansion and stability. IL-2 promotes high phosphorylated STAT5 (pSTAT5) levels within Tregs which cascades signaling events downstream to induce pro-survival protein production amongst other cellular events to sustain Treg viability and expansion. We have designed and engineered multiple novel modules which can provide Tregs with specific targeting via CAR molecules, a Phenotype Lock™ which maintains high FoxP3 expression and a synthetic receptor to trigger survival signals. Our results demonstrate that Tregs engineered with a CAR recognise and respond to the desired target antigen by upregulating an immune activation response. Tregs bestowed with the Phenotype Lock™ technology expressed and maintained high levels of FoxP3 expression along with other Treg-associated markers, supporting their suppressive function. The synthetic cytokine receptors developed utilise the pSTAT5 signalling pathway and mediate a constitutive signal with equivalent downstream transcriptional effects to the IL-2 signalling pathway. We have developed a toolbox of synthetic cytokine signaling technologies which consist of a tethered cytokine and a receptor dimerization approach. These approaches can be selected for engineering into the cell depending on the strength of pSTAT5 signalling required. The synthetic cytokine signaling allowed the engineered Tregs to extend their survival in vitro, importantly without secretion of pro-inflammatory cytokines. Gene expression analysis revealed that the CAR Tregs with the engineered modules expressed high levels of Treg stability and survival related genes, which supports the in vitro functional readouts. Furthermore, CAR Tregs equipped with the synthetic cytokine signaling demonstrated therapeutic capabilities and survived longer in murine models. In conclusion, we have demonstrated that our CAR, Phenotype Lock™ and synthetic cytokine signaling technologies can be used to engineer and enhance Tregs as a way to promote their specific targeting and durability whilst maintaining their suppressive function and phenotypic stability.

1813. Development of a Novel Allogeneic γδ-T Platform for Off-the-Shelf Adoptive Cell Therapy for Oncology and Autoimmune Diseases

Arash Nanbakhsh, Lukasz Wlodarek, Kevin Nguyen, Weijie Lan

Overland Pharma, South San Francisco, CA

Introduction: Despite significant clinical benefit for treating hematological malignancies and recent exciting development for autoimmune diseases, autologous cell therapy products face meaningful challenges in terms of expansion to broad patient population, including manufacture scale-up, high cost and certain severe adverse effects. Owing to their innate and MHC-independent cell killing capacities, γδ-T cells have gained increasing interest as a differentiated allogeneic cell type. Establishing robust expansion protocols and elucidating the functional properties of γδ-T cell subsets are fundamental to explore the therapeutic potential of γδ-T cells in both oncology and autoimmune diseases. **Methods:** γδ-T cells were enriched from PBMCs using multiple donors. Enriched γδ-T cells were transduced with virus constructs with different promoters and expanded under different culture conditions. The phenotypes of the cells were analyzed using multi-color full spectrum flow cytometry. The innate and CAR-mediated γδ-T cell killing activity were measured using flow cytometry and real-time imaging with Incucyte. In vivo target cell killing activity was demonstrated using NSG mice inoculated with luciferase expressing cancer cell lines. **Results:** We found that the abundance and composition of γδ-T varied significantly among different donors. We observed that the cytotoxicity properties of γδ-T cells, both innate- and CAR-dependent, were strongly influenced by donor variability and method of expansion. We developed efficient γδ-T cell expansion protocols that achieved up to >1,000,000-fold cell expansion over a 3-week period of culture without apparent signs of exhaustion or impaired cytotoxicity. Our expansion method generated potent Vδ2 T cells and a unique subset of Vδ1 T cells that highly express CD107, Granzyme B, IFN-γ, and IL-2. We screened viral constructs and identified viral envelops and promoters that support robust viral transduction and CAR expression in γδ-T cells. We found that CAR-γδ-T with mixture of both CAR-Vδ2 and -Vδ1 present maintained complete tumor control during a 30-day serial stimulation assay, whereas CAR-Vδ2 T cells alone failed to supress tumor growth beyond the first 7-days across all tested donors. Sequential rechallenge with target tumor cells ultimately led to selective expansion of CAR-



Vδ1 T cells. Vδ1 subtype enrichment could also be achieved in the absence of immune challenge with a small molecule compound. Finally, we demonstrated that CAR- γδ T cells could effectively control tumor growth in a NSG mouse model with disseminated tumor cells. **Conclusions:** We have established a unique and scalable allogeneic γδ-T platform with demonstrated CAR mediated in vitro and in vivo efficacies. We are able to generate Vδ1, Vδ2 and mixture of CAR- γδ T cells for potential off-the-shelf adoptive cell therapy in different cancer and autoimmune disease indications.

1814. Non-Viral Senolytic CRISPR CAR T Cell Products Autonomously Refine into Pure Cell Therapies

Lauren E. Sarko[1,2], Jeremiah Riendeau[3,4], Claire Shepley[1], David Givand[1], Roshini Traynor[1], Lei Zhao[5], Mackenzie Mnuk[1], Tyler Ulland[2], Mahau Dey[5], Melissa Skala[3,4], Krishanu Saha[1,3]

[1]Wisconsin Institute for Discovery, University of Wisconsin-Madison, Madison, WI,[2]Department of Pathology and Laboratory Medicine, University of Wisconsin-Madison, Madison, WI,[3]Department of Biomedical Engineering, University of Wisconsin-Madison, Madison, WI,[4]Morgridge Institute for Research, Madison, WI,[5]Department of Neurological Surgery, University of Wisconsin-Madison, Madison, WI

Cellular senescence is a biological process that reduces proliferation and helps to prevent the propagation of damaged cells. Controlling senescence within the body can be critical, as recent discoveries have identified its role in the pathophysiology of various disorders. Lysing senescent cells within the body using engineered cells can provide a new therapeutic modality to treat disease or prevent tissue dysfunction. Here, we exploit nonviral CRISPR genome editing reagents to efficiently generate T cells that express chimeric antigen receptors (CARs) against a senescence-associated cell surface protein, urokinase plasminogen activator receptor (uPAR). CAR T cells targeting uPAR were efficiently produced by knocking out the endogenous T cell receptor, alpha chain, gene (*TRAC*), and inserting a CAR transgene driven by the *TRAC* promoter. CAR T cells targeting murine and human uPAR proteins exhibit specific and significant cytotoxicity *in vitro* against induced and patient-derived senescent cells with limited off-target cytotoxicity against healthy dividing cells. During manufacturing, human *TRAC*-CAR cell products are autonomously refined into highly enriched CAR+ memory T cells, with purities reaching >98% CAR+/*TRAC*-/CD45RO+ phenotypes within weeks (*Figure*). Facile manufacturing of gene-edited CAR T cell products could enable new senolytic therapy for aging and various senescence-associated pathologies.

huPAR-*TRAC*-CAR T Cells target senescent uPAR+ T cells in culture and display a central memory phenotype after manufacturing. (**A**) Schematic of huPAR-*TRAC*-CAR T cells eliminating uPAR positive senescent cells. (**B**) Summary of flow cytometry for CAR transgene integration of huPAR-*TRAC*-CAR T cells on days 7 and 17 post-nucleofection. huPAR-*TRAC*-CAR T cells showed significantly increased mCherry expression from day 7 to 17 relative to Untransfected T cells. (**C**) Summary of flow cytometry of CAR-2A-mCherry/CD45RO double positivity from day 7 to 17. huPAR-*TRAC*-CAR (blue) n=3, untransfected control (grey) n=2. Ordinary one-way ANOVA; *p≤0.05; **p≤0.01; ***p≤0.001; ****p≤0.0001. ANOVA, analysis of variance.

1815. Characterization of CNTY-101, an Allogeneic Anti-CD19 iPSC-Derived NK Product, for the Treatment of B Cell-Driven Autoimmune Diseases

Mark Mendonca, Kaitlin Idank, Ciara Budd, Andriana Lebid, Dan Perry, Heidi Jessup, Buddha Gurung, Barry Morse, Jill Carton, Liam Campion, Michael F. Naso

Century Therapeutics, Philadelphia, PA

Achieving long-term remission in B cell-driven autoimmune diseases (AID), including Systemic Lupus Erythematosus (SLE), remains a substantial unmet need. Recently, numerous autologous anti-CD19 CAR T therapies have shown promise in treating patients affected by Systemic Lupus Erythematosus (SLE) by depleting autoreactive B cells. Allogeneic induced pluripotent stem cell (iPSC)-derived cells present a unique opportunity to offer a clonal, off-the-shelf cell therapy product. We describe a cell therapy product CNTY-101, with multiple precision gene edits, featuring antigen-specific killing of CD19+ B cells, homeostatic cytokine support for enhanced persistence, edits to prevent rejection by the patients' immune system, and a safety switch. In non-clinical studies, we demonstrate CNTY-101's ability to induce CD19-specific cytolysis of both CD19+ tumor cells and isolated B cells from multiple healthy and SLE patient donors. When compared with peripheral blood mononuclear cell (PBMC) derived CAR-T cells, CNTY-101 exhibits similar potency while observing less detectable inflammatory cytokine secretion after B cell depletion. The inclusion of the homeostatic cytokine transgene allows for the persistence of CNTY-101 several days after the depletion of CD19+ malignant and non-malignant B-cells. EGFRt is an elimination tag that can be engaged using anti-EGFR antibodies to deplete CNTY-101. The inclusion of Allo-EvasionTM edits (B2M and CIITA knockouts and HLA-E knock-in) allows for evasion from recipient PBMCs, enabling repeat dosing with and without lymphodepletion. CNTY-101, an off-the-shelf cell therapy product with multiple precision gene edits targeted to B Cell-driven diseases, including AID, demonstrates rapid B cell depletion with a favorable cytokine secretion profile, in vitro persistence and the opportunity for repeat dosing without host rejection.

1816. Universal Cloaking of Allogeneic Cell Therapies Against Natural Killer Cells via CD300a Agonism

Shuqi Zhang[1], Faith Thomas[1], Justin Fang[1], Jonathan Kurtz[1], Dustin Whitney[2], Gabriella Santone[1], Rodolfo Nazitto[1], David Monteiro[2], Daria Shlyueva[3], Francis Cervone[3], Chad Cowan[4], Grant Welstead[1]

[1]Discovery Biology, Clade Therapeutics, Cambridge, MA,[2]Computational Biology, Clade Therapeutics, Cambridge, MA,[3]Cell Engineering, Clade Therapeutics, Cambridge, MA,[4]Clade Therapeutics, Cambridge, MA

A major barrier to the persistence and efficacy of allogeneic, off-the-shelf T cell therapies is the host natural killer (NK) cell response. Natural ligand-based approaches, such as HLA-E, only inhibit subsets of NK cells whose frequencies vary host-to-host, preventing a universal solution to NK alloreactivity. Inspired by the earliest studies in inhibitory signaling, we engineered a class of synthetic ligands, called Trans Antigen Signaling Receptors (TASR), capable of agonizing inhibitory receptors previously inaccessible. One member, targeting CD300a, exhibited best-in-class performance and enhanced T cell persistence against all hosts tested (45/45), spanning diverse demographics and NK cell phenotypes. CAR-T cells co-expressing a CD300a TASR at the B2M locus and CD19-CAR at the TRAC locus via non-viral integration exhibited enhanced persistence and efficacy in a clinically relevant model system. Thus, CD300a TASRs represent a universal solution to NK alloreactivity, broadening the population that could be effectively treated by next-generation allogeneic cell therapies.

1817. Highly Stable Liquid IL-7 and IL-15 Closed System Solution Formulation for Sterility Assurance and Reproducible Biological Activity in Cell Therapy Application

Ezequiel Zylberberg[1], Juan Manuel Rodriguez[2], Julio Cesar Vega[2], Mahajoub B. Bello Roufai[3]

[1]Research and Process Development, Akron Biotech, Boca Raton, FL,[2]Research and Development, Laboratorio Pablo Cassará S.R.L,, Autónoma de Buenos Aires, Argentina,[3]Research and Process Development, Akron Biotech, FL, Sarasota, FL

Cytokines are important factors for T cell development and homeostasis. In addition to the TCR and costimulatory receptors, cytokines provide stimulatory signals for full T cell activation, and have pleiotropic effects on T cell proliferation, differentiation and function. Cytokines IL-2, IL-7 and IL-15 have been found to stimulate the growth of T cells and are used at specific concentration optimized depending on the production platforms. We have developed and distributed rHu IL-7 and rHu IL-15 in their lyophilized form and documented under Drug master File # MF026084. We have also launched our Closed system Solutions ™ (CSS) line of cGMP products that functionally closes critical unit operations in cell and gene therapy manufacturing workflow. Evolving cell therapy processes are requiring lower Million International Units (MIU), preferably in the single use format to accommodate speed, cell stimulation consistency (biological activity) and sterility assurance, moving away from the traditional lyophilized formats. Consequently, the future of the industry requires the development of formulations at low MIU, in which the biological activity of these cytokines is maintained for an extended period. However, cytokines are known to be susceptible to chemical and physical instability, especially at low concentration. They are also susceptible to aggregation, surface adsorption, and oxidation. Therefore, the formulation of the cytokines at lower protein concentrations in small bioprocessing bags, compatible with their chemical, physical and biological stability in an emerging industry need. Leveraging our decade long expertise in bioproducts including cytokines, we previously developed and launch a CSS format of rHu IL-2 that available on the market. Here we report the formulation development of our CSS format for rHu IL-7 and rHu IL-15 at low concentration and comparative results from three lead formulations designed based on their buffering and their compatibility with stabilizing agents, excipients and bioprocess bags to improve stability. We also report results comparing our formulated CSS format of rHu IL7 and rHu IL-15 to the traditional lyophilized format. The formulation development approach adopted for rHu IL-7 and rHu IL-15 CSS format could facilitate development of a wide range of cytokines in a format that meets new cell therapy processing modalities.

1818. Development and Evaluation of Immuno-Cell Growth Medium (Akron ICGM™): A Novel Xeno-Free Cell Expansion Medium Demonstrated to Support Superior Cell Activation, Viability, Transduction and Expansion

Jun Hung CHO[1], Cindy Farino Reyes[2], Darwing Rivas[3], Dennis O. Concepcion[1], Federico Franchi[2], Ryan R. Heetai[1], Ezequiel Zylberberg[4], Mahajoub Belcym Bello Roufai[1]

[1]Research and Process Development, Akron Biotech, FL, Sarasota, FL,[2]Cell Therapy, Cytiva, Marlborough, MA,[3]Research and Process Development, Akron Biotech, FL, Boca Raton, FL,[4]Research and Process Development, Akron Biotech, Boca Raton, FL

Over the past decade, significant progress has been made in T cell-based immunotherapy. Naturally occurring or genetically engineered T cells have been used to target cancer antigens in hematological malignancies and solid tumors. The approach has been proven to be promising and has been validated with recent clinical trial successes and FDA approvals of several Chimeric Antigen Receptor (CAR) T-cell therapy products. The treatment requires that T cells isolated from a patient blood be modified, culture-expanded ex vivo with a tumor cytotoxic phenotype and then re-infused back to the patient. Therefore, the development of growth medium that can effectively support ex vivo activation, transduction and expansion of isolated T-cells has been a point of focus for the industry with a few T-cell media already commercially available. Leveraging our decade long expertise in bioproducts including cytokines and human serum, we studied several media supplements to establish a basal T-cell media able to promote acceptable PBMC growth. From our initial development, five (5) Xeno-free lead formulations (A, B, C, D E) were nominated and further compared with commercially available T-cell media for PBMC expansion. Akron's Formulation C showed superior performance and was sent to several Akron partners for evaluation on their cell therapy platforms using T-cells isolated from healthy donors. Here,

we summarize data from our initial media development through the establishment of our five lead formulations and the comparison with commercially available T-cell media. We also report data obtained on T-cells from healthy donors evaluated of by Cytiva, one of the partners selected to test our novel Immuno-Cell Growth Medium (Akron ICGM™).

1819. New Technologies for CAR-T Characterization and Potency Testing

Christopher Dashiell, Julia Gilden, Pete Stecha, Aileen Paguio, Jim Hartnett, Brock Binkowski, Dan Lazar, Frank Fan, Mei Cong

Promega Corporation, Madison, WI

Despite significant clinical advances in CAR-T cell therapies for cancer, the ability to precisely and reproducibly analyze the potency and identity of these drug products remains a challenge. As new CAR-T products and production methodologies are developed, it is becoming increasingly important to be able to rigorously evaluate the relative potencies of each batch. We have developed two MOA-based bioluminescent assays that overcome challenges in quantitative assessment of T cell therapies. Both assays rely on split NanoBiT luciferase technology. In the HiBiT Target Cell Killing Assay, incubation of CAR-T cells with target cells stably expressing HiBiT results in lysis of the target cells and release of HiBiT proteins. These HiBiT proteins bind with high affinity to LgBiT in the detection reagent and form functional NanoBiT luciferase, resulting in production of light in proportion to target cell lysis. Lumit Immunoassays are a simple and homogeneous method for measuring cytokine production from engineered T cells. Monoclonal antibodies are covalently labeled with LgBiT and a low-affinity tag, SmBiT, which have negligible association in solution. When the antibodies are brought together on a common analyte, such as a cytokine, SmBiT and LgBiT can complement to form NanoBiT luciferase and produce light in proportion to the concentration of analyte in the sample. Lumit Immunoassays can be run directly on cells, removing media transfer, dilution, and wash steps that can be common sources of error. When autologous CAR-T products are being produced in parallel, it is essential to verify the identity of each product and ensure that it is administered to the correct patient. We will demonstrate an easy workflow for STR analysis that can be used to document the chain of identity for CAR-T products.

1820. Serum Proteomic Analysis Identifies Markers Associated with Anti-CD19 CAR T Therapeutic Response in Autoimmune Diseases

Justin Chou[1], Ricardo Grieshaber-Bouyer[2,3], Daniela Bohr[2,3], Christina Bergmann[2,3], Jule Taubmann[3], Fabian Müller[3,4], Aline Bozec[2,3], Tobias Rothe[2,3], Andreas Mackensen[3,4], James Chung[1], Georg Schett[2,3]

[1]Kyverna Therapeutics, Emeryville, CA,[2]Department of Internal Medicine 3 - Rheumatology and Immunology, Friedrich-Alexander Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany,[3]Deutsches Zentrum Immuntherapie, Friedrich-Alexander Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany,[4]Department of Internal Medicine 5-Hematology and Oncology, Friedrich-Alexander Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany

Background: Anti-CD19 CAR T-cell therapy has demonstrated promising therapeutic efficacy and tolerability in patients with systemic lupus erythematosus (SLE), dermatomyositis (DM), and systemic sclerosis (SSc)[1-4]. The broad, deep, and short duration of B-cell depletion possible with anti-CD19 CAR T-cell therapy may provide sustained treatment-free remission for patients with autoimmune disease; however, the immunological impact of CAR T-cell therapy remains unclear. *Objectives*: In this study, we evaluated immunologic mechanisms and explored novel biomarkers by analyzing serum proteomic profiles at baseline and remission. *Methods*: Serum samples were collected prior to conditioning chemotherapy (baseline) and 3 months post-CAR T-cell infusion for 3 SLE, 3 diffuse SSc, and 2 DM patients treated at the Friedrich-Alexander University Erlangen-Nürnberg. Additional serum samples from 10 normal, 7 SLE, and 7 SSc donors were obtained from ProteoGenex. More than 7000 proteins were profiled with SomaScan® technology, which uses probe-tagged protein-binding aptamers for high-throughput proteomic profiling with an NGS readout. Differentially expressed proteins were identified by Wilcoxon test and used for Reactome pathway analysis. *Results*: We first evaluated data quality by checking the proteins known to be modulated by CAR T-cell therapy. Levels of IgM, IgA, and IgE were significantly reduced at 3 months post-CD19-CAR T-cell infusion, while IgG showed no significant change. When comparing normal donors with patient-derived samples at baseline, we observed elevated IFN signaling molecules (CXCL10 and MX1) in SLE samples and endothelial dysfunction markers (VEGF and ANG2) in SSc samples. Our proteomic analysis showed that HSF-1-mediated heat shock response (HSPA1A, DNAJA4, etc.) and type I IFN signaling (IFIT3, ISG15, etc.) were the two major pathways downregulated after CD19-CAR T-cell therapy (Figure 1). Moreover, an autoantigen poly(U)-binding-splicing factor 60 kDa (PUF60) was also reduced at post-infusion. These markers are selectively expressed by innate immune cells and co-expressed with proteins related to neutrophil degranulation and IL12 signaling. *Conclusions*: Our analysis provides new insights into the potential mechanisms of CAR T-cell treatment in patients with autoimmune diseases. These findings may facilitate future identification of markers predictive of CAR T-cell therapy response. *References*: 1. Feng J, et al. *Blood*. 2022;140 (suppl 1):10335-

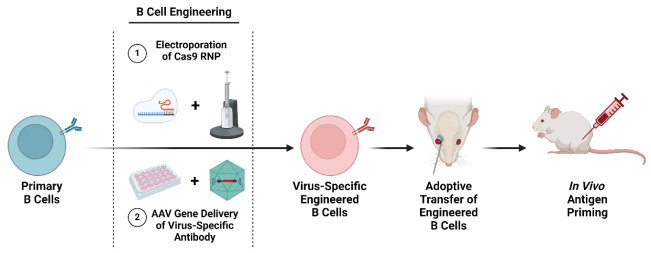
Heat shock protein mediated responses and type I IFN signatures were downregulated in patients who received anti-CD19 CAR T-cell therapy.

1821. eMHC-CAR as a Platform for Class I & Class II-Reactive Antigen-Specific T Cell Engagement, Depletion, and Tolerization

Cameron L. Gardner, Kerry Dobbs, Xiaobing Cui, Lindsay Whalen, Kristina Gurung, Ryan Grant, Sofia Makowska, Edward Dong, Hiromitsu Harimoto, Mattia G. Gollub, Eli N. Weinstein, Julie E. Norville, Elizabeth Wood

R&D, JURA Bio, Inc, Boston, MA



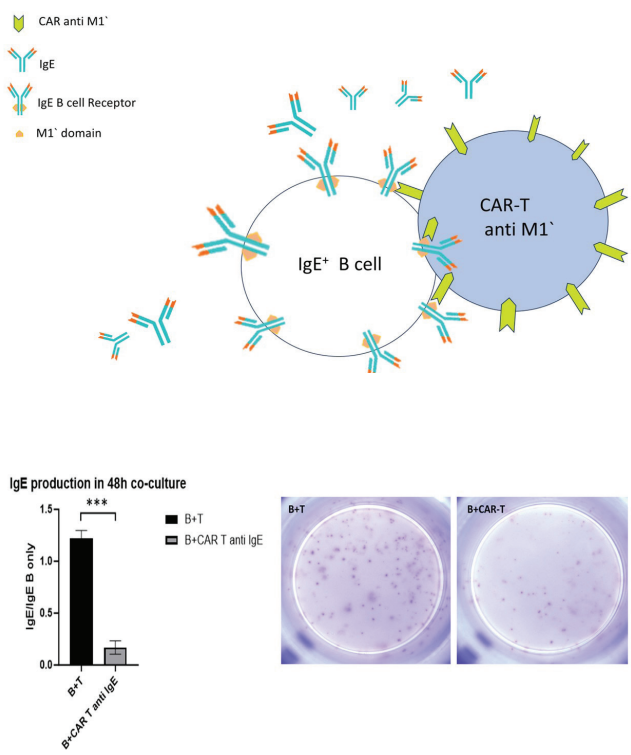
T cell mediated autoimmune diseases are driven by aberrant T cell recognition of innocuous peptides presented on major histocompatibility complexes I and II in healthy tissues. While the search space for peptide-MHC (pMHC) and TCR interactions is vast, there are a number of reported TCRs with crystal structure resolved cognate pMHC interactions. scFv based cell therapies targeting pan T cell markers have the potential to abrogate disease progression in autoimmune disease and T cell cancers, however targeting T cells in a non-specific manner carries significant risks such as immunosuppression, viral reemergence, cytokine release syndrome, neurotoxicity, and incomplete immune reconstitution in the case of bone marrow transplantation. Here, we present engineered major histocompatibility complex chimeric antigen receptors (eMHC-CARs), which functionalize the pMHC component of the pMHC-TCR immunological synapse to eliminate or tolerize TCR containing T cells which recognize a specified peptide driving pathogenesis. By functionalizing the pMHC trimer in crystal structure resolved pMHC-TCR interactions, we are able to target only T cells which interact with the specified peptide contributing to disease, leaving T cells without specificity to the pMHC complex untouched. To our knowledge, in addition to class I eMHC-CARS, we are the first to report human class II eMHC-CARs in human cells, and demonstrate that *in vitro*, and with preliminary *in vivo* mouse results, eMHC-CARs are specific, sensitive, and multifunctionalizable.

1822. Potent *In Vivo* Expansion of B Cells Engineered to Express Protective Antibodies

Grady Gastelum[1,2], Katrina Poljakov[1], Matthew Gray[3], Jennifer E. Adair[1], Justin Taylor[2]

[1]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Research Center, Seattle, WA,[2]Division of Infectious Diseases & International Health, University of Virginia, Charlottesville, VA,[3]Vaccine and Infectious Disease Division, Fred Hutchinson Cancer Research Center, Seattle, WA

The COVID-19 pandemic and an estimated 15-19 billion global respiratory virus infections annually showcase the significant risk respiratory viruses pose to public health. While vaccines have helped reduce this risk, inducing potent and durable protective antibodies against the major families of respiratory viruses remains a challenge. While antibody infusions can provide protection against respiratory viruses, protection is typically short-lived and can lead to viral escape. To overcome these challenges, our lab is developing a CRISPR-based method to engineer B cells to produce multiple potent and broad virus-specific antibodies to provide lifelong protection against multiple respiratory viruses. We have previously shown that primary B cells can be engineered to express a Respiratory Syncytial Virus (RSV)-specific antibody in place of the antibody naturally expressed by cells. Following adoptive transfer of a high number of engineered and differentiated B cells into wild-type mice, protective levels of antibody were achieved seven days post transfer and returned to baseline levels 18 days later. Building off this and other studies, we now focus our efforts on investigating and optimizing the long-term protective ability of antibody-engineered B cells. Here we demonstrate that adoptive transfer of a low number of engineered B cells followed by *in vivo* antigen priming augments the antigen-specific immune response to achieve protective titers within 7 days. Ongoing work in our lab is exploring the durability of these responses and how to optimize them, with the goal of maintaining high antibody titers with minimal need for antigen boosting.



Experimental Overview: Primary mouse B cell engineering is accomplished through electroporation of Cas9 ribonucleoprotein targeting the heavy chain locus and AAV-mediated gene delivery of the virus-specific antibody. The engineered B cells are then adoptively transferred into host mice followed by *in vivo* antigen priming injections.

1823. Chimeric Antigen Receptor T Cells Targeting IgE B Cell Receptor Successfully Eliminate IgE-B Cells and Specifically Abolish IgE Production *In Vitro*

Tali Stauber[1], Miri Fried Horowitz[1], Maayan Zaba[1], Iris Dotan[1], Fred Finkelman[2], Alessio D. Nahmad[3], David Ochayon[1], Eldar Carmel[4], Adi Barzel[1]

[1]Tel Aviv University, Tel Aviv, Israel,[2]Cincinnati Children's Hospital, Cincinnati, OH,[3]Belinson Hospital, Petach-Tikva, Israel,[4]Sheba Medical Center, Ramat Gan, Israel

The prevalence of IgE mediated allergies has risen dramatically in the westernized world. Current treatment for allergies fails to offer a robust cure. In an attempt to eliminate all IgE producing cells, other groups have designed chimeric antigen receptor (CAR) T cells targeting IgE. However, these CARs target IgE epitopes found both on secreted IgE and on IgE B cell receptors (BCRs), which are membrane bound IgE antibodies. Thus, these previous anti-IgE CAR designs were sensitive to both activation and saturation by free IgE and in some cases also by FcεR bound IgE. In order to specifically target IgE expressing B cells, rather than free IgE, Genentech has developed the monoclonal antibody (mAb) Quilizumab. Quilizumab targets an epitope on the M1' domain, found only in the longer of two splice isoforms of IgE BCRs. In adults with inadequately controlled allergic asthma, Quilizumab reduced serum total and allergen-specific IgE by 30-40 %, but had no impact on asthma exacerbations, lung function, or patient-reported symptom measures. We conjecture that Quilizumab based CAR T cells, will outperform the Quilizumab mAb as well as previous CAR designs, and may serve as a much needed remedy for IgE mediated allergy. Quilizumab based 2nd generation CARs were expressed on human primary T lymphocytes via retroviral transduction. We tested the potency of the therapy on engineered NALM-6 cell line expressing membranal IgE (mIgE, modeling a BCR). mIgE-targeting CAR-T cells successfully eliminated IgE$^+$ expressing NALM6 cells but not wild type NALM6 or NALM6 that express the short isoform of mIgE (lacking the M1` segment). This targeted elimination was accompanied by increase of gamma interferon production by the effector cells. Importantly, the addition of high amounts of free-IgE to the culture did not affect the activity of the CAR-T against its target. To test the potency of the CAR-Ts against primary IgE$^+$ B cells, which are extremely sparse in blood, we used B cells from human tonsils and induced their class switching to IgE. Upon 2 days of co culture of isolated B cells with CAR-T cells, or non-transduced T cells as control, our CAR-T cells abolished IgE production, as measured by ELISA, and eliminated IgE secreting cells, as evident by ELISPOT. This elimination was specific to IgE, as IgG production was unaffected. In the near future, we plan to examine the potency of our therapy in vivo, in a mouse allergy model. Since mice do not express the M1` domain we designed transgenic mice in which the murine extra membranal proximal domain (EMPD) is replaced by the human one. CAR-T cells targeting membrane bound IgE are thus envisioned as a curative therapy for IgE mediated allergies, providing sustained surveillance against IgE$^+$ B cell resurgence and relieving the patient from all atopic diseases.

Friday Posters: In Vivo Therapy Approaches

1825. Circular RNA-Based CAR Cell Therapy for Potent and Long-Lasting Anti-Tumor Activity

Ashlesha Odak, Kshitij Parag-Sharma, Kelvin Muriuki, Aidan Simpson, Monica L. Jaffee, Rio S. Boothello, Weiyu Zhao, Brett Rickeard, Shivani Gaikwad, Jackson H. Lange, Britt A. DiMarzio, Sanjana Manja, Emily A. Clinton, Eric Lebish, Kavya Borde, Lauren Gambill, Sarah C. Bening, Alexander C. Lemaire, Wuhbet D. Abraham, Ryan T. Sowell, Jaspreet S. Khurana, Prashant R. Nambiar, Jacob R. Becraft, Tasuku Kitada

Strand Therapeutics Inc., Boston, MA

Stably integrated ex vivo engineered Chimeric Antigen Receptor (CAR) T cell therapy approaches have been effective for the treatment of hematological malignancies. However, broader patient access is limited by extremely complex, time-consuming, and expensive manufacturing. Recently, safety concerns have also arisen from random vector integration leading to secondary malignancies that necessitated black box warnings by the FDA. Additionally, these therapies may face antigen loss or escape-related relapses that require re-treatment with the same or different CAR target but existing modalities and manufacturing processes pose challenges owing to the long time period from target validation to the availability of an injectable drug product.

In vivo engineered, mRNA-based cell therapies can overcome these limitations of current cell therapies. However, for such RNA-based cell therapies, limited duration of conventional mRNA encoded CAR expression may preclude their ability to drive complete and durable clinical responses. To address the transient nature of mRNA expression and improve efficacy, we developed circular RNA (circRNA) sequences that drive higher levels and longer duration of CAR expression. We demonstrate that these novel circRNAs drive long-lasting and superior levels of CAR expression in freshly isolated non-activated primary human T cells as well as freshly isolated non-activated human peripheral blood mononuclear cells (PBMCs). These circRNA-CAR cells drive potent cytotoxic responses against target tumor cells in short and long-term co-cultures as well as upon multiple rounds of target tumor cell exposure. We further tested these circRNA-CAR cells in a relevant tumor mouse model and have compared efficacy over linear modified RNA and lentivirally transduced CARs over time. Our RNA-based approach thus enables potent activity and offers the added advantage of swiftly addressing antigen loss or escape-related relapses while significantly reducing manufacturing complexity and vein-to-vein time for patients.

1827. Characterization of VivoVecTM Pharmacokinetics Following Intravenous or Intranodal Administration Using a Vector RNA Genome Method

Soo Min Koo

Umoja BioPharma, Seattle, WA

Umoja is developing the VivoVecTM platform, a lentiviral vector designed to generate CAR Tcells in vivo. We have previously shown that in vivo administration of VivoVecTM particles (which are surface engineered to bind, activate, and transduce T cells) results in specific generation of CAR T cells with potent anti-tumor activity in preclinical models. Because VivoVecTM will be administered directly to patients, an understanding of in vivo biodistribution and pharmacokinetics of the VivoVecTM particles is critical; We developed a reverse transcription (RT)-PCR based method to detect viral RNA genomes present in whole blood samples and used the assay to evaluate VivoVecTM pharmacokinetics (PK) following intravenous (IV), intraperitoneal (IP), or intralymph node injection in mouse and canine models. VivoVecTM RNA genomes in blood were measured at multiple timepoints (5 min to 1 week) in 2 preclinical animal models via three routes of administration (ROA): IV, IP, and intralymph node injection in beagles, and IV injection in C57BL/6 mice. mRNA was isolated from whole blood, reverse transcribed into cDNA, and subsequently amplified by qPCR using product sequence specific primers. Negative control without reverse transcriptase confirmed absence of background. Spike-recovery studies were performed with known vector copy numbers into PBS and animal blood as positive controls to analyze linearity, precision, reproducibility and sensitivity of the assay. The vector RNA genome assay demonstrated reproducible extraction of high purity VivoVecTM particle mRNA from canine and mouse whole blood samples, including over freeze-and-thaw cycles of blood samples, down to a sensitivity of 115 transducing units (TU)/ml blood in spike-recovery studies. In a mouse PK study, when 4.2×107 transducing unit (TU)/animal VivoVecTM (a dose known to generate functional CAR T cells in tumor-bearing humanized mice) was injected IV, vector genomes were detected in peripheral circulation up to 2 hours post administration. Peak VivoVecTM RNA genome levels were detected at 5 minutes post administration, with a 700-fold reduction in vector genomes observed between 5 minutes and 2 hours post administration. At later timepoints, all samples were below the detection limit of the qPCR method (10 copies/well). In a canine biodistribution studies assessing RNA genomes at multiple timepoints (5 min to 1 week post administration), similar VivoVecTM PK profile was shown as mice when administered IV and VivoVecTM RNA genomes were detected in blood samples 24 hours after IP injection. However, VivoVecTM RNA genomes were not detected in blood following intra-lymph node injection. In conclusion, we have developed an RNA genome assay that successfully detected our lentiviral drug production in whole blood with high sensitivity following multiple ROAs. At pharmacologically active doses VivoVecTM particles demonstrated a short half-life in blood following IV administration and remained detectable in the circulating blood stream for only approximately 2 hours.

1828. Compositional Optimization of Lipid Nanoparticle for Intracellular Delivery of Proteins

Xiaoya (Julia) Lu, Yining Zhu, Sachin Kammula, Hai-Quan Mao

Johns Hopkins University, Baltimore, MD

Statement of Purpose: Protein-based therapeutics targeting intracellular entities, such as the CRISPR-Cas9 system, have been employed in gene and immune therapies for diverse diseases. Despite considerable efforts, an efficient delivery system for the *in vivo* intracellular delivery of protein therapeutics is still lacking. Lipid nanoparticles (LNPs) have been engineered as carriers for mRNA encoding antigens with validated biosafety profile.[1] However, their application in protein delivery has been relatively unexplored. Previously, our lab has developed a multi-step screening method to optimize the type of helper lipid and component ratios in an LNP formulation for gene delivery.[2] In this study, we aim to optimize the formulation for gene-editing proteins including Cre recombinase and Cas9 using this platform. In detail, with *in vitro* screening with HEK293 Ai9 cell line, and cluster-mode *in vivo* screening in Ai9 mice, we aim to discover formulations potentially targeting the spleen for T cells and B cells gene editing. **Methods:** As shown in Figure 1**a**, we generated a 486-formulation LNP library with DLin-MC3-DMA as ionizable lipid, cholesterol, DMG-PEG2000, and one of six helper phospholipids that were previously used in FDA-approved or experimental LNP formulations. By varying the following parameters: (1) combined molar percentage of DLin-MC3-DMA and helper lipids; (2) weight ratio of cholesterol to DMG-PEG2000; (3) weight ratio of DLin-MC3-DMA to helper lipid; and (4) the weight ratio of total weights of lipid to protein, formulations were generated with Cre recombinase to screen *in vitro* on HEK293 Ai9 cell line. The top 50 formulations encapsulating Cre recombinase were then divided into 10 clusters and administered intravenously (*i.v.*) into Ai9 mice for i*n vivo* cluster-mode screening. Analyzed by flow cytometry, top three clusters with the highest gene editing efficiency in spleen immune cells will be selected and tested individually on Ai9 mice. **Results:** To select LNP formulations that can successfully deliver proteins with intracellular targets, we first evaluated gene editing efficiency of the whole library treated encapsulating Cre

recombinase and measured the percentage of tdTom expression in HEK293 Ai9 cells (Fig. 1**b**). The composition variation has generated significantly different gene editing efficiencies under each helper lipid. Of 486 LNP formulations, the 50 top-performing LNPs are shown in Figure 1**c**. To evaluate these formulations' *in vivo* systemic gene editing efficiency, the LNPs with the best *in vitro* performances were tested by *i.v.* injections on Ai9 mice for cluster-mode screening. Three clusters have shown promising tdTom expression levels in T cells and B cells (Fig. 1**d-e**). The individual formulations within these clusters will be further evaluated. **Conclusion:** This LNP screening platform allows for the identification of the best performing LNPs for intracellular delivery of protein potentially for gene editing. In the cluster-mode screening, we see a high level of gene editing events in immune cells in the spleen in multiple clusters, which will serve as solid evidence for our next individual formulation testing.

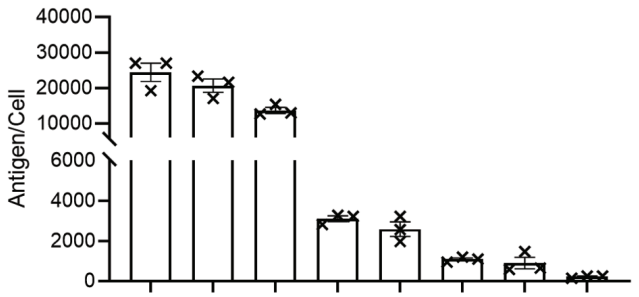
1831. Selective and Efficient *In Vivo* HSC Transduction in Humanized Mice Mediated by Capsid Modified HDAd Vectors

Aphrodite Georgakopoulou, Hongjie Wang, Chang Li, Andre Lieber

University of Washington, Seattle, WA

We developed an *in vivo* HSC gene therapy approach that consists of HSC mobilization and intravenous injection of HDAd vectors that target either CD46 or desmoglein 2 (DSG2), receptors that are expressed at high levels on HSCs. While we have demonstrated safety and efficacy of the *in vivo* approach in CD46-transgenic mice and rhesus macaques, studies in mice with a humanized hematopoietic system could facilitate its potential clinical translation. NBSGW mice engraft cryo-preserved human CD34$^+$ cells in the bone marrow without preconditioning, however human chimerism in peripheral blood is usually low, and mobilization of human cells by G-CSF/AMD3100 for *in vivo* HSC transduction is inefficient. We show that low-dose total body irradiation (100Rad) or busulfan treatment (12.5mg/kg) increases the percentage of human CD45$^+$ cells in PBMCs two- and five-fold, respectively. In low-dose busulfan conditioned humanized mice, at 6 weeks after CD34$^+$ cell transplantation, G-CSF/AMD3100 mobilization (over 7 days) resulted in >30,000 human CD34$^+$ cells in the periphery at 40 min after AMD3100 injection (15% of human CD45$^+$ cells were CD34$^+$ positive). At the peak of mobilization, humanized mice were intravenously injected with a CD46-targeting HDAd5/35++ vector or a DSG2-targeting HDAd6/3+-GFP vector. Four weeks later, mice received one round of O^{6}BG/BCNU *in vivo* selection treatment which resulted in an increase in GFP marking within peripheral blood human CD45$^+$ cells. At week 7 after *in vivo* HSC transduction, the percentages of GFP$^+$/CD45$^+$ cells in the periphery were 7±3.8% and 16.1±8.83% in HDAd5/35++-GFP and HDAd6/3+-GFP *in vivo* transduced mice, respectively. A similar pattern of GFP marking rates were found in different human lineages (CD19, CD33, CD3, CD235a, CD34) in the bone morrow of these mice. These data show that in humanized mice, human HSCs can be efficiently mobilized with GCSF/AMD3100 and *in vivo* transduced with HDAd vectors. We also demonstrated efficient HSC mobilization within hours by other agents, including the small molecule cxcr2 inhibitor tGROβ and the VLA4 inhibitor WU-106 (given together with AMD3100). Furthermore, we used the humanized mouse model to test a new HDAd vector platform that targets two HSC receptors, an HSC attachment receptor (CD46) and an HSC internalization receptor ($\alpha_6/\beta_{1/4}$integrins (CD49f). CD49f expression is largely restricted to stem cells, specifically to primitive HSCs. Retargeting to this receptor was achieved by replacing the RGD (Arg-Gly-Asp) motif within the Ad5 penton with the functional core motif of laminin chain A IKVAV (Ile-Lys-Val-Ala-Val). After *in vivo* HSC transduction in humanized mice, we found significantly higher percentages of GFP$^+$ cells within CD34$^+$ subsets that are enriched for primitive HSCs with the laminin-modified vector compared to the parental vector. For example, 7.6±1.69% and 17.3±3.4% GFP-positive CD34$^+$/CD38$^-$/CD45RA$^-$ cells were measured in the bone marrow of mice, 3 days after *in vivo* transduction with HDAd5/35++-GFP and HDAd5/35++_laminin, respectively. The transduction efficiency in more committed progenitors was not significantly different. This suggests that CD46/CD49f-targeted vectors more selectively transduce primitive HSCs *in vivo*. Furthermore, we found that the double-retargeted vector triggered less proinflammatory cytokine release after intravenous injection into mice. Taken together, this indicates that this new HDAd5/35++-laminin vector platform is safer and more selective for primitive HSCs after *in vivo* transduction. In summary, we demonstrated that humanized mice are a suitable model for validating and optimizing our *in vivo* HSC gene therapy approach.



1832. HSC Antigen Density and Changes with Mobilization: Important Considerations for *In Vivo* HSC Targeting and Depletion

Justin Thomas, Dnyanada Pande, Mark R. Enstrom, Hans-Peter Kiem, Stefan Radtke

Fred Hutchinson Cancer Center, Seattle, WA

Hematopoietic stem cell (HSC) gene therapy is a promising treatment option for a variety of genetic blood diseases/disorders. However, current approaches are performed *ex vivo*, require genotoxic myeloablation, and depend on sophisticated infrastructure similar to bone marrow transplantation. Thus, *ex vivo* HSC gene therapy is expensive, geographically restricted, and can cause conditioning-related side effects. Direct application of HSC-targeted gene therapy agents in vivo would overcome these bottlenecks. Simultaneously, new conditioning/selection strategies including epitope engineering are developed to selectively remove endogenous or unmodified HSCs using non-genotoxic antibody-based conditioning regimens, respectively. Both approaches depend on HSC-specific antigens for either targeted delivery or selective killing. However, HSC antigens are

often not restricted to HSCs only. These so-called "antigen sinks" can reduce the targeting efficiency, lead to unwanted ablation of immune cells, or cause off-target effects. Here, we investigated the expression and cell-surface abundance of commonly targeted HSC antigens using bulk/single-cell RNAseq and quantitative flow-cytometry. We further studied the impact of mobilization on the transcription and cell surface presentation of antigens to inform the best route for the in vivo administration of HSC-targeted agents. Single-cell and bulk RNAseq revealed high expression of CD34, CD45, and CD164, low expression of CD133 and CD117, and very low to undetectable levels of CD33, CD90, and EPCR. Upon mobilization, expression of HSC antigens decreased but patterns remained unchanged. Antigen quantification by flow-cytometry demonstrated a very high CD164, CD34, and CD45 presentation on HSC (Figure 1). Significantly lower abundance of CD90, CD133, CD117, CD33, and ECPR was seen (Figure 1). Of note, surface expression of CD117, CD33 and CD164 was reduced on HSCs after mobilization, whereas all other markers remained stable or increased in abundance. Finally, assessment of total antigen within the bone marrow and peripheral blood demonstrated high expression of CD45, CD33, and CD164 on non-HSCs. Our data shows that the selection of the antigen for in vivo HSC gene therapy, ablation, or selection strongly depends on the abundance, mode of administration, and off-target presentation. Most highly expressed antigens were either impacted by mobilization or not HSC-specific, while more HSC-specific antigens were only presented at a low density. Important for the in vivo application of gene therapy or selection agents, presentation of the antigen outside the hematopoietic system has to be considered to reach high on-target specific, avoid antigen sinks, and reduce unwanted off-target effects.

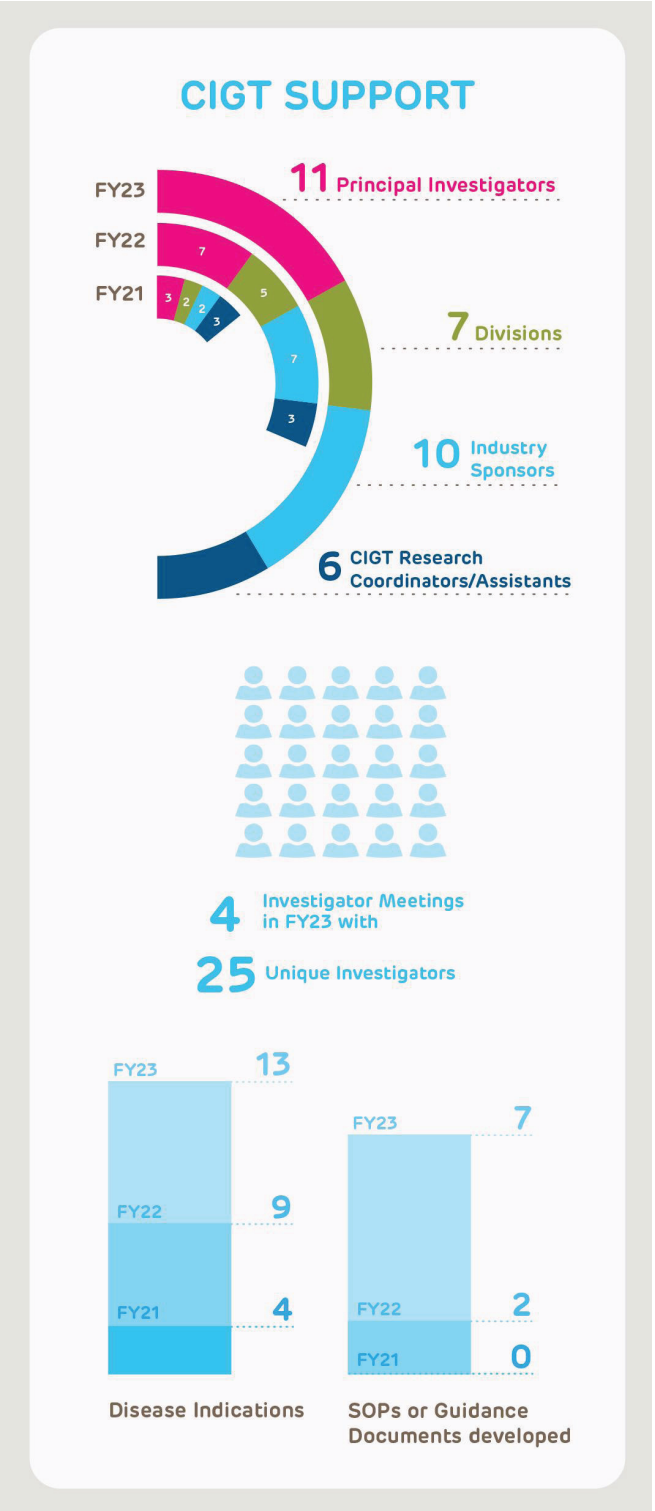
1833. Intravital Visualization of Angiogenesis Using Endothelial Progenitor Cells in Diabetic Peripheral Ischemia Mouse Models

Hyungjin Kwon, Kubra Akyildiz, Hyunseok Kim
IVIM Technology, Songpa-gu, Seoul, Korea, Republic of



Understanding the physiological mechanisms of angiogenesis is crucial in researching treatments for various metabolic disorders and cancers. Particularly, given the detrimental effects of diabetes-induced microvascular damage leading to necrosis in the extremities and retinal complications, comprehending angiogenesis becomes pivotal. Through vascular regeneration, there is potential for preventing and treating such diseases, thereby significantly impacting the quality of life. In this study, we aimed to visualize angiogenesis using *in vivo* fluorescence microscopy. We employed a commonly used diabetic hind limb ischemia mouse model. After inducing diabetes, we performed venous ligation in the hind limb and injected endothelial progenitor cells (EPCs) to observe cell engraftment and the extent of vascular formation over time. To establish the mouse model, we induced diabetes by intraperitoneal injection of streptozotocin to Balb/c-nu/nu, monitoring blood glucose continuously. Subsequently, we surgically induced hind limb ischemia by ligating and cutting two veins in the hind limb with black silk. In the experimental group, endogenous EGFP-EPCs were injected around the incision site, while the control group did not receive this injection. Following this, we observed the formation of neovessels using FSD647 fluorescent dye-conjugated CD31 antibodies, visualizing the process with a different fluorescence. On the third day after EPC injection, we observed the emergence of GFP-positive new vessels, with some vessels showing colocalization with the CD31 marker. By the seventh day, we could visualize GFP-positive vessels bypassing the incision site. On days 14 and 21, GFP-positive vessels connecting the incision site were observed. In this study, we utilized *in vivo* microscopy to track the progression of angiogenesis in the hind limb ischemia mouse model. The *in vivo* microscope proves indispensable for vascular research, offering the unique advantage of high-resolution, real-time observation of blood vessel generation and structure. Furthermore, its ability to facilitate repetitive imaging within a single subject reduces potential artifacts arising from individual variations, underscoring its significance in the study of blood vessel.

1834. A Centralized Multi-Disciplinary Approach for Safe and Efficient Delivery of *In Vivo* Gene Therapy

Julianne LaRosa[1], Sarah McCague[1], Juliana Small[1], Jennifer Harding[2], Amy Tara Waldman[3], Benjamin Samelson-Jones[1], Susan Matesanz[1], Lindsey A. George[1]
[1]Clinical In Vivo Gene Therapy, Children's Hospital of Philadelphia, Philadelphia, PA,[2]Clinical In Vivo Gene Therapy, Children's Hospital of Philadelphia, Philadelphia, PA,[3]Clinical In Vivo Gene Therapy, Children's Hospital of Phliadelphia, Philadelphia, PA

Recent clinical successes with adeno-associated virus gene therapy highlight the potential for gene-based therapies to transform the care of patients with monogenic disorders. Clinical gene therapy efforts have historically been siloed within clinical divisions based on disease-specific expertise. This creates communication challenges and hurdles to the standardization of gene therapy research and practice within and across institutions. The increasing number of investigational and FDA approved gene therapy products underscores the need for gene therapy centers in hospital systems across the country that are equipped with the clinical, research, and administrative infrastructure to administer gene therapy drugs safely and efficiently. The Clinical In Vivo Gene Therapy Group (CIGT) was established in 2021 at the Children's Hospital of Philadelphia (CHOP) to provide centralized support for gene therapy efforts throughout the institution. The research group includes physicians, clinical investigators, regulatory specialists, clinical research coordinators, operation specialists, and a multidisciplinary consult team. CIGT is focused on the delivery of gene therapy for both investigational and commercial products across clinical divisions. In order to address emergent toxicities surrounding

gene therapy, CIGT formed a clinical consult service composed of physicians from hematology, cardiology, nephrology, hepatology, neurology, immunology, and metabolism. On-call physicians follow the patient, lead multidisciplinary case discussions, and provide consensus recommendations. An automated institutional registry within the electronic medical record platform was also developed to implement recommended lab safety monitoring as well as track long-term safety and efficacy outcomes. CIGT provides interdisciplinary opportunities for its growing network of clinicians and scientists to support continued education and to foster collaboration. Working closely with hospital leadership and administration, CIGT provides guidance and creates best practices related to the successful onboarding of gene therapy products, covering all aspects of the process such as manufacturer purchasing agreements, informed consent, EMR templates, patient education, and best clinical practices. CIGT's infrastructure establishes a framework to safely and efficiently conduct in vivo gene therapy trials as well as implement state-of-the-art clinical care to optimize patient outcomes. Thus far, CIGT services have treated more than 120 patients from 15 countries with investigational and commercial in vivo gene therapy products. CIGT supports 11 principal investigators across 7 clinical divisions (hematology, ophthalmology, neurology, endocrinology, metabolism, audiology, and cardiology) with 16 ongoing clinical trials across all phases of the product lifecycle. The program's success can be attributed to its cross functional team and prioritization of safety, education, and collaboration. Through its various initiatives and responsive infrastructure, CIGT enables the responsible growth of in vivo gene therapy at CHOP to ensure continued, safe access to treatments for patients with rare genetic disorders.

1835. Scoring-Based High-Throughput Screening Processes for Promoting the Accuracy of *In Vivo* Directed Evolution

Hongyoung Choi[1], Soonil Kwon[1], Sung Jin Lee[1], Subin Cho[2], Jinyoung Kim[2], Dohoon Kim[3], Youngbin Park[3], Changmin Kang[1]

[1]GluGene Therapeutics, Seoul, Korea, Republic of,[2]Yonsei University, Seoul, Korea, Republic of,[3]GluGene Therapeutics, Daejeon, Korea, Republic of

Adeno-associated virus (AAV) has been utilized as a delivery vehicle for in vivo gene therapy due to its efficacy and safety. Nevertheless, wild-type AAVs pose challenges such as off-targeting and immune responses. Directed evolution emerges as the most potent method for engineering novel AAV vectors capable of addressing these issues. Through the application of directed evolution, coupled with Next-Generation Sequencing (NGS) and in silico analysis, high-throughput screening is facilitated to identify novel AAV vectors. Using barcode matching consensus, we established a long-read sequencing system that precisely reads over the entire capsid region. This allows us to trace the mutations selected AAV vectors have by searching the matched barcode sequences. We introduced a 7-mer peptide insertion and an error-prone capsid library based on wild-type AAV1. Through in vivo selection in several mouse disease models, we constructed an in silico score database of selected AAV variants. The scores reflect in vivo properties such as target cell specificity and off-target effects. It is essential that these scores accurately represent the properties for the high-throughput screening process. To demonstrate this, we conducted in vivo validation for high-score AAV variants and confirmed that the properties follow the trend of the scores. This consistency enhances the feasibility of the high-throughput screening system. We anticipate that this study will provide a more sophisticated AAV vector engineering platform.

1836. Universal ddPCR Assay for Quantifying Cellular Kinetics and Biodistribution of CAR-T Cell Therapies in Preclinical and Clinical Trials

Hyun-Jung Kim, Hui Liu, Eric Lachacz, Anton AI Rosenbaum, Sonia Terrillon

1Integrated Bioanalysis, Clinical Pharmacology & Safety Sciences, R&D, AstraZeneca, South San Francisco, CA

Chimeric antigen receptor (CAR)-T cell therapy is a remarkable breakthrough in adoptive cell therapies with promising achievements in the treatment of blood-related cancers. This rapidly growing class of biotherapeutics requires sophisticated bioanalytical assays to support preclinical and clinical studies. Droplet Digital PCR (ddPCR) is an emerging innovative technology in bioanalytical laboratories enabling absolute and sensitive quantification of therapeutic transgenes employed in CAR-T therapies. However, there are limited bioanalytical guidelines for the validation of performance for pre-clinical and clinical sample analysis using ddPCR. Here, we describe developing and validating a universal ddPCR assay and critical considerations for ddPCR-specific assay deployment for use across multiple autologous CAR-T therapy assets. Briefly, primers and a probe targeting an essential element of the lentiviral vector used for CAR-T cell generation were designed. We then employed the universal CAR-T ddPCR assay for absolute quantification of CAR transgene copies in the blood and tissues of xenograft mice after administration of CAR-T cells. These preclinical data informed the cellular kinetics, biodistribution, and safety profiles to support IND applications of multiple products. The universal assay was then qualified and validated in a fit-for-purpose manner to support clinical studies. The qualification and validation demonstrated the assay to have acceptable accuracy, precision, linearity, dilutional linearity, sensitivity, specificity, matrix effect, and extraction efficiency. Briefly, at least two-thirds of replicates for each sample must have ≥10,000 accepted droplets. For the validation run, all plates should have three different levels of positive control (PC) and one non-template control (NTC) in triplicates. The mean of at least two-thirds of replicates for each of the high and middle PCs must have %RE ±30% of the expected target copies/well with %CV ≤ 30% (%RE ±55% and %CV ≤55% for low PC). For linearity, R^2 of the observed vs. expected copies/well determined by the assay of six different QC levels in triplicate must be ≥ 0.980 across the range of tested QCs. For specificity, the mean value of the NTC and matrix-only controls must be < 2.5 copies/well (50% of anticipated LLOQ). Since there is limited regulatory or industry guidance on extraction efficiency acceptance criteria, DNA extraction efficiency from five different levels of CAR-T cells spiked into the blood matrix should be evaluated. Next, we deployed the validated universal ddPCR assay in clinical studies. Finally, we describe our view on the best practices and critical considerations for ddPCR assay validation and deployment. The universal ddPCR assay approach and the deployment and validation strategies described herein can be followed to enable the transfer and use of high-quality ddPCR assays across multiple cell therapy products in preclinical and clinical studies.

1837. Methodologies of High-Throughput Screening Platforms to Enhance the Successful Rates of *In Vivo* Directed Evolution

Soonil Kwon[1], Sung Jin Lee[1], Hongyoung Choi[1], Subin Cho[2], JinYoung Kim[2], Dohoon Kim[1], Youngbin Park[3], ChangMin Kang[1]

[1]GluGene Therapeutics, Seoul, Korea, Republic of,[2]Yonsei University, Seoul, Korea, Republic of,[3]GluGene Therapeutics, Daejeon, Korea, Republic of

Adeno-associated viruses (AAVs) have recently emerged as potent gene carriers for numerous in vivo gene therapy trials. However, delivering AAVs, typically naturally occurring AAVs, specifically to targets while mitigating their exposure to neutralizing antibodies still poses significant challenges. Engineering external capsids has been considered a critical strategy to address these issues. In this context, we present a convergent methodology that utilizes directed evolution combined with in silico high-throughput iteration processes to create novel AAV capsids, enhancing their infectivity for specific targets. AAV capsid libraries were established through the capsid engineering method, employing 7-mer peptide insertion and error-prone PCR with random point mutations. We introduced random barcode sequences to enhance library iteration efficacy and high-throughput screening feasibility. Subsequently, we constructed a database composed of selected capsid sequences based on in silico scoring. Importantly, variants that received high scores through our in silico iteration process exhibited augmented tropism for targets in animal models, validating the elevated accuracy of our established iteration and scoring system. We will discuss in detail the methodologies and algorithms devised

to enhance the accuracy of in vivo directed evolution, combined with our in silico vector engineering platform, for developing novel AAV vectors with improved targeting capabilities.

1838. The Impact of Primary Myoblasts on Macrophage Polarization *In Vitro*

Ananya Goyal[1], Trevor R. Cardinal[2]

[1]California Polytechnic State University, San Luis Obispo, San Luis Obispo, CA,[2]Cal Poly, San Luis Obispo, CA

Peripheral Artery Disease (PAD) is characterized by the buildup of atherosclerotic plaque in the lower extremities that leads to downstream ischemia and affects roughly 200 million people worldwide. Revascularization procedures are available, however, 22% of PAD patients are left amputated. Alternatively, a potential cell therapy avenue involves stimulating arteriogenesis. In arteriogenesis, vessels around an occluded artery expand to form a bypass to restore blood flow. Bone marrow mononuclear cells (BM-MNCs) have been evaluated as candidates for PAD, however, in large trials there was little evidence of increased arteriogenesis. One limitation is that transplanted BM-MNCs are separated from their niche and are unable to communicate effectively with the myo-vascular niche, rendering them less effective than a tissue resident progenitor cell. Myoblasts are proposed as a potential cell therapy candidate for arteriogenesis due to their innate proximity to the musculature surrounding collaterals. Previously, we found that myoblasts can increase collateral capillary arteriogenesis in lean mice of a strain that possess fewer native collaterals and collateral arteriogenesis in mice with diet induced obesity. Macrophage recruitment is impaired during arteriogenesis in DIO (diet-induced obese) mice, implying that the cell type critical for arteriogenesis. Studying the relationship between macrophages and myoblasts is critical for understanding how to stimulating arteriogenesis. A relationship between macrophages and myoblasts has already been characterized in skeletal muscle regeneration. Post-injury, there is a phenotypic switch from the pro-inflammatory M1 macrophages to the pro-regenerative M2 phenotype. This switch assists regeneration initiation and coordinates myogenic events. Knowing that macrophages and myoblasts work in tandem for skeletal regeneration provides evidence that their established ability to communicate can be utilized in other regeneration events. Furthermore, arteriogenesis is orchestrated by macrophages where M1 macrophages make the phenotypic switch towards the M2 phenotype. This switch promotes arteriogenesis and is necessary for revascularization. The purpose of this study is to observe whether primary myoblasts are the drivers of this phenotypic switch from M1 to M2 macrophages *in vitro*. In this study, we found that upon *in vitro* coculture of RAW 264.7 macrophages and primary myoblasts, M0 and M1 macrophages make this switch towards M2 after 48 hours, indicated by a higher axial ratio, a marker of M2. These data imply that myoblast signaling induces regenerative macrophages in vitro, and therefore may drive this polarization in vivo. Overall, the purpose of this research was to determine the impact that coculture with primary myoblasts would have on RAW 264.7 macrophage polarization. It was found that coculture drove M0 and M1 macrophages towards an M2-like phenotype. Together these discoveries push us closer to developing a cell therapy to treat PAD patients and can help patients on their last limb.

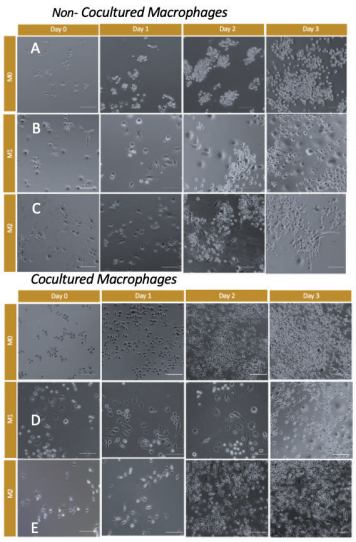


Figure 1. Differences in Macrophage Morphology in Cocultured with Primary Myoblasts vs Non-cocultured across 72 hours. A) Non-cocultured M0 macrophages across 72 hours (days 1-3). B) Non-cocultured M1 macrophages across 72 hours. C) Non-cocultured M2 macrophages across 72 hours. D) M0 macrophages cocultured with primary myoblasts before coculture (day 0) and across 72 hours. E) Cocultured M1 macrophages cocultured with primary myoblasts before coculture and across 72 hours. F) Cocultured M2 macrophages cocultured with primary myoblasts before coculture and across 72 hours. Images obtained at 10x magnification with an EVOS phase contrast microscope. Scale bar = 100um.

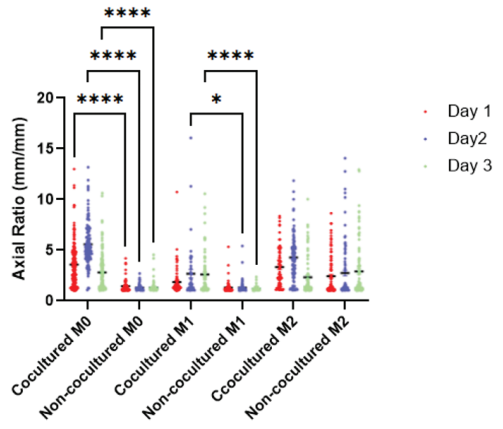

Figure 2. Differences in Axial Ratio of Macrophages Co-cultured or Not co-cultured with Myoblasts. Major Axis over Minor Axis of pre-polarized presumptive M0 (n = 105), M1 (n = 81), M2 (n=103) macrophages after 72 hours of co-culture compared to pre-polarized presumptive non-cocultured M0, M1, and M2 macrophages. Higher axial ratio is indicative of an elongated cell which provides evidence of M2 morphology. (*, p< 0.05 between co-cultured and not co-cultured of same time point for same polarization group.)

1839. *In Vivo* Delivery of an Engineered Lentiviral CAR19 Vector for the Treatment of Autoimmune Diseases

Daniel Grubaugh, Ronnie M. Russell, Debasish Boral, Aoi Wakabayashi, Corrine Little, Jeffery D. Foss, Julia L. A. Nguyen, James I. Andorko, Bruce C. Schnepp, Timothy D. Culp, Philip R. Johnson

Interius BioTherapeutics, Philadelphia, PA

Chimeric antigen receptor (CAR) T cell therapy has revolutionized the treatment of B cell malignancies and multiple myeloma. More recently, CAR T therapy has been highlighted as a potential intervention for autoimmune diseases. Conventional autologous CAR T therapy includes a multifaceted, complicated process including patient pretreatment using lymphodepleting chemotherapy, complex manufacturing and logistics for the generation and delivery of the

cell product which prolong vein-to-vein time. Alternative approaches meant to overcome these limitations, including allogenic CARs or faster manufacturing processes, are currently in clinical development. *In vivo* generation of CAR T cells is a fast-growing area of research, with the promise of reducing the complexity of autologous CAR generation, eliminating the need for lymphodepletion, and expanding patient access. We describe a lentiviral vector engineered to target CD7+ T cells and NK cells following a single intravenous administration to generate autologous CAR+ cells within the body, without lymphodepletion. This vector, INT2106, confers specific targeting of T cells and NK cells by pseudotyping the lentivirus with both a CD7 Binder and a detargeted VSV-G fusogen called "Gen 2.1 Fusogen". INT2106 delivers a fully human CAR19 transgene, resulting in the generation of functional CAR T and NK cells with specific activity against CD19+ B cells, the same cells targeted by autologous CAR T therapies being tested in clinical studies to combat autoimmune diseases. *In vitro* evaluation of INT2106 demonstrates specific transduction of CD7+ cells. Biologic activity of the fully human CAR19 was evident through specific killing of CD19-expressing B cell lymphoma lines across a range of Effector to Target cell ratios. This biological activity was confirmed to be dependent on CD19-expression on the tumor cells by data showing reduced killing of B cells with CD19 expression knocked out. Incubation of INT2106 with various B cell lymphoma lines or primary B cells isolated from healthy human donors does not result in the transduction of B cells, an important safety consideration regardless of whether the CAR cells are generated *in vivo* or *ex vivo*. An *in vivo* demonstration of INT2106 was performed using human CD34-engrafted NSG mice. Following treatment with INT2106 via a single intravenous tail vein injection, circulating B cells in vector-treated mice were depleted, with loss of CD19+ B cells across multiple tissues including the blood, spleen, and bone marrow. Coincident with B cell depletion, CAR19+ cells were detectable in the blood of treated mice, with peak concentrations measured approximately three weeks after administration. INT2106 treatment was well-tolerated with no vector associated safety signals observed. Taken together, these data suggest that intravenous administration of INT2106 can effectively target CD7+ cells, leading to functional CAR19+ cell generation and CD19+ B cell depletion, the intended biological effect. INT2106 is in development as an off-the-shelf treatment for autoimmune diseases without the need for patient preconditioning or cell manufacturing.

Friday Posters: Vector Product Engineering, Development, and Manufacturing

1840. Overcoming Traditional Limitations: GenScript's Advanced mRNA Applied Vector and Strain for Pertaining polyA Integrity and Efficient Plasmid Production

Xiaofei Long, Wenlu Zuo, Andrew Tsao, Qingwei Meng
GenScript Biotech Corporation, Nanjing, China

The burgeoning field of mRNA-based therapies and technologies, from personalized medicine to vaccine development, has catalyzed a growing demand for large-scale in vitro transcription (IVT) of mRNA. The prevalent methods for producing IVT mRNA typically utilize DNA templates derived from circular plasmids, offering efficient cloning of target DNA sequences and the advantages of straightforward bacterial propagation for rapid production. Among the various vectors, pUC57 and pVAX1 are particularly favoured by mRNA researchers. However, these traditional vectors are not without their challenges. They often face issues like less-than-ideal cloning efficiency, difficulties maintaining the stability and integrity of poly(A) sequences, and lower yields in plasmid production. These shortcomings can adversely affect the quality and quantity of IVT mRNA and prolong the preparation time for scalable IVT templates - a crucial aspect in therapeutic mRNA production and vaccine development. In response to these challenges, our team has developed a set of proprietary vectors, GS-mK and GS-CMV vectors, which are evolved versions of the conventional pUC57 and pVAX1 vectors, respectively. These vectors with built-in poly(A) tail sequences are specifically engineered for the efficient production of linearized IVT templates and many modifications include the removal of elements that negatively impact plasmid replication, DNA recombination, and poly(A) stability that enhance the PolyA integrity. Besides, Choosing the right bacterial strain for replicating plasmids with a poly(A) tail is crucial to maintaining the integrity of the poly(A) sequence. Bacteria strains exhibit varied levels of exonuclease activity, which can significantly affect the stability of the poly(A) tail in the plasmid DNA. However, even with some commercial strains to handle repetitive sequences, it may not fully resolve the instability issues associated with extended poly(A) sequences found in mRNA constructs. To tackle this challenge, GenScript has introduced a unique strain engineered to enhance the stability of poly(A) tails. The GenScript Poly(A) Strain v2 and v3 are composed of genetically edited genes or sequences, including *Rec*A, which have a direct or indirect impact on the recombination of cloned DNA. Extensive testing following cloning and large-scale plasmid preparation demonstrates its suitability for isolating plasmid clones that contain repeat elements like poly(A) tails.

1841. Breaking Barriers in Gene Therapy with Bacteriophage T4 Artificial Viral Vectors

Jingen Zhu, Venigalla B. Rao
Biology, The Catholic University of America, Washington, DC

The pursuit of effective gene therapy strategies has been significantly hampered by the limitations of existing viral vectors, particularly in the context of genetic disorders necessitating the delivery of large genes and/or genome editing complexes. Traditional viral vectors, such as adeno-associated viruses (AAVs) and lentiviruses, are limited by the cargo size, making them unsuitable for conditions like Duchenne muscular dystrophy (DMD), which is caused by mutations in the 2.2 MB dystrophin gene with an 11.2 kb coding region. We have developed a new bacteriophage-based approach to overcome these limitations by engineering bacteriophage T4 as an artificial viral vector (T4-AVV) for large gene delivery and genome remodeling. The T4 phage possesses a 120 × 86 nm capsid shell, capable of accommodating up to 171-Kbp therapeutic DNAs and thousands of protein copies. We engineered T4-AVVs by externally and internally incorporating various combinations of biomolecules, including DNA, RNA, proteins, and CRISPR ribonucleoproteins. Payload components are introduced

into the T4 capsid nanoparticles by sequential assembly *in vitro* using purified materials, and the assembled nanoparticles are coated with lipids to generate the AVVs. Remarkably, these T4-AVVs possess remarkable capabilities for delivering genetic material into human cells. They successfully packaged and delivered not only large genes, like the full-length dystrophin gene, but also performed complex genomic operations such as targeted genome editing, gene silencing, and site-specific recombination. These vectors demonstrated high efficiency in various applications, including the simultaneous delivery of multiple genes and proteins in their functional states. Furthermore, the T4-AVVs showed potential for broad applicability in gene therapy, offering a versatile and powerful tool for genome remodeling. Their ability to carry large genetic payloads and perform multiple genomic tasks in a single delivery system is particularly promising for treating disorders like DMD. The vectors' capacity to bypass the size limitations of traditional vectors opens new avenues for treating genetic disorders that involve large genes. In conclusion, the T4-AVVs offer a powerful tool for genome remodeling and broad applicability in gene therapy. In particular, AVVs in the future have the potential to transform therapies requiring delivery of large and multiple genes, genome editing machinery, targeted *in vivo* delivery, and personalized genetic medicine.

1842. Single-Use Fermenters for Plasmid and Minicircle DNA Production

[1]PlasmidFactory GmbH, Bielefeld, Germany,[2]Sartorius Stedim Biotech GmbH, Göttingen, Germany,[3]Sartorius Xell GmbH, Schloß Holte-Stukenbrock, Germany,[4]Sartorius Xell GmbH, Schloss Holte-Stukenbrock, Germany

There is a surge in demand for GMP-grade plasmid DNA as starting materials for manufacturing crucial viral vectors, especially for late-phase clinical trials and for commercialization. The employment of single-use systems reduces development times through higher batch to batch turnover, allowing quicker supply of clinical material. Single-Use fermenters have been well documented for animal cell culture applications whereas for microbial cultivations, two major limitations were noted: poor oxygen transfer capabilities and insufficient heat removal. The Biostat STR® Microbial single-use fermentation system has been designed specially to overcome these challenges. Following the recommendations for process engineering characterization by the DECHEMA expert group on single-use technology, a volumetric oxygen mass transfer coefficient (k_La) of up to 675 h^{-1}, a maximum specific power input of 3 kW/m^3 and a maximum cooling rate of 29 $K{\cdot}h^{-1}$ were noted. At the R&D facility of PlasmidFactory GmbH, the Biostat STR® Microbial with 40 L working volume was tested for the fermentation of optimal plasmid production strains of *Escherichia coli*. Our tests comprised of batch and fed-batch, small and large plasmids including those for the production of AAV vectors as well as a particularly adapted fermentation process for the production of *minicircle* DNA. In addition to cascading stirrer speed against the DO level, we set a second level of control through pure oxygen sparging (max. 7 $L{\cdot}min^{-1}$) during maximum stirrer speed (500 rpm). Temperature control at a stable 37 °C was successful throughout. Efficient single-use exhaust cooling ensured that the bag pressure never exceeded 10 mbar. A simple batch process yielded a maximum optical density after 16 h fermentation time. In terms of biomass yield per batch, DNA product yield per biomass as well as DNA product quality (plasmid DNA homogeneity), the Biostat STR® single-use fermenter offered similar results as compared to conventional stainless-steel fermenters. The purified plasmid DNA was successfully used for AAV production within HEK293 cells (AAV6 carrying a GFP reporter gene construct) at shake flask as well as 2 L Bioreactor scale. Measured genomic titer and capsid titer were similar to those achieved in parallel AAV production using DNA from stainless steel fermenters. In the *minicircle* fermentation, CGE analysis of the DNA product showed effective control of induction and the expected level of recombination to yield *minicircle* DNA in the supercoiled conformation. The DNA product after lysis was quantified to be 914 mg from a single batch which is expected to yield over 100 mg of pure *minicircle* DNA. One of the major product quality attributes is the absence of cross-contamination which forms the strongest case for single-use technology. This fermentation system proves that microbial cultivations in the single-use space are no longer a compromise on yield but rather represent a true possibility to shift from conventional sterilizable fermenters. For GMP, this becomes necessary to accelerate production while easing quality control challenges.

1843. Aldevron's Nanoplasmid™: A Next Generation Vector Manufacturing Platform for Gene and Cell Therapy

Jeremy Luke[1], Tyler Kozisek[1], Jason Devlin[1], Patrick Alfredo Paez[1], Denis Arutyunov[1], Aaron Carnes[2], James Williams[1], Seshidhar Reddy Police[3], Venkata Indurthi[1]

[1]Aldevron, Fargo, ND,[2]Aldevron, Lincoln, NE,[3]Aldevron, Boston, MA

The same plasmid manufacturing technology has been used for decades in vaccination, cell and gene therapy, and as a raw material in viral vector and mRNA production. While canonical *Escherichia coli* plasmids contain antibiotic resistance markers and have backbones that are greater than 2000 bp, smaller backbones were shown to have reduced cell-transfection-associated toxicity and transgene silencing. Aldevron's Nanoplasmid™ vector has a small backbone (<500 bp) and no antibiotic markers. It has proven to be a transformative replacement in various applications, offering greater safety and efficiency than traditional plasmids. Nanoplasmid vectors use the antibiotic-free *E. coli* maintenance system based on sucrose selection. Notably, these vectors also contain a specialized bacterial R6K replication origin in place of the traditional pUC origin, making the Nanoplasmid vectors replication-incompatible outside of a set of engineered strains. These features dramatically reduce the risk of horizontal gene transfer in case of inadvertent exposure to the plasmid. In addition, Nanoplasmid vectors can be produced in high yields (1-2 gram/L) and quality in bacterial fermentation using proprietary strains and growth conditions. Nanoplasmid transposon vectors and Nanoplasmid Homology-Directed Repair (HDR) donor template vectors for CRISPR/Cas9 mediated gene editing demonstrated superior cell viability and gene integration frequencies during non-viral CAR-T cell manufacturing.
• Poseida Therapeutics showed that Nanoplasmid vectors have better efficacy and equal safety in patients compared to standard plasmids

when used for CAR-T production with the piggyBac® transposition (*Clinical Trial NCT03288493, P BCMA-101*). • Genentech reported improved CRISPR HDR knock-in by comparing a linear and a traditional pUC plasmid against a Nanoplasmid vector as the donor template. Their studies concluded that Nanoplasmid vectors resulted in twice the production of edited CAR-T cells compared to the traditional pUC plasmid and three-fold compared to the linear donor (Oh et al., *Journal of Experimental Medicine*, 2022). • Editas Medicines used Nanoplasmid vectors for the Selection by Essential-gene Exon Knock-in (SLEEK) HDR approach, producing knock-in rates of 90% (Allen et al., *Nature Biotechnology,* 2023). • Stanford University researchers used Nanoplasmid vectors in a CRISPR method termed "Homology-Independent Targeted Insertion" (HITI) and achieved approximately 80% edited cells after the 14-day protocol (Hyatt Balke-Want et al., *Molecular Cancer*, 2023). Independent evidence suggests that using Aldevron's Nanoplasmid vector platform in CRISPR *ex vivo* gene editing applications leads to 80-90% editing rates and reduced cellular toxicity compared to traditional vectors.

1844. Manufacturing Process Development and Analytical Characterization of CBN-1000, a New Viral Vector Derived from Human Bocavirus

Gillian Payne[1], Joshua Merritt[2], George Richards[2], Po-Yi Ho[1], Yousuf Aqeel[1], Alfred G. Tamayo[1], Ryan Farrell[2], Frederick Metters[2], Sung Jo[1], Shu-Hao Liou[2], Brooke DeSimone[1], Pooneh Hajian[1]

[1]Analytical Sciences, Carbon Biosciences, Waltham, MA,[2]Process Development and Manufacturing, Carbon Biosciences, Waltham, MA

CBN-1000 is a new parvoviral vector derived from human bocavirus 1 (HBoV1) virus. The CBN-1000 capsid is remarkable in that it has specific tropism for differentiated human bronchial airway epithelium and is able to package an AAV2 ITR-flanked genome payload of >5.5 kb, which is significantly larger than the 4.7 kb cargo capacity of conventional AAV vectors. Because of the expanded payload size and lung tropism, CBN-1000 vectors are ideal for the delivery of genes for the treatment of genetic lung diseases which are too large for AAV vectors. CGT-001 is comprised of a CBN-1000 vector with the full-length gene for the Cystic Fibrosis Transmembrane Conductance Regulator (CFTR) for the treatment of patients with cystic fibrosis. A plasmid-based mammalian cell manufacturing process has been developed for the efficient packaging of a CFTR expression cassette into HBoV1 capsids. An affinity chromatography-free purification process has also been developed which results in high purity vector product. The process development, scale-up and manufacturing of this new hybrid vector and in-depth characterization of CGT-001 will be described.

1845. Navigating Pitfalls in the Adenovirus Development: From Drug Discovery to Clinics and Beyond

Emilie Gateau[1], Dmitrii Sorokin[1], Helmut Kewes[2], Petri Priha[3], Vasily Medvedev[1], Hanna P. Lesch[1]

[1]Exothera, Jumet, Belgium,[2]Cytiva, Cologne, Germany,[3]Valo Therapeutics Oy, Helsinki, Finland

Following COVID-19 pandemic response, there has been a steady increase in the number of clinical trials with recombinant Adenovirus (rAdV) for human gene therapy, oncolytic cancer therapy or as a human vaccine. There are several common pitfalls developers might encounter in their journey, including poor target identification of the proper lead candidates and serotypes as well as consideration of safety and efficacy which can all impact a program's success. We have built an Adenovirus platform with a rational CMC strategy to support the discovery process and to mitigate the risks during early stages of development. Analytical development serves as the foundational basis for the development of new therapies. We have been using qualified assays (viral particle concentration by ddPCR, infectious titer by TCID50, commercial titer kits, and next generation sequencing (NGS) for vector identity and genetic stability) to characterize, assess, and ensure the quality, safety, and efficacy of these complex products. We have performed ddPCR primer design and standardized sample treatment to improve the consistency of virus particle quantitative analysis across various adenovirus serotypes. Same approach is applicable for also for screening and selection of rare and chimeric serotypes. Preclinical decisions, like host cell line selection for virus seed stock generation and process development, are crucial for future clinical manufacturing. In addition, the use of standard cell lines like adherent HEK293 or A549 cells with safety concerns associated for the use of Fetal Bovine Serum (FBS). To address this concern, we have adapted an adherent A549 cell line to serum-free conditions by testing 5 different media over 5 passages and identifying 2 compositions of serum-free media, supporting cell growth. In the case of non-replicating adenoviruses, HEK293 cells may also increase the risks of contamination with Replication competent adenoviruses (RCA). We have preferred Cytiva's CAP™ cells, primary human amniocytes immortalized by modified adenoviral genetic E1/pIX functions, specifically designed to minimize RCA during production. These cells are fully documented and validated to meet regulatory requirements and they present good growth characteristics as well as improved quality (less than 1 RCA particle in 5E+10 rAdV particles in CAP cells, compared to 5-500 RCA particles in HEK293F cells). Early technological platform selection significantly influences clinical manufacturing challenges, such as scalability and batch consistency. We have been utilizing Design of Experiment (DoE) and mathematical modelling of the scale-dependent parameters to build a consistent manufacturing processes and scalability for stirred-tank, rocking angle and fixed-bed bioreactors, while working with suspension and adherent cells. As an example, for one of the oncolytic rAdV, produced in the adherent A549 cell line we identified three key process parameters using DoE approach at the small scale (T-Flasks), leading to 3.8 times higher productivity (infectious units per cm^2) compared to the reference process. An established factor-response mathematical model (RSq=0,96 and PValue=< 0,0001) was found reliable and was used to scale-up the process to the fixed-bed bioreactor and equivalent productivity increase (3,3 times) from reference process,

was maintained after application of the best DoE conditions to scale-X Hydro bioreactor at 2,4 m2 scale. Knowing about pitfalls on the road ahead and spending time and resources for critical decisions is the key to success in producing an adenoviral product. We have developed a wide variety of processes allowing safe production of AdV for all types of applications.

1846. Further Development of the TRiP System™: A Transgene Repression Technology Enhancing Lentiviral and AAV Vector Production

Ben M. Alberts[1], Cristina Nogueira[1], Magdalena Martin-Urdiroz[1], Alissa S. Bray[1], Ian A. Tovar Matthews[2], Desislava V. Simova[2], Magda Reis[3], Catarina R. Vieira[2], Adam Kuca[1], Elizabeth A. Ellis[2], Hannah J. Stewart[3], Jordan Wright[1], Kyriacos A. Mitrophanous[1], Nicholas G. Clarkson[2], Dan C. Farley[1]

[1]Innovation Group, Oxford Biomedica, Oxford, United Kingdom,[2]Process Development, Oxford Biomedica, Oxford, United Kingdom,[3]Product Feasibility Group, Oxford Biomedica, Oxford, United Kingdom

The impact of transgene expression during production of viral vectors can lead to changes in the feed material going into previously well-characterised processing steps, requiring extended process development. In addition, the total process yields can be lower than expected for typical 'benchmark' levels if the transgene affects vector particle assembly, release or activity, and the presence of the therapeutic protein within the final product may be undesirable. We previously developed the Transgene Repression in vector Production (TRiP) System to overcome these problems, since only the viral proteins will be expressed during production. TRiP employs the bacterial protein tryptophan RNA-binding attenuation protein (TRAP) from *Bacillus Subtilis*, which binds to its 55 nucleotide RNA binding sequence (tbs) inserted into the 5' UTR of the transgene mRNA to mediate a translation block. Here we report improvements to the TRiP System™ wherein a standardised, short TRiP 5' UTR-tbs sequence has been engineered to mediate both efficient transgene repression in production cells, and to maintain high expression in target cells. Upstream of the tbs, the TRiP 5' UTR comprises a 12 nucleotide leader derived from the human EF1α promoter with its native run of 5' terminal pyrimidines, which allow for predictable transcription initiation when paired with the typical constitutive promoters employed in gene therapy cassettes, as well as tissue-specific promoters. The tbs has been re-designed at its 3' end to overlap with the primary AUG codon of the transgene to better occlude it from scanning ribosomes when bound by TRAP, whilst also maintaining an efficient Kozak sequence for ribosomal RNA binding during translation initiation in target cells. We show improvements in production of LVs when the TRiP 5' UTR-tbs configuration is onboarded onto novel '2KO-LV' genomes (part of the TetraVecta™ System), which are mutated for aberrant splicing activity from the major splice donor in the packaging signal. In standard 3rd generation LVs, such aberrant splicing produces transgene-encoding mRNAs that the TRiP System™ represses much less efficiently, making the 2KO-LV platform the ideal partner to TRiP. Here we provide an example of the transition of a third-party LV-CAR product from small scale feasibility studies to a commercially relevant production scale model, utilising these and other novel LV production technologies. Over a 20-fold final yield increase was realised by utilising the 2KO-LV/TRiP technology components of the TetraVecta™ System, in combination with a novel LV production enhancer Ingenol-3-angelate (I3A) that contributed ~3-fold of this increase. Further, we show by mass spectrometry that the TRAP protein is detectable only as a minor residual (<1% of total protein) within HIV-1 based LV product that has been concentrated and purified by a commercially relevant process. Moreover, we have not been able to detect pre-existing antibodies to the TRAP protein in a screen of >160 healthy human sera, indicating that residual TRAP is unlikely to limit gene transfer. Finally, we applied the TRiP System™ to a wide range of transgenes within ssAAV vectors, including those containing a CMV-driven, pro-apoptotic Caspase-8 or Bax gene, where TRiP was able to fully rescue titres by 150-fold and 677-fold, respectively.

1847. Start with Stable: Stepping onto TetraVecta™ Packaging Cells to Make a Clearer Pathway to LentiStable™ Producer Cell Lines

Emma S. Whiteley[1], Emma Burton[2], Magdalena Martin-Urdiroz[1], Joana S. Boura[1], Ben M. Alberts[1], Jordan Wright[1], Kyriacos A. Mitrophanous[1], Hannah J. Stewart[2], Dan C. Farley[1]

[1]Innovation Group, Oxford Biomedica, Oxford, United Kingdom,[2]Product Feasibility Group, Oxford Biomedica, Oxford, United Kingdom

The use of HIV-1 based Lentiviral vectors (LVs) to deliver transgenes encoding Chimeric Antigen Receptors (CARs) is the industry standard in the generation of CAR-T cells for cancer immunotherapy. The commercial success of any given CAR-T therapy is multifaceted but is broadly in tension between the desire to traverse the clinical development pathway quickly, and the need to ensure a high-quality product is manufactured as economically as possible. The primary method of generating LV-CARs is via transient transfection of HEK293T cells (typically suspension, serum-free) at 50-200L scale, although up to 2000L is now feasible. The use of stable producer cell lines (PCLs) to manufacture LVs is desirable due to reduced costs, ability to scale to large volumes, improved batch consistency and a more streamlined production process, compared to the standard transient transfection process. However, transfection-based production is sufficient to provide enough LV product to service clinical trials and consequently is typically progressed for commercial supply in a number of jurisdictions. This creates an inertia that halts the possibility of realising the benefits of PCLs due to the need to perform comparability studies between LV product made by both processes. The generation of LV-CAR PCLs capable of producing high titre LV has had limited success until recently, due to the constitutive expression of the CAR molecule negatively impacting production cell survival. Oxford Biomedica (OXB) has developed the LV TetraVecta™ System, which enables effective repression of the transgene in production cells, thus opening the pathway to LentiStable™ LV-CAR PCLs. Since the generation of PCLs typically requires 6-9 months to complete, OXB also offers a transition platform that allows a flexible but simplified LV production process based on off-the-shelf TetraVecta™ packaging cell lines (PaCLs) that contain all necessary LV packaging components for

the production of LV particles, as well as TRiP System™ components that repress the transgene. Here we provide data exemplifying the use of TetraVecta™ PaCLs in the production of LV-CARs and demonstrate comparable or greater yields than the fully transient process. The process scaled well into a 7L Stirred Tank Reactor (STR), and following downstream processing, the concentrated and purified LV was capable of effectively transducing human primary T-cells. We envision that the use of TetraVecta™ PaCLs as the first step of LV-CAR product development will [1] reduce costs and logistics associated with sourcing GMP plasmids for all LV packaging components, [2] reduce process development timelines and improve batch-to-batch consistency owing to the invariance of LV particle production, and [3] close the comparability gap requirements between LV product made using PaCLs and PCLs. Should a PCL be developed in parallel to clinical trials a more straightforward transition to PCLs would be enabled, and the benefits of a fully transfection-free commercial product would be realised.

1848. Enabling Closed Chromatography Processes Using a Gamma Sterilized and Scalable Chromatography Product Platform from Small to Large Scale

Alexander Helling, Swapnil Chaudhari
Sartorius Stedim Biotech GmbH, Goettingen, Germany

With an increasing number of cell and gene therapy trials on the horizon, the demand for cost-effective and high-quality manufacturing of gene delivery tools such as viral vectors, exosomes and pDNA is growing. Although there is still little agreement on the optimal sequence of unit operations required for manufacturing high yields of vectors, chromatography, particularly anion exchange chromatography, is commonly used for primary capture from cell culture supernatant or polishing albeit with typically low recoveries or yields. Membrane chromatography has already proven to be an outstanding technology in terms of chromatographic performance, recovery or yield and productivity in several processes. This study illustrates the scalability of a cellulose-based membrane chromatography portfolio from development to manufacturing scale using both model and real-application feed streams. It includes strong (Q) anion, weak anion, and heparin functionalized membranes. The high permeability of the chromatographic membrane allows loading several hundred column (membrane) volumes without a significant pressure increase at a flow rate of 10 column volumes per minute thereby significantly reducing process times and minimizing the exposure time of the target to demanding process conditions. An outlook is provided regarding the commercial availability of this novel and innovative membrane chromatography portfolio designed for single use, closed and aseptic processing, which aids in implementing cost-effective and high-quality manufacturing of gene delivery tools such as viral vectors, exosomes and pDNA.

1850. Examining the Development Challenges of AAV and LVV Manufacturing Processes: A Comparative Perspective

Margherita Neri, Luca Allievi, Martina Brunati, Samuele Corbetta, Manuela Cota, Luca Crippa, Silvia Ungari, Emanuele Simonetti, Giuliana Vallanti
AGC Biologics, Milano, Italy

AGC biologics is a leading global CDMO, providing world-class development and manufacture of mammalian and microbial-based therapeutic proteins, plasmid DNA, viral vectors and genetically engineered cells. Adeno Associate Vectors (AAV) and Lentiviral vectors (LVV), produced with transient transfection in HEK293 and HEK293T cells are extensively used for genetic modification in gene therapy for *ex-vivo* and *in-vivo* treatments. AGC Biologics developed BravoAAV and ProntoLVV platforms for the manufacturing of AAV and LVV at different scales in adhesion and suspension. Both platforms are flexible to be adapted to different GOI (Gene Of Interest). Of note, BravoAAV positively applies to different AAV serotypes. The two classes of vectors we are dealing with (AAV and LVV) share some characteristics but are different from many points of view. These resulted in the development of dedicated manufacturing platforms even if starting from common process steps using same equipment and common set of reagents but that faced different challenges. We are going to compare the two manufacturing processes, step by step, underlining differences and common features. Starting point of the processes is the thawing of packaging cells. HEK 293T and HEK 293 cells are used for LVV and AAV production respectively. It has to be taken into account that those cells have different behavior in terms of growth rate and aggregation profile. Indeed, duplication time of HEK 293 cell is higher than HEK293T requiring more time to reach the correct cell density for transfection. Transient transfection is of course performed with dedicated plasmids, but with the same transfection reagent (PEIPro). Vector production after transfection requires more time for AAV compared to LVV, resulting in delayed harvests respect to LVV process. The strong proteic capsid of AAV ensures their higher resistance to shear stress, allowing to perform harvest later than for LVV and also HEK293 cell lysis. On the contrary, the presence of the envelope in LVV is the cause of the high sensitivity of the vector to temperature, pH and shear stress. For this reason, clarification of LVV produced in suspension is challenging, as the whole cell mass have to be separated from the supernatant. Historically, the purification of LVV has primarily relied on AEX Chromatography, whereas for AAV, a wide range of affinity resins is available on the market. Despite their high cost, these affinity resins ensure both high purity and good vector recovery. During the execution of concentration and diafiltration steps, AAV is more resistant to shear stress and high recoveries of infective vector are more easily achieved. In contrast, LVVs require more gentle conditions and are also susceptible to aggregation phenomena due to the stickiness of their envelopes, negatively affecting the last critical step: sterilizing filtration. Sterilizing filtration is performed with 0.22 μm filters for both platforms. Since LVV diameter is approximately 0.10 μm, the presence of vector aggregates can cause filter clogging and a decrease in recovery. The yield of this step for LVV is around 40-50%. Due to their compact size and reduced inclination to aggregate, AAVs demonstrate a more straightforward behavior during sterilizing filtration. These characteristics prevent membrane clogging and lead to

higher recovery rates in the process, up to 90%. Further details can be dissected considering application of vector (in-vivo vs ex-vivo), dose and transgene nature. Also regarding the analytical panel there are some assays that are shared by the products and others that are specific and dedicated. The knowledge of the biology of AAV and LVV and the implications in the manufacturing process and assay development is a key factor for the flexibility, capacity and capability of a CDMO.

1851. Transformative Advances in Lentiviral Vector Manufacturing: Unlocking Efficiency and Cost-Effectiveness with Tet-Off PCL Innovation

Soodeh Baghaee Ravari
Genezen, Technical Review, IN

Lentiviral vectors (LVV) serve as efficient tools for delivering therapeutic transgenes into both dividing and nondividing cells, facilitating sustained gene expression. However, challenges in current cGMP LVV production processes, utilizing transient transfection methods, include batch-to-batch variability and heightened costs associated with LVV manufacturing. These challenges contribute to the overall high production costs of Cell and Gene Therapy (CGT) products. In response to these challenges, Genezen has implemented a proven Tet-off Producer Cell Line (PCL) system to overcome the limitations of traditional production methods. Through meticulous evaluation, we have successfully adapted a PCL that consistently achieves raw IU titers exceeding 6e6/mL in four 200L productions across two distinct VSVG enveloped Transgenes of Interest (TOIs). This innovative approach demonstrated superior titers with better residual profile in a comparative study with one of the TOIs tested. The Tet-off PCL system offers numerous advantages, including improved downstream processing (DSP) with enhanced overall recoveries, a superior residual profile, and the ability to generate multiple sublots that can be combined into a super lot with functional titers surpassing 5e8 IU/mL.By eliminating the requirement for cGMP-grade plasmids in lentiviral vector production, Genezen's approach holds the promise of significantly reduced costs, improved commercial scalability, and consistent batch yields when compared to current industry-standard manufacturing processes. This innovation represents a substantial step forward in the field of gene and cell therapy, with the potential to enhance patient access to medicines based on lentiviral vectors.

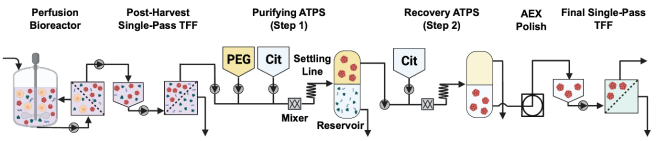
1852. Large-Scale Adherent Cell Manufacturing Platform for Stem Cell and Seed Train Applications

Matt Kremer
Univercells Technologies by Donaldson, Nivelles, Belgium

Adherent cell-based manufacturing platforms have long represented the gold standard for both stem cell and viral vector manufacturing applications, due to rapid implementation possibilities, straightforward process optimization and relatively high productivities. In recent years, they have however also been increasingly discarded as a viable option by organizations looking to achieve scale-up to commercial manufacturing. Limitations of traditional adherent manufacturing platforms largely justified this choice as they have historically been associated with poor scalability and high cost per dose. Efforts to use automated alternatives, such as packed-bed bioreactors, have provided significant improvements but remain limited by critical factors, such as poor scalability, high operating footprint, and, crucially, the inability to efficiently harvest cells from adherent bioreactors. This ability to harvest has been seen as a key limitation, not only for manufacturing of cells as a therapeutic agent but also in generating large-scale seed train for adherent cell-based viral vectors manufacturing. In this presentation, the speaker will unveil a novel approach unlocking cost-efficient large-scale manufacturing of adherent cells and cell-based products. An introduction to the scale-X™ bioreactor will be provided, demonstrating how structured fixed-bed technology enables low-cost, low-footprint automated cell harvest through a blend of enzymatic and mechanical actions. More specifically, the speaker will: - Present the results of an extensive study demonstrating efficient harvest of HEK293 and Vero cells for seed train applications using scale-X cell collect, with >90% viability of the harvested cells and proof-of-concept for fixed-bed to fixed-bed seed train - Showcase an intensified, automated seed train workflow with reduced process steps and drastic reduction in required clean room area - Detail how implementing this workflow enables significant cost reduction with 21%, 40% and 32% decrease of total facility-, materials- and labor- associated costs, respectively - Present several cases studies demonstrating the application of the scale-X cell collect to harvesting stem cell lines with high efficiency and high viability

1853. Developing High Titer Stable Producer Cell Line Platform for Lentiviral Vector Manufacture

Bofu Xue
Shenzhen Eureka Biotechnology Co., Limited, Shenzhen, China



Lentivirus is one of the widely used viral vectors in cell & gene therapy, and the mainstream production system is the four-plasmid transient transfection system which faces the challenges of high plasmids costs and batch variability at a commercial production scale. To address these challenges, Eureka Biotechnology has developed a suspension-mode, inducible lentiviral vector stable production system (EuLV System). Our stable production system comprises two innovative technology platforms: the packaging cell line (PCL) and the stable producer cell line (SPCL). The packaging cell line integrates lentivirus packaging components (Rev, Gag/Pol, and VSV-G) into the genome of suspension HEK293T cells. The PCL platform uses one plasmid transient transfection for LVV production, significantly reducing plasmid production costs and process complexity. The stable producer cell line platform offers a plasmid-free method for LVV production. It integrates the Gene of Interest (GOI) into the packaging cell line genome and utilizes double molecular switchers for precise gene expression control. This platform eliminates plasmid manufacture and transfection steps, produces 10 to 100 folds higher titers (2E8 TU/ml), enhances scalability, and greatly improves process robustness. It enables cost-effective, scalable, high-titer, and high-quality lentiviral vector production and is pivotal for the future of commercial-scale LVV manufacturing. The EuLV System simplifies the CMC process, and benefits to the cost down. It represents a promising solution for solving the bottlenecks of the current LVV manufacturing.

1854. Continuous Manufacturing for Viral Vectors Using an Aqueous Two-Phase Extraction Platform

Natalie M. Nold[1], Sheridan Waldack[1], Grace James[1], Emily Agustin-Mazariegos[2], Abigail Ruthenberg[1], Taravat Sarvari[1], Eric Pearson[1], Lynn Manchester[1], Trisha Colling[1], Amanda Bekkala[1], Bradley Priem[3], Justin Sargunas[3], Michael Betenbaugh[3], Caryn L. Heldt[1]

[1]Chemical Engineering, Michigan Technological University, Houghton, MI,[2]Grand Rapids Community College, Grand Rapids, MI,[3]Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, MD

Standard bioprocessing methods for viral vectors, which occur in batch mode, are outstandingly expensive. More economical manufacturing methods could alleviate the cost of these ground-breaking therapies. Continuous processing promises increased flexibility and productivity compared to traditional batch chromatography-based processes. Aqueous two-phase systems (ATPS) combine product capture and purification by partitioning the viral product and contaminating host-cell proteins and DNA to different phases. Our process consists of two stages: the first ATPS stage separates the bulk of the viral product from the bulk of the impurities, while the second stage recovers the viral product from the viscous polymer phase to ease further processing. ATPS relies on raw materials rather than expensive proprietary consumables such as chromatography resin, which translates into over 50% lower production costs and 90% lower capital costs compared to traditional processes above a 11 kg/year production scale. Optimization studies in batch mode have shown 66-100% overall product recovery for adeno-associated virus (AAV), herpes simplex virus (HSV), influenza B virus, and porcine parvovirus (PPV), with lentivirus results pending. A multi-hour continuous run of our two-step ATPS for PPV showed statistically similar PPV recovery results compared to batch studies. Batch studies showed a consistent output of contaminating protein (~11 g/mL) and DNA (~8 ng/mL) regardless of the input titer of these impurities. The output DNA titer for our continuous process matched that of batch studies, however, the output protein impurity titer was about five-fold higher at 61 mcg/mL. A polishing flow-through anion exchange membrane was added post-ATPS to provide more robust impurity removal. The filter succeeded in removing an additional 87% of DNA with 90% PPV recovery, but did not succeed in removing protein impurities. A flow-through cation exchange membrane will be tested in the future to help remove protein impurities. Continuous operation of ATPS requires in-process monitoring. One of our biggest challenges is control and monitoring of the mixing and settling. Turbidity monitoring using absorbance measurements at 800 nm ensures sufficient mixing and settling during ATPS. The turbidity readings were 20% higher for batch mixing as compared to the stirred mixing used in continuous ATPS. Turbidity was able to demonstrate that an inline static mixer was not sufficient to mix the phases and have desired separation of viral product and contaminants, as well as distinguish settled ATPS. A control strategy using turbidity measurements could be used to adjust mixing speed and to adjust settling time in order to reach sufficient mixing and settling rates. This proof-of-concept study demonstrates that a two-step ATPS could be incorporated into a fully continuous purification process that will make viral vector manufacturing more flexible and cost-effective.

Process diagram of an end-to-end viral vector purification system using ATPS.

1855. Overcoming Challenges to the Commercialization of Lentiviral-Based Therapies: A Scalable and Robust Production Process Using a Suspension Transient Transfection Platform

Jiasong Jiang[1], Leila M. Aneke[1], F. Michael Haller[1], Vijetha Bhat[1], Chien-Ting Li[1], Victor Paredes[1], Peng Wang[1], Miguel Betancourt[2], Thanh Dang[2], Phi Le[2], Aaron Bedee[2], Ares Ayandokon[2], Peng Lu[2], Shuo Lu[2], Mariya Viskovska[2], Senthil Ramaswamy[1], Wenling Dong[2], Bingnan Gu[1]

[1]Research & Development, Lonza Houston Inc., Houston, TX,[2]Process Development, Lonza Houston Inc., Houston, TX

Due to their ability to deliver larger cargo, transduce both dividing and non-dividing cells and maintain long-term and high expression levels, lentiviral vectors (LVV) are increasingly becoming a tool of choice in cell and gene therapy applications. This increases the pressure, particularly on CDMO's, to meet the markets' demand for safe, 3rd generation viral vectors with adaptable, scalable and high-yielding manufacturing processes. While continuing to develop new tools for LVV manufacture, such as a stable producer cell line, we are presenting here the results obtained for our proprietary HEK293T 2G7 suspension cell line for LVV production by transient transfection in serum-free, chemically-defined and animal component-free media and its subsequent downstream purification. The process was developed using LVV-CD19 as model construct in addition to the commonly used LVV-GFP due to altered downstream performance observed by us when switching the gene of interest from GFP to a therapeutically relevant gene. The obtained process was confirmed repeatedly in a 3 L STR for both LVV-GFP and LVV-CD19, transferred to our process development department and tested there at 50 L scale using LVV-CD19, with an overall process recovery, including clarification, of 24 %. The bulk drug substance (BDS) was analyzed for infective, genomic and capsid titer, as well as potency by T-Cell transduction and residual host cell DNA and host cell protein content.

1856. A Novel, Synthetic DNA Alternative for Lentiviral Vectors Manufacturing

Andreia M. Silva, Fabian Trick, David Wilson, Ivana Pastierikova, Luca Distefano, Marco Guarrera, Martin Cusack, Alexander Pekarsky, Jorge Omar Yanez Cuna, Joel de Beer

Anjarium Biosciences AG, Schlieren, Switzerland

Lentivirus vectors (LVV) represent vital products and tools within the cell and gene therapy domains. LVV are conventionally produced in

cellular expression systems upon transfection with plasmids of bacterial origin that encode the gene-of-interest (GOI), packaging proteins, and envelope proteins. Scaling up the production of these plasmids is costly, and time-consuming. We have developed a novel, optimized synthetic linear double-stranded DNA with customizable hairpin-ended structures for LVV production. Our cell-free, enzymatic production process is readily scalable and results in high-fidelity, high-yield, and high-purity DNA in a short timeframe. Additionally, our synthetic DNA constructs are devoid of bacterial backbone, thereby reducing the risk of introducing non-relevant and antibiotic resistance elements into the LVV production process - a significant safety and regulatory concern. Our DNA platform encodes the elements of a 3rd generation lentivirus system. LVV were produced by transient cell transfection at optimal conditions determined by Design of Experiments. Functionality and titer of the produced LVV was evaluated by cell transduction assay and p24 ELISA. Here, we show that synthetic DNA constructs codifying for the GOI, Rev, Gag-Pol, and VDV-G generated through our enzymatic, cell-free process are produced at high purity. GOIs encoded in our DNA platform include reporters of different size, anti-CD19 Chimeric Antigen Receptor (CAR), under the control of different promoters. All LVV produced were functional, effectively transducing HEK293T cells. CD19 CAR was also effectively expressed at the surface of Jurkat cells upon transduction with the produced LVV, further demonstrating the feasibility of our DNA in applications for CAR-T cell therapies development. In conclusion, our synthetic DNA platform can be used as an alternative to bacterial plasmids in LVV production.

1857. Efficient Separation of Plasmid Isoforms Using Anion Exchange Chromatography (AEX) and by Capillary Electrophoresis with Laser Induced Fluorescence Detection (CE-LIF)

Syam Pillai[1], Kiran Krishnan[1], Upul Halambage[1], John Bowen[2], Tatiana Nanda[1]

[1]Analytical Development, SK Pharmteco - US, King of Prussia, PA,[2]Plasmid Operations, SK Pharmteco - US, King of Prussia, PA

Precise qualitative and quantitative determination of individual plasmid DNA (pDNA) isoforms in the final product is the major quality determinant, as high purity supercoiled (SC) pDNA is a prerequisite for all gene therapy (GT) platforms. AEX -high performance liquid chromatography (HPLC) exploits the different physicochemical properties of the open circular (OC) linear (LN) and supercoiled (SC) pDNA in ascending salt gradients to separate the isoforms where SC isoforms with a higher charge density elute later than OC with a lower charge density. However, quantitative resolution of the OC and LN isoforms are challenging due to the physical retardation of OC isoforms in the chromatographic stationary phase and overlapping of LN isoforms with OC and SC isoforms. This challenge is further aggravated by the pDNA size, that contributed to the elasticity and other physicochemical factors related to hydrodynamics affecting the channel/pore size of the columns. Circular plasmids are sensitive to homologous recombination resulting in the formation of a dimeric molecule, in addition, to the multimers formed by the aggregation of plasmid during high salt purification processes. The AEX methods have limitation to precisely determine these dimers and multimers. In the present work, we introduce an AEX method for the effective separation of pDNA isoforms for the plasmid sizes ranging from 2.9 through 23.6 Kb size and development of a CE-LIF method for quantitation of the plasmid isoforms, specifically for the separation of dimeric/multimeric pDNA, and the comparison of two methods for a range of plasmid sizes for effective topology analysis. This will enable a unique opportunity to close the gap in a complete plasmid characterization process and ensure the highest quality plasmid for further GT manufacturing.

1858. Novel Ligand Outperforms State-of-the-Art Ligand in Lentivirus Purification by Anion Exchange Chromatography

Nicolas Meier, Andreia M. Silva, Fabian Trick, Joel de Beer

Anjarium Biosciences AG, Schlieren, Switzerland

Lentivirus vectors (LVV) are widely used in cell engineering for cell therapy applications, and are leveraged in the manufacturing of an increasing number of products such as CAR-T cells. LVV used for cell engineering are produced using cell expression systems at varying scales and thus their isolation from conditioned media containing host-cell and cell culture-derived contaminants is a crucial step during production. LVV purification is usually performed by anion exchange chromatography (AEX), but the state-of-the-art run conditions required often lead to significant loss of functional virus due to LVV's high sensitivity to pH, salt concentration, and shear stress. Here we present a novel functionalized resin that enhances the purification of LVVs, enabling the optimized high yield recovery of functional LVV under mild conditions, outperforming the benchmark ligand used for LVV purification. Different resin ligands were screened for optimal binding and elution of enveloped biological particles, with optimal elution conditions at salt concentrations ranging between 150-275 mM and pH 7.0-8.0. Collected fractions were analyzed for viral recovery by HEK293T cell transduction assay and p24 ELISA. Depletion of contaminants was assessed by total protein quantification assay, HEK293 Host Cell protein ELISA and QuantiFluor dsDNA assays. We show that LVV can be successfully purified in both capturing and polishing mode from a diverse set of clarified conditioned media. Due to the mild elution conditions, viral titer recoveries of up to 4-fold higher were achieved with nearly 2-fold improved contaminants clearance (HCP and dsDNA) compared to the benchmark DEAE ligand. Our novel ligand is a promising alternative in LVV downstream processing, leading to significant increases in process productivity by recovering purer LVV at high yield.

1859. Purification Platform for Viral Vectors Using Aqueous Two Phase Systems

Natalie M. Nold, Taravat Sarvari, Sheridan Waldack, Grace James, Abigail Ruthenberg, Liza Korolkov, Lynn Manchester, Trisha Colling, Amanda Bekkala, Eric Pearson, Caryn L. Heldt

Chemical Engineering, Michigan Technological University, Houghton, MI

The costly manufacturing methods used for viral vectors are a key reason why gene therapies can be prohibitively expensive, often costing over $1 million per patient treated. More economical manufacturing methods could lower costs and improve patient access. Continuous manufacturing could reduce the cost of viral vector manufacturing

by increasing process time while reducing both operating costs and capital costs. Unfortunately, traditional production methods, including ultracentrifugation and bind-and-elute chromatography, are not easily compatible with continuous operation. Our lab has developed a continuous purification method using aqueous two-phase systems (ATPS), which combines product capture and purification by partitioning the viral product and contaminating host-cell impurities to different aqueous phases. ATPS consists of polyethylene glycol polymer and citrate salt that separate at high concentrations into two aqueous phases. Since ATPS relies on biocompatible and environmentally-friendly raw materials rather than expensive proprietary consumables, such as chromatography resin, ATPS requires 50% lower production costs compared to traditional processes at large manufacturing scales. Our ATPS consists of two steps, as shown in Figure 1. The first step purifies the virus from host cell contaminants and the second step extracts the product from the viscous polymer phase to ease processing downstream. ATPS holds promise as a viral vector purification platform with 66-100% overall product recovery for adeno-associated virus (AAV), herpes simplex virus, porcine parvovirus (PPV), and influenza B virus; results are pending for lentivirus. ATPS delivers a consistent low output of impurities; for PPV ATPS, ATPS outputs ~11 mcg/mL of contaminating protein and ~8 ng/mL of contaminating DNA regardless of starting titer. ATPS ability to enrich the full capsid percentage of AAV will be tested using biolayer interferometry. Our investigation of ATPS for multiple viral vectors has uncovered the key driving forces of electrostatic and hydrophobic forces that enable quick process development for a wide variety of viral products. This could unlock cost-effective manufacturing for viral gene therapy vectors and make these ground-break therapies more affordable for patients.

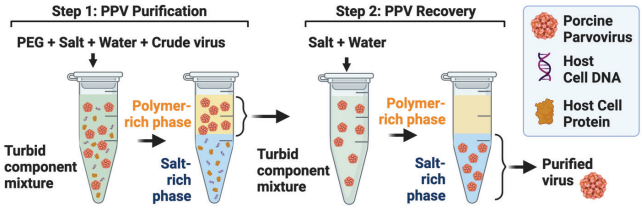


Figure 1: Schematic of the two-step ATPS process. PPV is purified from host cell impurities in the first ATPS step. Virus-laden PEG-rich phase is then mixed with fresh citrate at different chemical conditions to recover PPV into the salt phase in the second ATPS step. Figure created in Biorender.

Friday Posters: Cell Therapy Product Engineering, Development, and Manufacturing

1860. Mitigating Risk for Transfer of Living Materials into Closed Systems

Donald C. Singer[1], David J. Root[2]

[1]Ecolab Life Sciences, Phoenixville, PA,[2]Ecolab Life Sciences, Horsham, PA

One of the biggest challenges for developers and manufacturers of cell and gene therapies is to design a robust process to transfer living material into closed systems such as isolators, without introducing contamination into the grade A/ISO 5 area or damaging them from the bio-decontamination process. Different processes (automated and manual) and strategies are being taken into consideration by various cell therapy manufacturers, as well as some novel strategies to overcome this challenge. Use of isolators with automated bio-decontamination systems are becoming a first intent consideration for robust process design and should be integrated with procedures that ensure protection of living material viability.

1861. The Myth of the "Non-GMP" Space: The Criticality of Establishing Good Aseptic Practices in the Development Environment

Amanda Curtis

ValSource, Downingtown, PA

Microbial control concepts such as good aseptic practices and segregation control are well-known and accepted practices in GMP manufacturing of cell and gene therapies. However, a gap is still commonly seen in the development space, in which functions such as Research and Development or Process Development do not consistently consider and adhere to good aseptic practices when developing and designing new products and processes. Adherence to applicable microbial control concepts during the design and clinical phases can improve the quality of the work performed in the development space, lead to more robust processes, decrease the risk of contamination during process performance, and enhance the transfer of processes to the GMP environment. This presentation will discuss relevant microbial control concepts from the perspective of a GMP microbiologist with experience investigating and responding to contamination events in early phase clinical products with a contract manufacturing organization, in which patient treatment was ultimately delayed due to poor process design. The presentation will provide industry examples of contamination events in the development space and handoffs to the GMP space that could have been prevented or mitigated via application of microbial control concepts.

1862. Validation of a Spectral Flow Cytometry Platform for Use in a GxP Environment

Christopher Colvin[1], Emma Kraus[1], Austin Lawrence[1], Victoria Best[2], Sapna Varia[2]

[1]Analytical Sciences, AmplifyBio, West Jefferson, OH,[2]AmplifyBio, West Jefferson, OH

Background Spectral flow cytometry is a versatile and efficient platform for performing complex immunophenotyping and population biodistribution testing for discovery, preclinical and clinical immune-monitoring applications. Spectral flow cytometers utilize spectral unmixing technology, which allows for a large number of parameters (>25) to be interrogated simultaneously at relatively low cost. Though this increase in panel size allows for the detection of a broader range of markers, little is known about the platform's suitability for use in a GxP environment. The goal of this study was to qualify a 5-laser Cytek® Aurora using pre-defined reference samples to evaluate multiple performance parameters. *Methods* The Cytek® Aurora (5-laser, 64 channel with small particle detector configuration) and its SpectroFlow acquisition software were evaluated for a range of parameters that

included: template creation and user access control, template and file corruptibility, FCS integrity and data export, reference library performance, unmixing and compensation functions, small particle detection, precision, reproducibility, and accuracy. To assist with this process, commercially available 10-500 nm size beads, single color compensation beads, and characterized reference PBMCs were used. The Cytek® Aurora 25-color immunoprofiling assay (qualified by the vendor) was also used to eliminate effects of panel design and operator skill in the interpretation of instrument performance. All acquired data were analyzed using FlowJo Software. *Results* SpectroFlow acquisition software performed consistently and allowed for repeated use of access-controlled templates without corruption (n=15 independent runs). The spectral unmixing and traditional compensation algorithms were easy to use and showed comparable results when applied to a 7-parameter panel. When assessing spectral unmixing only, precision runs showed average %CVs of 9.4%, and average percent recoveries of 113% for populations of known frequency. The reference library, utilized by SpectroFlow for instrument setup, could also be used across different instrument settings without any effect on the accuracy of the data. The small particle detector, performed as indicated, consistently resolving bead standards ranging from 80-200 nm. Importantly, when testing the performance of the Cytek® Aurora system on a 25-color panel, there was no loss of resolution or accuracy noted, as the average %CV was 11.9%, and average recovery was 102%. In summary, spectral flow cytometry is a superior and cost-effective approach for applications that require high parameter testing, such as: product characterization, or immune monitoring/immunogenicity testing. The Cytek® Aurora also demonstrated flexibility for use in various discovery applications, due to its ability to toggle between compensation and unmixing, and its small particle detection function. Most importantly, its performance can also be qualified as suitable for use in a GxP environment.

1863. The AREM: A Systematic Risk-Based Approach to Contamination Control and Sterility Assurance for Aseptic Processing

Tiffany A. Baker[1], Darius Pillsbury[2]

[1]Valsource, Inc, Providence, RI,[2]Valsource Inc, New Paltz, NY

Establishing a robust Contamination Control Strategy (CCS) for an Advanced Therapy Medicinal Product (ATMP) also referred to as Cell and Gene Therapy Products is of utmost importance for success of consistent supply of drug product that is safe for patients and meets product quality requirements to support all stages of the product lifecycle. As most ATMPs are required to be sterile, aseptic processing is required at many steps of the manufacturing process. These manufacturing processes present unique and different challenges from those processes used for the manufacture of better understood biological and pharmaceutical product types. A lack of effective process controls can lead to contamination of drug product resulting in patients not receiving these important therapies and the overall clinical programs being significantly delayed and even study termination. As many of these novel manufacturing processes (e.g. for the manufacture of a cell therapy or gene-modified cell therapy) cannot be terminally sterilized, aseptic processing controls throughout the manufacture of the product over multiple unit operations and extended durations of time are required. Thus an assessment tool not only fit for fill and finish operations but also to the other process unit operations, many of which are highly manual and complex, is required for the purposes of managing the aseptic focused risks. In this presentation, a systematic approach to managing the unique risks of aseptic processing of ATMPs, the Aseptic Risk Evaluation Model (AREM) is presented. The AREM utilizes the collective product knowledge and process understanding and is compliant with the evolving global regulatory landscape and based on industry best practices. This risk-based approach has been successfully leveraged to improve processes that went on to be commercially approved. The objectives of this presentation are so that: • Attendees will gain tactical knowledge on how to perform a risk-based approach for all aseptic process steps using the Aseptic Risk Evaluation Method. • Attendees will learn how to leverage the output of the AREM to determine the strategy for process design improvement, APS design, aseptic operator qualification design, and a QA oversight model.• A Case Study overview will be provided to give attendees a real-time look at how the tool has been successfully used.

1864. Comparative Analysis of Ultra-Pure Recombinant Human Serum Albumin and Serum-Derived Human Albumin on Oxidative Stress, Expansion, Viability, and Phenotype of Human T Cells

Mark Stathos, Jake Hanks

InVitria, Aurora, CO

The rise of cell therapy has substantially increased the demand for inexpensive, effective, and consistent methods to grow primary human cells at large scale and in serum-free conditions. As in serum, human serum albumin (HSA) is often one of the most abundant proteins in culture systems for therapeutic cells. Despite this, the importance of HSA is often overlooked beyond its role in osmotic pressure regulation. However, HSA is also capable of binding to a diverse array of hormones, small molecules, and fatty acids. When serum-derived HSA is used in cell culture systems, these bound substances are also included whereas their levels are greatly reduced in culture systems using high purity delipidated recombinant HSA (rHSA). The effects of this difference on cell therapy products are unclear. We hypothesized that an ultrapure, delipidated rHSA, having more available binding sites, would better be able to reduce oxidative stress on cells resulting in beneficial changes to T cell phenotype such as a reduction in senescence and exhaustion. To that end, we characterized the phenotype of activated primary human T cells with flow panels designed to target several markers of exhaustion and senescence, cultured them in delipidated rHSA or serum-derived HSA for several days then recharacterized them using the same flow panels. Our results suggest that high purity albumin reduced expression of markers associated with undesirable phenotypes which shows promise for improving the efficacy of T cell therapies.

1865. Novel Experimental Approach to Improve Scale-Up of Microcarriers-Based Cell Culture in Bioreactors

Eyram Marcelle Koudji, Terri Jerbi, Alex Sargent

Process Development, Charles River Laboratories, Hanover, MD

The scaling of adherent cells cultivated on microcarriers in bioreactors can be challenging due to differences in the bioreactors' design and

shear force across multiple platforms. The difference in design makes scaling up the agitation particularly complex in striking a balance between maintaining all the microcarriers in suspension and using an optimal speed to reduce shear stress on the cells. Here, we compared different computational and experimental methods to determine the optimal agitation rate for expansion of adherent cells on microcarriers at small and large scales. We demonstrated a novel experimental approach to optimize agitation rate for microcarrier culture that was scalable in different bioreactors platforms. When compared to computational methods like tip-speed conversion and power input ratio, our approach substantially increased the agitation rate that was best for microcarriers suspension and cell expansion. Optimal agitation rate was consistent across the different working volumes of the bioreactors. This study shows that our novel experimental approach can improve scale-up of microcarriers-based cell culture compared to computational methods. Defining better methods to successfully scale adherent cell expansion in bioreactors is important to reduce cost, maximize cell yield, and produce a higher quality product.

1866. A New Tissue Culture Surface Enabling Serum-Free and Coating-Free Adherent Culture of Human Mesenchymal Stromal Cells

Josh DiGiacomo[1], Isha Dey[2], Rayees B. Ahamed[2], Kanika Singh[3], Arafat Fasuyi[1], Debra Johnson[1], Sune Sporring[4], Matthew Dallas[1]

[1]Thermo Fisher Scientific, Frederick, MD,[2]Thermo Fisher Scientific, Bengaluru, India,[3]Thermo Fisher Scientific, Frederick, India,[4]Thermo Fisher Scientific, Roskilde, Denmark

Due to their capabilities in differentiation, immune regulation, tissue repair, and cell signaling, human mesenchymal stromal cells (hMSCs) have found applications in therapies for a wide variety of diseases such as bone and cartilage disorders, diabetes, neurological disorders, and more. High quantities of hMSCs are required to prepare therapeutic doses and consequentially scale-up to larger cell cultures is required. Therefore, the process of culturing hMSCs needs to be efficient, reliable, and consistent in order to provide adequate quantities of cells for both research purposes and therapeutic development. The adherent culture of hMSCs typically requires the presence of serum and/or coating with extracellular matrix (ECM). These factors reduce the efficiency and reproducibility of the hMSC culture process by introducing variable culture conditions, requiring additional time, and adding extra costs. We recently developed the enhanced Nunclon™ Supra cell culture surface which eliminates these issues by allowing for the adherent culture of hMSCs under both serum-free and coating-free conditions. The treatment that generates the Supra surface can be applied to plastic cell culture vessels spanning a large range of sizes, from 96-well plates to T175 flasks. Using hMSCs derived from adipose tissue, bone marrow, and Warton's jelly, we demonstrated that serum-free, coating-free culture on the Nunclon™ Supra cell culture surface allows for comparable hMSC culture metrics such as adherence, doubling time, morphology, and dissociation compared with serum-free, ECM-coated culture on a standard cell culture surface. In addition, we also demonstrated that hMSCs cultured under serum-free, coating-free conditions on the Nunclon™ Supra surface maintain equivalent expression of multipotency markers and demonstrate comparable differentiation potential when compared to hMSCs cultured under serum-free, ECM-coated conditions. Taken together, these results indicate that the enhanced Nunclon™ Supra cell culture surface can play an important role in simplifying hMSC culture workflows and easing the transition to large volume hMSC culture.

1867. A Fast Extraction-Free Direct qPCR Method for Quantification of Residual Host Cell DNA in Viral Vector Products

Paul Li[1], Zexin Zhou[2], Ziqiang Li[2], Jiale Qu[2], Bin Liang[2], Jiayong Lao[2], Danlan Qiu[2]

[1]PackGene Biotech, Worcester, MA,[2]PackGene Biotech, Guangzhou, China

Residual host cell DNA (hcDNA) contamination presents a potential concern in purified viral vector products, including adeno-associated virus, adenovirus, and lentivirus. Regulatory agencies have established permissible limits to govern residual hcDNA levels in purified products. In the industrial cGMP setting, qPCR is widely acknowledged as the gold standard method for detecting residual host cell DNA. The inherent challenge with qPCR lies in its susceptibility to various sample matrices. Additionally, in viral vector products, a substantial portion of host cell DNA is either encapsulated within the viral capsid or attached to the capsid surface. Achieving effective hcDNA release necessitates a sample pretreatment method capable of degrading the capsid. The traditional approach involves employing a DNA extraction kit for the purification of hcDNA. However, this method is intricate and time-consuming, requiring skilled operators and potentially resulting in significant DNA loss. The recovery rate of DNA post-treatment may vary from 150% to 50%, introducing notable instability into quantitative hcDNA results and compromising detection accuracy. In response to these challenges, we have developed an extraction-free method utilizing a proprietary direct qPCR lysis buffer named AceLysis Buffer. The sample is diluted based on its hcDNA content, followed by a 1:1 mixture with AceLysis Buffer. Nucleic acids in the sample are released through 15 minutes of enzymatic digestion. The processed samples, following digestion and lysis, can be directly subjected to qPCR. This method, facile and expeditious in operation, obviates the need for high-temperature and prolonged DNA extraction, offering superior sample pretreatment performance compared to conventional methods. The recovery rate of DNA spiked into samples ranges from 85% to 110%, with a median of 95.53% (n=72), and the intermediate precision coefficient of variation (CV) is below 15%. In summary, the implementation of AceLysis Buffer for sample pretreatment expedites hcDNA detection and significantly enhances qPCR-based hcDNA detection, resulting in consistent and stable results.

1868. Performance Evaluation of an At-Line, Automated, and Rapid Mycoplasma Detection System for Cell and Gene Therapy Products

Ling Zhao, Zi Qin, Zhixing Yang

Huzhou Shenke Biotechnology Co., Ltd., Huzhou, China

Mycoplasma contaminations present frequent challenges in Cell and Gene Therapies. Unfortunately the compendial methods for their detection can be time-consuming, while general PCR methods require nucleic acid extraction and purification from samples. The AdvSHENTEK Mycoplasma DetectInnova System transformed RMM (rapid microbiological method) into a streamlined, fast, fully

automated, and easily portable laboratory system. It integrates nucleic acid extraction and real-time PCR assay, allowing a turnaround time of 2.5 hours from sample to result. Importantly it only requires less than 5 minutes of hands-on time, without specific PCR expertise to operate. The validation study shows the following feature: (1) Detection range: The AdvSHENTEK Mycoplasma DetectInnova System can load 4 different PCR assays in every run, and allow genomic DNA detection of over 180 species of Mycoplasma, Spiroplasma and Acholeplasma. The internal control in each sample ensure reliability of results by monitoring all steps from sample extraction through amplicon detection. (2) LOD (10cfu/mL) in different sample matrices: Limit of Detection (LoD) studies have been performed with a particular focus on species listed by the Pharmacopeias (not limited to below strains), in matrices of high protein, high cell density and media using 1 mL sample volume.Direct testing of 0.2 mL samples showed the positive results of mycoplasma detection by the system, so it is intended to facilitate in-process sample testing (raw materials, culture media, cell banks...) with very limited volume availability. (3) Specificity: The assay was unaffected by the presence of foreign genomic DNA of Clostridium (Clostridium acetobutylicum, Clostridium perfringens, Clostridium sporogenes), Lactobacillus (Lactobacterium thermophilum), streptococcus (Streptococcus pneumoniae, Streptococcus agalactiae, Streptococcus mutans), mammalian cell lines (CHO, Vero, 293T, HEK293, MDCK, NS0, Sf9, Hi5) and bacteria cell lines (E.coli, Pichia pastoris, Saccharomyces cerevisiae, Hansenula polymorpha) without any cross-reactivity. In conclusion, the AdvSHENTEK Mycoplasma DetectInnova System meets the pharmacopoeial requirements with a Limit of Detection of 10cfu/ml, and accommodates diverse sample types at various stages of Cell and Gene therapy manufacturing process, with the fully automated test system and hands-on time of less than 5 minutes. By utilizing pre-filled cassettes, the system significantly minimizes hands-on time, offering a streamlined solution for on-demand testing across various cell and gene therapy products. Table 1 MycoSHENTEK® Detection Level at 10 CFU/mL in Different Matrices

Sample Matrix	**Strain**			
Mycoplasma orale	Mycoplasma hyorhinis	Mycoplasma pneumoniae		
10 CFU/mL	**10 CFU/mL**	**10 CFU/mL**		
5% human albumin	24/24	24/24	24/24	
CHO-S	10^6 cells/mL	24/24	24/24	24/24
CHO-S	10^7 cells/mL	24/24	24/24	24/24
DMEM (20%FBS, 10%DMSO)	24/24	24/24	24/24	
ExpiCHO™ (10%DMSO)	24/24	24/24	24/24	

Note: 24/24=24 out of 24 test results positive

1869. Framework for Sustaining Excellence: Adapting Quality Systems in Advanced Therapies Amidst Dynamic and Fast-Paced Changes

Javier Cardenas
Azzur Group, LLC, Hatboro, PA, CA

Introduction: The rapid advancement of cell and gene therapies holds immense promise for revolutionizing medical treatment, yet the current landscape is marked by formidable challenges. Issues such as complex manufacturing processes, evolving technologies, and dynamic regulatory landscapes contribute to bottlenecks in product approvals. This abstract aims to address these challenges by exploring the adaptation of quality systems to streamline the approval process for cell and gene therapies. Methods: Our approach involved an extensive review of current regulatory guidelines and FDA / developer communications to gain insights into the existing regulatory frameworks governing cell and gene therapies. Additionally, we examined the progression of these therapies from academic discovery to the clinical and commercial manufacturing development lifecycle. This comprehensive analysis provided a foundation for designing a framework capable of adapting to the inherent variability in both the process and product as they evolve throughout the lifecycle. Results: The results of our research highlight the opportunity to design a dynamic framework that facilitates rapid adaptation to changes in the cell and gene therapy lifecycle. This framework allows for the swift integration of new technologies and methodologies, ensuring that quality systems and controls remain effective throughout the product development stages. Furthermore, our findings underscore the need for increased flexibility and interpretation within the regulatory landscape to accommodate the unique challenges posed by the evolving nature of these therapies. Conclusions: In conclusion, our review demonstrates that by streamlining quality systems and controls and implementing a flexible regulatory approach, significant time savings can be achieved in the approval process for cell and gene therapies. The adaptability of our framework ensures that regulatory requirements align seamlessly with the evolving nature of these therapies, ultimately expediting the translation of groundbreaking scientific discoveries into clinically and commercially viable treatments. This approach marks a crucial step towards unlocking the full potential of cell and gene therapies in a more efficient and timely manner.

1870. Strategies and Standards for Fit-for-Purpose Assay Design: A Focus on Cell Count and Cell Viability

Sumona Sarkar[1], Laura Pierce[2]
[1]Biosystems and Biomaterials Division, National Institute of Standards and Technology, Gaithersburg, MD,[2]National Institute of Standards and Technology, Gaithersburg, MD

The manufacturing and release of cellular therapy products (CTPs) requires high quality, robust, and validated analytical methods. Here we describe several international standardization efforts that support the fit-for-purpose development analytical methods to characterize cells and establish critical quality attributes. The ISO 23033 standard for the testing and characterization of CTPs provides a framework for establishing quality attribute that are product and MOA dependent

(fit-for-purpose). A series of ISO Cell Counting Standards (ISO 20391-1&2) establish methods for evaluating the quality of cell counting methods to support method selection and optimization. An ISO General Cell Viability standard (ISO/CD 8934) is currently under development to support the development of fit-for-purpose cell viability assays, where viability of cells is defined based on the intended use of the measurement. Use cases that demonstrate the utility of these standards are described for model Jurkat cell systems and model immunotherapy cell systems (Figure 1). These standards are critical for supporting innovation while reducing barriers to translation and reducing product development costs by easing the burden on any single entity to establish processes for analytical method development. The importance and utility of standards in cell and gene therapy is further supported by the recent deployment of the FDA CBER "Voluntary Consensus Standards Recognition Program for Regenerative Medicine Therapies" which has recognized several of the standards described here.

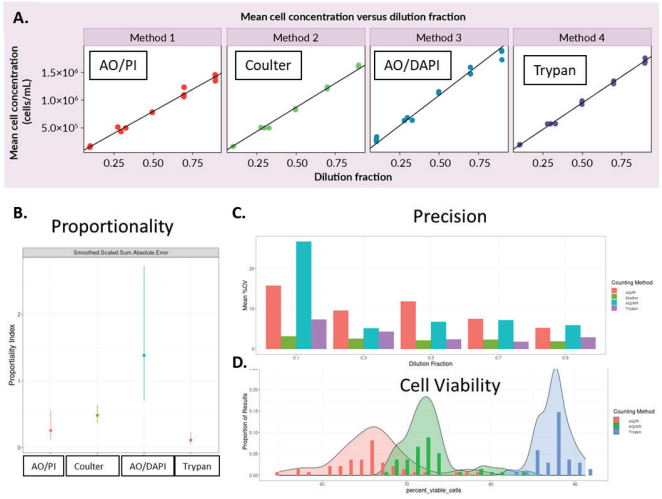

Figure 1: Example of using ISO 20391 to evaluate and compare the quality of different cell counting method using the open-source Cell Counting Method Evaluation Tool (COMET). Analysis indicates that AO/DAPI has a less proportional response than the other methods and AO/PI is less precise. The Coulter and Automated Trypan methods have similar performance, however, Coulter does not provide viability information. There is a bias in cell count and cell viability results. In this case, the Automated Trypan would be the selected method, for it's greater performance and ability to evaluate cell viability. However, the AO/PI can also be a reasonable candidate if for example the cell viability results are more meaningful for the application. These conclusions could be made without the use of a reference material or reference cell counting method. A) Mean cell concentration versus dilution fraction indicating average of the triplicate observations for each sample with error bars indicating the prediction intervals computed using the fitted flexible polynomial model. B) Proportionality Index (PI) value for each counting method, computed using the sum of the residuals. The vertical bars represent bootstrap confidence intervals computed at the requested confidence level. C) Mean %CV for each method at each dilution fraction. D) Histogram showing % viable cells for each method and the proportion of results at each measured viability

1871. Developing Image-Based Cell Assays to Effectively Monitor T-Cell Apoptosis and CAR Expression

Yongyang Huang[1], Ning Guo[2], Mackenzie Pierce[1], Leo L. Chan[1], Bo Lin[1], Yi Yang[2]

[1]Revvity Health Sciences, Inc., Lawrence, MA,[2]Novartis, Cambridge, MA

Chimeric antigen receptor (CAR)-T cell therapy is one of the novel cellular therapeutic options for cancer patients, such as the B-cell malignancies. To effectively develop and manufacture CAR-T products, it is imperative to identify and assess the critical quality attributes (CQAs) of CAR-T cells. Recently, the Food and Drug Administration (FDA) has published the chemistry manufacturing and controls (CMC) guidance for human gene therapy. Cell concentration, cell viability, and CAR expression are important quality attributes that should be reliably measured during the entire process. In this work, we developed an image-based method to quickly count viable T cell, measure viability, and assess CAR expression. Using this new method, we compare different gene delivery procedures to make CAR T cells, mostly through the electroporation process. Our results showed that high percentage of apoptotic cells were introduced during the electroporation process, regardless of the CAR vectors. Cell viabilities were checked daily with AO/PI dual fluorescent staining method and the viability data were correlated with apoptosis data. On Day 1 after transduction, measured cell viabilities of transduced SupT1 cell samples decreased to ~60% - ~70%. Compared to measured cell viabilities of un-transduced and electroporation SupT1 controls of over 90%, it was identified that the introduction of plasmids, other than the electroporation process itself, induced 20 - 30% additional cell death. Our apoptosis data further confirmed that most of the cell death after electroporation were potentially due to cell apoptosis. The transduced SupT1 cell samples were able to recover as their viabilities increased to >90% on Day 3. Percentages of CAR expression in transduced SupT1 cell samples were characterized by staining with APC-conjugated specific anti-CAR antibody. As for the percentages of CAR expression measurements, we observed similar CAR expression results in different transduced SupT1 cell samples on Day 1 and Day 2. We confirmed the percentages of CAR expression results using the flow cytometer and did not see significant differences between Cellaca® PLX Image Cytometer and flow cytometer results. With the advantages of ease of use, visual verification with captured cell images, and higher-throughput capability, Cellaca® PLX Image Cytometer may be potentially used as the convenient benchtop system for rapid assessment of the quantity and quality of CAR-T cells, which may ultimately improve the productivity of development and manufacture of CAR-T products.

Friday Posters: Pharmacology/ Toxicology Studies and Analytics/Assay Development

1872. Establishing Novel, Ultra-Sensitive, Widely Applicable qPCR and ddPCR Protocols to Support Gene and Cell Therapy

Bin Xu

Accurant Biotech, Cranbury, NJ

The FDA requires that a Quantitative Polymerase Chain Reaction method for gene therapy have a lower limit of quantitation (LLOQ) of less than 50 copies of viral gene in one microgram of DNA. However, the FDA has minimal guidance for other aspects of qPCR method validation. Thus, a fit-for-purpose adaptation of biological method validation guidelines from the FDA is commonly utilized for qPCR method development and validation by biopharmaceutical labs. Using this template, consensus parameters and criteria have been conceived in several white papers by leading scientists in qPCR applications. It is generally recognized that high concentrations > 500 ng / 100 µL of DNA template can dramatically decrease amplification efficiency due to insufficient denaturation of dsDNA. It is commonly recommended to use 10 to 100 ng of DNA template in 100 µL reaction. As FDA recommendations are listed per microgram of DNA, this means that an LLOQ of 5 copies / 100 µL reaction must be achieved. Such a task is exceptionally difficult to do reliably with current technologies. Moreover, if 20 ng of gDNA were used in the more common 20 µL qPCR reaction, it would require an even stricter reported LLOQ of 1 copy / reaction. To address this pressing issue, we employed a high concentration of **endonuclease-fragmented genomic DNA** 1 µg in 20 µL qPCR reactions (**Figure 1**). Through optimization, we were not only able to achieve good dilutional linearity (**Figure 2**) and acceptable amplification efficiencies (**Table 1**), but we found that such fragmented genomic DNA can make the assay more robust against changes in amplification efficiency, ensuring data reproducibility, while maintaining accuracy and precision very well under BMV guidelines. A reported LLOQ of 8 copies of target gene per 1 µg of DNA template can be achieved consistently (**Table 2**). In addition, we can use the reference gene Ct value to normalize target gene copy number in multiplex reactions. Thus, we assert that this optimized qPCR method represents a significant technical breakthrough and could mark a new chapter for qPCR applications. We have integrated this protocol into the validation of multiple qPCR methods, including a VSV-G gene qPCR assay for replicative component lentivirus as part of Car-T risk assessment, and a WPRE enhancer qPCR assay, which measures a sequence in the Car-T DNA construct to track Car-T cell populations. ddPCR has an advantage of offering absolute quantitation, a robust method that can often produce better LLOQ and LODs per reaction than qPCR. Our ddPCR strategy employed 300 ng endonuclease-fragmented template DNA in a 20 µL reaction. By adapting our novel set of protocols, we established a powerful ddPCR method development and validation system. Multiple ddPCR methods validated for different matrices, consistently reached an LLOQ between 1 to 8 copies per 20 µL reaction, equivalent to an LLOQ of 3.3 to 26.7 copies per 1 µg of DNA. **Table 3** shows data from a ddPCR run using blood DNA, demonstrating an LLOQ of 2 copies / 20 µL reaction, while **Figure 3** demonstrates that such a run exhibits near perfect dilutional linearity alongside a manufactured standard curve. In **Figure 4,** we provide a schematic that highlights our typical ddPCR method validation. In summary, our qPCR and ddPCR assay development and validation system presents an efficient methodology in quantitating target genes with ultrasensitivity, accuracy, and precision. Detailed technical information will be released in our presentation. Some recently published qPCR/ddPCR methods will be used as references to compare with our methods and results, to demonstrate how our novel methodologies advance the field.

Figure 1. Amplification Curves of 8 Calibrators in a Multiplex qPCR Assay

In this VSV-G qPCR assay for RCL activity, eight standard amplification curves (red) represent 8, 80, ..., 8 x 10^7 copies of VSV-G per 20 µL reaction per 1 µg genomic DNA. Conversely, the blue amplification curves represent a reference gene from the human genome.

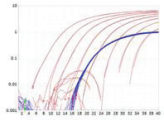

Figure 2. Linear Regression of 8 Calibrators in a Multiplex qPCR Assay

Our novel multiplex qPCR assay exhibits exceptionally high dilutional linearity ($r^2 > 0.999$) across the entire quantitation range (8 – 8 x 10^7 copies).

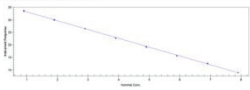

Figure 3. Linear Regression of 8 Calibrators in a Multiplex ddPCR Assay

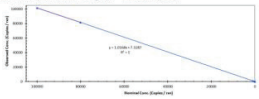
Our novel multiplex qPCR assay exhibits exceptionally high dilutional linearity ($r^2 > 0.999$) across the entire quantitation range (2 – 100000 copies).



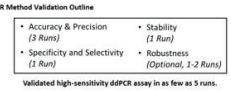


Figure 4. ddPCR Method Validation Outline

Validated high-sensitivity ddPCR assay in as few as 5 runs.

Table 1. Amplification Efficiencies of a Multiplex qPCR Assay at Various hgDNA Concentrations

TE Buffer	100 ng Undigested	1000 ng Undigested	1000 ng Digested
Amp. Efficiency	Amp. Efficiency	Amp. Efficiency	Amp. Efficiency
99.21%	92.54%	90.83%	91.49%
Ct (Std 1) = 9.229	Ct (Std 1) = 9.364	Ct (Std 1) = 9.190	Ct (Std 1) = 8.854

Table 2. The Multiplex qPCR Assay Exhibits Accuracy and Precision Well Within Acceptance Criteria between a Quantitation Range of 8 – 8x10^7 Copies / Reaction

For our novel qPCR assay, we observe accuracy and precision well within industry-established recommendations (%RE < ± 25% of nominal value, %CV < 25%) across the entire quantitation range (8 – 8x10^7 copies / reaction, corresponding to $\log_{10}$(copies/rxn) of 0.903 – 7.903).

Stds	Nominal Conc. $\log_{10}$(Copies/rxn)	Nominal Copies/rxn	TE Buffer		100 ng Undigested		1000 ng Undigested		1000 ng Digested	
			% RE	% CV	% RE	% CV	% RE	% CV	% RE	% CV
Std 1	7.903	8 x 10^7	0.1%	0.1%	0.4%	-1.9%	0.0%	-1.0%	0.2%	-1.2%
Std 2	6.903	8 x 10^6	0.0%	0.3%	0.0%	-0.2%	0.4%	0.3%	0.2%	0.0%
Std 3	5.903	8 x 10^5	0.4%	-0.2%	0.7%	0.7%	0.0%	1.4%	0.1%	0.5%
Std 4	4.903	8 x 10^4	0.3%	0.5%	0.5%	2.7%	0.5%	1.6%	0.4%	2.6%
Std 5	3.903	8 x 10^3	0.5%	0.9%	0.0%	3.4%	0.2%	0.7%	0.2%	2.3%

Table 3. Example of a Multiplex ddPCR Curve that Exhibits an Observed LLOQ of 2 Copies / 20 µL Reaction

In this mock standard curve that utilized our novel ddPCR assay, the standards spanning 100000 copies / 20 µL reaction (recommended ULOQ for the instrument by the manufacturer) down to 2 copies / 20 µL reaction exhibited an accuracy and precision that exceeded the current consensus acceptance criteria. Using this novel ddPCR assay, LLOQs ranging between 2 – 8 copies / 20 µL reaction are commonly observed for various matrices.

Stds	Nominal Conc. (Copies/ rxn)	Recorded Conc. (Copies / rxn)				% RE	% CV	PASS / FAIL Acceptance Criteria

Observed LLOQ for Curve: 2 copies / 20 µL Reaction								

GCC Consensus for ddPCR Method Validation Passing Criteria:

Expectations for Accuracy (%RE):
- %RE of < ±35% for samples with ≥ 50 copies / 20 µL ddPCR reaction.
- %RE of < ±50% for samples with < 50 copies / 20 µL ddPCR reaction.

Expectations for Precision (%CV):
- %CV of < 40% for samples with ≥ 50 copies / 20 µL ddPCR reaction.
- %CV of < 80% for samples with < 50 copies / 20 µL ddPCR reaction.

1873. mRNA/LNP Multiattribute Quantitation of Payload(s), Size and Heterogeneity with Size Exclusion Chromatography Coupled to Multiangle Light Scattering

Mateusz Imiolek[1], Lavelay Kizekai[2], Bala Addepalli[2], Szabolcs Fekete[1], Matthew Lauber[2]

[1]Waters Corporation, Geneva, Switzerland,[2]Waters Corporation, Milford, MA

Bringing cell and gene therapy drugs to market offers a chance for curing previously intractable diseases, but it comes with a formidable challenge of ensuring the safety and efficacy of increasingly complex therapeutics. These drugs are multicomponent ensembles (carrier + payloads), which means there are an array of critical quality attributes (CQAs) that must be monitored at each stage of their development - creating bottlenecks and delaying the process. High-throughput analytical methods that permit multiattribute measurements constitute a potential solution to this issue. Among the most efficient are chromatographic separations that can be coupled to advanced detectors, as with size exclusion chromatography paired with multiangle light scattering (SEC-MALS), which is of growing importance to emerging new modalities (AAVs, mRNA/LNPs etc.). Significant attention is being placed on creating fit-for-purpose SEC methods for lipid nanoparticles (LNPs) and their payload drug substances. Optimized widepore, low adsorption SEC columns (>450 Å) have been developed such that new techniques can be envisaged. Past investigators have applied a positive surface potential

gel permeation resin to perform LNP size exclusion chromatography. There is risk to this approach due to the potential adsorption and incomplete elution of free nucleic acid impurities. As such, we have alternatively investigated non-ionic, hydrophilic packing materials for SEC of LNPs. We have compared the recovery of the LNP materials across different columns and found optimal conditions that led to over >75% recovery with minimal tailing allowing for MALS mediated size, mass and heterogeneity measurements. Additional investigations are underway to further improve our understanding of analyte of recovery. Moreover, we developed conditions for a complete online disruption of the LNP carrier which enables a direct measurement of the nucleic acid payload(s) with a 2 ng as the limit of detection (LOD). We show that efficient size based separation is crucial for dual payload quantitation of gene editing therapy oriented LNPs containing both mRNA and gRNA. Various denaturing agents and LNP formulations (>5) were investigated to ensure universality of the disrupting conditions and the creation of a platform method. In summary, we demonstrate the versatile use of SEC-MALS to extract multiple CQAs (purity related e.g. RNA integrity or presence of process related impurities or strength related such as mRNA content) measurements for LNP RNA drug products and drug substances. With its deployability, SEC-MALS is coming to establish a cost and time-effective means to comprehensively characterizing a range of new nucleic acid therapies.

1874. Label-Free *In Vitro* Assay to Qualify Functional T-Cells as Starting Material for the Manufacturing of Advanced Therapies

Alberto Muniz[1], Vanessa Figliuolo Da Paz[1], Komali Pentakota[1], Rachel Beddard[2], Scott Jones[2], Anand Srinivasan[1]

[1]The Center for Innovations and Biodesign, BioBridge Global, San Antonio, TX,[2]Research and Development, BioBridge Global, San Antonio, TX

Background: Advanced therapies are hindered by the lack of standardization in the quality of the cells used as starting material for manufacturing. There are several manufacturing processes for CAR-T-cell therapies with many variabilities that affect the critical quality attributes of the resulting product. However, these processes seem to have the same measure of characterization, often limited to the expression of phenotypic markers. Qualification based on phenotypic markers do not truly account for the functional variabilities in the cells prior to manufacturing. Hence, the assessment of the function of donor-derived T-cells is crucial to the manufacturing and the potency of the product. Current *in vitro* methods for analyzing the function of T-cells suffer from long assay duration, fluorescence labeling, and a lack of data collection in real time. At BioBridge Global, we have developed an impedance-based label-free assay, for continuous monitoring of T-cells mediated killing of cancer cells as a measure of quality of the T-cells prior to manufacturing. **Methods:** T-cells were isolated from buffy coat of healthy donors and activated *in vitro* with anti-CD3 and anti-CD28. Epithelial lung cancer cell line A549 was used as a model for adherent tumor cells. Different concentrations of T-cells (effector) were challenged against A549 cells (target), and the rate of killing was quantified. The kinetics of activation of the T-cells was quantified between day-6 and day-9. The ability of T-cells to kill cancer cells was calculated by measuring the change in electrical impedance over time. This assay was also benchmarked with the current methodology of measuring cancer-cell killing using flow cytometry. **Results:** Our results demonstrated that the interaction of activated T-cells with cancer cells led to a decrease in impedance, indicating the killing of the cancer cells. T-cell mediated cytolysis of target cells was detected as early as 36 hours. The rate of T-cells killing cancer cells were directly correlated to the ratio of effector and target cells. The results obtained from our experiments performed with cells from three healthy donors demonstrated the variance in the functionality of T-cells as starting materials. We also observed differences in the rate of activation of T-cells derived from three healthy donors. **Conclusions:** In advanced therapies, we remain focused on the quality of the end product administered to the patients. It is equally important to invest significant attention to the functional attributes of the starting materials used to manufacture potent batches of cell and gene therapies. Our results demonstrate the potential of our assay as a quick and consistent method to qualify functional T-cells as starting material for the manufacturing of CAR-T cell therapies.

1875. Universal Pharmacokinetic Assessment of Anti-CD19 CAR-T Using Biocytometry

Martin Cienciala[1], Hynek Kasl[1], Pavel Fikar[1], Laura Berne[1], Monika Holubova[2,3], Daniel Lysak[2], Daniel Georgiev[1,4]

[1]Sampling Human, Inc., Berkeley, CA,[2]Department of Hematology and Oncology, University Hospital Pilsen, Pilsen, Czech Republic,[3]Biomedical Center of the Faculty of Medicine, Charles University, Pilsen, Czech Republic,[4]Faculty of Applied Sciences, University of West Bohemia, Pilsen, Czech Republic

Introduction: There is a critical clinical need for a technology capable of monitoring therapeutic activity in real time after infusion of cell therapies. High sensitivity cell enumeration of anti-CD19 CAR-T cells with a wide dynamic range was performed using biocytometry. This proof-of-concept study establishes the performance capability of the platform, employing the CD19 antigen for universal anti-CD19 CAR-T detection. The platform employs a homogeneous workflow, enabling routine testing of patients undergoing treatment and providing high resolution activity data of therapeutic cells in vivo. Methods:The performance of the platform was evaluated using a dilution series of anti-CD19 CAR-T cells in peripheral blood. The samples were prepared by combining PBMCs collected from a patient undergoing CAR-T therapy with peripheral blood isolated from a healthy individual. Each sample containing the equivalent of 1×105 leukocytes was further analyzed using the biocytometry workflow and BIOS(anti-CD19CAR) bioparticle system. Samples were processed without any additional washing or separation steps, with assay readout being performed on a microplate reader. Results: The technical validation of biocytometry demonstrated strong alignment with flow cytometry analysis. The sensitivity threshold for routine assessments was established at 1×10-4. Notably, biocytometry consistently showed a null limit of blank in samples devoid of any CAR-T cells, representing a significant improvement over flow cytometry, which can produce false positive events when employing methodology for universal CAR-T assessment. Conclusion: Biocytometry facilitates the universal quantification of anti-CD19 CAR-T cells and notably exhibits no background signal in samples obtained from healthy individuals. The unique homogeneous assay workflow provides a significant advantage for clinicians, featuring

a streamlined, high-throughput protocol that can be easily performed by laboratory technicians with minimal training requirements. Continued refinement of this platform promises to significantly improve the sensitivity of pharmacokinetic measurements, extending beyond the current limit of 1×10-4, holding substantial promise for future applications such as precision re-dosing.

1876. Impact of Pre-Existing Neutralizing Antibodies on Transduction, Safety, and Shedding of AAVhu68.FXN Following Intraparenchymal Injection into the Dentate Nucleus

Gourav R. Choudhury[1], Juliette Hordeaux[1], H. Isaac Chen[2], Joel M. Stein[3], Cecilia D. Dyer[1], Chelsea K. Wallace[1], Elizabeth L. Buza[1], Jessica A. Chichester[1], Liyang Han[1], Peter Bell[1], James M. Wilson[1]

[1]Gene Therapy Program, University of Pennsylvania, Philadelphia, PA,[2]Department of Neurosurgery, University of Pennsylvania, Philadelphia, PA,[3]Department of Radiology, University of Pennsylvania, Philadelphia, PA

Neutralizing antibodies (NAbs) generated in response to natural adeno-associated virus (AAV) exposure represent a major obstacle to the success of intravenous AAV-based gene therapies. NAbs can significantly impede AAV transduction and reduce drug safety; thus, high NAb titers are an exclusion criterion for many AAV-based clinical trials. The high prevalence of NAbs in humans renders many potential patients ineligible to participate. However, the brain is an immunologically privileged site, and some studies suggest that direct brain administration might be effective for correcting diseases that affect the central nervous system in an NAb-positive patient. Therefore, the development of safe and effective AAV gene therapies for neurological diseases such as Friedreich's ataxia involves understanding the potential impact of circulating NAbs on vector transduction and transgene expression in the brain. In the current study, we sought to evaluate the impact of circulating NAbs on AAV vector transduction and transgene expression following intraparenchymal injection to the brain. Rhesus macaques (*Macaca mulatta*) with variable antibody titers (0 to 1:160; NAb <5 (n=1); NAb 1: 20 (n=1), NAb 1: 160 (n=1)) received magnetic resonance imaging-guided bilateral injections of AAVhu68.hFXN at $1.6x10^9$ genome copies to the dentate nuclei (DN). We monitored the animals for 28 days via daily clinical observation, periodic blood work, and cerebrospinal fluid (CSF) collection. Brains were collected and processed for histopathological and transgene expression analysis upon necropsy (Day 28). All animals remained clinically unremarkable throughout the study and survived until the study endpoint. Evaluation of blood and CSF clinical pathology (including liver enzymes, coagulation parameters and biomarkers for cardiotoxicity) were unremarkable across the groups. Similarly, serum biomarkers for cardiac toxicity and coagulopathies were unremarkable in the treated animals. Intraparenchymal administration of the AAV vector did not induce a NAb response, even in those animals with high circulating NAb levels at dosing. Vector shedding was not detected in urine or feces at any time point. Evaluation of transgene expression via in situ hybridization indicated that similar hFXN expression levels in the DN were achieved in all treated animals independent of circulating NAb levels at the time of vector administration. In conclusion, the current study demonstrated that the presence of circulating NAbs did not impact vector transduction or transgene expression in monkeys upon intra-dentate nucleus administration of AAV vector, and that the treatment was safe and well tolerated. These preclinical data provide support for extending clinical trial inclusion criteria to permit the participation of NAb-positive patients in AAV-based clinical trials involving direct AAV administration to the brain.

1877. Is My Next-Generation Sequencing Deep Enough?

Tommaso Ocari[1], Takahiro Nemoto[2], Emilia Zin[1], Deniz Dalkara[1], Ulisse Ferrari[1]

[1]Institut de la Vision, Sorbonne Université, CNRS, Inserm, Paris, France,[2]Premium Research Institute for Human Metaverse Medicine (WPI-PRIMe), Osaka, Japan

Next-generation sequencing (NGS) has revolutionized genomics research since the early 2000s. Thanks to this technique, some fields of evolutionary biology such as directed evolution and deep mutational scanning have benefited from the availability of big data, improving the characterization of variants with desired properties. In these cases, NGS is used to screen biological libraries in order to measure the concentrations of different mutants by reading and counting them. Yet, because of several amplification steps in the experimental protocols, like PCR amplification or bacterial growth, NGS datasets suffer from large noise errors that are often neglected. To gain deeper insight in this phenomenon we have developed a statistical model of the entire NGS protocol, incorporating the exponential processes, inspired by Galton-Watson process theory. Our model predicts a simple proportionality law between the variance and the mean of the counts data, that we have validated in both real data and in-silico simulations. Finally, starting from this noise model, we provided a practical guideline on the optimal NGS depth for accurately measuring concentrations.

1878. De-Risking Clinical Trials Leveraging MRI-Guided Intraparenchymal Delivery by Validating Commercially Available Infusion Pumps for Gene and Cell Therapy Infusions

Stephanie Korszen, Princeton Saroha, Nate Willliams, Juan Carrasquillo, Chip Smith, Zachary Carr, Jeremy Stigall, Ernesto Salegio

ClearPoint Neuro, Inc., Solana Beach, CA

One of the most promising routes of administration (ROAs) for gene and cell therapies intended for the treatment of neurological disorders is direct intraparenchymal brain delivery. This ROA significantly reduces the volume of therapeutic needed and the risk of off-target toxicity, while also ensuring the therapy reaches its intended target. To facilitate the biodistribution of therapeutics within the desired target regions, a pressurized driving force such as that of convection-enhanced delivery (CED) is recommended. This requires an infusion pump with the ability to accurately and consistently deliver infusates on a microliter scale and at slow flow rates. An additional challenge is presented when performing infusions with MRI-guidance, as the infusion pump also needs to be MRI compatible. Most commercially available infusion pumps cleared for clinical use are not suitable for

MRI-guided intraparenchymal infusions, due to insufficient accuracy, inability to deliver at low flow rates, lack of MRI compatibility, or prohibitively high hold up / dead volumes required. In this study, we evaluated 3 commercially available infusion pumps using a buffer of similar density to that of suspension buffers currently used in many cell and gene therapy products. As part of our compatibility design to mimic a clinically-relevant pressurized system, we evaluated the accuracy and reliability of fluid delivery at the intended flow rates and volumes while delivering into an agar gel that mimics the backpressure of brain tissue. Our results indicated that there are multiple infusions pumps that can achieve sufficient accuracy at the desired flow rates and volumes used in clinical trials and preclinical studies of intraparenchymally-delivered therapeutics. The data and findings presented herein provide useful information when establishing drug delivery systems that will ultimately affect the design and conduct of associated clinical trials.

1879. MRI-Guided Intracerebroventricular and Intraparenchymal Dosing in a Swine Model

Maggie A. Mohr, Andy R. Carlson, Jenifer A. Sweet, Vinisha A. Pandya, Mark Johnson, Christen Simon
Northern Biomedical Research, Norton Shores, MI

Convection-enhanced delivery (CED) of gene and cell therapies directly into the brain offers a more precise therapeutic target when compared with systemic delivery. Moreover, bypassing the blood brain barrier decreases the risk of systemic toxicity. Real-time guidance using magnetic resonance imaging (MRI) allows for accurate targeting of regions of interest while considering individual differences in brain anatomy and vasculature, allowing immediate adjustments to be made to prevent delivery into unintended regions and subsequent off-target effects. Demonstrating safety and efficacy of new gene and cell therapies in large animal models is a fundamental step in pre-clinical translational research involving CED. Furthermore, choosing size-relevant models for clinical imaging and surgical techniques is paramount to the success and translation of pre-clinical studies. The large animal model of choice for many years has been the non-human primate (NHP), but due to disruptions in the NHP supply chain, it is necessary to evaluate alternative species. Pigs are gaining considerable attention as size-relevant models for clinical imaging and surgical techniques. The current study aimed to determine the efficacy of MRI-guided intracerebroventricular (ICV) and intraparenchymal CED in Gottingen minipigs using a custom-designed MR-compatible frame. Here we demonstrate successful MRI-guided ICV dosing using CED in the Gottingen minipig. Additionally, we demonstrate successful MRI-guided CED into several intraparenchymal sites, including the caudate, putamen, and substantia nigra of the Gottingen minipig. The success of this study demonstrates the practicality of the Gottingen minipig as an alternative large animal model in a pre-clinical setting for MRI-guided testing of therapeutics using CED.

1880. Achieving Uniform Vector Genome Transduction in the Brain Tissue after Intraparenchymal Delivery of Adeno-Associated Virus Gene Therapy Using Computational Fluid Dynamics and Quantitative Systems Pharmacology Modeling

Glen Ko, Zhiwei Zhang, Jiaolong Jiang, Victor (Seungchan) Yang, John Pappas
RES Group, Needham Heights, MA

Introduction: Gene therapy for neurodegenerative diseases like Alzheimer's, Parkinson's, and Huntington's often relies on intraparenchymal (IP) delivery, directly infusing the target tissue. While this ensures that the therapy reaches target areas, localized high vector genome transduction may pose risks of immunogenicity or toxicity. A mathematical model offers a method for investigating infusion conditions, enabling the delivery of an effective dose across a broad target area while minimizing exposure to localized high levels. **Methods**: Our model combines Computational Fluid Dynamics (CFD) to describe the hydrodynamics of the viral vector in tissue extracellular matrix, and Quantitative Systems Pharmacology (QSP) to describe the biological steps of the vector transduction (entry to the cell, cytoplasmic and nuclear processing, therapeutic protein expression). We have applied the CFD-QSP model to examine the infusion conditions of IP delivery to basal ganglia tissues for gene therapy treatment of Huntington's disease. **Results**: The CFD-QSP model successfully described the hydrodynamic flow of the infusate in the extracellular space and cellular uptake/processing of the therapeutic vector. Key findings include: (1) Spatial distribution of vector genome transduction is influenced by the competition between vector particle entry and intracellular trafficking governed by the vector particle characteristics, and the flow velocity in the extracellular space governed by infusion volume and rate and tissue size. (2) Achieving a uniform spatial distribution of the vector genome transduction becomes more difficult for larger tissues, posing translational challenges from preclinical data in smaller species to humans. (3) Enhancing uniform spatial distribution is feasible by optimizing infusion conditions, which include the number and strategic placement of infusions within the tissue. **Conclusion**: Calibrated to preclinical data, the novel CFD-QSP model for gene therapy delivery to brain tissues via IP administration provides a useful tool to study optimum infusion parameters for supporting human dose selection in clinical trials.

1881. Intraparenchymal Infusions to Deep Brain Structures Using Low Field MRI

Katelyn L. McKnight[1], Yixuan Liu[2], Russell R. Lonser[2], Orlando P. Simonetti[2], Stephanie Korszen[1], Kyle C. Wu[2]
[1]ClearPoint Neuro, Inc., Solana Beach, CA,[2]The Ohio State University Wexner Medical Center, Columbus, OH

The blood brain barrier (BBB) poses a significant challenge to delivering therapeutics for treatment of neurologic disorders. While many development efforts are focused on trying to develop treatments that can be delivered systemically (i.e., intravenous infusion), advances in image guided technologies have significantly improved the ability to deliver gene and cell therapies to targets within the

central nervous system (CNS) with extreme precision. The safest and most feasible approach for direct delivery employs a percutaneous approach paired with intraprocedural magnetic resonance imaging (MRI) technology; allowing for safe and accurate delivery that can be monitored in near real-time. Given the increasing volume of clinical trials in CNS gene and cell therapies that require direct delivery, the role of visualizing infusions within the brain is essential to scale-up of neurosurgical delivery. To this aim, the work herein presents the first study of intraparenchymal infusion guided by low field MRI. The 0.55T MAGNETOM Free.Max (Siemens Healthineers AG; Erlangen, Germany) was first validated for accuracy using a phantom, and was then used with an intraoperative MRI stereotactic frame (ClearPoint Neuro, Solana Beach, CA) to infuse contrast agent into multiple targets within the CNS of Yorkshire pigs. The results herein confirm the ability of the Free.Max to achieve submillimetric accuracy in targeting, and present imaging from infusions to the pig thalamus. These initial findings show great promise in the potential for eventually obviating the need to utilize high field MRI and greatly improve the affordability, accessibility, and surgical workflow options of direct brain delivery of gene and cell therapies.

1882. Characterization of Dorsal Root Ganglionopathy Following Intrathecal Delivery of High-Dose AAV9.CAG.EGFP Vector to Adult Rats

Yulia Dzhashiashvili, Brian M. Kelly, Greglynn D. Gibbs, Joan Wicks, Esteban A. Engel, Elizabeth Ramsburg

Spark Therapeutics, Inc., Philadelphia, PA

Intra-cerebrospinal fluid (CSF) AAV administration, as well as intravenous (IV) AAV administration, especially at high doses, have been reported to result in adverse histopathological findings in dorsal root ganglia (DRGs) of non-human primates (NHPs) and other animal species, including rats. Considering that DRG toxicity is an emerging safety concern for central nervous system (CNS)-directed AAV gene therapies, understanding the pathophysiology of the toxicity is critical to evaluating the risks associated with AAV vectors. In this study, we delivered AAV9 vector at a high dose ($3.1e^{12}$ vg) to lumbar CSF of adult Wistar Han rats to: 1) evaluate the susceptibility of the rat species to AAV-induced DRG pathology; 2) investigate their relevance as a preclinical model to monitor DRG toxicity, using non-invasive biomarker and neurofunctional assessments. At 45 days post-AAV administration, the microscopic histopathological changes in DRGs, such as increased cellularity, neuronal degeneration, and mononuclear cell infiltration, were predominantly minimal-to-mild in severity. The transduction efficacy, as evidenced by vector genome levels in DRGs, was positively correlated with levels of neurofilament light chain (NF-L), a biomarker of neuroaxonal injury, in plasma and serum of AAV-injected rats. A time-course analysis of NFL in serum revealed that values peaked between 15 to 30 days post-AAV administration. Moreover, nerve conduction velocity (NCV) of sciatic nerve, measured at 30 days post-dosing, was found to be significantly reduced compared to baseline NCV. To gain insights into mechanisms of DRG toxicity, a subset of animals was injected with AAV9 vector containing a modified CAG.EGFP cassette, which lacks both the Kozak sequence and the initial ATG codon, resulting in dramatically diminished EGFP protein expression. Notably, the severity of neuropathological findings in these animals was comparable to that observed in animals injected with AAV9 vector containing a full-length CAG.EGFP expression cassette. This suggests that the toxicity is not caused solely by transgene overexpression, as other reports have indicated. Overall, the data from this study support the possibility of using rats as a preclinical model for AAV-induced DRG toxicity assessment.

1883. Characterization of a Novel C9orf72 $(G4C2)_{80}$ Knockin Rat Model

Claire Meurice[1], Zhengyu Luo[1,2], Renee Bodinizzo[3], Yao Chen[4], Jaunetta Hill[5], Ye He[1,2], John Bladon[1,2], Juliana Laverde Paz[6], Zane Zeier[6], Mikhail Levit[4], Robert Jackson[1,2], James Dodge[5], Martin Goulet[1], Steven Rodriguez[5], Giulio Tomassy[1], Christian Mueller[1]

[1]Genomic Medicine Unit, Sanofi, Waltham, MA,[2]In Vivo Working Group, Sanofi, Cambridge, MA,[3]In Vivo Research Center, Sanofi, Cambridge, MA,[4]Precision Medicine and Computational Biology, Sanofi, Cambridge, MA,[5]Rare and Neurological Disease, Sanofi, Cambridge, MA,[6]University of Miami Miller School of Medicine, Miami, FL

GGGGCC (G4C2) hexanucleotide repeat expansion in the first intronic region of open reading frame 72 on chromosome 9 (C9orf72) is the most common genetic cause of Amyotrophic Lateral Sclerosis (ALS). G4C2 repeat expansion alters the expression of C9orf72 splice variants, leading to haploinsufficiency and gain of function toxicity: aberrant expression of pathological C9orf72 variants, RNA toxicity, and production of toxic dipeptide repeat proteins (DPRs). Understanding of mechanisms that lead to the development of C9orf72-ALS is complicated by the lack of effective rodent models that recapitulate disease progression. Developing such models is paramount for advancing our understanding of the disease and for the preclinical exploration of novel therapies. The C9orf72 $(G4C2)_{80}$ knockin rat model is a new model reported to exhibit motor and grip strength impairment as early as 8-mths-old, C9orf72 haploinsufficiency and an abnormal immune phenotype; the original publication did not explore all hallmarks of the disease (e.g., RNA foci, DPRs). To evaluate the usefulness of this model for preclinical research, we established and monitored a new colony of C9orf72 $(G4C2)_{80}$ knockin rats at Sanofi, aged them through 16-mths-old, and performed all *in vivo* procedures according to IACUC approved protocols at an accredited institution. Extensive behavioral characterization - locomotor, coordination, gait and grip strength assessments, using Open Field, Rotarod, Catwalk and Grip Force Test respectively - revealed no genotype dependent abnormalities, and this was corroborated by a lack of change in serum neurofilament-light and pathological assessments of brain, spinal cord and muscle following necropsy. While C9orf72 knockin rats exhibited C9orf72 haploinsufficiency, as previously published, and frequent sense and infrequent antisense foci, no dipeptide repeat proteins were detected up to 16-mths-old by IHC. Sanofi colony rats also did not have the published immune phenotype: altered thymus and cervical lymph node weight. Our results suggest that while C9orf72 $(G4C2)_{80}$ knockin rats exhibit haploinsufficiency and RNA foci, this model may be used for some pharmacokinetics/pharmacodynamic studies, but it does not provide a useful tool for efficacy studies.

Friday Posters: Molecular and Cellular Methods

1884. Assay Validation and Clinical Sample Stability of Recombinant AAV Vector in Five Human Shedding Matrices

Christopher Mcpharlin[1], Haiyan Ma[1], Allison Swarthout[1], Kristin N. Bell[1], Peter Ross[2]

[1]Northern Biomolecular Services, Kalamazoo, MI,[2]Bioanalytical, Kriya Therapeutics, Durham, NC

KRIYA-748 is an AAV-based vector that delivers a gated ion channel to the trigeminal nerve for trigeminal neuralgia, a disease characterized by frequent, debilitating facial pain attacks. Once expressed, the channel is activated by orally-administered varenicline ("Chantix®") leading to reduced excitation of transduced neurons. Assessments of vector shedding in clinical gene therapy trials are important to understand the likelihood of transmission of vector to untreated individuals and to provide information for environmental assessment. Regulatory authorities recommend the use of quantitative polymerase chain reaction (qPCR) assays to analyze vector shedding because of the high sensitivity and specificity of this method. Current guidance provides latitude in the approach used for vector shedding assessments based on product-specific variables such as route of administration, replication competent vs. incompetent vectors, and presence of potentially oncolytic transgenes. For vector shedding, assay validation provides a thorough understanding of the capabilities and limits of the method which in turn allow for higher confidence in the results. Since vector shedding studies are typically conducted in multiple matrices each with their own particular challenges for qPCR detection, it is important to understand how different matrices impact the reported result, the recoveries of the vector genomes from each matrix, and the stability of the test article vector genomes in these matrices. Here we report the method validation of a qPCR assay for analysis of recombinant AAV (rAAV) vector genomes across five human clinical matrices; plasma, tear swab, saliva, nasal swab, and urine, and recommend parameters to evaluate during method development and validation for similar replication incompetent AAV gene therapy products. The recoveries of the vector genomes from the five matrices and the stability of the vector genomes in the five matrices were then evaluated using the validated qPCR assay. **Method Validation, Results, and Conclusion:** Ten validation runs were performed with serially diluted DNA standards, negative controls, and QCs, plated in the presence of DNA extracted from each of the shedding matrices evaluated. Each completed run met the validation acceptance criteria for target gene amplification. The ULOQ, LLOQ, and LOD were 10^8, 50, and 10 double stranded copies per reaction, respectively. All five shedding matrices QC sets passed acceptance criteria demonstrating that target DNA detection in plasma, urine, saliva, tear swab, and nasal swab can be accurately and precisely interpolated from a standard curve that does not contain matrix genomic DNA. The extensive evaluation of the fit-for-purpose validation parameters confirms the applicability of the qPCR method for clinical vector shedding assessments. **Recoveries of Vector Genomes from Five Clinical Matrices:** 39% - 55% from plasma; 111% - 140% from urine; 58% - 70% from tear swab; 59% - 70% from saliva swab; 56% - 69% from nasal swab. **Stability of Vector Genomes in Five Clinical Matrices:** The rAAV vector genomes were found stable when tested under the following storage conditions: 4 hours @ RT (15 to 30°C), 24 hours @ 2 to 8°C, 3 cycles of freeze/thaw, 1 month @ -10 to -30°C, 1 month @ -60 to -90°C, and 6 months @ -60 to -90°C.

1885. Characterization of Residual DNA Impurities in rAAV-Based Therapies through Short and Long-Read Sequencing

Jawhara Karam, Tomoko Maekawa

Passage Bio, Philadelphia, PA

The genetic payload of recombinant adeno-associated viral (rAAV) vectors is a critical quality attribute for the vector's efficacy and safety. Impurities (e.g., residual DNA derived from host cells and plasmids utilized during the manufacturing process) in rAAV therapies must be kept at minimal levels to reduce the potential of adverse events in patients. Therefore, characterizing residual DNA within the rAAV vector remains of paramount concern for manufacturers. Gold-standard methods to quantify DNA copies, such as qPCR and ddPCR, are used to quantitate the concentration of residuals in a product. However, these methods rely on the presence of a short amplicon and may underestimate the total number of residuals by failing to detect residuals without the amplicon sequence. Therefore, we established short and long-read next-generation-sequencing methods for a more thorough characterization of residual DNAs within the sample. Illumina short-read sequencing is advantageous in the fact that reads across short regions of sample DNA have a high level of depth coverage. However, Illumina cannot provide a complete size distribution of residuals since sample DNA must be fragmented as part of the library preparation. Furthermore, size selection during library preparation reduces the presence of residual fragments below the targeted fragment size. To address these gaps, long-read sequencing utilizing the Oxford Nanopore platform was performed in conjunction with Illumina short-read sequencing. Downstream analysis for both sequencing methods involved quality control and mapping to reference sequences. Samples are first mapped to the cis plasmid containing the transgene, followed by mapping to the rep/cap plasmid, helper plasmid, human genome, E. coli, and lambda phage. Illumina data showed ≥ 99% of reads mapping to the rAAV genome with up to 1% residual DNA impurities. Comparable results were demonstrated with long-read sequencing. Furthermore, the long-read sequencing data provided insight into the size distribution of residual DNA from the host organism, cis plasmid backbone, and plasmids (helper and rep/cap). Together, this information can be used to provide a more complete profile of the impurities present in rAAV vectors.

1886. Quantification of Residual Plasmid DNA Impurities Utilizing Short and Long ddPCR Amplicons

Sarah Monaco, Tomoko Maekawa

Passage Bio, Philadelphia, PA

Passage Bio is a gene therapy company developing recombinant adeno-associated viral (rAAV) products using a triple transient transfection system with a cis plasmid containing the transgene, a Helper plasmid, and a RepCap plasmid. To assess product quality and safety, it is essential to monitor process-related impurities including residual

plasmid DNA concentrations. The current residual plasmid DNA assay for GMP release testing utilizes a short Droplet Digital™ PCR (ddPCR) amplicon targeting the Kanamycin resistance gene (KanaR), present in all three plasmids. The current method quantifies total residual plasmid concentration, but cannot determine contributions from each plasmid, which is critical for evaluating potential adverse events in patients (e.g., introduction of a potential oncogene derived from the helper plasmid). To circumvent this limitation we developed short ddPCR amplicon assays to specifically quantify residual Helper and RepCap plasmid DNA. Our results demonstrate that the cis plasmid (~80%) is the largest contributor to residual plasmid DNA impurities, followed by the RepCap plasmid (~15%) and the Helper plasmid (~5%); despite the 1:10:10 molar ratio used during transfection. We also developed long ddPCR amplicon (~700bp) methods to assess the size distribution of each residual plasmid DNA, which is important due to safety limitations setting a threshold on larger amplicons in products. We found that residual cis plasmid DNA (most likely originating from the cis plasmid backbone) was longer in size than that from the Helper and RepCap plasmid-specific sequences. Collectively, our results indicate that residual plasmid DNA impurities from the cis plasmid backbone may present a greater likelihood of assembly into rAAV vectors due to their proximity to ITRs. Our novel ddPCR methods are a useful tool for product characterization studies as well as future process development.

1887. Development of an *In Vitro* Potency Assay for an AAV Gene Therapy Delivering a Functional Version of *SHANK3*

Michael A. Murphy, Michael De Petrillo, Kalyn Bauldwin

Analytical Development and QC, Advanced Medicine Partners, Durham, NC

Patients with *SHANK3* haploinsufficiency present with a debilitating neurodevelopmental disorder including Phelan-McDermid syndrome (PMS) that is characterized by severe intellectual disabilities, impaired or absent speech and language, deficits in motor skills, behavioral challenges, and autism and/or autistic features. SHANK3 is enriched in glutamatergic synapses where it participates in regulation of postsynaptic signaling by acting as a molecular scaffold through its interactions with other proteins located in the postsynaptic density. JAG201 is an AAV9-based gene therapy intended to deliver a functional version of *SHANK3* to treat PMS and *SHANK3* haploinsufficiency caused by loss of function mutation. Due to DNA packaging constraints of AAV capsids and the large size (1731 amino acids) of the multidomain-containing SHANK3, Jaguar Gene Therapy developed JAG201 to express a miniature version of human SHANK3 (miniSHANK3). To support product development, an *in vitro* assay was developed to characterize the potency of JAG201. The assay uses SHANK3 knockout (SKO) cells and is based upon the SHANK3 mechanism of action in which the protein functions as a scaffold within the postsynaptic density. Following transduction of the SKO cells with JAG201, cell lysates are prepared and added to microplates coated with a peptide from a SHANK3 binding protein. After capture of miniSHANK3 to the microplate through its interaction with the coated protein, an antibody specific for a second SHANK3 binding protein is used in conjunction with a horseradish peroxidase-conjugated antibody and a suitable enzyme substrate to produce antibody-specific fluorescence. The level of fluorescence is proportional to the quantity of SHANK3 binding partner and functional miniSHANK3 present in the lysate. Upon completion of initial development, the assay was qualified for accuracy, precision, linearity, range, and stability indication. All qualification results indicate that the assay is suitable for measuring potency to support JAG201 lot release and stability monitoring. Clinical testing of JAG201 is slated to start this year.

1888. A Novel Technology for Accurate Quantification of Viral Genome and Determination of Lipid Nanoparticle Encapsulation Efficiency

Subhanjan Mondal, Kevin Hsiao, Nathan Feirer

Promega Corporation, Fitchburg, WI

Adeno-associated viral (AAV) vectors show great promise as a delivery system for gene therapy. However, development of robust methods for quantitation, infectivity and dose-determination has remained a challenge. Lipid nanoparticles (LNP) have also emerged as a successful non-viral delivery system as evident from the success of the COVID-19 vaccines. For LNP characterization methods for determining encapsulation efficiency remains a technical gap. In this work we show that through use of a membrane impermeable small molecule (TruTiter Reagent) that binds to nucleic acid both DNA or RNA) and covalently conjugates with it we can accurately and consistently determine AAV viral genome titers and LNP encapsulation efficiency. For quantification of AAV viral genome titer, samples are typically pretreated with DNase to remove vector and packaging plasmid DNAs, and often time followed by proteinase K treatment to remove DNase and release DNase -resistant packaged viral genomes. The challenges using DNase include the incomplete digestion resulting in residual DNA outside the capsids and the inaccessibility of DNase to nucleic acid from partially ruptured viral capsids due to the large size of DNase. To address these challenges using TruTiter Reagent we first show that it is effectively excluded from AAV particles at all tested concentrations (< 100uM). We then developed a workflow for determination of viral genome titers that involves addition of the TruTiter™ reagent at 10uM to a sample for 30 minutes. This covalently crosslinks any nucleic acid that is free or from ruptured viruses. Then a neutralization solution is added that stops the crosslinking process, followed by proteinase K treatment to release the protected DNA. The sample is then analyzed using qPCR or dPCR. To determine if genome titer measurement using TruTiter results in accurate and consistent measurements, we treated AAV of different serotypes (AAV2, AAV9 and AAV8) with different temperature and cell lysis agents typically used in AAV manufacturing process and determined genome titers using both DNase and TruTiter™ methods. For samples treated at 65°C, the DNase treatment showed a two times higher average genome unit measurement and a 2.7 times greater standard deviation, indicative of TruTiter™ method being more robust for genome titer measurements. For both detergents genome tittering showed a greater standard deviation compared to the TruTiter™ method. This study demonstrates the inherent variability in viral genome quantitation when using DNase, and the variability is reduced when using a small molecule-based approach. Encapsulation efficiency for LNP is an important parameter for optimizing the right type of lipid or understanding LNP storage condition. TruTiter™ Reagent is excluded from the LNP particle, thus protecting the nucleic acid inside

and is utilized to determine encapsulation efficiency. We observed that lipids used in LNP are often inhibitors of Reverse Transcriptase and DNA polymerase making nucleic acid purification a prerequisite for analyzing LNP encapsulation efficiency. First, we used GFP mRNA encapsulated in a LNP and treated at different temperatures (22°C, 42°C and 55°C) to induce rupture of the lipid nanoparticle. Encapsulation efficiency was determined using PicoGreen or the TruTiter technology. TruTiter shows a significant reduction in encapsulation efficiency with increase in temperature whereas PicoGreen did not show any appreciable loss of encapsulation even when the LNP structural integrity was lost. Next, we used in *vitro* transcribed RNA (Firefly luciferase) and incubated with transfection reagents that do or do not form LNP complexes. Each sample was treated with and without the TruTiter™ Reagent. After the neutralization and nucleic acid extraction, nucleic acid was analyzed for amplification of the target gene using RT-qPCR.

1889. Development of Novel Bioluminescent Assays for Sensitive and Specific Quantitation of Double-Stranded RNA in mRNA Therapeutics

Jeff Nelson, Rich Moravec, Jun Wang, Jim Hartnett, Mei Cong, Jamison Grailer

Promega Corporation, Madison, WI

mRNA-based therapeutics have shown clinical efficacy, evidenced by the success of the mRNA vaccines for SARS-CoV-2. mRNA drug substance is typically generated by in vitro transcription (IVT). One byproduct and contaminant of IVT is the formation of double-stranded RNA (dsRNA). dsRNA is highly immunogenic, can induce inflammation and cell death, and inhibit protein translation, including the protein encoded by the therapeutic mRNA. As such, dsRNA must be measured for all IVT products to ensure safety and efficacy. However, existing dot bot and ELISA technology to detect dsRNA is neither sensitive nor quantitative. Herein, we describe the development of novel assay technologies for sensitive and specific quantitation of dsRNA in IVT products and following encapsulation of IVT products in lipid nanoparticles (LNPs). First, NanoBiT® split luciferase was applied to detect dsRNA in IVT drug substance. dsRNA binding domains were genetically attached to either SmBiT or LgBiT. In the presence of dsRNA, the SmBiT and LgBiT fusions bind via the dsRNA binding domains, resulting in dimerization and the complementation of functional NanoBiT® luciferase. NanoBiT® then generates light which is proportional to the amount of dsRNA in the sample. The assay detects dsRNA greater than or equal to 30 base pairs and is independent of the size and sequence of the dsRNA contaminant. The assay does not cross-react with single-stranded RNA or DNA and is highly sensitive, with a limit of quantitation less than 100 pg/ml. As a complementary tool to the biochemical assay, we developed a cell-based bioassay to detect dsRNA encapsulated in LNPs. dsRNA/LNPs are taken up by endocytosis where Toll-like receptor 3 (TLR3) detects dsRNA. Activation of TLR3 initiates a signaling pathway that is detected by a TLR3 pathway-specific promoter driving luciferase expression. This pathway likely represents the most physiologically relevant readout of dsRNA bioactivity. Both assays are developed in "add-mix-read" format with no wash steps or media transfer, and exhibit robust, sensitive, and repeatable performance for specific detection of dsRNA in mixed solutions.

1890. Comprehensive Analysis of Off-Target and On-Target Effects Resulting from Liver-Directed CRISPR-Cas9-Mediated Gene Targeting with Adeno-Associated Viral Vectors

Kshitiz Singh[1], Raffaele Fronza[2], Hanneke Evens[1], Marinee Chuah[1], Thierry Vandendriessche[3]

[1]Department of Gene Therapy & Regenerative Medicine, Free University of Brussels (VUB), Brussels, Belgium,[2]ProtaGene CGT GmbH, Heidelberg, Germany,[3]Free University of Brussels (VUB), Brussels, Belgium

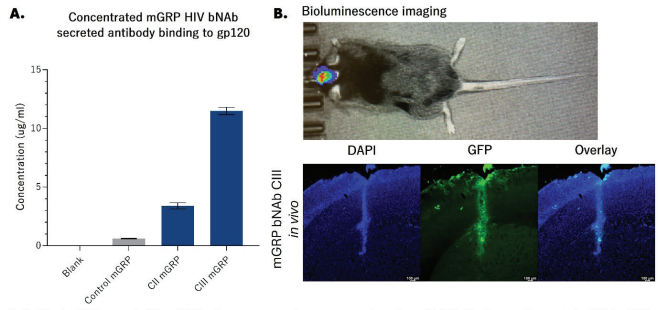
Comprehensive genome-wide studies are needed to assess the consequences of adeno-associated virus (AAV) vector-mediated CRISPR-Cas-based gene editing. In this study, we evaluated CRISPR-Cas-mediated on-target and off-target effects and examined the genomic integration events of AAV vectors employed to deliver the CRISPR-Cas components to the liver in neonatal mice. The guide RNA (gRNA) was specifically designed to target the coagulation factor IX gene (*F9*). Whole-genome sequencing (WGS) was conducted to examine the on-target and off-target insertions/deletions (indels). On-target editing events were quantified using the CRISPResso algorithm, revealing efficient CRISPR targeting (36.45 ± 18.29%) in the *F9* locus. In contrast, off-target effects were very rare or below the WGS detection limit since only one single putative insertion was detected out of 118 reads (n = 3), based on >100 computationally predicted off-target sites. Genome-wide AAV integration events were identified by WGS and Shearing Extension Primer Tag Selection Ligation-Mediated PCR (S-EPTS/LM-PCR), demonstrating that AAV integration occurred preferentially in the CRISPR-Cas9 induced double-strand DNA breaks in the F9 locus. In contrast, AAV integrations outside this locus were not in proximity to any of ~5000 putative computationally predicted off-target sites (median distance of 70 kb) and likely represent canonical CRISPR-Cas9-independent AAV integrations.

1891. Real-Time Phase Shift Imaging and Single-Cell Tracking of Human Placental Cells for Discovering Alterations Induced During Lentiviral Transduction

Sarah E. Wachtman[1], Martin Rodriguez[1], Nicholas P. Edenhoffer[1], Ritu M. Ramamurthy[1], Christopher Doering[2], H. Trent Spencer[2], Anthony Atala[1], Christopher D. Porada[1], M Graça D. Almeida-Porada[1]

[1]Fetal Research and Therapy Program, Wake Forest Institute for Regenerative Medicine, Winston Salem, NC,[2]Dept. of Pediatrics, Aflac Cancer and Blood Disorders Center, Emory University and Children's Healthcare of Atlanta, Atlanta, GA

Cells that have been genetically engineered using viral vectors to encode therapeutic proteins have tremendous clinical potential. While characterization of the final clinical product is usually performed several passages after transduction, little is known about cellular kinetics and dynamics during and immediately after transduction. Therefore, multiple testing approaches were used to determine the



effects of lentiviral vector (LV) transduction on various cellular parameters. Real-time phase shift imaging and single-cell tracking of human placental cells (PLCs) transduced using a LV encoding a bioengineered FVIII transgene, mcoET3 (MOI = 5 and 10) was employed to investigate how LV transduction affects PLC kinetics and morphology during this period. PLC were cultured in a PHI HoloMonitor M4 and scanned for a total of 5 passages: one passage prior to transduction (36hrs), during transduction (24hrs), and three passages post-transduction (36hrs each). Non-transduced PLC (PLC-NT), PLC-MOI 5, and PLC-MOI 10 were monitored in parallel, and the experiment was repeated 3 times. Thirteen parameters of cell kinetics were monitored: proliferation, motility, motility speed, cell family tree, phase shift, optical volume, optical thickness, eccentricity, irregularity, surface area, migration, roughness, and roughness kurtosis. After the final monitoring session, RNA, DNA, and culture media were collected to quantify endogenous FVIII/vector-encoded FVIII expression (RT-qPCR), vector copy number (VCN; by qPCR), and FVIII activity (aPTT assay). FVIII mRNA expression, FVIII activity, and VCN confirmed efficient PLC transduction proportional to the MOI used. Baseline kinetics of the PLCs prior to transduction exhibited changes in motility (μm; matched pairs t-test, p=0.009), motility speed (μm/h; p=0.002), eccentricity (p=0.04), and irregularity (p=0.017). Within the first 4hrs post-transduction, both the PLC-MOI 5 and PLC-MOI 10 groups showed a statistically significant decrease in cell motility speed (μm/h) and optical volume (μm^3) when compared to the PLC-NT controls. Interestingly, by passage three post-transduction, all cell kinetic parameters normalized to baseline, and no significant differences were found between the groups. We hypothesize that because a decreased optical volume (OV) is most often due to the gain or loss of osmotically active solutes, it is possible that *clathrin-mediated endocytosis* of the LV leads to osmotic changes causing an OV decrease. Likewise, microtubules and microfilaments have dual functions, dynamically maintaining cell shape and enabling motility. MAP1-family proteins bind along the microtubule lattice and help tether incoming viral capsids to the microtubular network, thereby promoting cytoplasmic trafficking. Thus, it is possible that the presence of LV particles induces dysfunction of the microfilament network leading to decreased cell motility. However, by passage three, the abnormalities in cell function are restored to normal. These studies are critical to the continued development of LV-modified PLC, which are being developed for in utero applications. Further studies investigating how LV transduction affects each of these parameters and correlating them with specific biologic functions are underway.

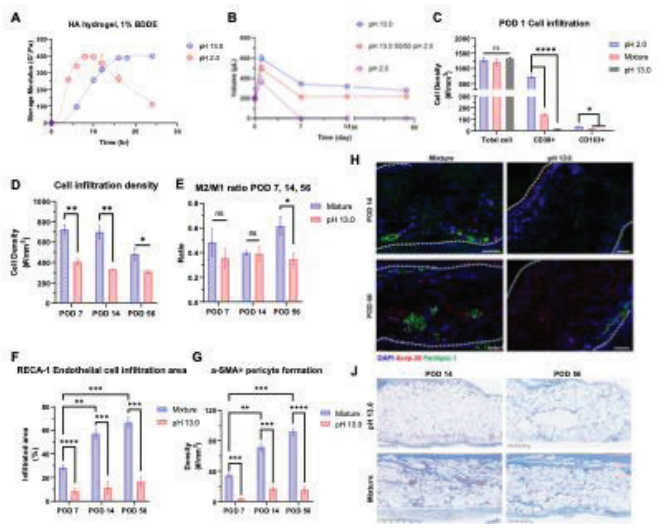
1892. Development of HIV Neutralizing-Antibody Expressing Glial Progenitor Cells for Viral Clearance from the Brain

Lorissa Ingsay McDougall[1], Abdolrahim Abassi[2], Mohammad Sajadi[2], Alonso Heredia[2], Linda Chang[1], Yajie Liang[1], Chengyan Chu[1], Miroslaw Janowski[1], Piotr Walczak[1]

[1]Diagnostic Radiology and Nuclear Medicine, University of Maryland, Baltimore, Baltimore, MD,[2]Institute of Human Virology, University of Maryland, Baltimore, Baltimore, MD

Human immunodeficiency virus (HIV) infection occurs when CD4 T-cells recognize and bind the viral envelope glycoproteins on the chemokine receptor 5 (CCR5), enabling the virus to hijack these T-cells and spread throughout the lymph system and blood. Fortunately, due to improvements in the detection and treatment of HIV, the mortality rate has dropped to only 2%. However, a person with HIV (PWH) will be dependent on lifelong anti-retroviral medications, which often leads to complications involving liver and kidney toxicity, lipid changes in the gut, and neurological changes. Additionally, these treatments are inefficient at eradicating viral reservoirs from the brain, which often leads to systemic re-infection upon drug cessation. Therefore, our research aims to develop a protocol for the engineering of broad neutralizing antibody (bNAb) expressing primary glial progenitor cells (GRPs) by introducing a lentiviral construct encoding a bNAb against HIV. GRPs mature into support cells of the brain, which, when injected inter-arterially (IA), have been proposed to migrate across the endothelium into the brain and thus are our model of choice for the clearance of HIV-infected cells. Additionally, the lentiviral constructs were designed to include the heavy and light chains of the antibody, a linker and cleavage site, as well as a green fluorescent protein (GFP) for detection. We have shown successful transduction of the constructs (CII and CIII) in luciferin-producing immortalized mouse GRP cells (mGRP) through FACS cell sorting and release of the bNAbs *via* ELISA detection and flow cytometry of glycoprotein expressing B-lymphocyte cells. Additionally, stereotactic injection of these cells into the brains of IL34+ NOG mice identified survival of the mGRPs after three days *via* BLI imaging of luciferin metabolic activity and GFP-positive cells in the needle track of the brain slices. Therefore, we expect to observe antibody binding with GFP localization after injection of the mGRPs into humanized HIV-infected mice. Additionally, the development of genetically engineered primary mGRPs will allow for IA injection and a broader distribution of the cells in the brain, and a higher rate of HIV infected cell neutralization.

A. ELISA of mGRP control, CII and CIII cell supernatant shows greater detection of bNAb binding to glycoprotein 120 (gp120) when compared to the control in both CII (increase of 2.8ug/ml) and CIII (increase of 10.9ug/ml). **B.** BLI imaging of the mGRP cells three days post injection into the IL34+ NOG mice identified cell survival, and immunofluorescence of the GFP-positive mGRPs in the mouse brain.



1893. Pro-Angiogenic Response to Hyaluronic Acid Hydrogel Matrix with a Tunable Degradation Profile

Kailei Ding, Jiayuan Kong, Hexiang Feng, Hai-Quan Mao

Johns Hopkins University, Baltimore, MD

Statement of Purpose: Hyaluronic acid (HA) hydrogel is widely used for cell theapy and tissue engineering due to its excellent biocompatibility and biodegradability profile. Here, we developed an HA hydrogel with tunable degradation kinetics by combining two HA hydrogel microparticles with different degradation rates, and tested the

hypothesis that the tunable, gradual degradation profile can enhance the recruitment and immunomodulation of host immune cells and improve the pro-angiogenic property of the hydrogel in vivo. We evaluated macrophage infiltration and polarization, hydrogel volume retention, pro-angiogenic effect, and subsequent soft tissue remodeling within the HA hydrogel. **Methods:** We first crosslinked HA using 1,4-butanediol diglycidyl ether (BDDE) at pH 2.0 and pH 13.0 to obtain two HA microgels with distinctively different degradation rates. To generate HA hydrogel with a tunable degradation rate, we mixed the two microgels at 1:1 ratio. The degradation rates of hydrogels were monitored by shear storage modulus (G') over time. The microgels prepared at pH 2.0, pH 13, and the mixed microgels (1:1 ratio) were tested to assess *in vivo* degradation and cell infiltration following subcutaneous injection in Sprague-Dawley rats (8-10 week old). $CD38^+$ and $CD163^+$ macrophages were examined by immunostaining. The pro-angiogenic and adipogenesis responses were assessed via immunostaining of endothelial cells/pericytes and adipocytes/collagen deposition, respectively. **Results:** HA hydrogels crosslinked with BDDE at pH 2.0 and pH 13.0 showed similar storage modulus (G'~250 Pa) but a distinct degradation profile (Fig. 1A). The shape retention and cell infiltration were examined after subcutaneous injection (Fig. 1B). The pH 2.0 HA hydrogel degraded within 7 days whereas the pH 13 hydrogel retained more than 50% of the peak volume by day 56. A substantial level of infiltrated macrophages was observed in the pH 2.0 microgel at 1 day post-injection due to rapid degradation (Fig. 1C). The microgel mixture consistently showed a higher macrophage count than the pH 13 microgel from day 7 to 56 post-injection (Fig. 1D-E). At both time points, endothelial cell (RECA-1+) and pericyte (-SMA+) infiltration was significantly greater in the microgel mixture than the pH 13 microgel (Fig. 1 F-G). Furthermore, the microgel mixture induced a higher degree of adipogenesis than the pH 13 microgel (Fig. 1H). Masson trichrome staining indicates more cellular content, collagen deposition, and neo-tissue formation in the microgel mixture at day 56 post injection compared to the pH 13 microgel (Fig. 1J). **Conclusion:** The engineered hydrolysable HA microgel mixture with a tunable degradation profile creates pores within the HA hydrogel gradually after implantation *in vivo*. The degraded HA microgel may serve as a biostimulatory cue facilitating infiltration and polarization of host macrophages to augment pro-angiogenic responses and potentially tissue remodeling. **Figure 1.** (A) Shear storage modulus change during the gelation process. (B) Volume retention of hydrogels *in vivo* over time. (C-E) Cell infiltration and polarization at 1 (C) and 7, 14, and 56 days (D-E) after subcutaneous injection in SD rats. (F-G) Endothelial cells infiltration (F) and pericytes formation (G) at 7, 14, 56 days after injection. (H-J) Adipose tissue formation (H) and collagen deposition (J) at 14 and 56 days after injection.

1894. A Rapid and Scalable 96-Well Platform to Screen CARs and TCRs

Ana Chadbourne, Alexander Boucher, Elise Kim, Peter Moua, Christopher B. Driscoll, Shen Lu, Joshua Ferrell, Andrew Basinski, Stacie Seidel, Cherylene Plewa

ElevateBio, Waltham, MA

Autologous adoptive cell transfer (ACT) therapy has revolutionized the landscape of cancer treatments and has shown great promise for patients with otherwise non-viable therapeutic alternatives. The early success of autologous Chimeric Antigen Receptor (CAR)-T therapies in heme indications in the clinic led to a rapid application to the solid tumor setting, expansion to allogeneic and iPSc derived cell modalities, as well as to other cells of the immune system such as NKs and macrophages. Regardless of the modality, identification of a target binder that will give rise to the CAR or T cell receptor (TCR) construct is a necessary first step in the development of engineered cell therapies. Screening platforms for nomination of CAR and TCR constructs typically rely on high throughput platforms for which the initial criteria involve selection of binder molecules that express at reasonable levels on the T cell surface. These platforms are seldom scalable, utilize non-MOI normalized lentiviral vector preparations and functional readouts are typically limited to IFNg production which may or may not correlate with cytotoxic activity. When using these platforms, top-candidate selection relies on time-consuming, larger-scale engineered cell production to produce enough cells to run *in vitro* functional assays required for candidate nomination and validation in *in vivo* tumor models. Here we report a rapid, mid-throughput, comprehensive, scalable CAR/TCR screening platform for the selection of candidate CARs and TCRs in primary T cells. The platform relies on a scalable mid-throughput lentiviral vector production platform, and a 96-well scalable T cell expansion that produces enough cells for characterization and functional assays including vector copy number (VCN), surface binder expression and function. The platform was utilized to screen candidate CARs by surface expression and VCN, tonic signaling, functional activation by engineered cell lines as well as cell lines expressing endogenous high, medium and low levels of target.

Within 3 rounds of screening, we were able to nominate top candidates ready for *in vivo* testing. Our proprietary CAR/TCR platform thus allows acceleration of nomination of binders for faster development of CAR and TCR therapies.

Friday Posters: Cell Therapy and Cell-Based Gene Therapy Trials

1895. Trial in Progress: A Phase 1/2 Study to Investigate the Safety and Efficacy of OBX-115 Engineered Tumor-Infiltrating Lymphocyte (TIL) Cell Therapy in Patients (Pts) with Advanced Solid Tumors

Adam J. Schoenfeld[1], Allison Betof Warner[2], Sajeve S. Thomas[3], Omid Hamid[4], Gino K. In[5], Alexander N. Shoushtari[1], Yazan Samhouri[6], Parameswaran Hari[7], Giridharan Ramsingh[7], Prakash Prabhakar[7], Lauren Mclaughlin[7], Jason A. Chesney[8]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Stanford University School of Medicine, Stanford, CA,[3]Orlando Health Cancer Institute, Orlando, FL,[4]The Angeles Clinic and Research Institute, Los Angeles, CA,[5]Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA,[6]Allegheny Health Network Cancer Institute, Pittsburgh, PA,[7]Obsidian Therapeutics, Inc., Cambridge, MA,[8]UofL Health – Brown Cancer Center, Louisville, KY

Introduction: Immune checkpoint inhibitors (ICI) have improved outcomes for pts with solid tumor malignancies; however, most pts relapse and treatment options in this setting are limited. Unengineered TIL cell therapy has shown promising efficacy in pts with ICI-resistant melanoma (Rohaan *NEJM* 2022, Chesney *JITC* 2022) and non-small cell lung cancer ([NSCLC] Creelan *Nat Med* 2021, Schoenfeld SITC 2021), but requires co-administration of systemic high-dose IL2, which is associated with safety risks and limits pt eligibility. OBX-115 TIL are engineered to express membrane-bound IL15 (mbIL15) under dose-dependent regulation using acetazolamide (ACZ), an FDA-approved small-molecule diuretic, avoiding the need for high-dose IL2. A first-in-human single-institution study (NCT05470283) evaluating the safety of OBX-115 in metastatic melanoma is enrolling. The current study (NCT06060613) is enrolling pts with solid tumors at multiple US sites using centralized manufacturing. **Methods:** This phase 1/2, single-arm, open-label, nonrandomized, multicenter study will assess the safety, tolerability, and efficacy of the OBX-115 engineered autologous TIL cell therapy regimen in pts with unresectable or metastatic melanoma resistant to ICI and relapsed/refractory metastatic NSCLC (Table). Primary objectives of Phase 1 are to characterize safety and tolerability and identify a recommended Phase 2 dose of OBX-115 + ACZ; Phase 2 will evaluate efficacy (ORR using RECIST v1.1 responses) of the regimen. Cryopreserved OBX-115 is generated from the pt's own tumor tissue procured by surgical excision or core needle biopsy, and is infused after standard- or low-dose (based on clinical status) lymphodepletion (cyclophosphamide and fludarabine). ACZ is administered at cohort-defined doses once daily for up to 10 days, with optional ACZ redosing at Week 6-8 for up to 10 days in pts without radiographic response. No systemic high-dose IL2 is administered. Two sites are open and recruiting, with additional sites being activated.

Key Eligibility Criteria	
Key Inclusion Criteria	**Key Exclusion Criteria**
Age ≥18 years	Uveal melanoma
Histologically confirmed diagnosis of unresectable Stage IIIC, IIID, or Stage IV metastatic melanoma with documented radiographic disease progression after systemic therapy containing a PD-1- or PD-L1-blocking antibody (if adjuvant setting, progression during or within 12 weeks after the last dose) and received a BRAF inhibitor ± MEK inhibitor if *BRAF* V600 mutation-positive *OR* Histologically confirmed diagnosis of metastatic NSCLC previously treated with an approved systemic therapy for metastatic disease (including an ICI-based regimen and/or targeted therapy where applicable) and progressed, no longer deriving benefit, or unable to continue due to treatment intolerance	Active autoimmune disease, including active uveitis or any other medical illness that would pose increased risks for study participation
≥1 lesion suitable for OBX-115 manufacturing, with expected minimum of 1.5-cm diameter; minimally invasive tumor tissue procurement (core needle biopsy) may be considered on a case-by-case basis after discussion with the Medical Monitor	Prior allogeneic organ transplant, allogeneic cell therapy, or genetically engineered cell therapy (not including autologous stem cell or unengineered TIL cell therapy)
≥1 RECIST 1.1-measurable lesion remaining after tumor tissue procurement	Systemic steroid therapy >10 mg/day of prednisone or equivalent
ECOG performance status 0 or 1	
Estimated life expectancy >6 months	

1896. Interim Safety and Efficacy of Anti-CD70 CAR-NKT (CGC729) for Patients with Advanced Renal Cell Carcinoma

Jian Zhang[1], Weina Shen[1], Muyu Kuang[1], Feifei Guo[2], Yuanyuan Qu[1], Hailiang Zhang[1], Guohai Shi[1], Dalong Cao[1], Dong Han[2], Yingmin Zhang[2], Shuyang He[2], Dingwei Ye[1]

[1]Fudan University Shanghai Cancer Center, Shanghai, China,[2]Curegenetics LLC, Suzhou, China

Background: Tumor heterogeneity and suppressive tumor microenvironment (TME) are major barriers to successful chimeric antigen receptor (CAR) T cell therapy in solid tumors. Natural killer T (NKT) cells, a subset of innate-like T cells, have emerged as a novel platform for the treatment of solid tumors owing to NKT's multifactorial antitumor and TME modulation properties. Here we describe interim findings from an investigator-initiated trial (IIT) of

CGC729, an autologous anti-CD70 CAR-NKT product, in patients with advanced clear cell renal cell carcinoma (ccRCC). **Methods:** This is a single-arm, open-label IIT (NCT06182735) using 3 + 3 design to evaluate the safety and efficacy of CGC729 at three dose levels including $5\times10^6/m^2$ (DL1), $1.5\times10^7/m^2$ (DL2), and $4.5\times10^7/m^2$ cells (DL3). As of Jan. 2024, five patients who received at least 2 prior lines of therapy were enrolled and treated with a single infusion of CGC729 following a 3-day lymphodepletion regimen (fludarabine $25mg/m^2$/day; cyclophosphamide $250mg/m^2$/day). At the time of the presentation, at least six patients will have been treated with 3-9 months follow-up. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded based on ASTCT criteria, and adverse effects were evaluated according to CTCAE 5.0. **Results:** As of the Jan. 22 data cutoff, four patients (DL1=3; DL2=1) were eligible for safety evaluation. Adverse events were manageable, and no dose-limiting toxicities (DLT) were observed. The most common adverse events were lymphodepletion associated reduction of neutrophils, platelets, and white blood cells; however, no > Grade 2 cytopenia was observed by Day 28. One patient (0102) in DL1 had Grade 2 CRS resolved within 24 hours. The same patient developed Grade 2 ICANS and was resolved with corticosteroids. No CRS or ICANS was observed in the other two patients in DL1 and the one patient in DL2. The overall response rate (ORR) in DL1 at Week 12 was 66.7% (2/3), and the ORR among ccRCC $CD70^+$ patients (0101 and 0103) was 100% (2/2). Those two $CD70^+$ patients had deep tumor reduction of 48.4% at Week 20 and 70.8% at Week 12, respectively (Figure 1A). Notably, both $CD70^+$ patients had low CD70 expression (H-score < 100) in ccRCC indicating CGC729 may have the potential to target CD70-low patients. Patient 0102 in DL1 was ccRCC $CD70^-$ and experienced progress disease (PD) on Day 28. Among four patients evaluable for PK, robust CAR-NKT expansion in the peripheral blood was observed in all patients including Patient 0102 who had negative CD70 expression in ccRCC. CGC729 had peak expansion between Day 14 and Day 28, and it persisted up to Week 20 (Figure 1B). Moreover, $CD70^+$ T cells in the peripheral blood decreased significantly after CGC729 infusion and remained at a low level up to Week 20, indicating a durable activity of CGC729. **Conclusion:** Interim analysis of this first-in-human trial of anti-CD70 CAR-NKT demonstrates a manageable safety profile and promising antitumor activity for the treatment of advanced ccRCC.

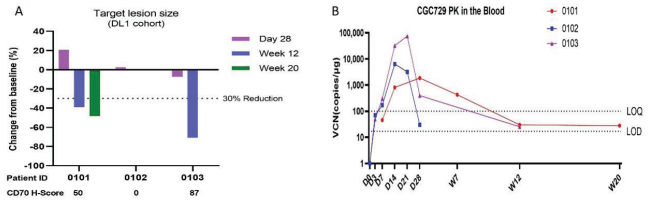


Figure 1: CGC729 had deep anti-tumor activity (A) accompanied with robust expansion and durable persistence (B) in DL1.

1897. Phase I Study of GUCY2C CAR-T Therapy IM96 in Metastatic Colorectal Cancer Patients

Changsong Qi[1], Chang Liu[1], Jian Li[1], Jifang Gong[1], Xicheng Wang[1], Zhenghang Wang[1], Xin'an Lu[2], Ting He[2], Yanping Ding[2], Fei Wu[2], Dongqun Liu[2], Lin Shen[1]

[1]Peking University Cancer Hospital and Institute, Beijing, China,[2]Beijing Imunopharm Technology Co., Ltd, Beijing, China

Background: The clinical outcomes of metastatic colorectal cancer (mCRC) therapies are limited, especially for liver metastasis. Guanylyl cyclase 2C (GUCY2C) is ectopically expressed in all stages of CRC and intestinally-restricted. GUCY2C-targeted CAR-T (IM96) was developed and phase I study was conducted to evaluate the safety and efficacy (NCT05287165). *Methods*: In this open-label, 3+3 dose-escalation study, IM96 was evaluated in GUCY2C-positive mCRC patients (pts) failed to ≥3 lines of therapies. Bridging therapies were allowed. Pts were pre-treated with fludarabine and cyclophosphamide, and received a single infusion of IM96 at the dose of 3×10^8 (DL1), 6×10^8 (DL2), 12×10^8 (DL3), or 20×10^8 (DL4) CAR-T cells. Dose-expansion study was performed at DL3. The primary objectives were safety and toxicity, and the secondary objectives were efficacy and pharmacokinetic profile. *Results*: As of December 2023, 20 pts were enrolled and infused with IM96. The follow-up time was 7-19 months for all pts. The median age was 52.5, and 11/20 cases were male. Liver metastasis was found in 11/20 cases (55%). Genetic testing revealed proficient mismatch repair (pMMR) in 20/20 pts (100%), KRAS mutation in 12/20 pts (60.0%), NRAS mutation in 1/20 pts (5.0%), and BRAF mutation in 3/20 pts (15.0%). Bridging therapies were used in 19 pts. Only 1/20 pt (5.0%) showed neurotoxicity and ≥grade 3 cytokine release syndromes (CRS). Grade 1-2 CRS occurred in 16/20 pts (80.0%) with dramatic increase of interleukin-6. Grade 1-3 rash was observed in 14/20 pts (70.0%). Grade 3 diarrhea occurred in 11/20 pts (55.0%), and grade 1-3 oral mucositis appeared in 7/20 pts (35.0%), only in DL2, DL3 and DL4 groups. Dose-limiting toxicity and maximum tolerated dose were not achieved. Among 19 evaluable pts, the disease control rate (DCR) was 73.7%, and the objective response rate (ORR) was 26.3%. In DL3 group, pts showed an ORR of 40.0%, nevertheless of liver metastasis or not. Six pts in DL3 group were evaluated as stable disease (SD) after treatment for 1 month. Among them, 4/6 pts (66.7%) turned to partial response (PR) and 2/6 pts (33.3%) retained SD. The median progression-free survival time was 7 months in DL3 group. No responding Pts showed disease progression within 6 months. Tumor responses were correlated with significant decreases in CEA levels among all pts. *Conclusions*: This study demonstrated that IM96 has durable efficacy with acceptable safety profile in pMMR mCRC pts, in particularly, showing high therapeutic potential in liver metastasis pts.

1898. Product Attributes of Tumor Associated Antigen (TAA) T Cells May Inform Clinical Responses in Pediatric Patients with CNS Tumors

Stephanie Gomez[1], Ashley Geiger[1], Rachel DiCioccio[1], Melanie Grant[1], Haili Lang[1], Abeer Shibli[1], Anushree Datar[1], Emily Reynolds[1], Christopher A. Lazarski[1], Mariah Jensen-Wachspress[1], Gloria Pezzella[1], Daisy Ayala-Gomez[1], Jay Tanna[1], Fahmida Hoq[1], Chase D. McCann[1], Patrick J. Hanley[1], Lindsay B. Kilburn[2], Brian R. [1]Center for Cancer and Immunology Research, Children's National Hospital, Washington, DC,[2]Center for Cancer and Blood Disorders, Children's National Hospital, Washington, DC

BACKGROUND: Central nervous system (CNS) tumors are the most common, and deadliest, solid tumor in children, and there is an urgent need for novel therapies. The polyclonal nature of multi antigen-specific T cells may provide a clinical benefit to patients with high-risk brain tumors where intratumoral heterogeneity plays a prominent role in therapeutic resistance. **OBJECTIVE:** To determine safety and feasibility of multi tumor associated antigen T (TAA-T) cells in patients with CNS tumors. **METHODS/DESIGN:** Pediatric patients with CNS malignancies enrolled in a phase I dose escalation study (NCT03652545) were infused with ex vivo expanded, autologous T cells. T cells were pulsed with peptide libraries spanning tumor-associated antigens: WT1, PRAME, and Survivin. TAA-T cell product characterization and preliminary clinical outcomes were examined for patients diagnosed with diffuse intrinsic pontine gliomas (Arm A, n = 8) or recurrent/progressive non-brainstem CNS malignancies without lymphodepletion (Arm B, n = 18). To determine immunophenotype, TAA-T cell products were characterized by flow cytometry. TAA-T cell product specificity was determined by assessing reactivity through IFNg enzyme-linked immunosorbent spot (ELISpot) assay following re-stimulation with TAA or control peptide pools. **RESULTS/DISCUSSION:** In Arm A, the median overall survival (OS) was 14 months, compared to a historical median OS of 10 months. One patient in Arm A had a progression-free survival (PFS) of 11 months and an OS of 32 months. In Arm B median PFS was 7 months, and 3 patients out of 18 treated remain alive with stable disease more than 2 years after infusion. We observed a dose level effect across all patients analyzed, in which increased TAA-T dose was associated with prolonged disease stabilization. Additionally, our results suggest that superior TAA-T cell products (defined as specific by ELISpot and >75% alpha beta T cells) are associated with prolonged PFS. Future directions include testing personalized, neoantigen-specific T cells in patients with CNS malignancies (IMPACT trial).

1899. Case Report of Patient with Castrate Resistant Prostate Cancer Achieving Clinical Benefit PostTGFβRdn on PSMA-Redirected CAR-T Cells

Naomi B. Haas[1], Vivek Narayan[1], Julie Barber-Rotenberg[2], Katie Alexander[1], Vanessa Gonzalez[1], Carly Stein[1], Carl H. June[2], Joseph A. Fraietta[2]

[1]Abramson Cancer Center, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA

Introduction: Transforming growth factor-β (TGFβRdn) on prostate specific membrane antigen (PSMA)-redirected CAR-T cells following lymphodepletion (LD) chemotherapy in our Phase I trial was feasible, generally safe and showed both T-cell proliferation and persistence in 14 treated patients with metastatic castrate resistant prostate cancer (CRPC) (Nat Med. 2022 Apr;28(4):724-734. PMC10308799). However, no patient demonstrated long term control of prostate cancer. Here we report clinical improvement and post-treatment correlative analyses of a patient with metastatic CRPC treated in an expansion cohort of the PSMA-redirected and TGFβRdn co-expressing CAR-T cell trial.The patient is a 77 yo male with stage IV group 4 CRPC and known bone metastases previously treated with a luteinizing hormone-releasing hormone agonist and an androgen receptor secondary inhibitor therapy, followed by sipuleucil therapy and then docetaxel therapy upon progression. He then received LD chemotherapy, consisting of cyclophosphamide (300 mg/m^2) and fludarabine (30 mg/m^2), followed four days later by an infusion of CART-PSMA-TGFβRDN (1 x 10^8 CAR+ PSMA cells). The next day, he experienced Grade 2 Cytokine Release Syndrome (CRS), which was managed with supportive intravenous (IV) fluids. His initial post-treatment course was notable for grade 2 cytokine release syndrome (CRS), managed with IV fluids, tocilizumab and dexamethasone, as well as an unexplained syncopal event. He was discharged from inpatient monitoring on day 6, following clinical stability and improvement in post-LD chemotherapy cytopenias. However, the next day he experienced several syncopal events accompanied by a hemophagocytic-like (HLH) syndrome manifesting with transaminitis, elevated ferritin, and low platelets, requiring rehospitalization and a prolonged dexamethasone taper. Notably his bone pain resolved, and he sustained a PSA decline of 17.7% decrease at 12 weeks and 13.5% decline at D85 accompanied by CAR-T expansion and persistence which continued after recovery from the HLH-like syndrome and steroid wean. CAR-T by PCR analysis was detected in both blood and bone biopsy at day 36. CT imaging was stable at 12 weeks although bone scan showed new uptake. The patient is asymptomatic at 6 months. Methods: Serum samples obtained pre- and post- CART-PSMA-TGFβRDN infusion and cryopreserved at −80 °C were analyzed for cytokine measurements using either a human cytokine magnetic 30-plex panel (Life Technologies) or a 31-plex panel (Millipore Sigma). Multiplex assay for all cytokines were obtained at multiple timepoints (days 1-71). IL-18 soluble proteins were obtained in a separate assay. Bone biopsy at metastatic tumor site was obtained pre and post treatment (day 36). PCR amplification for peripheral blood and tumor samples (QuantStudio 3D digital PCR instrument) was previously described). Results: Cytokines demonstrated 40-50x increase in IL2, IL6 and a 10x increase in interferon-γ following CAR-T infusion. Sustained high IL18 levels accompanied the HLH-like syndrome. CAR-T was detectable in the blood (57265.61 copies/

μg DNA, peak day 28) and bone metastases (36401.59 copies/μg, day 36) by PCR. Conclusion: This is the first clinical improvement using PSMA-redirected and TGFβRdn co-expressing CAR-T in metastatic CRPC. Elevated IL18 and IL-2 levels may be indicative of PSMA TGFβRdn CAR-T response.

1900. Trial in Progress: A Phase 1, First in Human Clinical Trial for T-Plex, a Multiplexed, Enhanced T Cell Receptor-Engineered T Cell Therapy (TCR-T) for Solid Tumors

Justin Moser[1], Brian Pico[2], Brian Henick[3], Rom Leidner[4], Yazan Samhouri[5], James Isaacs[6], Jared Weiss[7], Michael Hurwitz[8], Jaspreet Grewal[9], Jason Luke[10], Shrikanta Chattopadhyay[11], Yun Wang[11], Marlyane Motta[11], Jim Murray[11], Debora Barton[11], Dawn Pinchasik[11], Gavin MacBeath[11], Sajeve Thomas[12]

[1]HonorHealth Research Institute, Scottsdale, AZ,[2]Memorial Healthcare System, Pembroke Pines, FL,[3]Columbia University Medical Center, New York, NY,[4]Providence Cancer Institute, Portland, OR,[5]Allegheny Health Network, Pittsburgh, PA,[6]Cleveland Clinic, Cleveland, OH,[7]University of North Carolina at Chapel Hill, Chapel Hill, NC,[8]Yale School of Medicine, New Haven, CT,[9]Norton Healthcare, Louisville, KY,[10]University of Pittsburgh Medical Center, Pittsburgh, PA,[11]TScan Therapeutics, Waltham, MA,[12]Orlando Health, Orlando, FL

Checkpoint immunotherapies have revolutionized solid tumor treatment yet durably benefit a minority of patients, as they rely on endogenous anti-tumor T cells. A potential solution for patients lacking functional endogenous anti-tumor T cells is engineering their T cells with exogenous T cell receptors (TCRs) to target and kill tumor cells. Initial clinical trials with TCR engineered T cell therapies (TCR-Ts) targeted single tumor antigens on single HLA and produced partial, short-lasting responses. Solid tumors are notoriously heterogenous with highly variable antigen expression and have an immunosuppressive microenvironment. Recent discoveries also identified HLA loss of heterozygosity in up to 40% of solid tumors, allowing tumor cells to evade T cell attack. To overcome this heterogeneity and immune evasion, TScan has developed T-Plex, a multiplexed cell therapy comprising two to three different TCR-Ts, chosen from a collection of TCR-Ts called the ImmunoBank, to target different tumor antigens on different HLA types with confirmed tumor expression. To deepen clinical responses, TCR-T cells are engineered to express CD8α/β co-receptors that, in preclinical experiments, enable CD4+ helper T cells to have >100-fold improved cytotoxicity and cytokine secretion over CD4+ cells expressing the TCR alone. To allow T cell persistence despite immunosuppressive TGF-β in the tumor microenvironment, TCR-T cells also express the dominant negative TGF-β receptor, enabling ~10-fold improved proliferation in the presence of TGF-β compared to T cells expressing the TCR and CD8α/β co-receptors alone. The Phase 1 study utilizes a separate screening protocol to pre-identify patients with head and neck, cervical, anogenital cancers, NSCLC, and melanoma, any time during standard clinical care, enabling rapid enrollment into the treatment protocol upon disease progression. Screening comprises germline HLA testing, and archival tumor testing for antigen expression and HLA loss. As HLA loss is restricted to only half the HLA genes, this strategy enables selection of TCR-Ts that target antigens and HLAs on the genes that are not lost, thereby overcoming common mechanisms of tumor cell escape from immune attack. Treatment includes standard, non-myeloablative lymphodepletion followed by one or two doses of T-Plex infused 28 days apart. Dose escalation under the interval 3+3 design starts with testing single TCR-Ts in dose levels 1 and 2. Thereafter, TCR-Ts are combined and escalated in dose levels 3 and 4. TCR-Ts currently in the master protocol target PRAME, MAGE-A1 or HPV16 on HLA-A*02:01 or MAGE-A1 on HLA-C*07:02. Additional TCR-Ts added to the ImmunoBank and master protocol go through dose levels 1 and 2 as single therapies before becoming available for multiplexed dose levels 3 and 4. Primary endpoints include safety, feasibility and identifying the recommended Phase 2 dose. Secondary endpoints are rates and durations of response, and exploratory endpoints measure T cell activation and persistence. The goal of the ImmunoBank is to enable up to 80% of patients with common solid tumors to qualify for multiplexed TCR-T therapy.

1901. Trial in Progress: A Phase 1 Trial of TSC-100 and TSC-101, Engineered T Cell Therapies That Target Minor Histocompatibility Antigens to Eliminate Residual Disease After Hematopoietic Cell Transplantation

Monzr Al Malki[1], Alla Keyzner[2], Hyung Suh[3], Uday Popat[4], Saar Gill[5], Yi-Bin Chen[6], Melhelm Solh[7], Joseph Uberti[8], Lohith Gowda[9], Erica Buonomo[10], Yun Wang[10], Jim Murray[10], Gavin MacBeath[10], Debora Barton[10], Shrikanta Chattopadhyay[10], Ran Reshef[11]

[1]City of Hope, Duarte, CA,[2]Mount Sinai Hospital, New York, NY,[3]Hackensack University, Hackensack, NJ,[4]MD Anderson Cancer Center, Houston, TX,[5]University of Pennsylvania, Philadelphia, PA,[6]Massachusetts General Hospital, Boston, MA,[7]Northside Hospital, Atlanta, GA,[8]Karmanos Cancer Institute, Detroit, MI,[9]Yale University, New Haven, CT,[10]TScan Therapeutics, Waltham, MA,[11]Colombia University, New York, NY

Engineered T cell therapies such as CAR-T cell therapies have transformed the treatment of B-cell but not non-B cell hematologic malignancies. Allogeneic hematopoietic cell transplantation (HCT) remains the best curative option for hematologic malignancies but ~40% of patients relapse post-HCT with up to 90% mortality due to residual disease post-HCT. A potential solution is targeting minor histocompatibility antigens (MiHAs) that are homogenously expressed on all hematopoietic cells and are genetically mismatched between donors and patients undergoing HCT. These mismatches enable engineered T cells to selectively eliminate residual patient hematopoietic cells, normal or malignant, leaving donor cells untouched. TScan has developed allogeneic donor derived T-cell products TSC-100 and TSC-101, targeting MiHAs HA-1 and HA-2 respectively, both presented on HLA-A*02:01. By choosing HCT patients who are HLA-A*02:01 positive (>98% of whom are either HA-1 or HA-2 positive) and donors who are either HLA-A*02:01 or MiHA negative, TSC-100 or TSC-101 can potentially eliminate all residual patient-derived hematopoietic cells after HCT, to prevent disease relapse. Study NCT05473910 is a multi-center, multi-arm, non-randomized controlled Phase 1 umbrella study evaluating the feasibility, safety and preliminary efficacy of TSC-100 and TSC-101. Inclusion criteria include adults with AML, MDS or

ALL eligible for reduced intensity conditioning-based haploidentical donor transplantation from HLA or MiHA mismatched donors. HLA-A*02:01-positive patients undergo HA-1/ HA-2 testing and are assigned to either TSC-100 or TSC-101 treatment arms in addition to HCT. HLA-A*02:01-negative patients in the control arm receive HCT alone. Upon count recovery after HCT, patients in treatment arms receive either TSC-100 or TSC-101, administered as single or two doses. Primary endpoints include adverse event profiles and dose limiting toxicities. Secondary endpoints include relapse rates, disease-free survival and overall survival. Exploratory endpoints include surrogates of efficacy such as donor chimerism rates and kinetics and minimal residual disease (MRD) rates. Donor chimerism is measured by standard STR-based and novel high-sensitivity NGS-based assays to quantify residual patient-derived hematopoietic cells. MRD is measured before and after HCT using flow cytometry and NGS. Together, these assays measure elimination of residual patient hematopoietic cells, malignant or normal, and could provide early evidence of biological activity.

1902. Clinical Validation and Mechanistic Insights of ThisCART: A Novel Allogeneic Platform Enhancing CAR-T Signaling via Intracellular TCRαβ/CD3 Retention

Jun Li[1], Lei Xue[2], Sujun Li[2], Ling He[1], Kaichun Liu[1], Rong Jin[1], Tao Wang[1], Yinhang Zhang[1], Shanshan Chen[1], Yulian Gao[1], Dan Liu[1], Liyun Yang[1], Xingbing Wang[2]

[1]Fundamenta Therapeutics, Suzhou, China,[2]The First Affiliated Hospital of USTC, AnHui, China

Background: Current allogeneic CAR-T cell therapies face challenges with post-infusion expansion and efficacy. In response, we developed ThisCART, a non-genetic editing, allogeneic platform that significantly enhances CAR-T cell expansion and efficacy. This is achieved through a novel approach of intracellular retention of membrane proteins, reducing surface expression of TCRαβ/CD3 complexes and HLA-I molecules. Our lead product, ThisCART19, has demonstrated superior efficacy compared to conventional AutoCART19 in preclinical and early clinical studies for B-ALL. **Methods:** In the clinical trial NCT04384393, we assessed the safety and efficacy of ThisCART19 in patients with B-cell malignancies. Post-lymphodepletion, participants received infusions of ThisCART19 and AutoCART19, both personalized from the patient's own T cells, in equal proportions. Safety and efficacy were the primary endpoints, evaluated on Day 28 post-infusion and throughout extended follow-up. Mechanistic insights were gained through comprehensive multi-omics studies, including RNAseq, whole-cell proteomics, and phosphoproteomics. **Results:** ThisCART19 showed enhanced expansion and an improved safety profile in vivo. As of 01 January 2024, Two patients diagnosed as relapse/refractory acute B cell leukemia (R/R B-ALL) were enrolled in the clinical trial. Pt1 is a 55yo male with Ph-positive B-ALL (36% blasts) who relapsed after multiagent chemotherapy and TKIs. Pt2 is a 16yo male with CNS leukemia (78.5% blasts) after multiagent chemotherapy. No DLTs or ICANS were observed. Pt1 experienced Grade 1 CRS that resolved without treatment, and Pt2 experienced Grade 2 CRS that resolved after tocilizumab and corticosteroids. Complete remission with MRD-negative status was achieved by Day 28. Pharmacodynamic analysis indicated a significant expansion of CAR-T cells, predominantly in the CAR+TCR- subset, highlighting autonomous CAR signaling enhancement. Multi-omics analysis identified upregulation in JAK-STAT, PI3K-Akt, and NFKB pathways, suggesting improved cell proliferation, survival, anti-apoptotic activity, and effector function. This molecular profiling provides a mechanistic understanding of ThisCART19A's therapeutic efficacy. **Conclusion:** The ThisCART platform marks a transformative advancement in allogeneic CAR-T cell therapy. By enhancing CAR signaling autonomously through a unique intracellular retention of TCRαβ/CD3 complexes, ThisCART has shown promising safety and efficacy in early clinical trials. Its potential in reshaping the treatment landscape for hematological and autoimmune disorders positions ThisCART as a crucial development in cellular therapeutics.

1903. Interim Analysis on Neurological Outcomes in Hurler Syndrome Patients Treated with Autologous *Ex Vivo* Hematopoietic Stem Cell Gene Therapy

Giulia Consiglieri[1], Francesca Fumagalli[1], Francesca Tucci[1], Chiara Filisetti[1], Matilde Cossutta[1], Stefano Scarparo[1], Marina Sarzana[1], Cristina Puricelli[1], Francesca Ciotti[1], Maurizio Barbera[1], Silvia Darin[1], Rossella Parini[1], Cristina Baldoli[1], Bernhard Rudolf Gentner[2], Alessandro Aiuti[3], Maria Ester Bernardo[1]

[1]San Raffaele Telethon Institute for Gene Therapy, Milano, Italy,[2]SR-TIGET, Lausanne, Switzerland,[3]San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), Milan, Italy

Introduction: Early treatment with allogeneic haematopoietic stem cell transplantation (HSCT) has been demonstrated in many cases to prevent deterioration of cognitive function in Mucopolysaccharidosis type I Hurler (MPSIH) patients. Nevertheless, HSCT is not able to fully address central nervous system (CNS) manifestations, leaving patients with residual disease burden (doi: 10.1016/j.ymgme.2021.03.002). The neurological outcomes of 8 MPSIH patients enrolled in a phase I/II study (NCT03488394) of autologous *ex vivo* hematopoietic stem cell gene therapy (HSC-GT, also known as OTL-203) were evaluated up to 4 years after treatment. *Methods*: IDUA activity, dermatan (DS) and heparan sulphate (HS) levels were measured in cerebral spinal fluid (CSF) at baseline and at different timepoints after HSC-GT. Ages of achievement of motor and language milestones were compared with the window of achievement defined by the World Health Organization (WHO) in healthy children. Gross and fine motor skills were analyzed using the Peabody Developmental Motor Scales, while measurement of cognitive functions was evaluated by the Bayley Scales of Infant and Toddler Development and the Wechsler Preschool and Primary Scale of Intelligence. Typical MRI brain abnormalities were assessed by a specific neuroradiologic scoring system previously developed for MPSIH patients treated with HSCT. *Results*: From 3 months after GT, IDUA activity became detectable in CSF and persisted over time, accompanied by local reduction of both DS and HS with undetectable DS in 7/8 patients at +4 year-follow-up. Motor and language milestones were accomplished in all patients at the latest follow up, either at a normal or delayed time for age, except for one patient who suffers

from behavioral issues preventing the subject from demonstrating his full neurocognitive abilities, determined to be unrelated to treatment. Regarding motor abilities, we observed a stability of normality or a gain of normality in 5/8 patients in terms of total motor quotient (TMQ) and gross motor quotient (GMQ) at last follow-up, while fine motor quotients (FMQ) remained or became normal after treatment in 7/8 patients. After HSC-GT 7/8 patients continued to gain cognitive skills in line with typically developing children. All patients experienced an improvement or stabilization of the brain MRI scores with a significant reduction of the typical brain abnormalities. Compared to baseline, brain MRI images at last follow-up showed a meaningful reduction of multiple enlarged perivascular space and of subarachnoid space enlargement, regression of faint white matter alterations and normal progression of myelination. *Conclusions*: This preliminary neurological analysis suggests biochemical detoxification in the CSF and initial clinical response in terms of motor and cognitive abilities up to 4 years after treatment, except for one patient with behavioral issues preventing him from demonstrating his full neurocognitive abilities, determined to be unrelated to treatment. CSF detoxification suggests migration of gene-modified cells across the blood brain barrier and local engraftment in the CNS. Neuroradiological modifications are consistent with biochemical and clinical outcomes. A longer follow-up and a prospective comparison with HSCT are needed to draw definitive conclusions on the effect of HSC-GT on the typical neurological manifestations of MPSIH.

1904. Non-Neurological, Non-Skeletal Outcomes After Autologous Hematopoietic Stem Cell Gene Therapy in Hurler Patients: Retrospective Comparison with Allogeneic Hematopoietic Stem Cell Transplantation

Introduction: Preliminary results of a phase I/II study (NCT03488394) of autologous *ex vivo* hematopoietic stem and progenitor cells gene therapy (HSC-GT) in 8 Mucopolysaccharidosis type I Hurler syndrome (MPSIH) patients demonstrated superior metabolic correction compared to allogeneic haematopoietic stem cell transplantation (HSCT). Nevertheless, HSC-GT effects on corneal clouding (CC), hearing loss (HL), carpal tunnel syndrome (CTS) and cardiac involvement have not been extensively reported. We analysed for the first time these outcomes after HSC-GT and performed a retrospective comparison with an external cohort of MPSIH patients undergoing HSCT. *Methods:* MPSIH patients who received HSC-GT (N= 8) were compared to retrospectively collected data from MPSIH patients treated with HSCT (N= 9) in Vall d'Hebron Hospital, Barcelona. Patient and transplant characteristics are reported in Table 1. 2/9 HSCT patients experienced primary graft failure and required a second HSCT. CC was assessed using clinical grading score (Fahnehjelm KT, et al. Acta Opthalmol 2012 for HSC-GT), HL was evaluated using brainstem auditory evoked responses. Cardiac function was studied by echocardiography, CTS by median nerve electroneurography. HSC-GT patients were followed-up for a median of 4 years (range: 4-5), while HSCT patients for a median of 15 years (range: 4-21). To enable appropriate comparison, the analysis was performed within the same time window (4-5 years after treatment). *Results:* At baseline, all subjects had evidence of mild to moderate CC. Of HSC-GT patients, 3/8 achieved CC resolution and 5/8 had mild CC at last follow-up. In HSCT cohort, no patient experienced CC resolution with all showing moderate CC at 5-year after HSCT. In HSC-GT cohort at baseline, 50% of patients had mild to severe HL. An improvement in most of the patients was observed with 4/7 showing normal hearing function at last follow-up. In HSCT cohort, 7/9 had mild or moderate HL at baseline with an improvement at 5-year follow-up as 4/9 showed normal hearing function. ENT surgery incidence and timing after treatment was comparable in the 2 cohorts. In HSC-GT-cohort none of the patients developed severe cardiomyopathy or valvular disease, while in HSCT-cohort 2/9 patients experienced progression of valvular insufficiency, not requiring valve replacement. One HSC-GT patient underwent CT surgery before treatment, and another 6 months after HSC-GT due to pre-existing severe damage before treatment. The remaining patients did not develop CTS. In HSCT cohort 7/9 patients developed CTS, requiring surgery at a median of 3.7 years post-HSCT. *Conclusion:* Our results indicate stability or improvement of CC, HL, cardiac manifestations and CTS in MPSIH patients after HSC-GT up to 4-year after treatment. A longer follow-up and a prospective comparison with HSCT patients are required to draw definitive conclusions on the efficacy of HSC-GT in addressing these disease manifestations.

Table 1: Patient and transplant characteristics of the HSPC-GT and HSCT cohorts.

	HSPC-GT	HSCT
Number of patients (M/F)	8 (6/2)	9 (5/4)
Median age at treatment, months (range)	23.5 (14-34)	25 (17-29)
Type of conditioning	Busulfan + Fludarabine§	Busulfan + Cyclophosphamide/Fludarabine
Median enzyme level pre treatment (range)	0.3 (0-3) µmol/L/h	0.02 (0.01-0.08) nmol/h/mg proteins
Median enzyme level post treatment (range)	101.3 (40.7-145.1) µmol/L/h at 4 years after HSPC-GT	5.4 (4.6-11.3) nmol/h/mg proteins at 5 years after HSCT
Median follow-up, years (range)	4 (4-5)	15 (4-21)

§ also received rituximab as part of the pre-transplant regimen
For HSC-GT, reference values for IDUA in DBS stratified by age: 6 months to <6 years of age: 3.81-35.04 µmol/L/h; 6 to 18 years: 2.27-22.56 µmol/L/h. For HSCT patients IDUA on Leukocytes: normal values 1.6-8.7 nmol/hour/mg protein

1905. Lentiviral Haematopoietic Stem Cell Gene Therapy for Late Juvenile Metachromatic Leukodystrophy

Valeria Calbi[1], Vera Gallo[1], Fabiola De Mattia[1], Alberto Zambon[2,3], Salvatore Recupero[1], Elena Sophia Fratini[1], Alessandra Clerici[1], Francesco Morena[4], Sabata Martino[4], Jean Brooks[5], Alan Richardson[5], Laura Cambpell[5], Maria Ester Bernardo[1,3], Alessandro Aiuti[1,3], Francesca Fumagalli[1]

[1]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milano, Italy,[2]Neurology & Neurophysiology Unit, IRCCS San Raffaele Scientific Institute, Milano, Italy,[3]Vita-Salute San Raffaele University, Milano, Italy,[4]Department of Chemistry, Biology and Biotechnologies, University of Perugia, Perugia, Italy,[5]Orchard Therapeutics (Europe) Limited, London, United Kingdom

Background Metachromatic Leukodystrophy (MLD) is a rare, disabling and fatal lysosomal storage disease. Atidarsagene autotemcel (arsa-cel) is a hematopoietic stem cell (HSC) gene therapy (GT) and consists of autologous CD34+ cells transduced ex vivo with a lentiviral vector encoding for the human ARSA gene, infused after intravenous myeloablative busulfan conditioning. Arsa-cel has shown favorable long-term outcomes in early-onset MLD; however, its risk-benefit profile in late onset variants, in particular the Late Juvenile subtype (LJ), has not yet been investigated. **Methods** This ongoing phase III trial (NCT04283227) is investigating the safety and efficacy of arsa-cel in pre-symptomatic or early-symptomatic (able to walk independently and without cognitive decline) LJ-MLD patients (expected or actual symptom onset between 7th and 17th birthday). Here we report preliminary engraftment and safety data from an *ad hoc* interim analysis. **Results** As of January 2024, all 6 patients planned in the protocol have been enrolled and treated. Four patients were pre-symptomatic and 2 were early-symptomatic. Before enrolment in this study, one patient underwent allogeneic HSC transplant; however, she experienced autologous reconstitution with absence of donor chimerism, enabling eligibility for HSC-GT. Median age at GT was 10.4 years (range 2.7-15.5 years). Stem cell source was mobilized peripheral blood. After transduction, the infused drug product median dose was 23.1x10^6 CD34+cells/kg (range 16-28.94x10^6 CD34+cells/kg) with a median vector copy number (VCN)/cell of 3 (range 2-5).All patients received myeloablative conditioning with busulfan with a final cumulative target area under the curve of 85 mg*h/L. After a median follow-up of 15.4 months (range 0.2 to 21.8 months) all patients are alive with no treatment-related serious adverse events. The type and nature of adverse events were consistent with the known safety profile of busulfan. There were no malignancies, no evidence of abnormal clonal expansion or replication-competent lentivirus, and no evidence of immune response against ARSA enzyme. All 5 patients with available post-treatment data achieved normal hematological reconstitution and engraftment of transduced cells in line with previous experience in early-onset MLD. Median time to neutrophil and platelet engraftment was 33.0 days (range 26-42) and 26 days (range 25-46), respectively. At 90 days post-treatment, median VCN in peripheral blood mononuclear cells (PBMCs) and CD15+ cells were 0.49 and 0.82 copies/cell, respectively; the percentage of transduced bone marrow progenitors ranged between 23.81 and 81.25%. ARSA activity was restored and reached supranormal levels in PBMCs and restored to normal levels in cerebrospinal fluid (CNS pharmacodynamic efficacy measure) at 6 months post-treatment. **Conclusion** This analysis demonstrates that the initial results on engraftment, ARSA activity, safety, and drug product characteristics for arsa-cel in LJ-MLD were similar to those reported in early-onset MLD.

1906. Clinical Efficacy and Safety of Gene Therapy for Transfusion-Dependent β-Thalassemia Patients with Quick Engraftment of Genetically Modified Hematopoietic Stem Cells

Introduction Clinical evaluation of autologous hematopoietic stem cell (HSC)-based gene therapies for β-thalassemia major patients have been well-advanced in the US and Europe but not in other parts of the world. **Methods** We conducted non-randomized, single-dose, open-label clinical trials of HSC-based gene therapy in representative β-thalassemia major patients in China. We treated 17 patients using their own HSCs after transduced *ex vivo* with KL003, a lentiviral vector expressing a functional β-globin gene. We then monitored patients closely for efficacy and safety of KL003 treatment, including stem cell engraftment, hematopoietic reconstitution/recovery, need for blood transfusion, and adverse events. **Results** The median engraftment time for 11 patients with <5,000 μg/L ferritin at enrollment was 13 days for neutrophils (range: 8-15 days) and 19 days (range: 13-28 days) for platelets, respectively. This is a significant improvement compared with much longer engraftment time (i.e. approximately 4 weeks for neutrophils and 6 weeks for platelets) previously reported for autologous HSC-based gene therapies. The median day for platelet counts to reach above 50×10^9/L was 22 days (range: 11-63 days), representing a much quicker platelet recovery compared with 8 weeks reported previously. On the other hand, for a cohort of 6 patients with ≥5,000 μg/L ferritin at enrollment, the median engraftment time was 14.5 days for neutrophils (range: 9-18 days) and 39 days for platelets (range: 19-121 days), respectively. Platelet engraftment was significantly delayed compared with the cohort of patients with <5,000 μg/L ferritin at enrollment (p value = 0.0240). The median day for platelet counts of this group to rebound above 50×10^9/L was 87.5 days (range: 33 days to >231 days), which was significantly delayed (p value = 0.0015) compared with those of patients with <5,000 μg/L ferritin at enrollment. These results may represent a common challenge for treating patients with severe iron overload. Importantly, blood transfusion was no longer needed for 16 of 17 patients with a median day 18 (range:

10-177 days) after treatment, 1 week faster than previously reported. The longest duration without blood transfusion for these patients has been 24 months thus far. The safety profile was consistent with that typical of busulfan-based myeloablation conditioning. There were no severe adverse events associated with KL003 treatment. **Conclusion** Our clinical trial results demonstrate potentially curative outcomes of KL003 in β-thalassemia major patients, including those in poor clinical condition (e.g, with severe iron overload (≥5,000 μg/L ferritin)), which account for the majority of the β-thalassemia major patients in developing countries. In addition, our optimized transduction process of HSCs might have contributed to maintaining stemness of HSCs, which is essential for quick engraftment but often gets lost during *ex vivo* manipulation. This has led to significantly faster engraftment and better efficacy without severe adverse effect. Thus, KL003 could provide a potential functional cure for β-thalassemia major patients.

1907. First-in-Human Use of Platelet-Derived FVIII for Severe Hemophilia a with a History Inhibitors

[1]Pediatrics, Medical College of Wisconsin, Milwaukee, WI,[2]Children's Research Institute, Children's Wisconsin, Milwaukee, WI,[3]Blood Research Institute, Versiti, Milwaukee, WI,[4]Translab, Boston Children's Hospital, Boston, MA,[5]Medicine, Medical College of Wisconsin, Milwaukee, WI,[6]Indiana University, Gene Therapy Testing Laboratory, Indianapolis, IN,[7]Microbiology, University of Pennsylvania School of Medicine, Philadelphia, PA,[8]Medical College of Wisconsin, Milwaukee, WI,[9]Institute for Health and Society, Medical College of Wisconsin, Milwaukee, WI

Introduction: Platelettargeted gene therapy with human factor VIII (FVIII) has established hemostasis in animal models with severe hemophilia A (HEMA) without eliciting inhibitory antibodies. Here we describe feasibility, safety and efficacy in subject 1 treated on a first-in-human phase 1 trial that targets FVIII synthesis and storage within platelet αgranules for delivery at the site of vascular injury for HEMA for longterm hemostasis. **Method:** Eligible are HEMA patients ≥18 years with a history of inhibitors to FVIII (≥0.6 Bethesda Units [BU]/ml). Autologous CD34+ cells transduced with a lentivector encoding the *ITGA2B* gene promoter driving expression of human Bdomaindeleted FVIII in megakaryocytes are infused after reducedintensity cytoreduction with fludarabine and melphalan. Primary endpoints of feasibility and safety are defined as 1) feasibility of the cell manufacturing procedure by the availability of ≥4 x 10^6/kg transduced CD34+ cells with viability ≥70% and undetectable microbial contamination and 2) safety defined as hematopoietic recovery ≤28 days of infusion and absence of ≥ grade 3 toxicity. **Results:** Subject 1 is a 29 year old male with HEMA and a history of inhibitors (2.6 BU/ml). Immune tolerance to FVIII was established with a no inhibitor titer at enrollment. Hemostatic prophylaxis was maintained with emicizumab and recombinant FVIII for breakthrough bleeding. The cell product yielded 6.73 x 10^6/kg viable CD34+ cells post-transduction with a vector copy number (VCN) of 1.16 copies/cell. Biologically active FVIII:C levels were 101.32 mU/10^6 megakaryocytes. ***Primary Outcomes*** showed excellent tolerance of the treatment plan with a cell product meeting release criteria with neutrophil recovery (≥0.5 x 10^9/L) and platelet transfusion independence (≥50 x 10^9/L) achieved at 15 days post-infusion sustained >18 months. Hospitalization duration was 21 days. There was no breakthrough bleeding during collection and hospitalization and there was no unexpected toxicity ≥ grade 1. Emicizumab was discontinued 3.6 months postinfusion after detecting significant VCN in whole blood. ***Secondary Outcomes*** at 18 months follow up showed 1) absence of replication competent lentivirus and inhibitory antibodies, 2) gene integration site analysis with highly polyclonal insertion with no notable integration near oncoassociated genes, 3) whole blood VCN ≈0.27 from 3-18 months posttransplant consistent with FVIII:C detected stabilized at ≈10 mU/10^8 platelets, 4) normal platelet count/function, and 5) *ex vivo* blood clotting parameters observed complete transition from emicizumab to platelet FVIII maintaining hemostasis throughout. Of note, the patient's joint health mobility score improved from 11 pre- to 9 post-transplant, and annualized bleeding rate decreased from 9.6 pre- to 0.0 for entire 18 months post-infusion. **Conclusion:** This report demonstrates feasibility, safety and efficacy in subject 1 with HEMA and a history of inhibitors who received lentivector gene therapy to induce megakaryocytes to synthesize and store FVIII in platelets. These findings extend the potential to treat HEMA patients ineligible for current FDA approved gene therapy.

1908. Outcomes Post Infusions of Autologous HIV-Specific T Cells Targeting Conserved HIV Epitopes in Individuals with HIV on Antiretroviral Therapy (NCT03485963)

Danielle K. Sohai[1], Michael D. Keller[1], Patrick J. Hanley[1], Fahmida Hoq[1], Divyesh Kukadiya[1], Anushree Datar[1], Emily Reynolds[1], Dennis C. Copertino[2], Christopher Lazarski[1], Chase D. [1]Children's National Hospital, Washington, DC,[2]Weill-Cornell Medicine, New York, NY,[3]The George Washington University, Washington, DC,[4]Simon Fraser University, Burnaby, BC, Canada,[5]Whitman-Walker Health, Washington, DC

There are nearly 40 million people living with HIV (PLWH) worldwide. Antiretroviral therapy (ART) suppresses HIV replication to clinically undetectable levels, but ART is not curative because it does not eliminate the latent HIV reservoir. During untreated HIV, infected cells are cleared by an active CD8+ T cell response, which suggests that T cell responses are critical to HIV control. However, viral immune escape mechanisms, including mutations in immunogenic T cell epitopes, can reduce antiviral immune responses. Thus, T cell therapy targeting conserved HIV epitopes is a promising cure strategy for PLWH. In a phase 1 clinical trial, we evaluated the safety, virologic,

and immunologic responses of autologous HIV-specific T cells that were expanded to target conserved epitopes in HIV Gag and Pol as well as HIV Nef (HST-NEETs) in PLWH on ART. Six participants (4M, 2F; 33-57 years) received two infusions ($2x10^7$ cells/m^2 BSA/dose) of autologous HST-NEETs. HSTNEET infusions were well tolerated with seven grade 1 and one grade 2 adverse events that were possibly product related in only 2 participants following infusions. HST-NEET products were predominantly CD3+CD8+ effector memory T cells with variable expression of activation markers. Epitope mapping of the products identified 13 CD8-restricted epitopes, including repeated Nef epitopes in 3/6 participants. Peripheral blood mononuclear cells (PBMCs) were isolated at each follow-up timepoint to evaluate changes in HIV-specific T cell responses, anti-HIV antibody responses, size of the HIV reservoir in CD4+ T cells, and expansion and persistence of HIV-reactive T cell clones pre versus post infusion. HIV-specific T cell responses increased in 4/6 participants post infusions as assessed by IFNγ ELISpot. Anti-HIV gp120 envelope-specific antibody responses were maintained in all participants. Following infusions, we observed decreases in genome-intact HIV proviruses in 3/6 participants and decreases in the defective HIV proviruses in 2/6 participants. TCR profiling of HST-NEET products and followup PBMCs was used to evaluate the expansion and persistence of HIV-reactive T cell clones associated with the HST-NEET products in the participants. TCR profiling of sorted HIV-reactive T cells from the HST-NEET products and participant PBMCs demonstrated polyclonality (median, 9 clones; range, 1-137 clones/sample), where ≤4 T cell clones that were present in the HST-NEETs showed expansion and persistence in participant PBMCs for >45 weeks post-infusion. Two HST-NEET products showed Nef specificity, with expansion and persistence of Nef-reactive T cell clones in participants post infusion. T cell responses targeting a conserved Gag epitope (SPRTLNAWV) in one participant coincided with the expansion and persistence of a high frequency Gag/Pol reactive T cell clone: CASRPGTTYNEQFF. In sum, we report that administrations of HST-NEETs to PLWH without prescribed lymphodepletion were safe. HIV-specific T cell expansion was observed in the peripheral blood of all participants post infusion with decreases in genome-intact HIV proviruses in 3/6 participants. This promising therapeutic approach presents opportunities for combination therapies for HIV cure strategies.
