Submitted to Proceedings of the National Academy of Sciences of the United States of America

Protected areas (PAs) play an important role in conserving biodiversity and providing ecosystem services, yet their effectiveness is increasingly undermined by funding shortfalls. Using lions (*Panthera leo*) as a proxy for PA health, we assessed available funding relative to budget requirements for PAs in Africa's savannahs. We compiled a novel dataset of 2015 funding for 282 state-owned PAs with lions. We applied three methods to estimate the minimum funding required for effective conservation of lions, and calculated deficits in PAs where available funding did not meet estimated need. We estimated minimum required funding as \$978/km² per year based on the cost of effectively managing lions in nine reserves by the African Parks Network; \$1,271/km² based on modelled costs of managing lions at ≥50% carrying capacity across diverse conditions in 115 PAs; and \$2,030/km² based on Packer et al.'s cost of managing lions in 22 unfenced PAs. PAs with lions require a total of \$1.2-2.4 billion annually, or ~\$1,000-2,000/km², yet PAs received only \$381 million annually, or a median of \$200/km². Ninety-six percent of range countries had funding deficits in at least one PA, with 88-94% of PAs with lions funded insufficiently. In funding-deficit PAs, available funding satisfied just 10-20% of PA requirements on average and deficits total \$0.9-2.1 billion. African governments and the international community need to increase the funding available for management by three to six times if PAs are to effectively conserve lions and other species and provide vital ecological and economic benefits to local communities.

budget | conservation effectiveness | deficit | funding need | management

Introduction

Protected areas (PAs) are the foundation of international efforts to secure biodiversity (1, 2). PAs play a critical role in conserving high-priority species, including the African lion (*Panthera leo*), one of the most iconic symbols of Africa and a proxy for ecological health (3, 4). At least 56% of lion range falls within PAs, and the species reaches its highest population densities in PAs with high prey densities and where lion populations are well-managed and protected from primary threats (3, 5). Shortfalls in funding, combined with mounting human pressures, have weakened the management capacity in many African PAs and contributed to rapid declines in numbers of lions, their prey and other species (6-9). Lion numbers have decreased by 43% in just two decades, to as few as 23,000-35,000 wild individuals (8, 10). If managed optimally, Africa's PAs could theoretically support three to four times more wild lions than the current continental total, which would secure the ecosystems that lions encompass and allow for conservation gains for many other species (3).

Investing more financial resources into Africa's PAs would not only strengthen the conservation of lions and their ecosystems, but also generate social and economic benefits for Africa and the world at large. Africa's PAs encompass species and areas of natural heritage that are of great symbolic and cultural significance both within Africa and elsewhere, perhaps most notably in

the West (4, 11, 12). PAs also support and supply vital ecosystem services to African countries (13-15) and bolster and diversify rural and national economies via nature-based tourism (9, 16-18). Visitation to parks and reserves has been increasing in Africa to the extent that in Southern Africa, for instance, ecotourism generates as much as farming, forestry and fishing combined (19, 20).

However, Africa's PAs are often underfunded, and receive less international support than their global value merits or than is required to unlock their economic or ecological potential. While many African governments spend proportionally more on PA networks relative to their economic means than countries in other parts of the world (21), rapidly declining wildlife populations and the poaching crisis in Africa indicate that such expenditures are insufficient to protect wildlife (22). In addition, funding levels are widely divergent among African countries, with a handful of countries investing sufficiently, while the majority invests far less than is required for the effective functioning of PAs (23). Continent-wide funding of PAs is so low that most African countries risk losing the majority of their remaining wildlife resources before they have chance to benefit from them in economic terms (11). As PAs become depleted and ecologically degraded, benefits from tourism earnings decrease relative to those from conversion of the land to agriculture or development, making PAs increasingly difficult to justify in economic and political terms (24, 25). As a

Significance

Protected areas (PAs) are the cornerstone of conservation yet funding inadequacies undermine effectiveness in safeguarding biodiversity and ecosystem services. Successfully funding PAs requires reliable estimates of management costs. Using the conservation needs of lions as a proxy for wildlife more generally, we compiled a dataset of funding in Africa's PAs with lions and estimated a minimum target for effectively conserving the species. PAs with lions require \$1.2-2.4 billion or \$1,000-2,000/km² annually, yet receive just \$381 million or \$200/km² (median) annually. Nearly all PAs with lions are inadequately funded, with deficits totalling \$0.9-2.1 billion. Governments and donors must invest in PAs to prevent further declines of wildlife, and to foster the economic, social and environmental benefits that healthy PAs can confer.

* Minimum funding requirement based on each method: African Parks Network = \$978/km²; our study = \$1,271/km²; Packer et al. 2013 = \$2,030/km².

[†] State contributions for the Democratic Republic of Congo totalled ~\$3,000.

[‡] Data were not available but experts indicated that state budgets were close to \$0/km².

[§] Median does not accurately represent the right-skewed distribution of donor funding in Zimbabwe, where 50% of 22 PAs received < \$1/km² and 50% received a median of \$272/km².

[¶] Represents an underestimation, as South Africa estimates did not include donor data and Chad did not include state data.

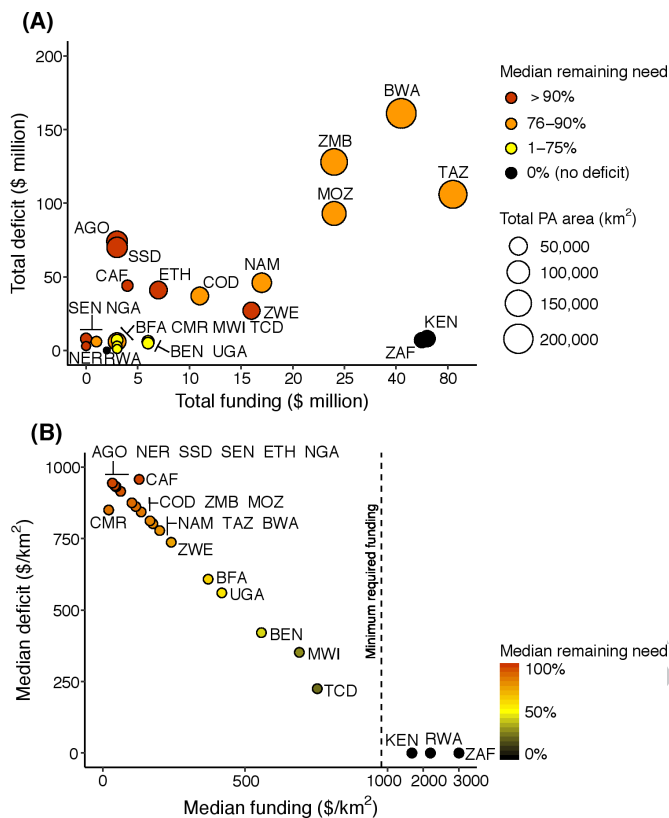

Fig. 1. The most underfunded countries for lion conservation, in terms of (A) total and (B) median available funding and remaining shortfalls for effective conservation of Africa's protected areas (PAs) with lions. Median remaining need represents the average percentage of funding needed to meet the estimated required minimum. Minimum required funding and deficits represent lower-end estimates based on the African Parks Network method (\$978/km²). See Table 1 and 2 for the number of deficit PAs in each country, country rankings and ISO country code.

result, many PAs have already been downsized, downgraded or degazetted (9, 26).

Investment in PAs must clearly be increased, but by how much is unclear. Budgets are notoriously challenging to track due to some state wildlife authorities' unwillingness to make their budgets available publicly and given variations in accounting methodologies between countries (27). Reputable estimates for African PA budgets are valuable but are now 10–34 years out of date due to the rapidly increasing and diversifying anthropogenic pressures on PAs (23, 28–30). A reassessment of the costs of maintaining Africa's PAs amidst current threats is urgently needed.

Lions are a useful species for assessing funding requirements for PAs. The species is listed as 'Vulnerable' on the International Union for Conservation of Nature (IUCN) Red List and affected by a wide range of threats, including habitat loss, prey depletion, retaliatory killing by people and targeted poaching, which also drive declines in many other wildlife species (31). Hence, their conservation status is emblematic of the human pressures facing wildlife more generally in Africa (10). Because lions are a keystone and umbrella species, adequate investment to secure their future is likely to protect numerous other species, as well as preserve ecosystem function and safeguard the long-term viability of Africa's PAs (4, 32).

Here we report on the funding available for Africa's PAs with lions and use three different methods to estimate the minimum amount required for effective conservation of the species. We also explore associations between funding, management capacity and PA characteristics to identify the patterns and magnitude

of financial shortfalls. This work provides a minimum financial target for conserving lions and more broadly securing the ecological and economic services offered by PAs on which people and biodiversity depend.

Results

We collected funding data for 282 PAs covering 1.2 million km² in 23 of 27 African lion range countries. Africa's PAs with lions receive a minimum of \$381 million in total funding annually (Table 1). Annual funding varied widely among individual PAs, from \$6/km² to \$17,449/km², with a median of \$200/km². When PAs were aggregated at a national scale, PAs in Cameroon received the lowest investment (median of \$21/km²), while PAs in four other countries (Angola, Niger, South Sudan and Senegal) also received less than \$50/km² in total funding (Table 1; Fig. 1). Even Tanzania, which supports ~40% of the global lion population, and most of the other countries that contain at least 1,000 lions (Zambia, Central African Republic, Mozambique, Botswana and Zimbabwe; 8), suffer from severe under-resourcing, with median budgets of less than \$300/km² (Table 1). Some countries, like Tanzania, are characterised by relatively higher budgets for national parks, but lower budgets for other types of PA, which comprises the majority of the protected estate. At the other end of the spectrum, three countries showed budgets above \$1,600/km² (Kenya, Rwanda and South Africa; Table 1). Funding was marginally higher in East Africa (median of \$265/km²) than Southern (\$200/km²) or West-Central Africa (262/km²; SI Table 1).

Three independent methods estimated that an annual minimum funding requirement of ~\$1,000–\$2,000/km² is necessary 'on average' for PAs to effectively conserve lions. African Parks Network spent a mean of \$978 ± \$773/km² per year (range: \$497–1,833/km²). Our study model determined a higher threshold of \$1,271/km² for 'effective' PAs (95% CI = \$457–\$2,423/km²; SI Table 2, SI Fig. 1). Packer et al.'s inflation-adjusted estimate represented the highest requirement at \$2,030/km².

These estimates predict that Africa's PAs with lions require a total of at least \$1.2–2.4 billion annually to conserve lions effectively (Table 1). Among countries, total funding requirements generally ranged with the number of PAs and PA area with lions, such as from as low as \$1 million in Rwanda (number of PAs with lions: n = 1 PA) and \$3 million in Niger (n = 2) and Chad (n = 1), to as high as \$203 million in Botswana (n = 49) and \$225 million in Tanzania (n = 37) based on the African Parks Network method (Table 1).

In comparing available to required funding for effective conservation, we estimated a total annual deficit ranging from \$0.9–2.1 billion across all assessed PAs (SI Table 3). Funding deficits existed in 88% (African Parks Network) to 94% (Packer et al.) of PAs with lions (Fig. 2). Of 23 countries assessed, 22 countries (96%) had at least one PA with deficit, and PAs in only three countries were funded above minimum funding requirements on average (Kenya, South Africa and Rwanda, the last which was the only country without PA deficit, although n = 1 PA; Table 2; Fig. 1B, SI Table 4). As expected, the highest total deficits occurred in countries with the most and largest PAs with lions, in Botswana (n = 49 PAs), Zambia (n = 35), Tanzania (n = 37) and Mozambique (n = 21; Fig. 1A). In ranking countries by median deficit per km², the highest deficits occurred in the Central African Republic (\$944–2,009/km²; n = 4) and Angola (\$944–1,996/km²; n = 1), where only 1–2% and 2–3% of funding needs were met on average, respectively (Table 2; Fig. 1B).

In PAs with deficits, just 10–20% of funding requirements were available on average (SI Table 4). Funding shortfalls were widespread and extensive: 27–59% of countries in deficit showed shortages of > 90% of required funding on average (Fig. 3). The

Table 2. The most underfunded countries for protected area (PA) management and lion conservation. Countries are ranked from highest to lowest median deficit among PAs with lions, as estimated by the African Parks Network method, the approach with the lowest minimum funding requirement (\$978/km²). More detail on PA deficits in countries that contain very few PAs with deficits (e.g. Kenya and South Africa) can be found in *SI Table 4*, which shows median deficits by country calculated using only PAs with deficits.

^{*} Median percent of unmet minimum required funding relative to total available funding by PA

[†] See Table 1 for total number of PAs in each country

Fig. 2. Annual funding (\$/km²) for 282 African PAs with lions (black circles) compared to minimum required need as estimated by the African Parks Network method (\$978/km²), our study method (\$1,271/km²) and the Packer et al. method (\$2,030/km²). In total, 249 (88% of total), 252 (89%), and 266 (94%) of PAs failed to meet the minimum benchmarks of the African Parks Network, our study, and Packer et al. method, respectively.

vast majority of countries (87%) reported a lower average available funding per km² across all PAs than even the lowest \$978/km² amount estimated as necessary for effective conservation of lions

(Table 1). Only three of all countries assessed (South Africa, Rwanda and Kenya) showed average funding levels higher than the minimum needed (Table 1), and even in these relatively well-funded countries a significant proportion of PAs showed deficits (2 of 13 PAs in South Africa and up to 17 of 20 PAs in Kenya; Fig. 1, Table 2).

State funding was twice as large as donor support (Table 1). State funding per unit area was more than three times as high in Southern Africa than other regions, whereas donor funding per unit area was higher in West-Central Africa than other regions (*SI Table 1*). Accordingly, several Southern (Botswana, Namibia) and East African countries (Kenya, Tanzania) were especially reliant on state support, while several West-Central (Democratic Republic of the Congo and Central African Republic) and Southern African countries (Angola, Malawi) were largely reliant on donor contributions (Fig. 4).

Higher funding per km² was associated with smaller-sized, fully fenced PAs that contained rhinos and supported active tourism, and that were part of a Transfrontier Conservation Area (TFCA), jointly managed by a non-profit organisation and located in a country with lower corruption (model fit $R^2 = 0.98$; *SI Table 5*, *SI Fig. 2*). Donor contributions were higher in smaller, fully fenced PAs of IUCN categories I or II that supported active tourism, were co-managed by a non-profit partner and located in countries with lower GDP ($R^2 = 0.91$; *SI Tables 6-7*). Greater state funding was associated with smaller PAs that contained rhinos and were part of a TFCA and IUCN categories I or II, that

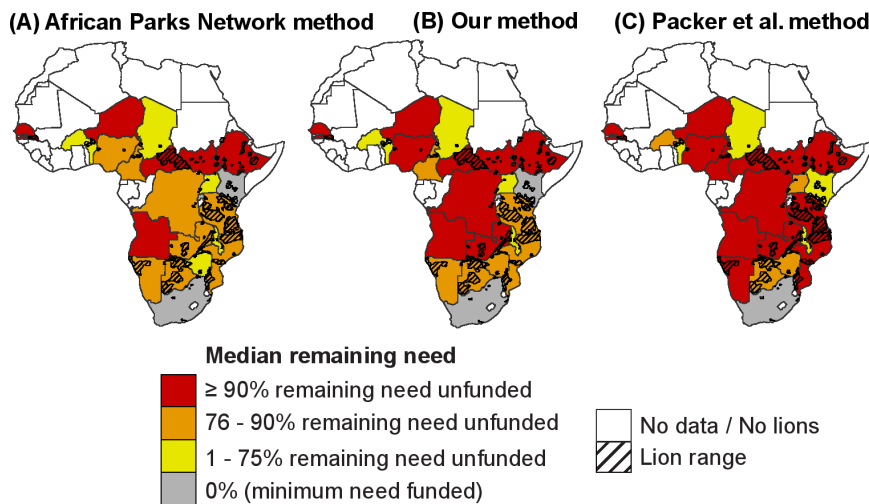

Fig. 3. Average funding shortfalls for lion conservation in protected areas (PAs) in 23 of 27 lion range countries. The 'median remaining need' represents the average (median) funding shortfall in PAs, calculated by comparing available funding for PA management to the required funding to effectively conserve lions. Minimum funding requirements were based on three estimation methods: (A) African Parks Network (\$978/km² per year), (B) our study method (\$1,271/km²) and (C) Packer et al. method (\$2,030/km²). All assessed countries except Rwanda showed at least one PA with deficit. See Table 2 and SI Table 4 for more detail on median deficit and the number of PAs with funding shortfalls in each country.

Fig. 4. Proportion of state versus donor contributions to management funding in 282 of Africa's protected areas (PAs) with lions. Data excludes South Africa and Chad, where data were not available on donor or state contributions, respectively.

were located in East Africa and in countries with higher GDP, and that were not co-managed by a non-profit ($R^2 = 0.91$; SI Table 8).

Among PAs, higher funding per km² was associated with higher management capacity ($r = 0.54$, $P < 0.001$; Fig. 5A), lower threat to wildlife ($r = -0.28$, $P = 0.001$; Fig. 5B) and the availability of more staff and patrol vehicles ($r = 0.67$ and $r = 0.71$, respectively, both $p < 0.001$; Fig. 5C, Fig. 5D). In turn, greater management capacity was associated with a lower threat to wildlife ($r = -0.28$, $P = 0.003$) and more staff and vehicles ($r = 0.42$ and $r = 0.44$, respectively, both $p < 0.001$).

Discussion

Our findings reveal major deficits in the management funding of Africa's PAs with lions. For PAs to achieve baseline effective conservation of lions (which reflects effective management more generally), overall funding must be increased by three to six times to meet minimum need, i.e. adding \$0.9-2.1 billion to supplement the \$381 million of total annual funding already available. Existing funding is highly skewed, with a minority of PAs funded above minimum required levels, while the majority of PAs and countries receive a fraction of the funding needed to conserve lion populations and broader ecosystems effectively.

In some countries (e.g. South Sudan, Zimbabwe), though moderate funding from the state is available, substantial proportions are tied up for salaries, leaving modest amounts for operations. Unless action is taken to increase the resourcing of most PAs in African savannahs, lions and many other species are likely to suffer continued steep declines in number and distribution, with serious ecological and economic ramifications. Countries with some of the largest PA networks, such as Botswana, Tanzania and Zambia experience some of the largest deficits in spite of strong political commitments to conservation. This presents an opportunity for additional donor support for conservation efforts in these countries, given the impressive contribution of land for conservation, the difficulty associated with securing such vast areas and the significance of these areas for the conservation of a wide range of species valued worldwide.

Our results are consistent with prior studies in highlighting the importance of management budgets for effective conservation of African wildlife. Inadequate PA funding in part leads to the wildlife population declines observed in many of Africa's PAs, and helps explain the severity of declines in charismatic species such as rhinos, elephants and increasingly lions (3, 5, 10, 33-35). Our finding that lower funding was associated with greater threats to wildlife suggests that management funding does not scale with the degree of threat and that threats are exacerbated in the absence of adequate funding. Adequate budgets are required to develop and maintain infrastructure, to purchase and maintain vehicles and other equipment and to train, deploy and motivate staff (2, 36). In the absence of sufficient funding (and even with adequate funding in circumstances of weak PA governance and management), field staff can become ineffective. In the worst cases, poorly paid or unmotivated staff can actually contribute to wildlife declines due to the social and financial gains that can be derived from engaging in illegal activities such as poaching (37).

Efforts are drastically needed to raise the management budgets of PAs to \$1,000-2,000/km² to effectively conserve lions and their broader ecosystems. The African Parks Network method (\$978/km²) represented the tried-and-true costs of managing stable and increasing lion populations in nine effective PAs with varying management conditions. African Parks have proven highly effective in the field and also at fundraising, due in part to their commitment to financial accountability. The African Parks Network method may yield the lowest estimates of budget requirements because their budgets are less likely to be affected by leakages to corruption or inefficiencies than those of some state wildlife authorities. Channelling an elevated proportion of funding to PAs through accountable NGO partners engaged in collabora-

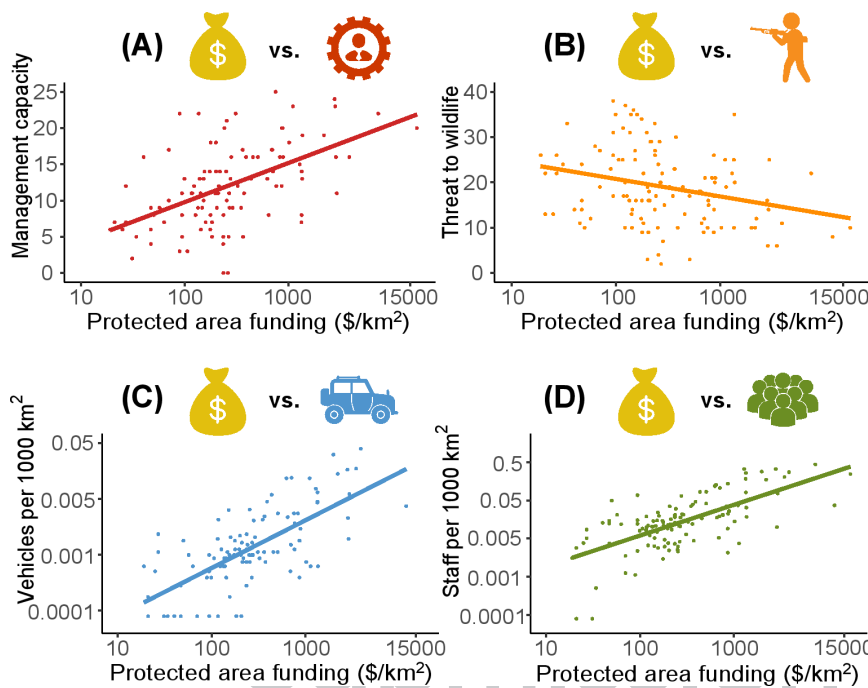

Fig. 5. Associations between funding in 125 Africa's protected areas with lions and (A) management capacity, (B) threats to wildlife, (C), vehicles available for patrols and (D) numbers of management staff (C). The 125 PAs are a subset of the 282 state-owned PAs for which both funding and the relevant data were available. Lines indicate the relationship directionality of Pearson correlations.

tive management partnerships represents one potential means of reducing loss of donor funding to corruption (38). Efforts to build the capacity of PA authorities to manage finances transparently are also important. Our study method (\$1,271/km²) considered a broader spectrum of management conditions across 115 PAs with lions and identified the funding threshold that best predicted PAs maintaining lion populations at $\geq 50\%$ of carrying capacity. Packer et al.'s method (\$2,030/km²) represented the high-end costs associated with managing unfenced, free-roaming lion populations. Collectively, these estimates represent a gradient of real-world management conditions and costs for effectively conserving lions. Although estimates are higher than prior (and now outdated) estimates of required funding, such as \$174–424/km² for forest parks in Central Africa in 2004 (29) and \$459/km² for parks Africa-wide in 1984 (28), our estimates approximate the \$1,010/km² estimated need for managing tigers in Asia (39) (all figures in 2015 USD).

We emphasise that the two higher-end estimates (\$1,271/km² and \$2,030/km², or \$1.2–2.4 billion total annually across all PAs with lions) are the minimum amounts necessary under current conditions to manage lion populations at half of the potential population size. However, 50% of carrying capacity is a low benchmark for conservation effectiveness, particularly for lions which have such great ecological and economic value. In addition, some of the PAs with lions at 50% of estimated carrying capacity are suffering ongoing declines (10), such that even larger budgets may be required to manage stable or growing populations of lions and their prey, and yield long-term security for the species.

Additional considerations. We caution that our study does not provide insights into the requirements for the management of individual PAs, which likely vary significantly with the extent of threat and the geographic location, habitat type and degree of remoteness. Large PAs are likely to benefit from economies of scale, as certain infrastructure developments are necessary regardless of the size of an area, and because larger areas will be more insulated from threats than smaller areas. Similarly, costs are likely to be higher in countries where corruption causes funding to be squandered (40). Additionally, in PAs where there

is little or no infrastructure, such as the newly gazetted Luengue-Luiana and Mavinga National Parks in Angola, the required capital investment would be significantly greater than the operational costs used in our calculations. If PAs receive the increase in funding that we recommend, all wildlife species would benefit; that said, our estimates may not reflect the additional funding potentially needed to conserve rhinos (and to a lesser extent, elephants), due to the high prices obtained by illegal wildlife traders for their horns/tusks and the vigour with which poachers pursue them (41–43).

The costs of managing Africa's PAs and conserving species such as lions are likely to grow with time. Pressure on wildlife due to poaching for body parts for the illegal wildlife trade is severe, with an increasing range of species being affected (including lions), which makes PA management more difficult and expensive (3, 43). Africa's human population is growing faster than other parts of the world, which will increase pressure for land and natural resources contained within PAs (44, 45). Conversely, costs could be reduced by increasing the involvement of local communities in PA management and decision-making, thereby increasing their engagement and sense of ownership (12, 16, 46).

Funding protected areas for Africa's future. Greater investment in Africa's PAs is urgently needed, and is likely to yield significant social, economic and ecological benefits. PAs provide essential ecosystem services via the provisioning of clean water and other natural resources (13–15), which can reduce poverty, promote human health and improve the well-being of rural communities (47, 48). Wildlife-based tourism in PAs has significant potential to act as a vehicle for sustainable economic development and job creation in many African countries, particularly in rural areas with few alternatives (7). The ecotourism industry already generates \$34 billion of revenue in sub-Saharan Africa, and the tourism industry more broadly creates nearly 6 million jobs (49, 50). Lions represent a key aspect of this success and are one of the most popular attractions to visitors of Africa's PAs (51). Tourism revenue represents a crucial means for African countries to diversify economies and reduce reliance on finite resources such as minerals, and on agriculture and livestock, which are vulnerable to climate change (52). The potential social

and economic benefits associated with functioning PA networks build a strong case for the investment of general development aid funding to augment the traditional conservation-focused funding in PA management. An allocation of just 2% of the \$51 billion allocated to development in Africa would likely cover the deficits facing PAs from a lion conservation perspective (53). Such investments to PAs should be normalised as part of the international development financial portfolio to support maturing tourism economies and protect the environmental services provided by PAs to people's health and general well-being. These benefits would increase if care was taken to maximise the extent to which benefits from tourism and PAs accrue to communities. Potential approaches include providing communities with part or complete ownership of concessions within PAs and, where funding permits, use of 'performance payments' (54, 55), while taking care to avoid elite capture. Similarly, developed countries could consider 'debt-for-nature' schemes, where debt alleviation is provided in return for PA investment by the host nation (56). Creative donor investment could assist many African countries to optimise the commercial viability of their PAs, especially in PAs with high deficits (Fig. 1) where state funding is in short supply (Fig. 4).

Over recent years, increasing effort has promoted community-based conservation areas outside of PAs, which are essential for maintaining landscape connectivity and intact ranges of far-roaming species such as lions. However, while such investments are essential, we urge the conservation and donor community to ensure that sufficient focus is given to the management and protection of PAs in order to maintain the 'backbone' of conserved landscapes. PAs should not be assumed to be adequately protected by virtue of their legal status. In addition to funding needs, improving the effectiveness with which existing funds are used is also essential. This means avoiding corruption and seeking options to provide long-term, drip-feed funding for PAs, rather than the large, non-recurrent funding packages commonly provided by multi-lateral funding agencies (11). To this end, collaborative management partnerships between NGOs and state wildlife authorities (such as those practiced by African Parks) are of potentially high value and should be a funding priority (38).

Conclusion

PAs in Africa are facing a funding shortfall of at least \$0.9 billion and up to \$2.1 billion for effective conservation of lions. Without significant increases in the amount of funding, PAs will not be able to fulfil the ecological, economic or social objectives for which they were established. The current budget deficit facing Africa's PAs is surmountable, but currently represents a great risk that lions and many other wildlife species will continue to decline in number and ultimately disappear from the majority of PAs in lion range (10). Such losses would mean that many African countries would lose their most iconic wildlife species before benefitting significantly from them.

Methods

Our methods comprised four main steps. First, we compiled a novel database of available funding in PAs with lions, which to our knowledge represents the most comprehensive and up-to-date database of its kind. Second, we applied three methods to estimate different thresholds of minimum funding required for effective conservation of lions. Third, we used required funding estimates to calculate deficits in PAs where available funding did not meet need. Fourth, we addressed the patterns and importance of funding for conservation by examining associations between funding and PA characteristics and management resources.

Available funding. We gathered data on the total funding available for management of PAs. Our study focused on state-owned PAs containing lions and located within lion range in Africa (*SI Appendix 1*). Total funding comprised 'state' (funding contributed by the PA country government) and 'donor' (funding contributed by non-state groups, including non-profit organisations, charitable foundations and bi- and multi-lateral agencies) funding. Management funding included costs related to staff, law enforcement, maintenance of infrastructure and roads, habitat management and

engagement with adjacent communities. Sources broadly included (see *SI Appendix 2* for details): 1) expert surveys (see (3) for methods), 2) wildlife authorities, 3) 50 non-profit organisations involved in PA management, 4) private hunting companies and 5) major donors involved in PA management, such as foundations, non-profit organisations and multi-lateral government agencies. We obtained both state and donor funding data from 282 state-owned PAs with lions and in 23 countries, except for in Chad, where we were not able to obtain state data, and South Africa, where we could not comprehensively capture donor contributions (however, state budgets for PAs in South Africa are substantially higher than other countries and sufficient for effective lion management (3)). We emphasise the major challenges associated with obtaining budget data (*SI Appendix 3*) but are confident that our estimates are of the correct order of magnitude and constitute the most up-to-date and accurate data available.

From each source, we gathered information on the PA and the years over which funding was spent, tracking whether funds were channelled to other organisations to avoid double-counting resources. We primarily obtained budget data for the fiscal year spanning 2015–2016, but in rare cases where data was not otherwise available, we included data from several years before (no earlier than 2009) or after (2017). All financial data (and numbers reported in this paper) were converted to US\$ at the average exchange rate from the year of origin (57) and scaled to USD in 2015 to account for inflation (58). To comply with requests for anonymity from our informants and reduce the vulnerability of poorly-funded PAs (exposure to funding levels could make them a target for threats such as poaching), we report results on individual PA data without mentioning PAs by name and present aggregated PA data at the country level. However, upon request, we will provide PA-level data to researchers or conservationists who demonstrate constructive ideas for further analysis. We calculated PA average funding (including funding requirements and deficits) using medians to prevent misrepresentation due to a minority of highly funded PAs. All statistical analyses were done using R (59).

Minimum funding requirements and deficits. We applied three methods to consider a range of cost estimates of the minimum funding required for effective lion conservation:

(1) African Parks Network method: We acquired data on management budgets for each PA managed by the African Parks Network, a non-profit organisation delegated management responsibility by state wildlife authorities for nine PAs as of 2015. Since both lions and prey species were stable or increasing in all nine PAs (3), we assumed that the levels of management investment were adequate for effective lion conservation. We calculated the minimum funding requirement as the amount that African Parks Network spent in 2015 on capital investments plus operating costs associated with management in each of their PAs. 'Capital investments' included: buildings, roads, airstrips, fencing, vehicles, aircraft, office equipment, furniture, tools, radio communications equipment and other fixed assets.

(2) Our study method: We used logistic regression to determine the minimum funding level that best predicted PA 'effectiveness' for 115 PAs for which we had funding and lion population data. We defined 'effective' PAs as PAs where lions occurred at $\geq 50\%$ of estimated carrying capacity, based on the potential ungulate biomass that could likely be supported given prevailing rainfall and soil conditions at each site (3). We acquired data on potential carrying capacity for lions at each PA (60) and paired these with data on lion population estimates from (3). Using effectiveness as a predictor variable and total funding (\$/km²) as a required response variable from a pool of 35 candidate variables (*SI Table 1*), we built a multivariate model to predict PA effectiveness. We then identified the funding threshold that best discriminated effective from non-effective PAs (see *SI Appendix 4* for details).

(3) Packer et al. method: We applied Packer et al.'s (5) finding based on 22 PAs that \$2,000/km² of operational costs is required to maintain lions in unfenced PA at $\geq 50\%$ carrying capacity, representing the high-end costs of managing free-roaming lions. Expert surveys indicated that most of the PAs in our dataset were unfenced (72%). We adjusted Packer et al.'s estimate to USD in the year 2015.

Using these estimates of required funding, we calculated funding needs and deficits for each PA and then aggregated PAs by country. PA funding need (in \$) was calculated as the minimum funding requirement (\$/km²) multiplied by PA area (km²). PA funding deficit (\$) was calculated as the funding need (\$) minus available funding (\$); positive deficits indicate greater need than available funding and deficits were minimized at \$0, since our approach aimed to assess baseline funding adequacy. PA funding deficit per area (\$/km²) was calculated as PA deficit (\$) divided by PA area (km²). Country totals for funding need and deficit (\$) were calculated by summing PA need and deficit (\$), respectively, for PAs in each country. When calculating budget deficits on a national and continental level, budget surpluses that occurred in a minority of PAs were not 'carried over' to other PAs to reduce overall estimated deficit, but were treated as zero deficit, reflecting the fact that such surpluses are generally not transferred to other PAs.

PA characteristics. We used a linear regression framework to assess what PA characteristics were associated with higher total, state and donor funding (see *SI Appendix 4* for details). For this analysis we used a subset of 128 PAs for which we had expert information from surveys. We assessed 36 variables (derived from a range of sources, including published papers, publicly avail-

able datasets and expert surveys) relating to governance, socioeconomic, management and ecological characteristics for each PA (*SI Table 9*).

Management factors. Expert surveys also collected information on how funding was associated with management resources and threats to wildlife. Experts were asked to provide information on (see (3) for details): 1) the number of vehicles and rangers available for management; 2) a rating of different aspects of management capacity on a scale of 1-5, which we summed to generate an overall 'management capacity score'; and 3) a rating of the severity of 11 specific threats to wildlife on a scale of 1-5, which we summed to generate an overall 'threat to wildlife score'. We calculated Pearson correlations to examine relationships among total funding, management resources (vehicles and staff), management capacity and threats to wildlife.
