Adolescent Schooling and Adult Labor Supply: Evidence from
COVID-19 School Closures and Reopenings in Kenya
Pierre E. Biscaye, Dennis Egger, and Utz J. Pape

S1. Additional Figures and Tables

Figure S1.1. Kenya COVID-19 Cases, Pandemic Policy, and Data Collection Timeline

Source: Authors based on information from COVID-19 government response timeline for Kenya, Kenya COVID Tracker, Presidency of Kenya, Kenya Ministry of Education Twitter feed, COVID-19 Data Repository by the Center for Systems Science and Engineering (CSSE) at Johns Hopkins University.

Note: The figure shows the evolution of weekly confirmed COVID-19 cases in Kenya over time, along with the timing of key pandemic policy changes. The red bar indicates the partial school reopening on 12 October, the focus of the analysis. “Relaxation of some restrictions” indicates that one or more of the initial pandemic constraints were at least partially reduced. Specific policy changes are outlined in supplementary online appendix S2.

Figure S1.2. Childcare Arrangements When Children Are Out of School

Source: Authors’ analysis based on data from the RRPS.
Note: Respondents are asked to specify all of the situations where a randomly selected child spent at least some time when out of school in the past week. “Somewhere else” combines “daycare/other childcare” and “at home with a maid/domestic helper.” The figure uses information on childcare arrangements for analysis sample households with at least one child in any grade from 3 to 9, but the distribution is nearly identical when considering all households with children.

Figure S1.3. Mean Respondent Childcare Hours by Treatment Group and Sex over Time

Source: Authors’ analysis based on data from the RRPS.
Note: The figure shows mean respondent childcare hours in the last seven days by treatment status and sex over time, along with 95 percent confidence intervals around the treated group means. Childcare hours include time spent doing other activities while caring for children. Treated households have a child enrolled in grade 4 or 8, and control households have a child enrolled in grade 3, 5, 6, 7, or 9. Mixed households with children in both grade groups are not shown. The red bars indicate changes in Kenya’s school closures policy.

Figure S1.4. Mean Child Hours in Household Agricultural Work by Grade, Randomly Selected Children in Survey Round 3

Source: Authors' analysis based on data from the RRPS.

Note: The figure shows mean child hours in household agriculture in the last seven days by grade of the randomly selected child for survey round 3, which coincides with the partial school reopening for grades 4, 8, and 12. Hours for individual children are not available for survey rounds 1 and 2 while schools were closed.

Table S1.1. Comparison of Analysis Sample to Other Survey Households

Sample	(1) All households	(2) Households with children	(3) Analysis sample households	(4) All HHs ever using child farm labor	(5) Analysis HHs ever using child farm labor
Observations	7,171	4,901	1,590	1,494	631
<i>Household characteristics</i>					
Female household head	0.32 (0.47)	0.30 (0.46)	0.29 (0.45)	0.28 (0.45)	0.26 (0.44)
Count adults	2.40 (1.28)	2.61 (1.27)	2.61 (1.21)	2.77 (1.32)	2.70 (1.19)
Count of all kids age 0–17	1.44 (1.72)	1.98 (1.75)	3.12 (1.60)	2.43 (1.97)	3.44 (1.73)

Childcare hours in last 7 days	43.67 (43.20)	43.71 (43.21)	48.34 (44.73)	44.09 (43.61)	49.49 (45.91)

Source: Authors' analysis based on data from the RRP5.

Note: The table compares means for household and respondent characteristics across different samples of survey households. Data are from the first time a household is observed, typically in survey round 1 (May–early July) while schools were fully closed. Column 1 includes all households surveyed at least once in the first four rounds of the survey. Column 2 includes households with any children. Column 3 includes analysis sample households: those with at least one child in grades 3–9. Column 4 includes all households reporting any child HH ag work at any point during the first four rounds of the survey. Column 5 is the same but restricted to analysis sample households. “HH” indicates “household”.

Table S1.2. Baseline Balance by Treatment Status

	Control mean (SD)	Treat difference (SE)	Mixed difference (SE)

Observations	1,590	1,590
Outcome mean	0.590	0.397

Source: Authors' analysis based on data from the RRPS.

Note: This table presents correlates of whether the household is above the mean for a normalized index of household wealth (based on housing and asset ownership before the pandemic) and whether the household reports any children engaged in household agricultural work. Data are from the first time a household is observed in the RRPS. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

S2. Major Pandemic Policy Changes in Kenya

The following outline summarizes when major nationwide pandemic-related policies were implemented and relaxed over the course of 2020 after the first COVID-19 cases in Kenya on March 13. The dates for the announcements of new restrictive policies are in *italics* and the dates when these policies were relaxed or ended are in **bold**. We also include announcements related to school closures, even though policies did not necessarily change with these announcements. Most policies were extended multiple times after first being imposed; we do not list the dates of policy extensions, except for school closures.

- *March 13–20*
 - Suspend all public gatherings, meetings, games, events
 - Ban on gatherings of more than 10 people
 - All schools closed
 - Recommend working from home where possible
 - Ban on foreigner entry; quarantine requirements for entry of nationals and visa holders
 - Public transport asked to reduce to 60 percent of capacity
- *March 24–27*
 - Ban on national and international flights
 - Closure of bars and restaurants for in-person service
 - Direct cash payments implemented for vulnerable citizens
 - Stay at home requirements imposed, except for “essential” trips
 - Curfew imposed from 17:00 to 05:00 hours
 - Public transit closed between “infected” and “not infected” areas
- April 26: School closures extended to June 4
- **April 27**: Partial reopening of restaurants for take-out service
- June 6: School closures extended until further guidance from the Ministry of Health
- **June 7**: Nightly curfew revised to between 21:00 and 04:00 hours
- June 24: Announcement that school might reopen on September 1
- **July 7**
 - Phased reopening of religious gatherings
 - Up to 100 people permitted to attend weddings and funerals
 - Local air travel within Kenya to resume July 15
 - International air travel to resume August 1
- July 7: Announcement that schools will remain closed until January 2021, final exams are cancelled, and students would repeat the year; colleges and universities following strict guidelines might reopen in September
- **July 27**
 - Restaurants reopened, must close by 19:00 hours
 - Ban on sale of alcoholic drinks and beverages in eateries and restaurants
- **August 27**
 - Restaurants may remain open until 20:00 hours
 - Ban on sale of secondhand clothing lifted
 - Licensed hotels may sell alcohol
- September 15: Ministry of Education releases guidelines for safe reopening of schools

- September 21: Ministry of Education calls all teachers to report back to schools by September 28
- **September 27**
 - Nightly curfew revised to between 23:00 and 04:00 hours
 - Bars may reopen; restaurants and eateries may sell alcohol; bars, restaurants, and eateries may remain open until 22:00 hours
 - Religious gatherings may open for up to 1/3 of capacity
 - Up to 200 people may attend funerals and weddings
- October 6: Ministry of Education announces that students in examination grades (4, 8, and 12) shall return to classes on October 12
- **October 12:** Students in examination grades (4, 8, and 12) to return to classes
- *November 4*
 - Requests for government work to be done remotely when possible
 - Political gatherings suspended
 - Nightly curfew revised to between 22:00 and 04:00 hours
 - Bars, restaurants, and eateries must close by 21:00 hours
- November 4: Announcement that schools to fully reopen in January 2021
- **January 4:** Schools fully reopen

Other policies were implemented that specifically affected certain parts of the country. For example, on April 6 the government instituted a 21 day movement ban/lockdown for Nairobi, Kilifi, Kwale, and Mombasa, and Mandera was added soon after. This lockdown was extended multiple times. These were the only counties affected. The lockdowns for Kilifi and Kwale ended on June 7 and those for Nairobi, Mombasa, and Mandera ended on July 8.

S3. Data

Data come from the Kenya COVID-19 Rapid Response Phone Surveys (RRPS), collected by the Kenya National Bureau of Statistics with support from the World Bank and the University of California at Berkeley. [Pape et al. \(2021\)](#) describe the survey methodology and implementation in detail.

The main RRPS sample is drawn from the nationally representative Kenya Integrated Household Budget Survey (KIHBS) conducted in 2015–2016: 9,009 households that were interviewed and provided a phone number served as the primary sampling frame for the RRPS. All households in the sample were targeted in each round regardless of whether they were reached in a previous round. By the fourth round of the RRPS, 5,499 KIHBS households had been successfully surveyed at least once. The KIHBS sample is supplemented by random digit dialing (RDD). From a sampling frame of 5,000 randomly selected numbers, of which 4,075 were active, 1,554 households had completed at least one survey by round 4.

The sample is intended to be representative of the population of Kenya using cell phones. In the 2019 Kenya Continuous Household Survey 80 percent of households nationally report owning a mobile phone, though certain counties—notably in the northeast—have much lower mobile phone penetration. [Pape et al. \(2021\)](#) report that KIHBS households that provided a phone number and those that were successfully surveyed in the RRPS have better socioeconomic conditions—measured by housing materials and asset ownership—than households that did not provide a phone number or that did but were not reached for the RRPS. The RRPS data include household survey weights adjusting for selection and differential

response rates across counties and rural/urban strata, attempting to recover national representativeness. We do not apply these household weights for our analyses.

We primarily use data from the first three rounds of the RRPS, covering May–November 2020, and also construct measures for February 2020, before the first COVID-19 cases in Kenya, using recall questions from the first time a household was surveyed. We show data on household agricultural labor for later rounds of the RRPS covering January–October 2021 to show how outcomes evolved after schools fully reopened and for comparison with reports during the same months in 2020. Each round lasted approximately 2.5 months and covered a representative cross-section of households each week within each round. The order in which households were called was randomized in the first survey round and maintained in all subsequent rounds.

Due to a survey coding error, in round 1 women were requested as survey respondents whenever they were available, leading to a higher share of female respondents. Subsequent rounds were conducted with the same respondent unless they could not be reached. The survey team attempted to reach the target respondent at least five times across several days and hours of the day before moving on to speak to any other knowledgeable household member in order to avoid replacing the respondent. Due to this non-random selection of respondents, household characteristics differ by whether the baseline respondent is female or male. The surveys include information on household composition, assets and housing, labor outcomes for household adults, and child schooling and care, as well as more general household information and COVID-specific modules. Detailed questions on child care, schooling, labor, and other outcomes are included for a randomly selected child in each round.

Data on childcare arrangements for a randomly selected child include questions on which household member has primary responsibility for the child's care, which household member was with the child in the last 15 minutes, and where and in whose company the child stayed during the day when out of school (from a set of general categories).³⁵ The surveys also ask respondents for their hours spent on childcare in the last seven days.³⁶ Childcare hours from other household adults are measured starting in round 3, while childcare hours from all household children combined and all non-household members combined are included starting in round 4, after schools fully reopened.

In the first survey round, respondents are asked about their housing characteristics and ownership of selected assets before March 2020. We consider whether the dwelling has a primary floor material other than earth, dung, or palm and a primary wall material of cement, stone, bricks, adobe, or wood planks, and whether the household owned a radio, mattress, refrigerator, and mobile phone (the four most commonly reported assets). We normalize each of these components, sum them, and normalize the sum across the entire survey sample to construct our normalized wealth index.

Labor supply is captured using modules on household agricultural production, household enterprise, and wage employment. For both household agricultural production and for each household enterprise, respondents report all household adults engaged in those activities over the last seven days and their hours of work. Wage employment is reported for each household adult. An individual not working in a given activity is coded as working 0 hours. Recall on labor supply for February 2020 is only available for survey respondents. The survey also includes data on total child hours spent working in household agriculture in the last seven days in each round, and hours for a randomly selected child starting in round 3. Households also report whether they hired any outside workers to work on household agricultural activities.

35 Respondents are instructed to select all childcare arrangements used. Nevertheless, respondents might omit types of childcare that are used less frequently or that are seen as less socially acceptable (e.g., leaving a child at home by themselves).

36 The survey asks “In the last seven days, how many hours did you spend doing childcare?” and does not distinguish between time actively spent caring for a child and time spent on other activities while responsible for a child. We topcode reported childcare hours at 140, or 20 hours a day. Over 15 percent of respondents in our analysis sample indicate spending at least this many hours on childcare.

Respondents report estimates of total household earnings from agricultural activities and from household enterprises over the last 14 days. For the few households with multiple enterprises, we sum earnings and profits across enterprises. Wage earnings in the last 14 days are reported for individual wage workers. For comparability with the measures of household agriculture and enterprise earnings, we aggregate wage earnings to the household level. Earnings data are limited—for all activities the 90th percentile of household earnings in the analysis sample is 0—in part due to a focus on the last 14 days, which does not accommodate seasonality or other variability in earnings.

We winsorize reported individual hours of work and household earnings across activities at the 99th percentile. We winsorize reported childcare hours at 140 per week.

S4. Robustness

Figure S4.1. Mean Adult Work Hours by Treatment Group over Time

Source: Authors’ analysis based on data from the RRPIS.

Note: The figure shows mean total work hours in the last seven days for adults in control households over time (dashed line), and in each period we add to this the estimated treatment effect with 95 percent confidence intervals using the results from supplementary online appendix [Table S4.1](#). For the reference time period in that regression we show the treated group mean and 95 percent confidence interval. Data on February (pre-pandemic) working hours are not shown as they are only available for the respondent. Treated households have a child enrolled in grade 4 or 8, and control households have a child enrolled in grade 3, 5, 6, 7, or 9. Mixed households with children in both grade groups are not shown. The red bars indicate changes in Kenya’s school closures policy. We fail to reject that the treated differences in the periods while schools are closed are jointly 0 ($p = 0.58$).

Figure S4.2. Impacts of Partial School Reopening on Adult Work Hours, Varying Sample

Source: Authors' analysis based on data from the RRPS.

Note: The figure presents estimated coefficients and 95 percent confidence intervals for the effect of $\text{Post} \times \text{Treat}$ from equation (1) for varying samples and treatment definitions. Only coefficients for treatment households are shown. The outcome is total work hours in the seven days prior to the interview, taking a value of 0 for individuals not working. We first test robustness to dropping mixed households and households surveyed in round 3 before the partial reopening (which do not inform identification of treatment effects) and to changing the definition of “Post” to the date the reopening was announced (between survey rounds 2 and 3). The main sample includes adults ages 18+. We then test robustness to focusing on survey respondents, adults age 18–65, adults age 25–50, and adults identified as potential parents—between 14 and 55 years older than the oldest household child—or sole caregivers (the only household adult). We also test the robustness to varying the grades included in the treatment group definitions. Omitting grade 6 students from the control definition focuses just on students in grades immediately adjacent to those treated. Including grade 2 students in the control group mirrors the inclusion of grade 6 relative to grade 8. Omitting grade 9 students prevents comparing primary to secondary school students. Adding grade 12 students to the treatment definition and grade 10 and 11 students to the control definition expands the definition to include all grades eligible for the partial reopening. The definition of mixed households is updated accordingly in all cases.

Table S4.1. Impact of Partial Reopening on Adult Labor Supply in the Last Seven Days, by Time Period

	(1) Engaged in any work in last 7 days	(2) Total work hours in last 7 days
Treat × May–Jun	0.02 (0.06)	1.75 (2.27)
Treat × Aug 16–Oct 11	−0.05 (0.07)	−0.86 (2.74)
Treat × Oct 12–Nov	0.07 (0.07)	4.91** (2.40)
Mixed × May–Jun	0.04 (0.06)	0.55 (2.28)
Mixed × Aug 16–Oct 11	0.10 (0.07)	2.54 (2.74)
Mixed × Oct 12–Nov	0.11* (0.06)	1.83 (2.31)
Observations	8,694	8,694
Mean, pre-reopen control	0.59	16.21
<i>p</i> -value, pre-reopening coefs jointly 0 for treatment	0.58	0.49

Source: Authors' analysis based on data from the RRRPS.

Note: This table presents estimates from supplementary online appendix Figure S4.1 of the interaction between Treat and time period from equation (1), where Post is replaced with time period dummies, which also enter separately into the equation. The reference period is July–August 15, while schools were closed and before the partial reopening was announced. We show *p*-values from the *F*-test that the coefficients for May–June and Aug–Oct 11 are jointly 0 for treated households. Observations include data for all household adults (age 18+) from May to November 2020, and include treated households with children in grade 4 or 8 (indicated by “Treat”), control households with children in an adjacent grade, and “Mixed” households with both types of children. Regressions include household and month fixed effects. SEs clustered at household level. * *p* < 0.1, ** *p* < 0.05, *** *p* < 0.01

Table S4.2. Impacts of Partial School Reopening on Adult Work Hours, Varying Controls

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Post	–	−3.28*** (0.95)	–	–	–	−2.26** (0.88)	0.97 (0.65)

Post × Mixed	0.93 (1.79)	0.92 (1.81)	0.92 (1.79)	0.29 (1.36)	0.95 (1.80)	0.97 (1.68)	−0.23 (1.23)
Observations	8,694	8,694	8,694	8,694	7,898	7,898	7,898
Mean, pre-reopen control	16.21	16.21	16.21	16.21	16.05	16.05	16.05
Household FE	Y	Y	Y	Y	N	N	N
Individual FE	N	N	N	N	Y	N	N
Month FE	Y	N	Y	Y	Y	N	N
Individual controls	N	N	Y	Y	N	N	Y
Household controls	N	N	N	Y	N	N	Y

Source: Authors' analysis based on data from the RRRPS.

Note: This table presents estimates of equation (1) with varying controls. The dependent variable is total working hours over the last seven days, taking a value of 0 for individuals not working. Observations include data from May to November 2020, and include treated households with children in grade 4 or 8 (indicated by “Treat”), control households with children in an adjacent grade, and “Mixed” households with both. “Post” is a dummy for being observed on or after the partial school reopening on October 12. Column 1 is the primary specification. Individual controls include sex, age, and household head status. Household controls include number of adults, young children (age 0–4), and school-age children (5–17) in the household, dummies for engagement in agriculture and in enterprise, and the sex of the survey respondent. The sample is smaller in columns 5–7 because some adults are only observed once. SEs clustered at household level. * *p* < 0.1, ** *p* < 0.05, *** *p* < 0.01

Table S4.3. Correlates of Adult Childcare Hours in Last Seven Days

	(1) Childcare hours, last 7 days
Female (=1)	12.26*** (1.13)
Respondent (=1)	3.70*** (0.84)
Household head (=1)	-0.23 (0.99)
2 children in HH	0.07 (2.04)
3 children in HH	-0.18 (2.19)
4+ children in HH	1.03 (2.38)
Female × 2 children	0.37 (1.61)
Female × 3 children	2.94* (1.62)
Female × 4+ children	1.11 (1.81)
Respondent × 2 children	1.15 (1.16)
Respondent × 3 children	-0.67 (1.20)
Respondent × 4+ children	1.35 (1.26)
Household head × 2 children	-1.15 (1.42)
Household head × 3 children	1.47 (1.48)
Household head × 4+ children	0.38 (1.64)
Observations	15,328
Mean, male non-resp non-head 0 kids	10.52

Source: Authors' analysis based on data from the RRPS.

Note: The table presents correlates of childcare hours in the last seven days for all adults (age 18+) in the RRPS in survey rounds 3 and 4 when data on childcare for all adults was collected. Standard errors are clustered at the household level.

Source: Authors' analysis based on data from the RRPS.

Note: This table presents estimates of equation (1) but interacting a characteristic Z with all right-hand side variables except the household fixed effects, separately for women and men. The dependent variable is total adult work hours over the last seven days. Observations include data from May to November 2020, and include treated households with children in grade 4 or 8 (indicated by “Treat”), control households with children in an adjacent grade, and “Mixed” households with both. The total observations across women and men add up to 8,350 rather than 8,694 as in the main analysis because some individuals only appear in their household in a subset of survey rounds. “Post” is a dummy for being observed on or after the partial school reopening on October 12. Regressions include household and month fixed effects. SEs clustered at household level. The first columns show average effects for the full sample of households. In the following columns, coefficients with Z = 1 represent the sum of the Post × Treat and Post × Treat × Z terms, and analogously for Mixed households, with standard errors calculated using the *xtlncom* package in Stata. We include p-values for tests of whether the interaction term is equal to 0. The column labels indicate which characteristic Z is being used. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

Source: Authors' analysis based on data from the RRP5.

Note: This table presents the results shown in Figure 4. The dependent variable is total working hours over the last seven days, with individuals not working coded as working 0 hours. In each regression a characteristic Z is interacted with all right-hand-side variables except the household fixed effects. Coefficients with Z = 1 represent the sum of the Post × Treat and Post × Treat × Z terms, and analogously for Mixed households, with standard errors calculated using the *xlincom* package in Stata. We include *p*-values for tests of whether the interaction term is equal to 0. The column label indicates which characteristic Z is being used. Columns 1–5 interact treatment with individual characteristics, and columns 6–9 interact treatment with household characteristics. Closures work participation is based on any participation in a given sector from May to October 11, 2020. Samples sizes for these analyses are lower because certain adults were not listed in household rosters during any baseline round surveys, leading to missing information on closures work engagement. “Large urban” is a dummy for location in one of Kenya’s largest urban areas (Nairobi, Mombasa, Nakuru, Kisumu, Kiambu) relative to any rural area, while “Urban” is a dummy for location in any urban area. Private school enrollment is measured across all household children. Observations include data from May to November 2020, and include adults age 18+ in treated households with children in grade 4 or 8 (indicated by “Treat”), control households with children in an adjacent grade, and “Mixed” households with both. “Post” is a dummy for being observed on or after the partial school reopening on October 12. Regressions include household and month fixed effects. SEs clustered at household level.

S6. A Simple Static Partial Equilibrium Model of Childcare and Labor Supply

We develop a simple model of adult labor supply and childcare decisions to generate predictions to take to the data. The model considers a static problem for adult household members with children. For simplicity, we assume that household adults take decisions jointly, and thus model the decision as that of a single person. We focus on a static, partial equilibrium labor-supply decision, and set aside possible impacts of shocks to labor demand to focus on shocks to the adolescent school availability. Key aspects of the context that we aim to reflect in the model are the availability of child labor in household agriculture and childcare of younger children by older children. To reflect women's larger role in childcare in this setting, we assume that female adult household members have either a comparative advantage in childcare of younger children or, similarly, that social norms are such that the costs of refraining from childcare for women (or the cost of engaging in childcare for men) are exogenously larger. Moreover, in line with our data, we assume economies of scale in childcare provision, as well as the ability of the caregiver to combine some types of childcare with household production in agriculture.

Household adults get utility $U = U(C, L, \{Q_k\}_{k=1}^N)$ from consumption, leisure, and the well-being of k household children. They can spend time on leisure, wage work for a fixed wage, home production,³⁷ and childcare and face a time constraint $T = L + t_w + t_h + t_c$. Wage work earns a wage w . Home production $H = H(t_h, X, S)$ is a concave function satisfying the Inada conditions, which depends on the adult time input and other household characteristics X such as the availability of household agricultural land or existence of a household enterprise, as well as the availability of child labor (which is a function of the age distribution of children and school closure policy S). We normalize the price of consumption to 1 and assume that household production can be sold at this same price.

Adults provide childcare $CCM = \psi_g(t_c + \theta_h t_h)$, which includes “active” childcare time t_c focused on children as well as some portion θ of home production time that simultaneously provides passive childcare. The variable ψ_g is a cost-shifter for childcare provision that takes on smaller values for men than for women.³⁸ Adult childcare is a public good that all household children can access, reflecting the economies of scale we observe in this context.

Total childcare for child k is given by $CC_k = CCM + I_k$, adults' childcare provision plus any childcare provided by older children.³⁹ All children receive the same amount of care from household adults, but childcare from other children varies based on the age distribution of siblings. Total informal childcare available to the household $I = I(X, S)$ is a function of household characteristics (notably the presence of older siblings) and of school closures; older siblings provide more informal childcare when schools are closed. Child well-being $Q_k = Q_k(CC_k, \overline{CC}_k(\text{age}_k, S))$ is a concave function of childcare provided to the child and their minimum required care.⁴⁰ Minimum required care $\overline{CC}_k(\text{age}_k, S)$ decreases with age, and for school-age children it increases when schools are closed.

Adults take as given household characteristics X such as presence of other adults and child composition, school closure policy S , and non-labor income Y . We model S as a binary variable taking a value of 1 if schools are closed and 0 otherwise.⁴¹

37 The key distinction this model makes is between a work sector which accommodates both simultaneous childcare and child labor contribution, and another work sector which does not. We therefore primarily think of the home production activity as being household agriculture, with household enterprise activities being a form of home production which has some of the same characteristics but less so.

38 This cost-shifter can be rationalized in multiple ways. It could be that women's childcare hours count for more relative to men's due to a social expectation of women to provide childcare, or a social stigma of childcare for men. This shifter is also isomorphic to a model where women are relatively more productive in childcare, and require fewer hours to achieve the same increase in child welfare.

39 Very few households in the data use non-household sources of childcare, so we abstract away from this possibility.

40 We can think of this as a Stone–Geary type of function.

41 Although S may vary by child, as in the case of the partial school reopening in Kenya, we abstract from this point.

Adults' static optimization problem is

$$\begin{aligned}
& \max_{t_w, t_b, t_c} U(C, L, \{Q_k\}_{k=1}^N) \\
& \text{subject to } C = wt_w + H(t_b, X, S) + Y, \\
& T = L + t_w + t_b + t_c, \\
& L \geq 0, \quad t_w \geq 0, \quad t_b \geq 0, \quad t_c \geq 0, \\
& CC_k = \psi_g(t_c + \theta_b t_b) + I_k, \\
& \sum_{k=1}^N I_k \leq I(X, S), \\
& Q_k = Q_k(CC_k, \overline{CC}_k(\text{age}_k, S)).
\end{aligned}$$

Adults maximize their utility over choices of time use, subject to the following constraints: (a) the household budget constraint, (b) their time endowment, (c) non-negativity constraints on time use, (d) the childcare provision function, (e) availability of childcare from older siblings, and (f) the child well-being function. The budget constraint states that spending on consumption must equal the sum of wage income, the value of home production, and non-labor income.

We are interested in the impacts of changes in school closure policy S on adult labor supply t_w and t_b . The variable S enters the model through childcare needs, the availability of sibling childcare, and household child labor availability. We expect $\overline{CC}_k(\text{age}_k, 1) > \overline{CC}_k(\text{age}_k, 0)$ for children enrolled in school, meaning schools being open decreases household childcare needs. On the other hand, $I(X, 1) > I(X, 0)$ for households with older children, as those children can provide more informal childcare when schools are closed. Moreover, $H(t_b, X, 1) > H(t_b, X, 0)$ as children may contribute more to home production when they are home from school.

Adults thus trade off their time among wage work, home production, childcare, and leisure, at an interior solution setting the marginal returns to each equal to each other:

$$u'_C w = u'_C H'_t(X, S) + \phi(\{\text{age}_k\}_{k=1}^N, S, \psi_g) \theta_b = \phi(\{\text{age}_k\}_{k=1}^N, S, \psi_g) = u'_L,$$

where these terms are, respectively, the marginal utility of working one more hour for a wage w , the marginal utility of an additional hour in home production (providing both consumption and some child well-being value due to joint work and childcare), the marginal value to adults of an additional hour of childcare, and the marginal utility of an additional hour of leisure, and where we define

$$\phi = \sum_{k=1}^N u'_{Q_k} Q'_k(\text{age}_k, S) \psi_g.$$

School reopening (moving from $S = 1$ to $S = 0$) affects the solution to adults' problem through two channels. First, it lowers child labor in home production, thus likely raising the marginal return of adults working in home production after school reopenings ($H'_t(X, 0) > H'_t(X, 1)$). Second, it changes the net demand (and thus net return) to childcare for the remaining children. When there are no other children present, the utility return to adult childcare hours decreases for sure ($\phi(K = 1, S = 1) < \phi(K = 1, S = 0)$), which also reduces the return to work in home production. But when there are other children present, the sign of this effect is ambiguous and depends on the age distribution of remaining children. When remaining children are very young, for instance, the marginal utility from adult childcare may actually *increase*, since the school reopening decreases sibling childcare ($I(X, 1) > I(X, 0)$) and changes the household childcare constraint.

The simple model thus allows us to generate several hypotheses for the effect of schools reopening to take to the data. First, in households where *all* children return to school, hours spent in childcare should

decline, while labor supply overall should increase. The decline in childcare should be greater for a younger child returning to school. Second, adults with young children will likely be providing a higher level of childcare on average when schools are open: sibling childcare falls as older siblings return to school, but childcare needs remain high since these are driven relatively more by younger children. Sibling childcare may be particularly affected by a girl child returning to school. Labor supply may therefore decrease in households with young children given the increased marginal utility from adult childcare.

Third, if women play a larger role in childcare (as is the case in our setting), either because children benefit more from female care, or because social norms and economic circumstances are such that men's social cost to childcare are larger, then $\psi_{\text{female}} > \psi_{\text{male}}$. This suggests that women should engage in more childcare overall, and that school closures should impact their childcare hours more. They will also be more likely to supply relatively more labor to home production, as this can be combined with childcare whereas wage work cannot. If, in addition, we suppose that childcare needs and norms for infants and young children are particularly gendered, then labor-supply responses to school reopening when young children remain present in the household should be particularly muted (or even reversed) for women relative to men.

Finally, in households which used child labor for home production while schools were closed, adult labor supply in home production should increase after schools reopen to make up for lost child labor. This increase should be more pronounced in households which depend more on home production and which lack access to hired labor, such as poorer agricultural households. Households with better access to hired labor may respond to reduced child labor by increasing hired outside agricultural labor rather than household adult agricultural labor, if the opportunity cost of household adult labor is greater than the cost of hired labor.
