## **INTRODUCTION**

### **Updated Data Extraction**

The major pre-occupation of the Centre's activity during the last year has been the transformation of the database from tabulated practice summaries by disease and by week to a unique person linked database. The transformation was sought because our information requirements often call for links between events, for example, the link between influenza vaccination, co-morbidity and subsequent respiratory infection.

In making this upgrade, a number of issues have had to be addressed. Complete anonymity of all data transferred has been essential. Each time a data extraction takes place we take the selected items recorded since 2003 thereby retaining recent historical links such as co-morbidities and vaccination procedures. The selected information is confined to specified Read code entries for a minimum set of registration data (month and year of birth, post code (excluding the last two digits), date of initial registration and date and reason for de-registration). No extraction of free text is made. The selected Read codes are those concerning morbidity and selected prescribing and vaccination codes – mainly antibiotics and antivirals.

This revised extraction routine has required us to increase our computer capacity and this has generated a lot of work in order for material to be processed. At the point of writing this report, we are now receiving data in this form from 27 of our practices.

### **Practice Network**

The network has been stable in the last few years but problems do arise when practices change their supplier. The problems reported in last years Annual Report in relation to The Phoenix Partnership software have not yet been resolved.

### **Influenza News**

At the time of writing this report we have seen the emergence of swine flu in England. It has been reassuring to note that one of our swabbing practices detected the first case of virologically confirmed swine flu in a person who had not recently returned from Mexico or the USA or who was in immediate contact with such a visitor. This emphasises the importance of the swabbing practices and we wish to encourage greater involvement in this programme.

During 2008, we requested the 'Connecting for Health' Read coding group to supply a suite of Read codes to supply influenza virology results and we are pleased to report that this has now been introduced.

We have completed a study of the estimation of influenza vaccine effectiveness using a case/control design whereby a proportion of influenza positive swabs received from vaccinated patients are compared with the equivalent in non-vaccinated persons. This work has involved collaboration with colleagues in Scotland, other European countries and with a programme known as EpiConcept

managed by epidemiologists in France. We hope to be successful in retaining this association into next winter. In connection with this project we have appointed Hayley Durnall as Practice Liaison Officer and during the early part of 2009 she has been engaged in a programme of practice visits. We have submitted this work for publication.

About two years ago, we introduced the Supplementary Respiratory Reports in order to provide more detailed information on the incidence of influenza like illnesses, especially in the context of possible pandemic preparedness. The reports make estimations of the number of cases of flu like illnesses and other respiratory conditions in each Strategic Health Authority. These reports are available on our website [www.rcgp.org.uk/rsc](http://www.rcgp.org.uk/rsc).

## **Research**

Research involved in the last twelve months has mainly been concerned with influenza. The vaccine effectiveness project has been mentioned above. We are also involved in the European project estimating the burden of influenza in young children primarily to assess the potential benefits of routine vaccination.

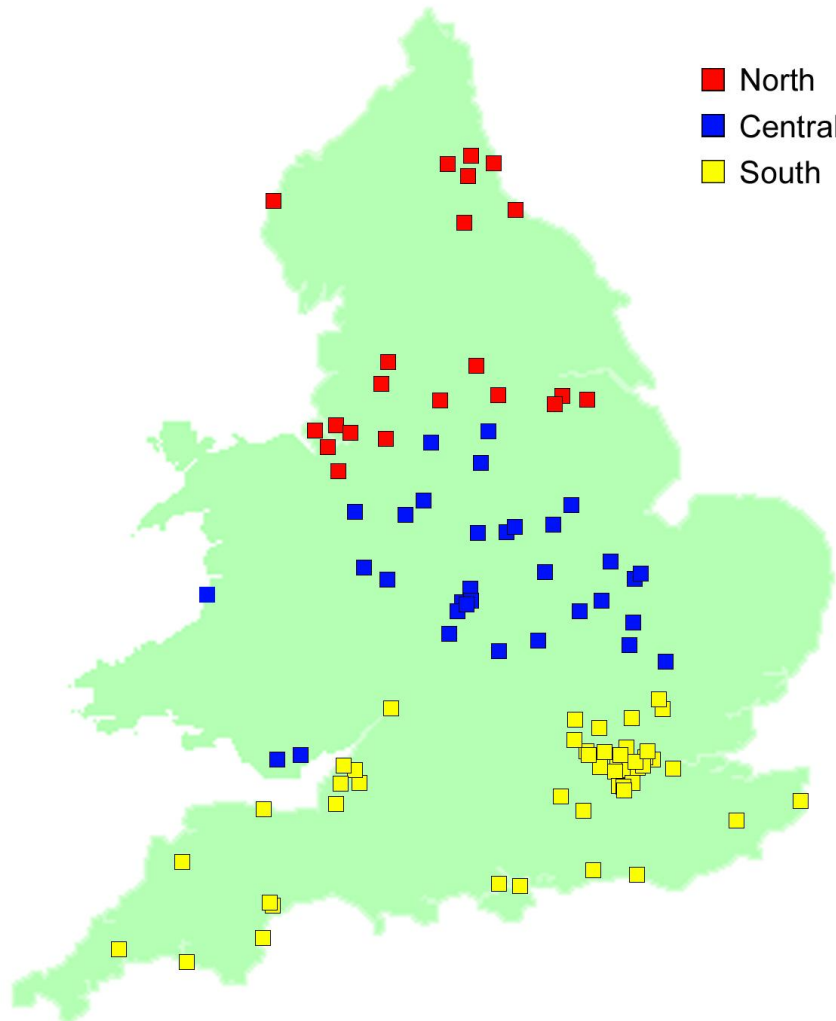

## **Theme of this Report**

This report will be presented in the traditional format with reviews of disease incidence trends over recent years. As a specific theme of the report however, we will examine the relationship between Weekly Returns Service incidence data and reports of virus identification submitted to the Health Protection Agency.

## PARTICIPATING PRACTICES

During 2008 a total of 100 practices contributed to the WRS and these are indicated on the map (Figure 1). These were distributed by computer system as follow: EMIS, 57; Torex Synergy, 22; Torex GP Premiere, 4; In Practice Systems, 17. Six practices migrated to The Phoenix Partnership (TPP) using SystemOne.

*Figure 1: Sentinel practice sites*

The WRS population under surveillance in the three supra-regional groups (North, Central, and South) is compared with nationally equivalent data (summed from mid-year regional population estimates for 2007 provided by the ONS) in Table 1. In Table 2 we provide information on population representation by health authority region

Each weekly report is made on the basis of information received within 2 days after the end of the recording period. Thus for the first weekly report, data received by Wednesday covers the week ending the previous Sunday and for the second report data received by Friday covers the week ending the previous Wednesday. In addition, the database is subsequently updated with any delayed data thus resulting in three possible population denominators; the population on which the contemporary

weekly report is based, the updated population on which the annual report is based and the entire network population which we use to consider the network representativeness by age. These three populations are compared by week in Figure 2. The provisional population and the updated population are very similar in most weeks. There are sometimes problems around major holiday periods when, for example, computers are inadvertently switched off in the practices. Occasionally we encounter technical problems with particular software but these have become much less frequent.

Figure 2: Population on which provisional and final weekly reports were based compared with total available population in 2008.

The consistency of reporting is disclosed by the analysis presented in Table 3 which gives the number of practices and GP principals in each region who have contributed to the WRS in 2008. There are always some new recruits and a few practices who are involved in changing their software supplier during the year and thus we would not expect there to be complete recording throughout the 52 weeks. Seventy three of the 100 practices were able to deliver data for 50 weeks or more. The Service now provides a second weekly report which has been introduced at no extra cost and we are pleased to report that this service is now regularly based on a population exceeding 600,000. The maximum population ever reported in the contemporary weekly report occurred in week 29 and included 936739 persons.

## PRESENTATION OF DATA

The main presentation of results in this report follows that of previous reports and was summarised in the annual report for the year 2000. Appendix 1 contains the time period definitions for the 4-weekly, quarterly and annual periods and the mean weekly population by age and gender. Appendix 2 summarises annual data for the diseases which have been reported for twenty-five years or more in the WRS. Each table in the appendices includes information on the mean weekly incidence over thirteen four-weekly periods, four quarterly periods and the total year. Also included are the number of episodes (categorised first or new) and the number of consultations reported within each age and gender group. Separate data are available for males and females covering the age groups less than 1 year, 1-4 years, 5-14 years, 15-24 years, 25-44 years, 45-64 years, 65-74 years and 75 years and over. For some reported diseases, minor revision of disease titles has resulted in departure from strict alphabetic order. Appendix 3 presents population and incidence data for three regions (North, Central and South) for the selected common diseases included in Appendix 2. These data are restricted to quarterly and annual periods but are otherwise presented in the same detail as those in Appendix 2. The separation into regions North, Central and South has previously been based on lines of separation between Liverpool and Hull; Bristol and Ipswich. This separation into the three supra-regional groupings has been revised to align with the boundaries of Strategic Health Authorities (Box 1). For convenience, Wales is included in the Central region.

*Box 1: Strategic Health Authorities by supra-regional group*

North	Central	South
Northumberland, Tyne & Wear	Trent	North Central London
County Durham & Tees Valley	Leicestershire, Northamptonshire & Rutland	North East London
Cumbria & Lancashire	Birmingham & Black Country	North West London
Cheshire & Merseyside	Shropshire & Staffordshire	South East London
Greater Manchester	West Midlands South	South West London
North & East Yorkshire & North Lincs.	Norfolk, Suffolk & Cambridgeshire	Surrey & Sussex
West Yorkshire	Essex	Kent & Medway
South Yorkshire	Bedford & Hertfordshire	Thames Valley
	Wales	Hampshire & Isle of Wight
		Avon, Gloucestershire & Wiltshire
		Dorset & Somerset
		South West Peninsula

Appendix 4 describes the mean weekly incidence of disease by chapter of the ICD. Disease grouping in this way is a particular advantage for illnesses such as mental disorder where persons can receive multiple entries of very similar Read codes. Appendix 5 provides an analysis of selected diseases illustrating the capacity of the WRS to deliver information on any specified disease.

Those selected span a wide range of disorders and a wide range of disease prevalence and are presented in ICD order.

## TRENDS IN THE INCIDENCE OF DISEASE

The main statistic presented in the report is the mean weekly incidence in a given period expressed as a rate per 100,000 population. Incidence in this context is of an episode of illness. As in previous reports we summarise trends in Table 4 and in Table 5 there are a selection of example diseases which have been incorporated in the report over the last 30 or more years. It is important to realise however that the information system can deliver incidence data on all disease codes.

In the analysis of trends, diseases are grouped into broad categories and trends discussed firstly as a general overview and secondly in relation to specific diagnosis.

### *Gastro Intestinal Disorders*

Incidence rates of infectious intestinal disease have fallen dramatically over the last ten years; the current mean weekly rate being 17 as compared with 38 in 1999. Incidence of acute appendicitis, duodenal ulcer and gastric ulcer was all reduced by the same margin. However, no reduction was seen in the incidence of non-infective enteritis and colitis which has remained fairly constant over the last 10 years.

### *Respiratory Disorders*

There have been some substantial reductions in respiratory tract infections; approximately two thirds of those reported in 1999. These reductions are highly consistent over a wide range of respiratory diagnoses and are seen for example in acute bronchitis, tonsillitis and sinusitis. The reduction in common cold is slightly less. Reductions in more serious illnesses, such as pneumonia and tracheitis are in general more substantial. Incidence of acute otitis media has fallen by 40% and the rate of asthma attack follows the same general pattern with a reduction of 50%. The reduction of incidence of hay fever is less dramatic, but patient experience is highly variable each year depending on the weather conditions. There is a substantial reduction in the incidence of influenza like illness but the timing of influenza epidemics each winter tends to vary the reduction. In some calendar years there is little influenza whereas in others epidemics occur in the early part of the year and at the end. Looking over a longer time series, incidence of influenza related disease has been falling gradually over many years.

### *Vaccine preventable diseases (excluding influenza)*

By comparison with ten years ago, the most dramatic reduction has been reported in rubella. Rates of measles and mumps are very low and have changed little. However, there is a big annual variation with a particularly high rate of mumps reported in 2005. The reported rate of whooping cough remains very low.

### *Parasitic and Fungal Infections*

The most dramatic change has been in the incidence of scabies, which has currently reported a mean weekly incidence of 1.5 per 100,000 compared to 8.5 in 1999. There is a well known secular trend in the incidence of scabies and this is substantiated by these data. Data for pediculosis show a similar but not quite such a dramatic trend. The peak incidence of scabies occurred in the year 2000, whereas for pediculosis it was in 1996. The incidence of tinea has remained constant over the last ten years. Threadworm has reduced slightly. The incidence of molluscum contagiosum was also less in 2008 than it has been recently and there is now less candida than there was in 1999.

### *Sexually Related Disorders*

Candida has been mentioned above. The WRS shows continual reductions year by year in the incidence of trichomonosis vaginalis and of nonspecific urethritis. Nevertheless, these consistent reductions do not point to any overall decrease in the level of sexually transmitted disorders. In parallel there have not been increases in urinary tract infections, inflammatory diseases of the prostate, orchitis or of inflammatory disease of the female pelvic organs.

### *Subcutaneous Skin Disorders*

There have been reductions in the incidence of subcutaneous skin tissue infections but rates of atopic eczema and dermatitis have been constant. Rates of psoriasis and pityriasis rosea are little different from those experienced in recent years. Herpes simplex has changed little

### *Myocardial Vascular Disease*

The decrease in the incidence of acute myocardial infarction continued in 2008, which is now less than half the rate of that reported in 1999. The same is true for cerebrovascular accident.

### *Mental Illness*

Though there have been changes in the reporting of depression, rates of anxiety have not changed to any great degree.

### *Malignant Neoplasm Prostate*

The current reduction in the incidence of carcinoma of the prostate is not reflected in our prevalence reports which have reported fairly constant prevalence over the last ten years. As quality of treatment improves and the diagnosis is made earlier, an increase in prevalence may be seen due to patients consulting more frequently after first diagnosis.

### *Bone Cancers*

Life expectancy has increased substantially. The fact that incidence seems to be decreasing and that prevalence has not increased suggests that the true incidence of these conditions is not increasing.

### *Other Conditions*

Rates of rheumatoid arthritis and of ankylosing spondylitis have fallen over the last ten years.

*Table 4: Mean weekly incidence of common infections (per 100,000 all ages) 1999-2008*

## **THE LINK BETWEEN WEEKLY RETURNS SERVICE DATA ON DISEASE INCIDENCE AND NATIONAL REPORTS ON VIROLOGY**

### **Importance of Virology Reporting**

Viruses are common causes of respiratory infections in all age groups. In the study based on the 1991 morbidity survey in general practice (MSGP4) approximately 30% of the population consulted with new episodes of respiratory infections during the course of a year and half of these were because of respiratory infections. There has been a general decline in respiratory infections since that time, though collectively they continue to pose a considerable burden for health care in English general practice. Information on the impact of these conditions is routinely available in the Weekly Returns Service and for many of them this data set goes back as far as 1967.

Alongside the clinical incidence data there is information available from national reporting of viruses through the laboratory system of the Health Protection Agency (HPA) and voluntary reporting systems of hospital laboratories. These reports are consolidated by the HPA and made available as a national data source. Since reports contain only positive virology results there is no denominator for establishing rates, as the number of negative tests is unknown. Although there is a repertoire of laboratory tests, specimens are not consistently tested using more than one or two of them or for more than a limited range of viruses. Since the introduction of virological detection and identification by Polymerase Chain Reaction (PCR) many specimens have been investigated for several viruses, especially closely related viruses for example influenza, Respiratory Syncytial Virus (RSV) and selected common respiratory viruses.

Structured programmes of routine virological investigations are essential to improving our understanding of common viral infections in the community. In 1993, in collaboration with the HPA, we introduced an influenza monitoring programme. In this Annual Report, we examine the links between national reported information on respiratory viruses and weekly incidence data reported in the WRS.

Virology data available on respiratory viruses over the last 20 years include reports of adenovirus, coronavirus, influenza, parainfluenza, rhinovirus and RSV. The vast majority of virological investigation and case reporting is conducted during the winter period (Figure 3).

Figure 3: Total 20 year percentage of all virology reporting for all ages by 4 week periods.

There have been approximately 300,000 virus reports submitted to the Health Protection Agency over the last 20 years with the majority submitted from young children (Figure 4). Of these reports, 60% were from children less than one year of age and less than 5% were from the 16% of the population aged over 65 years. More than 80% of deaths occur in this age group. The annual average of 15,000 virology reports per year should be seen against an estimate of around 10 million persons consulting each year with respiratory infections.

Figure 4: Age distribution of virus reports to HPA 1988 to 2007 with percentage population for 2007 above each column.

## Respiratory viruses

Respiratory infections have a high impact on primary care usage by people of all ages. Most of these infections are almost certainly caused by viruses and are responsible for much of the inappropriate prescribing of antibiotics. During the winter period, respiratory infections contribute substantially to the pressure on hospital admissions, especially in the elderly. The delay patterns between the presentation to a GP and serious adverse outcome strongly suggests that for the majority of sufferers, the initial viral infection is the main challenge rather than a possible secondary bacterial complication. Acute bronchitis and influenza like illness are the diagnoses with the greatest impact on healthcare.

Viruses are classified according to their genetic composition into the ribonucleic acid (RNA) and deoxy-ribonucleic acid (DNA) groups. Although some of these viruses are reasonably exclusive in causing illness in the respiratory tract, the ill effects of others can be much more general and it is not uncommon for the same virus to cause gastroenteritis as well as respiratory symptoms. In this section, we shall consider information on a number of the more common viruses and the relative impact on respiratory infections.

### Adenoviruses

Adenoviruses are double stranded DNA viruses that typically cause a wide range of respiratory illnesses. The virus has 52 human serotypes and some of these cause other illness such as gastroenteritis and even cystitis. Transmission is generally by direct contact including faeco-oral transmission or waterborne transmission. These viruses circulate throughout the year. Adenovirus infections are frequently reported in children, though they can cause illnesses in adults (Figure 5). The seasonal pattern is consistent with that of the incidence of respiratory infections generally, though not with any specific diagnosis.

Figure 5: Age specific percentage of adenovirus reports from 2007 and 2008 compared with 20-year total.

## Coronaviruses

Coronaviruses (CoV) are genomically large RNA viruses that normally infect the upper respiratory and gastrointestinal tract of mammals and birds. The most publicized human coronavirus is Severe Acute Respiratory Syndrome (SARS-CoV), which was responsible for the severe respiratory virus outbreak in Hong Kong and Canada in 1997. There was considerable concern when it first appeared that it was the onset of an influenza pandemic. Coronaviruses are reported during the winter and early spring in all age groups (Figure 6). The significance and economic burden of coronaviruses as causes of upper respiratory infections is hard to address because the virus is difficult to grow in the laboratory. The number of laboratory reports over recent years is significantly less than for most other respiratory viruses.

Figure 6: Age specific percentage of coronavirus reports from 2007 and 2008 compared with 20-year total.

## Influenza

The influenza virus is an RNA virus belonging to the family Orthomyxoviridae. There are three serotypes, A B and C although influenza C is only rarely a cause for clinically significant illness in humans. Influenza A viruses are further classified by their surface antigens, haemagglutinin (H) and neuraminidase (N). The virus can undergo mutations of these surface antigens which lead to antigenic drift. Antigenic shift describes a more radical change to the genetic makeup of the influenza virus. Continuing antigenic drift explains the need for regular annual updating of the influenza vaccine composition. Antigenic shift produces radically different viruses resulting in a pandemic threat. There are sixteen recognised haemagglutinins and nine neuraminidases. Not all these variants cause infection in humans but the capacity for mutation is such that a new variant (whatever the haemagglutinin and neuraminidase composition) may sufficiently mutate resulting in human infection. Hence, the concern over the avian flu (H5N1) infection remains and the risk of this being a pandemic virus has not diminished by the emergence of swine flu (H1N1).

The H5 type viruses have hitherto not been associated with infections in humans and do not spread between humans except in the most exceptional circumstances. Cases that have occurred have involved very close links between humans and infected poultry.

Influenza is normally a self-limiting acute infection which spreads easily from person to person and particularly between children. It can affect all ages but the disease is generally more serious in vulnerable persons such as the elderly and those with underlying conditions, affecting cardio pulmonary function or impairing the immune system. Epidemics occur in most winters in temperate regions of the world and the mainstay of influenza management focuses on annual vaccination of those in risk groups. Reports of influenza virus infection received by the Health Protection Agency in the last 20 years are summarised in Figure 7. The age specific pattern of reporting does not exactly match the clinical incidence data of influenza-like illness reported in the WRS but, with large numbers of cases in persons between 15 and 64 years, it differs substantially from all other viruses reported.

*Figure 7: Age specific percentage of influenza reports from 2007 and 2008 compared with 20-year total.*

**Parainfluenza**

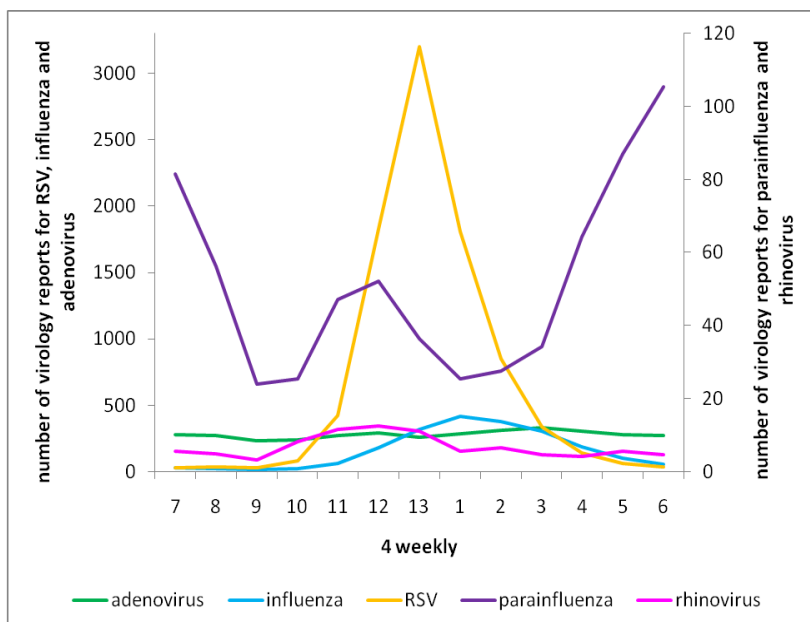

Human parainfluenza viruses (HPIVs) are RNA viruses belonging to the paramyxovirus family. HPIVs cause both upper and lower respiratory tract infections in young children. They are particularly associated with the incidence of croup, though we could not detect the same seasonal pattern in the incidence of croup, possibly because it is only one of the viruses causing this condition. Distribution by age in reports received over the last 20 years is shown in Figure 8. This virus is not often reported in adults.

Figure 8: Age specific percentage of parainfluenza reports from 2007 and 2008 compared with 20-year total.

The seasonal pattern of parainfluenza virus reports differs markedly from those of many other common respiratory viruses with the majority reported in mid summer and a few during December, when other respiratory infections are common (Figure 9).

Figure 9: Average number of reports made to the Health Protection Agency of common respiratory viruses in 4 weekly periods over 20 years.

## Rhinovirus

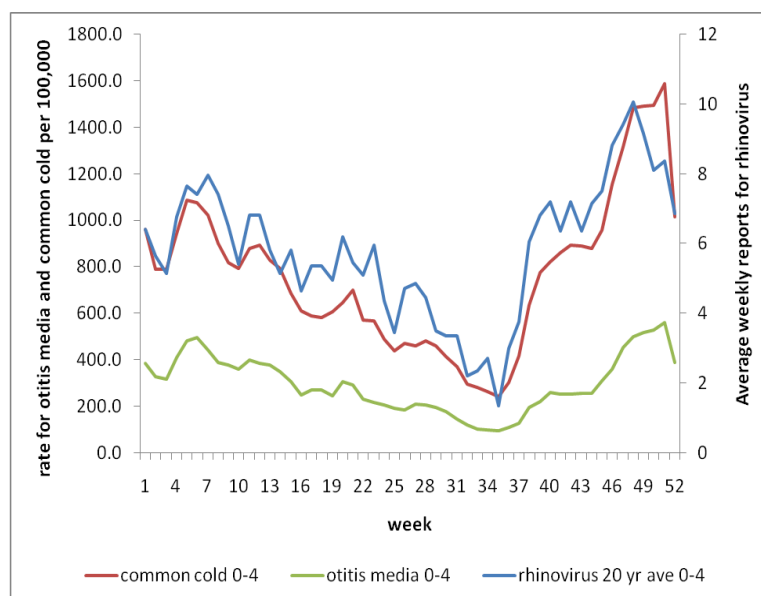

Rhinoviruses are RNA viruses belonging to the Picornaviridae family. There are more than 100 serotypes, approximately 35% of these cause illness in humans, especially in winter. Rhinoviruses are the most frequent cause of common cold and are most commonly reported in children under the age of 5 years (Figure 10).

Figure 10: Age specific percentage of rhinovirus reports from 2007 and 2008 compared with 20-year total.

Eustachian tube dysfunction and the development of otitis media commonly occurs with common cold whatever the viral aetiology but is particularly evident in relation to rhinovirus reports (Figure 11).

Figure 11: Incidence of common cold, otitis media and rhinovirus reporting in 0-4 age groups.

Laryngitis and tracheitis can be either the direct result of respiratory viral infection or secondary bacterial complications often attributable to co-infection with *Staphylococcus aureus*. The incidence of laryngitis and tracheitis also broadly follow the same seasonal pattern as that for rhinovirus reports.

**Respiratory Syncytial Virus (RSV)**

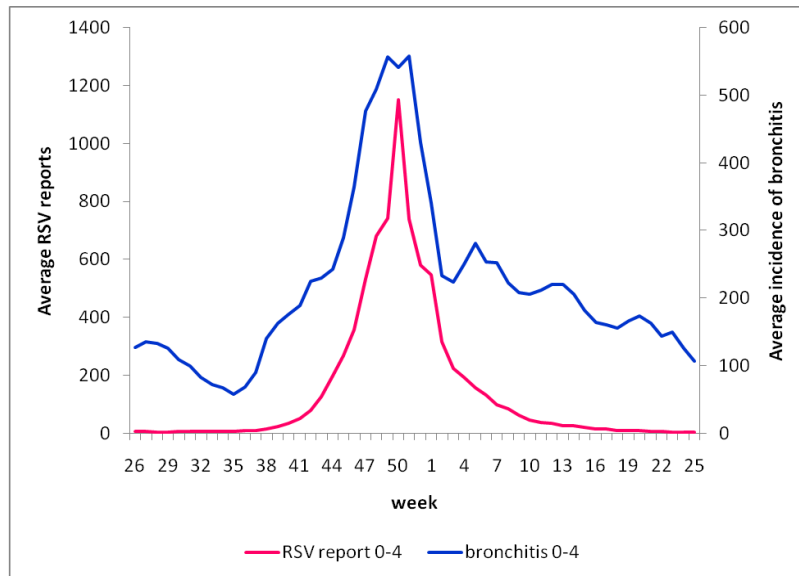

Respiratory Syncytial Virus is an RNA virus belonging to the Paramyxoviridae family. There are two main serotypes (A and B) and they are the major cause of lower respiratory infections in children, with epidemics during most winters in temperate climates. RSV infections tend to be exclusively reported in children; 85% in children less than 2 years and 95% in children less than 5 years of age (Figure 12). RSV is the most common cause of hospital admission for respiratory infections in young children and exceeds those attributable to influenza. The separate effects of influenza and RSV are difficult to disentangle because they commonly circulate at the same time during winter. In addition, co-infection with more than one respiratory virus is not uncommon.

*Figure 12: Age specific percentage of RSV reports from 2007 and 2008 compared with 20-year total.*

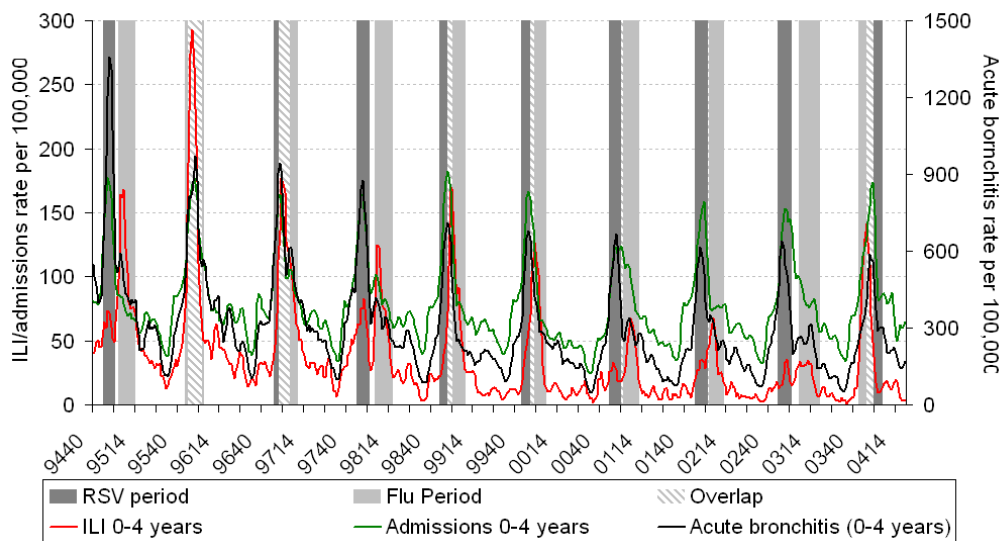

Of all the respiratory diagnoses made in children, acute bronchitis is the most closely associated with RSV infections (Figure 13). The reported incidence of acute bronchitis in children is highly consistent with national reporting of RSV.

Figure 13: Average incidence of acute bronchitis and RSV reports in children age 0-4 years.

In Figure 14, we describe the incidence of both influenza like illness and acute bronchitis in children 0-4 years set against a background of influenza and RSV and respiratory syncytial virus active periods. A virus active period is defined as those consecutive weeks which include a minimum of 70% of the reports during that winter for the specific virus. In addition, the graph displays the admission rate for acute respiratory episodes reported in hospital episode statistics. The peak of admissions in winter is consistently related to the incidence of acute bronchitis. Figure 14 also demonstrates that the incidence of influenza like illness is closely aligned to the influenza active period and acute bronchitis to the RSV period.

Figure 14: Incidence of ILI in children in virus active periods (influenza and RSV)

The problem of RSV as a cause of acute bronchitis in the elderly remains a conundrum. Experience in the Weekly Returns Service has shown that the incidence of acute bronchitis in the elderly is two or three weeks behind that of its incidence in young children (Figure 15).

Figure 15: Acute bronchitis weekly incidence in 0-4 and 65+ age groups by winter weeks in alternate years 1995-2002.

Delays in consultation pose a particular problem for the interpretation of data on RSV. Elderly persons tend not to consult in the early phases of minor respiratory viral infections unless they experience severe constitutional symptoms which are unusual in RSV infection. The net result is that they delay consulting their GP for several days thus making it difficult to get a suitable specimen to identify RSV. More work is needed investigating the impact of this virus.

## Conclusion

Most respiratory viruses have a broad impact on both the upper and lower respiratory tracts and few are associated exclusively with particular disease syndromes. If we are to gain a better understanding of the impact of these viruses we need to identify them specifically. Though this is not to be taken as applicable to investigating all persons generally when they consult doctors, it adds to the pressure for improved virological investigation in sentinel practice networks.

## INFLUENZA SWABBING

For more than a decade, the RCGP Research & Surveillance Centre has collaborated with the HPA on the RCGP/HPA Clinical Virological Surveillance (influenza swabbing) study. Each autumn, practices who participate in the WRS are invited to take nose/throat swabs from patients presenting with ILI symptoms and post them to the HPA where they are examined for influenza and respiratory syncytial virus (RSV). Results are returned to the practice using rapid analysis methods within 24-48 hours and traditional isolation by culture about 5-7 days later. Full instructions and swabbing kits are provided to practices who decide to participate in the scheme and there is no cost to the practices involved. The purpose of this virological examination is primarily to identify influenza viruses in order to inform the health service of imminent problems, to check the strain type against previous circulating viruses and strains included in the current vaccine and finally, to assist in decision making with regard to the choice of strain to be included in next year's vaccine.

Between week 40/2008 and week 20/2009, 1943 swabs were submitted from 53 WRS practices. In total, there were 695 positive samples and in Table 6 we present the results of virological investigation. Overall 35.8% of the investigations were virus positive, a value which reaches around 40% during the peak influenza weeks. Human metapneumovirus (hMPV) is a newly identified respiratory pathogen that has been predominately associated with causing respiratory disease in young children. It is associated with a range of illnesses from mild infection to severe bronchiolitis and pneumonia and 20 submitted swabs (1%) were found to be positive for this virus. In week 19, the first of the swine lineage (H1) viruses were seen and at week 20, there had been 5 swabs positive for this virus. These are included in the total Influenza A (H1) figure in the table. Figure 16 compares RCGP episode incidence rates for ILI with virology results and also provides weekly incidence data from 2007/08 as a further comparison.

Figure 16: Analysis of samples taken in the 2008/09 RCGP/HPA influenza swabbing study compared to RCGP influenza rates over the last two winters.

We greatly appreciate the collaboration of practices in this project. The integration of clinical and laboratory data on influenza and other respiratory viruses as conducted in the WRS has given the service a high reputation in international circles concerned with influenza surveillance.

## MEDIAN CONTACT DAYS

Contact frequency is described in Table 7 and in Figures 17, 18 & 19. The measure used is the numbers of days on which the 'average' patient makes contact with the practice, for the purpose of consulting a doctor or nurse practitioner. On average, males contact their GP on 6 days per year and females 9 days per year. The increased frequency of contact amongst persons 65 years and over, occurring between weeks 41 and 47 is due to the influenza vaccination program.

*Table 7: Average annual person contact days per 100 population by age group and gender.*

	All ages	<1	1-4	5-14	15-24	25-44	45-64	65-74	75+
Males	604	1425	577	270	310	386	662	1214	1657
Females	864	1328	541	288	671	809	884	1259	1628

*Figure 17: Median contact days per 100 persons by week during 2008 in age groups <1, 1-4 & 5-14 years*

*Figure 18: Median contact days per 100 persons by week during 2008 in age groups 15-24 and 25-44 years.*

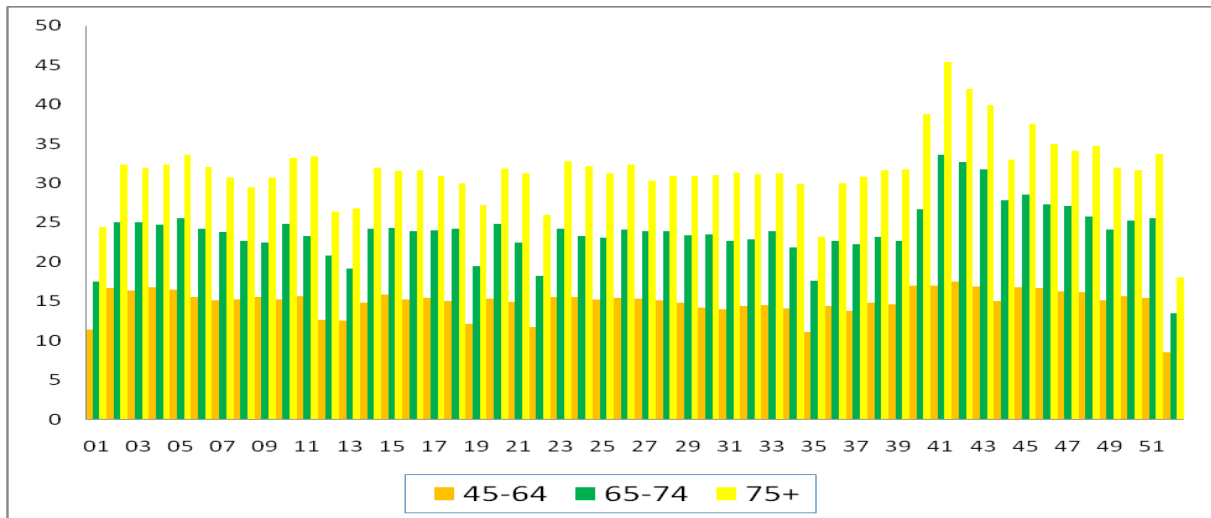

Figure 19: Median contact days per 100 persons by week during 2008 in age groups 45-64, 65-74 and 75 plus years.

## **ALERT CONDITIONS**

The regional data shown in Appendix 4 are used in the graphical presentation of data on selected 'alert conditions' which are compared with weekly national average rates over recent years in our routine reporting. These data are organised in groups reflecting:

- Water and food borne disorders
- Environmentally sensitive disorders
- Respiratory infections
- Vaccine sensitive disorders
- Skin contagions
- Disorders affecting the nervous system
- Genito-urinary system disorders

In Figures 20 a-l, a selection of the graphs which are included in our weekly Communicable and Respiratory Disease Report are presented. The full set is published weekly on our website: [www.rcgp.org.uk/rsc](http://www.rcgp.org.uk/rsc)

These data are presented without comment, the graphical presentation being largely self explanatory.

Figures 20 a-l: Selected alert conditions: incidence per 100,000 per week, all ages, by region in 2008 compared with 9 year average (1999-2007)

## VALIDATION OF DIAGNOSIS

Follow up enquiries are made when certain disorders of particular interest are reported, mainly because of their potential to be prevented by vaccination (see Table 8 below). In 2008, a total of 250 such cases were reported; 17 measles, 110 mumps, 8 rubella, 21 whooping cough, 27 meningitis and 67 hepatitis. Replies were received regarding 166 (66%) of all cases. Of these, 38 cases were confirmed by laboratory tests and 97 were not revised, but based on clinical evidence only. There were no coding errors reported. Six patients could not be traced.

The number of reported cases of mumps fell again for the third year running to 110 in 2008. Of the 77 replies received, 5 cases had serological confirmation of mumps, 12 cases were revised to other conditions and 1 case had no serological confirmation, the diagnosis having been made on clinical observations only.

Of the other diseases reported, cases of measles decreased from last year from 31 to 17 cases. Whooping cough rose from 11 to 21 cases and meningitis decreased from 49 to 27 cases. Reported cases of hepatitis decreased slightly from 68 cases in 2007 to 67 in 2008. Of the 47 replies received, 29 were confirmed by laboratory investigation; none as type A, 5 as type B, 24 as type C.

*Table 8: Validation of Diagnosis 2008*

	Measles		Mumps		Rubella		Wh. Cough		Meningitis		Hepatitis		TOTAL	
	n	%	n	%	n	%	n	%	n	%	n	%	n	%

## INFLUENZA VACCINATION

The cumulative weekly data for influenza vaccinations are shown in Figure 21. The rates shown are marginally less than those reported by the Department of Health and based on accumulative data collected by PCTs. The small difference seen arises because of limited failure to use the influenza vaccine specific administration code which is necessary for WRS purposes, though this is not the sole method used by all practices when recording vaccinations.

*Figure 21: Cumulative Influenza Vaccination Uptake % Comparison between 2007/8 and 2008/9: uptake by week (as percentage of the population) in age groups 45-64, 65-74 and 75+ years*

## APPENDIX 1

### TIME PERIOD DEFINITIONS

Mean weekly incidence per 100,000 population in a 4 weekly, quarterly and annual periods defined as follows:

#### 4 weekly periods (2008)

1	31/12/07 – 27/01	6	19/05 – 15/06	11	06/10 – 02/11
2	28/01 – 24/02	7	16/06 – 13/07	12	03/11 – 30/11
3	25/02 – 23/03	8	14/07 – 10/08	13	01/12 – 28/12
4	24/03 – 20/04	9	11/08 – 07/09		
5	21/04 – 18/05	10	08/09 – 05/10		

#### Quarterly Periods

1 <sup>st</sup>	31/12/07 – 30/03	2 <sup>nd</sup>	31/03 – 29/06
3 <sup>rd</sup>	30/06 – 28/09	4 <sup>th</sup>	29/09 – 28/12

#### Annual Period

31/12/2007 – 28/12/2008

#### MEAN WEEKLY POPULATION FOR 2008 = 908004

		<1	1-4	5-14	15-24	25-44	45-64	65-75	75+
MALES	447235	5153	21603	54610	55068	131469	118026	34789	26517
FEMALES	460769	5026	20581	51789	55036	132431	116560	37979	41367

## **APPENDIX 2**

### **ANALYSIS FOR DISEASES TRADITIONALLY REPORTED (ALL REGIONS)**

- **Mean weekly incidence by age and sex groupings,  
by illness surveyed, by period: rates per 100,000**
- **Numbers of episodes and consultations reported  
for the full year by age and sex group**
- **Tabular data are presented in alphabetical order of disease**

Mean weekly incidence rate per 100,000 Persons.

ICD9 540~543

**Appendicitis (540~543)**

**ANALYSIS BY ICD IX CHAPTER**

- **Mean weekly incidence by sex and age groupings, by chapter surveyed, by period: rates per 100,000**
- **Numbers of episodes and consultations reported for the full year by sex and age group**
- **Tabular data are presented in ICD Chapter order**

Mean weekly incidence rate per 100,000 Persons.

ICD9 001~139

**Infectious Parasitic Diseases (001~139)**
